# Introduction

# About This Reference

This Reference covers all Polyspace Bug Finder products:

- Polyspace Bug Finder
- Polyspace Bug Finder Server™
- Polyspace Access™

Depending on how you set up a Bug Finder run, you might be running an analysis from one of these locations:

- **Desktop**: If you are running an analysis and reviewing the results on your desktop, you use Polyspace Bug Finder. More specifically, you use the Polyspace user interface or the `polyspace-bug-finder` command to run an analysis.
- **Server**: If you are running an analysis on a server, or reviewing the results from a server run on a web browse, you use:
  - Polyspace Bug Finder Server, more specifically, the `polyspace-bug-finder-server` command, to run the analysis.
  - Polyspace Access to host the analysis results (for review on a web browser).
- **IDE**: If you are running an analysis on the current file in your Integration Development Environment (IDE), you use Polyspace as You Code in your IDEs (or the `polyspace-bug-finder-access` command). Polyspace as You Code is a feature available with Polyspace Access.

Whatever your platform, the Bug Finder analysis engine underlies all Bug Finder products. In particular, most analysis options, commands and result types are common to all three platforms.

# Polyspace Analysis Options

2

# Analysis Options

# Source code language (-lang)

Specify language of source files

## Description

Specify the language of your source files. Before specifying other configuration options, choose this option because other options change depending on your language selection. This option applies to both dynamic testing and static analysis.

If you add files during project setup, the language selection can change from the default.

| Files Added | Source Code Language |
|---|---|
| Only files with extension `.c` | `C` |
| Only files with extension `.cpp` or `.cc` | `CPP` |
| Files with extension `.c`, `.cpp`, and `.cc` | `C-CPP` |

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. See “Dependencies” on page 2-2 for ways in which the source code language can be automatically determined.

**Command line and options file**: Use the option `-lang`. See “Command-Line Information” on page 2-3.

## Settings

**Default:** Based on file extensions.

`C`

If your project contains only C files, choose this setting. This value restricts the verification to C language conventions. All files are interpreted as C files, regardless of their file extension.

`CPP`

If your project contains only C++ files, choose this setting. This value restricts the verification to C++ language conventions. All files are interpreted as C++ files, regardless of their file extension.

`C-CPP`

If your project contains C and C++ source files, choose this setting. This value allows for C and C ++ language conventions. `.c` files are interpreted as C files. Other file extensions are interpreted as C++ files.

## Dependencies

- The language option allows and disallows many options and option values. Some options change depending on your language selection. For more information, see the individual analysis option pages.

- If you create a Polyspace project or options file from your build system using the `polyspace-configure` command or `polyspaceConfigure` function, the value of this option is determined by the file extensions.

  For a project with both `.c` and `.cpp` files, the language option `C-CPP` is used. During the analysis, each file is compiled based on the language standard determined by the file extensions. After the compilation, Polyspace verifies such mixed projects as C++ projects.

## Tips

For a project with both `.c` and `.cpp` files, if you use the language `C-CPP`, each file is compiled based on the language standard determined by the file extensions. After the compilation, Polyspace verifies such mixed projects as C++ projects.

In particular, the analysis links all files as C++ files. Because of differences in linking behavior between C and C++, you might see differences in linking errors or warnings when C files in the mixed C-C++ projects are compiled with language `C-CPP` versus language `C`.

## Command-Line Information

**Parameter:** `-lang`
**Value:** `c | cpp| c-cpp`
**Default:** Based on file extensions
**Example (Bug Finder):** `polyspace-bug-finder -lang c-cpp -sources "`*`file1.c,file2.cpp`*`"`
**Example (Code Prover):** `polyspace-code-prover -lang cpp -sources "`*`file1.cpp,file2.cpp`*`"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c-cpp -sources "`*`file1.c,file2.cpp`*`"`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang cpp -sources "`*`file1.cpp,file2.cpp`*`"`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources "`*`file1.c,file2.c`*`"`
**Example (Code Prover):** `polyspace-code-prover -lang c -sources "`*`file1.c,file2.c`*`"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources "`*`file1.c,file2.c`*`"`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang c -sources "`*`file1.c,file2.c`*`"`

# C standard version (`-c-version`)

Specify C language standard followed in source code

## Description

Specify the C language standard that you follow in your source code. This option applies to both dynamic testing and static analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. See “Dependencies” on page 2-5 for other options that you must enable.

**Command line and options file**: Use the option `-c-version`. See “Command-Line Information” on page 2-5.

### Why Use This Option

Use this option so that Polyspace can allow features specific to a C standard version during compilation. For instance, if you compile with GCC using the flag `-ansi` or `-std=c90`, specify `c90` for this option. If you are not sure of the language standard, specify `defined-by-compiler`.

For instance, suppose you use the boolean data type `_Bool` in your code. This type is defined in the C99 standard but unknown in prior standards such as C90. If the Polyspace compilation follows the C90 standard, you can see compilation errors.

Some MISRA C™ rules are different based on whether you use the C90 or C99 standard. For instance, MISRA C C:2012 Rule 5.2 requires that identifiers in the same scope and name space shall be distinct. If you use the C90 standard, different identifiers that have the same first 31 characters violate this rule. If you use the C99 standard, the number of characters increase to 63.

## Settings

**Default:** `defined-by-compiler`

`defined-by-compiler`

The analysis uses a standard based on your specification for `Compiler (-compiler)`.

See “C/C++ Language Standard Used in Polyspace Analysis”.

`c90`

The analysis uses the C90 Standard (ISO®/IEC 9899:1990).

`c99`

The analysis uses the C99 Standard (ISO/IEC 9899:1999).

`c11`

The analysis uses the C11 Standard (ISO/IEC 9899:2011).

See also “C11 Language Elements Supported in Polyspace”.

`c17`

The analysis uses the C17 Standard (ISO/IEC 9899:2018).

This version addresses defects in C11 Standard but does not introduce new language features. The value of the `__STDC_VERSION__` macro is increased to `201710L`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.
- If you create a project or options file from your build system using the `polyspace-configure` command or `polyspaceConfigure` function, the value of this option is automatically determined from your build system.

  If the build system uses different standards for different files, the subsequent Polyspace analysis can emulate your build system and use different standards for compiling those files. If you open such a project in the Polyspace user interface, the option value is shown as `defined-by-compiler`. However, instead of one standard, Polyspace uses the hidden option `-options-for-sources` to associate different standards with different files.

## Command-Line Information

**Parameter:** `-c-version`
**Value:** `defined-by-compiler` | `c90` | `c99` | `c11` | `c17`
**Default:** `defined-by-compiler`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources "`*`file1.c,file2.c`*`" -c-version c90`
**Example (Code Prover):** `polyspace-code-prover -lang c -sources "`*`file1.c,file2.c`*`" -c-version c90`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources "`*`file1.c,file2.c`*`" -c-version c90`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang c -sources "`*`file1.c,file2.c`*`" -c-version c90`

# C++ standard version (-cpp-version)

Specify C++ language standard followed in source code

## Description

Specify the C++ language standard that you follow in your source code. This option applies to both dynamic testing and static analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. See "Dependencies" on page 2-7 for other options that you must enable.

**Command line and options file**: Use the option -cpp-version. See "Command-Line Information" on page 2-7.

### Why Use This Option

Use this option so that Polyspace can allow features from a specific version of the C++ language standard during compilation. For instance, if you compile with GCC using the flag -std=c++11 or -std=gnu++11, specify cpp11 for this option. If you are not sure of the language standard, specify defined-by-compiler.

For instance, suppose you use range-based for loops. This type of for loop is defined in the C++11 standard but unrecognized in prior standards such as C++03. If the Polyspace compilation uses the C ++03 standard, you can see compilation errors.

To check if your compiler allows features specific to a standard, compile code with macros specific to the standard using compiler settings that you typically use. For instance, to check for C++11-specific features, compile this code. The code contains a C++11-specific keyword nullptr. If the macro __cplusplus is not 201103L (indicating C++11), this keyword is used and causes a compilation error.

```
#if defined(__cplusplus) && __cplusplus >= 201103L
    /* C++11 compiler */
#else
    void* ptr = nullptr;
#endif
```

If the code compiles, use cpp11 for this option.

## Settings

**Default:** defined-by-compiler

defined-by-compiler

The analysis uses a standard based on your specification for Compiler (-compiler).

See "C/C++ Language Standard Used in Polyspace Analysis".

`cpp03`

The analysis uses the C++03 Standard (ISO/IEC 14882:2003).

`cpp11`

The analysis uses the C++11 Standard (ISO/IEC 14882:2011).

See also “C++11 Language Elements Supported in Polyspace”.

`cpp14`

The analysis uses the C++14 Standard (ISO/IEC 14882:2014).

See also “C++14 Language Elements Supported in Polyspace”.

`cpp17`

The analysis uses the C++17 Standard (ISO/IEC 14882:2017).

See also “C++17 Language Elements Supported in Polyspace”.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `CPP` or `C-CPP`.
- If you create a project or options file from your build system using the `polyspace-configure` command or `polyspaceConfigure` function, the value of this option is automatically determined from your build system.

  If the build system uses different standards for different files, the subsequent Polyspace analysis can emulate your build system and use different standards for compiling those files. If you open such a project in the Polyspace user interface, the option value is shown as `defined-by-compiler`. However, instead of one standard, Polyspace uses multiple standards for compiling the files. The analysis uses the hidden option `-options-for-sources` to associate different standards with different files.

## Command-Line Information

**Parameter:** `-cpp-version`
**Value:** `defined-by-compiler` | `cpp03` | `cpp11` | `cpp14` | `cpp17`
**Default:** `defined-by-compiler`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources "`*`file1.c,file2.c`*`" -cpp-version cpp11`
**Example (Code Prover):** `polyspace-code-prover -lang c -sources "`*`file1.c,file2.c`*`" -cpp-version cpp11`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources "`*`file1.c,file2.c`*`" -cpp-version cpp11`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang c -sources "`*`file1.c,file2.c`*`" -cpp-version cpp11`

# Compiler (-compiler)

Specify the compiler that you use to build your source code

## Description

Specify the compiler that you use to build your source code.

Polyspace fully supports the most common compilers used to develop embedded applications. See the list below. For these compilers, you can run analysis simply by specifying your compiler and target processor. For other compilers, specify `generic` as compiler name. If you face compilation errors, explicitly define compiler-specific extensions to work around the errors.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option `-compiler`. See “Command-Line Information” on page 2-17.

### Why Use This Option

Polyspace uses this information to interpret syntax that is not part of the C/C++ Standard, but comes from language extensions.

For example, the option allows additional language keywords, such as `sfr`, `sbit`, and `bit`. If you do not specify your compiler, these additional keywords can cause compilation errors during Polyspace analysis.

Polyspace does not actually invoke your compiler for compilation. In particular:

- You cannot specify compiler flags directly in the Polyspace analysis. To emulate your compiler flags, trace your build command or manually specify equivalent Polyspace analysis options. See “Specify Target Environment and Compiler Behavior”.
- Code Prover has a linking policy that is stricter than regular compilers. For instance, if your compiler allows declaration mismatches with specific compiler options, you cannot emulate this linking policy in Code Prover. See “Troubleshoot Compilation and Linking Errors” (Polyspace Code Prover).

## Settings

**Default:** `generic`

### GCC Compilers

`gnu3.4`

Analysis allows GCC 3.4 syntax.

`gnu4.6`

Analysis allows GCC 4.6 syntax.

`gnu4.7`

Analysis allows GCC 4.7 syntax.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu4.8`

Analysis allows GCC 4.8 syntax.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu4.9`

Analysis allows GCC 4.9 syntax.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu5.x`

Analysis allows GCC 5.x syntax. For a list of available GCC 5.x releases, see GCC releases.

If you select `gnu5.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu6.x`

Analysis allows GCC 6.x syntax. For a list of available GCC 6.x releases, see GCC releases.

If you select `gnu6.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu7.x`

Analysis allows GCC 7.x syntax. For a list of available GCC 7.x releases, see GCC releases.

If you select `gnu7.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu8.x`

Analysis allows GCC 8.x syntax. For a list of available GCC 8.x releases, see GCC releases.

If you select `gnu8.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`..

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu9.x`

Analysis allows GCC 9.x syntax. For a list of available GCC 9.x releases, see GCC releases.

If you select `gnu9.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu10.x`

Analysis allows GCC 10.x syntax. For a list of available GCC 10.x releases, see GCC releases.

If you select `gnu10.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu11.x`

Analysis allows GCC 11.x syntax. For a list of available GCC 11.x releases, see GCC releases.

If you select `gnu11.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

`gnu12.x`

Analysis allows GCC 12.x syntax. For a list of available GCC 12.x releases, see GCC releases.

If you select `gnu12.x`, you can specify only a subset of GCC based compiler targets by using the option `Target processor type (-target)`. To specify other targets that are not part of this subset, use the option `Generic target options`.

For unsupported GCC extensions, see “Limitations” on page 2-15.

### Clang Compilers

`clang3.x`

Analysis allows Clang syntax for these versions:

- 3.5.0, 3.5.1, and 3.5.2
- 3.6.0, 3.6.1, and 3.6.2
- 3.7.0 and 3.7.1
- 3.8.0 and 3.8.1
- 3.9.0 and 3.9.1

`clang4.x`

Analysis allows Clang 4.0.0, and 4.0.1 syntax.

`clang5.x`

Analysis allows Clang 5.0.0, 5.0.1, and 5.0.2 syntax.

`clang6.x`

Analysis allows Clang 6.0.0 and 6.0.1 syntax.

`clang7.x`

Analysis allows Clang 7.0.0, 7.0.1, and 7.1.0 syntax.

`clang8.x`

Analysis allows Clang 8.0.0 and 8.0.1 syntax.

`clang9.x`

Analysis allows Clang 9.0.0 and 9.0.1 syntax.

`clang10.x`

Analysis allows Clang 10.0.0 and 10.0.1 syntax.

`clang11.x`

Analysis allows Clang 11.0.0, 11.0.1, and 11.1.0 syntax.

`clang12.x`

Analysis allows Clang 12.0.0 and 12.0.1 syntax.

`clang13.x`

Analysis allows Clang 13.0.0 and 13.0.1 syntax.

#### Visual Studio Compilers

`visual9.0`

Analysis allows Microsoft® Visual C++® 2008 syntax.

`visual10.0`

Analysis allows Microsoft Visual C++ 2010 syntax.

`visual11.0`

Analysis allows Microsoft Visual C++ 2012 syntax.

`visual12.0`

Analysis allows Microsoft Visual C++ 2013 syntax.

`visual14.0`

Analysis allows Microsoft Visual C++ 2015 syntax (supports Microsoft Visual Studio® update 2).

`visual15.x`

Analysis allows Microsoft Visual C++ 2017 syntax. For a list of available Microsoft Visual Studio 2017 versions, see Visual Studio 2017 Release Notes History.

`visual16.x`

Analysis allows Microsoft Visual C++ 2019 syntax. For a list of available Microsoft Visual Studio 2019 versions, see Visual Studio 2019 Release Notes History.

#### Other Compilers

`armcc`

Analysis allows non-ANSI® C syntax and semantics associated with the ARM® v5 compiler.

If you select `armcc`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the ARM v5 compiler.

See `ARM v5 Compiler (-compiler armcc)`.

`armclang`

Analysis allows non-ANSI C syntax and semantics associated with the ARM v6 compiler.

If you select `armclang`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the ARM v6 compiler.

See `ARM v6 Compiler (-compiler armclang)`.

`codewarrior`

Analysis allows non-ANSI C syntax and semantics associated with the NXP CodeWarrior® compiler.

If you select `codewarrior`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the NXP CodeWarrior compiler.

See `NXP CodeWarrior Compiler (-compiler codewarrior)`.

`cosmic`

Analysis allows non-ANSI C syntax and semantics associated with the Cosmic compiler.

If you select `cosmic`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the Comic compiler.

See `Cosmic Compiler (-compiler cosmic)`.

`diab`

Analysis allows non-ANSI C syntax and semantics associated with the Wind River® Diab compiler.

If you select `diab`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the Wind River Diab compiler.

See `Diab Compiler (-compiler diab)`.

`generic`

Analysis allows only standard syntax.

The language standard is determined by your choice for the following options:

- `C standard version (-c-version)`
- `C++ standard version (-cpp-version)`

If you do not specify a standard explicitly, the standard depends on your choice of compiler.

`greenhills`

Analysis allows non-ANSI C syntax and semantics associated with a Green Hills® compiler.

If you select `greenhills`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for a Green Hills compiler.

See `Green Hills Compiler (-compiler greenhills)`.

`iar`

Analysis allows non-ANSI C syntax and semantics associated with the compilers from IAR Systems (www.iar.com).

`iar-ew`

Analysis allows non-ANSI C syntax and semantics associated with the IAR Embedded Workbench compiler.

If you select `iar-ew`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the IAR Embedded Workbench compiler.

See `IAR Embedded Workbench Compiler (-compiler iar-ew)`.

`intel`

Analysis allows non-ANSI C syntax and semantics associated with the Intel® C++ Compiler Classic (icc/icl) compiler.

If you select `intel`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the Intel C++ Compiler Classic (icc/icl) compiler.

See `Intel C++ Compiler Classic (icc/icl) (-compiler intel)`.

`keil`

Analysis allows non-ANSI C syntax and semantics associated with the Keil products from ARM (www.keil.com).

`microchip`

Analysis allows non-ANSI C syntax and semantics associated with the MPLAB XC8 C compiler.

If you select `microchip`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the MPLAB XC8 C compiler.

See `MPLAB XC8 C Compiler (-compiler microchip)`.

`renesas`

Analysis allows non-ANSI C syntax and semantics associated with the Renesas® compiler.

If you select `renesas`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the Renesas compiler.

See `Renesas Compiler (-compiler renesas)`.

`tasking`

Analysis allows non-ANSI C syntax and semantics associated with the TASKING compiler.

If you select `tasking`,in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the TASKING compiler.

See `TASKING Compiler (-compiler tasking)`.

`ti`

Analysis allows non-ANSI C syntax and semantics associated with the Texas Instruments® compiler.

If you select `ti`, in the user interface of the Polyspace desktop products, the option `Target processor type (-target)` shows only the targets that are allowed for the Texas Instruments compiler.

See `Texas Instruments Compiler (-compiler ti)`.

## Tips

- Your compiler specification determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.
  - To override the macro definition, use the option `Preprocessor definitions (-D)`.
  - To undefine a macro, use the option `Disabled preprocessor definitions (-U)`.
- If you use a Visual Studio compiler, you must use a `Target processor type (-target)` option that sets `long long` to 64 bits. Compatible targets include: `i386`, `sparc`, `m68k`, `powerpc`, `tms320c3x`, `sharc21x61`, `mpc5xx`, `x86_64`, or `mcpu` with `long long` set to 64 (`-long-long-is-64bits` at the command line).
- If you use the option `Check JSF AV C++ rules (-jsf-coding-rules)`, select the compiler `generic`. If you use another compiler, Polyspace cannot check the JSF® coding rules that require conforming to the ISO standard. For example, AV Rule 8: "All code shall conform to ISO/IEC 14882:2002(E) standard C++."

## Limitations

### GNU Compilers

Polyspace does not support certain features of GNU compilers:

- **GNU® compilers versions 4.7 and later:**
  - Nested functions.

    For instance, the function `bar` is nested in function `foo`:

    ```
    int foo (int a, int b)
    {
      int bar (int c) { return c * c; }

      return bar (a) + bar (b);
    }
    ```
  - Binary operations with vector types where one operand uses the shorthand notation for uniform vectors.

    For instance, in the addition operation, `2+a`, 2 is used as a shorthand notation for {2,2,2,2}.

    ```
    typedef int v4si __attribute__ ((vector_size (16)));
    v4si res, a = {1,2,3,4};

    res = 2 + a;  /* means {2,2,2,2} + a  */
    ```
  - Forward declaration of function parameters.

    For instance, the parameter `len` is forward declared:

    ```
    void func (int len; char data[len][len], int len)
    {
      /* … */
    }
    ```
  - Complex integer data types.

However, complex floating point data types are supported.

- Initialization of structures with flexible array members using an initialization list.

  For instance, the structure S has a flexible array member tab. A variable of type S is directly initialized with an initialization list.

  ```
  struct S {
      int x;
      int tab[];            /* flexible array member - not supported */
  };
  struct S s = { 0, 1, 2} ;
  ```

  You see a warning during analysis and a red check in the results when you dereference, for instance, s.tab[1].
- 128-bit variables.

  Polyspace cannot analyze this data type semantically. Bug Finder allows use of 128-bit data types, but Code Prover shows a compilation error if you use such a data type, for instance, the GCC extension __float128.

- **GNU compilers version 7.x:**

  - Type names _FloatN and _FloatNx are not semantically supported. The analysis treats them as type float, double, or long double.
  - Constants of type _FloatN or _FloatNx with suffixes fN, FN, or fNx, such as 1.2f123 or 2.3F64x are not supported.

### Visual Studio Compilers

Polyspace does not support certain features of Visual Studio compilers:

- C++ Accelerated Massive Parallelism (AMP).

  C++ AMP is a Visual Studio feature that accelerates your C++ code execution for certain types of data-parallel hardware on specific targets. You typically use the restrict keyword to enable this feature.

  ```
  void Buffer() restrict(amp)
  {
    ...
  }
  ```
- __assume statements.

  You typically use __assume with a condition that is false. The statement indicates that the optimizer must assume the condition to be henceforth true. Code Prover cannot reconcile this contradiction. You get the error:

  ```
  Asked for compulsory presence of absent entity : assert
  ```
- Managed Extensions for C++ (required for the .NET Framework), or its successor, C++/CLI (C++ modified for Common Language Infrastructure)
- __declspec keyword with attributes other than noreturn, nothrow, selectany or thread.

### Polyspace System Headers

If you do not specify the path to your compiler headers, Polyspace uses its own system headers and your project might not compile even if your code compiles with your compiler.

To make sure that Polyspace uses your compiler header files, run `polyspace-configure` or specify the paths to your compiler header files manually. See "Provide Standard Library Headers for Polyspace Analysis".

## Command-Line Information

**Parameter:** `-compiler`
**Value (GCC):** `gnu3.4 | gnu4.6 | gnu4.7 | gnu4.8 | gnu4.9 | gnu5.x | gnu6.x | gnu7.x | gnu8.x | gnu9.x | gnu10.x | gnu11.x | gnu12.x`
**Value (Clang):** `clang3.x | clang4.x | clang5.x | clang6.x | clang7.x | clang8.x | clang9.x | clang10.x | clang11.x | clang12.x | clang13.x`
**Value (Visual Studio):** `visual10.0 | visual11.0 | visual12.0 | visual14.0 | visual15.x | visual16.x | visual9.0`
**Value (Other):** `armcc | armclang | codewarrior | cosmic | diab | generic | greenhills | iar | iar-ew | intel | keil | microchip | renesas | tasking | ti`
**Default:** `generic`
**Example 1 (Bug Finder):** `polyspace-bug-finder -lang c -sources "`*`file1.c,file2.c`*`" -compiler gnu4.6`
**Example 2 (Bug Finder):** `polyspace-bug-finder -lang cpp -sources "`*`file1.cpp,file2.cpp`*`" -compiler visual9.0`
**Example 1 (Code Prover):** `polyspace-code-prover -lang c -sources "`*`file1.c,file2.c`*`" -lang c -compiler gnu4.6`
**Example 2 (Code Prover):** `polyspace-code-prover -lang cpp -sources "`*`file1.cpp,file2.cpp`*`" -compiler visual9.0`
**Example 1 (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources "`*`file1.c,file2.c`*`" -compiler gnu4.6`
**Example 2 (Bug Finder Server):** `polyspace-bug-finder-server -lang cpp -sources "`*`file1.cpp,file2.cpp`*`" -compiler visual9.0`
**Example 1 (Code Prover Server):** `polyspace-code-prover-server -lang c -sources "`*`file1.c,file2.c`*`" -lang c -compiler gnu4.6`
**Example 2 (Code Prover Server):** `polyspace-code-prover-server -lang cpp -sources "`*`file1.cpp,file2.cpp`*`" -compiler visual9.0`

# Target processor type (`-target`)

Specify size of data types and endianness by selecting a predefined target processor

## Description

Specify the processor on which you deploy your code.

The target processor determines the sizes of fundamental data types and the endianness of the target machine. You can analyze code intended for an unlisted processor type by using one of the other processor types, if they share common data properties.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. To see the sizes of types, click the **Edit** button to the right of the **Target processor type** drop-down list.

For some compilers, in the user interface, you see only the processors allowed for that compiler. For these compilers, you also cannot see the data type sizes in the user interface. See the links in the table below for the data type sizes.

**Command line and options file**: Use the option `-target`. See “Command-Line Information” on page 2-20.

### Why Use This Option

You specify a target processor so that some of the Polyspace run-time checks are tailored to the data type sizes and other properties of that processor.

For instance, a variable can overflow for smaller values on a 32-bit processor such as i386 compared to a 64-bit processor such as x86_64. If you select x86_64 for your Polyspace analysis, but deploy your code to the i386 processor, your Polyspace results are not always applicable.

Once you select a target processor, you can specify if the default sign of char is signed or unsigned. To determine which signedness to specify, compile this code using the compiler settings that you typically use:

```
#include <limits.h>
int array[(char)UCHAR_MAX]; /* If char is signed, the array size is -1
```

If the code compiles, the default sign of char is unsigned. For instance, on a GCC compiler, the code compiles with the `-fsigned-char` flag and fails to compile with the `-funsigned-char` flag.

## Settings

**Default:** `i386`

This table shows the size of each fundamental data type that Polyspace considers. For some targets, you can modify the default size by clicking the **Edit** button to the right of the **Target processor type** drop-down list. The optional values for those targets are shown in [brackets] in the table.

| Target | char | short | int | long | long long | float | double | long double[a] | ptr | Default sign of char | endian | Alignment |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| i386 | 8 | 16 | 32 | 32 | 64 | 32 | 64 | 96 | 32 | signed | Little | 32 |
| sparc | 8 | 16 | 32 | 32 | 64 | 32 | 64 | 128 | 32 | signed | Big | 64 |
| m68k[b] | 8 | 16 | 32 | 32 | 64 | 32 | 64 | 96 | 32 | signed | Big | 64 |
| powerpc | 8 | 16 | 32 | 32 | 64 | 32 | 64 | 128 | 32 | unsigned | Big | 64 |
| c-167 | 8 | 16 | 16 | 32 | 32 | 32 | 64 | 64 | 16 | signed | Little | 64 |
| tms320c3x | 32 | 32 | 32 | 32 | 64 | 32 | 32 | 64 | 32 | signed | Little | 32 |
| sharc21x61 | 32 | 32 | 32 | 32 | 64 | 32 | 32 [64] | 32 [64] | 32 | signed | Little | 32 |
| necv850 | 8 | 16 | 32 | 32 | 32 | 32 | 32 | 64 | 32 | signed | Little | 32 |
| hc08[c] | 8 | 16 | 16 [32] | 32 | 32 | 32 | 32 [64] | 32 [64] | 16[d] | unsigned | Big | 32 |
| hc12 | 8 | 16 | 16 [32] | 32 | 32 | 32 | 32 [64] | 32 [64] | 32[6] | signed | Big | 32 |
| mpc5xx | 8 | 16 | 32 | 32 | 64 | 32 | 32 [64] | 32 [64] | 32 | signed | Big | 32 |
| c18 | 8 | 16 | 16 | 32 [24][e] | 32 | 32 | 32 | 32 | 16 [24] | signed | Little | 8 |
| x86_64 | 8 | 16 | 32 | 64 [32][f] | 64 | 32 | 64 | 128 | 64 | signed | Little | 128 |
| mcpu... (Advanced)[g] | 8 [16] | 8 [16] | 16 [32] | 32 | 32 [64] | 32 | 32 [64] | 32 [64] | 16 [32] | signed | Little | 32 |

[a] For targets where the size of `long double` is greater than 64 bits, the size used for computations is not always the same as the size listed in this table. The exceptions are:

- For targets `i386`, `x86_64` and `m68k`, 80 bits are used for computations, following the practice in common compilers.
- For the target `tms320c3x`, 40 bits are used for computation, following the TMS320C3x specifications.
- If you use a Visual compiler, the size of `long double` used for computations is the same as size of `double`, following the specification of Visual C++ compilers.

[b] The M68k family (68000, 68020, and so on) includes the “ColdFire” processor

[c] Non-ANSI C specified keywords and compiler implementation-dependent pragmas and interrupt facilities are not taken into account by this support

[d] All kinds of pointers (near or far pointer) have 2 bytes (hc08) or 4 bytes (hc12) of width physically.

[e] The `c18` target supports the type `short long` as 24 bits in size.

[f] Use option `-long-is-32bits` to support Microsoft C/C++ Win64 target.

[g] `mcpu` is a reconfigurable Micro Controller/Processor Unit target. You can use this type to configure one or more generic targets. For more information, see `Generic target options`.

## Tips

- If your processor is not listed, use a similar processor that shares the same characteristics, or create an `mcpu` generic target processor. See `Generic target options`.
- You can also create a custom target by explicitly stating sizes of fundamental types and so on with the option `-custom-target`.
- If your configuration uses both `-custom-target` and `-target` to specify targets, the analysis uses the target that you specify with `-custom-target`.

## Command-Line Information

**Parameter:** `-target`
**Value:** `i386 | sparc | m68k | powerpc | c-167 | tms320c3x | sharc21x61 | necv850 | hc08 | hc12 | mpc5xx | c18 | x86_64 | mcpu`
**Default:** `i386`

**Example (Bug Finder):** `polyspace-bug-finder -target m68k`
**Example (Code Prover):** `polyspace-code-prover -target m68k`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -target m68k`
**Example (Code Prover Server):** `polyspace-code-prover-server -target m68k`

You can override the default values for some targets by using specific command-line options. See the section **Command-Line Options** in `Generic target options`.

# ARM v5 Compiler (-compiler armcc)

Specify ARM v5 compiler

## Description

Specify armcc for the Compiler (-compiler) option if you compile your code with a ARM v5 compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select armcc for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for a ARM v5 compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine, and certain keyword definitions.

If you specify the armcc compiler, you must specify the path to your compiler header files. See "Provide Standard Library Headers for Polyspace Analysis".

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option -dump-preprocessing-info.

- To override the macro definition, use the option Preprocessor definitions (-D).
- To undefine a macro, use the option Disabled preprocessor definitions (-U).

## Command-Line Information

**Parameter:** -compiler armcc -target
**Value:** arm
**Default:** arm
**Example (Bug Finder):** polyspace-bug-finder -compiler armcc -target arm
**Example (Code Prover):** polyspace-code-prover -compiler armcc -target arm
**Example (Bug Finder Server):** polyspace-bug-finder-server -compiler armcc -target arm
**Example (Code Prover Server):** polyspace-code-prover-server -compiler armcc -target arm

## Tips

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

# ARM v6 Compiler (`-compiler armclang`)

Specify ARM v6 compiler

## Description

Specify `armclang` for the `Compiler (-compiler)` option if you compile your code with a ARM v6 compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select `armclang` for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for a ARM v6 compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine, and certain keyword definitions.

If you specify the `armclang` compiler, you must specify the path to your compiler header files. See “Provide Standard Library Headers for Polyspace Analysis”.

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.

- To override the macro definition, use the option `Preprocessor definitions (-D)`.
- To undefine a macro, use the option `Disabled preprocessor definitions (-U)`.

## Command-Line Information

**Parameter:** `-compiler armclang -target`
**Value:** `arm | arm64`
**Default:** `arm`
**Example (Bug Finder):** `polyspace-bug-finder -compiler armclang -target arm64`
**Example (Code Prover):** `polyspace-code-prover -compiler armclang -target arm64`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler armclang -target arm64`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler armclang -target arm64`

# Diab Compiler (`-compiler diab`)

Specify the Wind River Diab compiler

## Description

Specify `diab` for `Compiler (-compiler)` if you compile your code using the Wind River Diab compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select `diab` for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for the Diab compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine and certain keyword definitions.

If you specify the `diab` compiler, you must specify the path to your compiler header files. See “Provide Standard Library Headers for Polyspace Analysis”.

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.

- To override the macro definition, use the option `Preprocessor definitions (-D)`.
- To undefine a macro, use the option `Disabled preprocessor definitions (-U)`.

## Tips

- Polyspace does not support these Diab compiler features:
  - The preprocessor directives `#assert` and `#unassert`. Your code compiles but the software does not interpret these directives semantically.
  - Single-character constants in `#if` directives having the same value as the same character constant in the execution character set. Your code compiles but Polyspace does not consider that the character constants have the same value.
  - The extended `sizeof()` syntax using two arguments. For example, `sizeof(char, 2)`. Your code does not compile with Polyspace when you use this feature.
  - Statement expressions. For example, `({int y; y=foo(); y;})`. Your code does not compile with Polyspace when you use this feature.
  - The use of regular expressions with the `defined` preprocessor operator. For example `#if defined ("BSP_HW*")`. Your code does not compile with Polyspace when you use this feature.
- If you encounter errors during Polyspace analysis, see “Fix Polyspace Compilation Errors Related to Diab Compiler”.

- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

### Command-Line Information

**Parameter:** `-compiler diab -target`
**Value:** `i386 | powerpc | arm | coldfire | mips | mcore | rh850 | superh | tricore`
**Default:** `powerpc`
**Example (Bug Finder):** `polyspace-bug-finder -compiler diab -target tricore`
**Example (Code Prover):** `polyspace-code-prover -compiler diab -target tricore`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler diab -target tricore`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler diab -target tricore`

## Version History

# Green Hills Compiler (-compiler greenhills)

Specify Green Hills compiler

## Description

Specify greenhills for Compiler (-compiler) if you compile your code using a Green Hills compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select greenhills for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for a Green Hills compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine and certain keyword definitions.

If you specify the greenhills compiler, you must specify the path to your compiler header files. See “Provide Standard Library Headers for Polyspace Analysis”.

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option -dump-preprocessing-info.

- To override the macro definition, use the option Preprocessor definitions (-D).
- To undefine a macro, use the option Disabled preprocessor definitions (-U).

## Tips

- If you encounter errors during a Polyspace analysis, see “Fix Polyspace Compilation Errors Related to Green Hills Compiler”
- Polyspace supports the embedded configuration for the i386 target. If your x86 Green Hills compiler is configured for native Windows® development, you can see compilation errors or incorrect analysis results with Code Prover. Contact Technical Support.

  For instance, Green Hills compilers consider a size of 12 bytes for long double for embedded targets, but 8 bytes for native Windows. Polyspace considers 12 bytes by default.
- If you create a Polyspace project from a build command that uses a Green Hills compiler, the compiler options -filetype and -os_dir are not implemented in the project. To emulate the -os_dir option, you can explicitly add the path argument of the option as an include folder to your Polyspace project.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## Command-Line Information

**Parameter:** `-compiler greenhills -target`
**Value:** `powerpc | powerpc64 | arm | arm64 | tricore | rh850 | arm | i386 | x86_64`
**Default:** `powerpc`
**Example (Bug Finder):** `polyspace-bug-finder -compiler greenhills -target arm`
**Example (Code Prover):** `polyspace-code-prover -compiler greenhills -target arm`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler greenhills -target arm`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler greenhills -target arm`

# IAR Embedded Workbench Compiler (-compiler iar-ew)

Specify IAR Embedded Workbench compiler

## Description

Specify iar-ew for Compiler (-compiler) if you compile your code using a IAR Embedded Workbench compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select iar-ew for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for a IAR Embedded Workbench compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine and certain keyword definitions.

If you specify the iar-ew compiler, you must specify the path to your compiler header files. See "Provide Standard Library Headers for Polyspace Analysis".

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option -dump-preprocessing-info.

- To override the macro definition, use the option Preprocessor definitions (-D).
- To undefine a macro, use the option Disabled preprocessor definitions (-U).

## Tips

- Polyspace does not support the use of $Super$$ and $Sub$$ to patch symbol definitions. For instance, the following code compiles correctly, but Polyspace considers that main() calls the extern func ($Super$$func) instead of the function func defined in this code ($Sub$$func):

```
/* void func() declared in another file */
extern void $Super$$func(int i);

int setup = 0;

void setup_func(int i) {
  setup = i;
}

/* this function should be called instead of the original extern func() */
void $Sub$$func(int i) {
  setup_foo(i);
  /* does some extra setup work */
  /* ... */
}

int main() {
  assert(setup = 0);
  func(1); // Should call $Sub$$func instead of $Super$$func
  assert(setup = 1);
  return 0;
}
```

To make sure that Polyspace calls the correct function when analyzing your code, replace all instance of `$Sub$$` with an empty string in all your files after preprocessing. See `Command/script to apply to preprocessed files (-post-preprocessing-command)`.

- Polyspace does not support some constructs specific to the IAR compiler.

  For the list of unsupported constructs, see `codeprover_limitations.pdf` in *`polyspaceroot`*`\polyspace\verifier\code_prover_desktop`. Here, *`polyspaceroot`* is the MATLAB® installation folder, for instance, `C:\Program Files\Polyspace\R2019a`.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## Command-Line Information

**Parameter:** `-compiler iar-ew -target`
**Value:** `arm | avr | msp430 | rh850 | riscv | rl78`
**Default:** `arm`
**Example (Bug Finder):** `polyspace-bug-finder -compiler iar-ew -target rl78`
**Example (Code Prover):** `polyspace-code-prover -compiler iar-ew -target rl78`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler iar-ew -target rl78`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler iar-ew -target rl78`

# Intel C++ Compiler Classic (icc/icl) (-compiler intel)

Specify Intel C++ Compiler Classic (icc/icl)

## Description

Specify intel for the Compiler (-compiler) option if you compile your code with an Intel C++ Compiler Classic (icc/icl) compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select intel for **Compiler**, in the user interface, you see only the processors allowed for a Intel C++ Compiler Classic (icc/icl) compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine, and certain keyword definitions.

If you specify the intel compiler, you must specify the path to your compiler header files. See "Provide Standard Library Headers for Polyspace Analysis".

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

## Command-Line Information

**Parameter:** -compiler intel -target
**Value:** x86_64
**Default:** x86_64
**Example (Bug Finder):** polyspace-bug-finder -compiler intel -target x86_64
**Example (Code Prover):** polyspace-code-prover -compiler intel -target x86_64
**Example (Bug Finder Server):** polyspace-bug-finder-server -compiler intel -target x86_64

# MPLAB XC8 C Compiler (-compiler microchip)

Specify MPLAB XC8 C compiler

## Description

Specify microchip for the Compiler (-compiler) option if you compile your code with a MPLAB XC8 C compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select microchip for **Compiler**, in the user interface, you see only the processors allowed for a MPLAB XC8 C compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine, and certain keyword definitions.

If you specify the microchip compiler, you must specify the path to your compiler header files. See "Provide Standard Library Headers for Polyspace Analysis".

## Settings

To see the default sizes in bits for the fundamental types that the target uses, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option -dump-preprocessing-info.

- To override the macro definition, use the option Preprocessor definitions (-D).
- To undefine a macro, use the option Disabled preprocessor definitions (-U).

## Tip

- Polyspace does not support the Atmel families of processors, such as AVR, TinyAVR, MegaAVR, XMEGA, and SAM32.
- Polyspace does not support the CPP/P1 or C18 Microchip front-end. This front-end is activated by the compiler when you compile your code with the C90 version of the Standard.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## Command-Line Information

**Parameter:** -compiler microchip -target
**Value:** pic
**Default:** pic
**Example (Bug Finder):** polyspace-bug-finder -compiler microchip -target pic
**Example (Code Prover):** polyspace-code-prover -compiler microchip -target pic
**Example (Bug Finder Server):** polyspace-bug-finder-server -compiler microchip -target pic

"Specify Target Environment and Compiler Behavior"

# TASKING Compiler (-compiler tasking)

Specify the Altium TASKING compiler

## Description

Specify `tasking` for `Compiler (-compiler)` if you compile your code using the Altium® TASKING compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select `tasking` for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for the TASKING compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine and certain keyword definitions.

If you specify the `tasking` compiler, you must specify the path to your compiler header files. See “Provide Standard Library Headers for Polyspace Analysis”.

The software supports different versions of the TASKING compiler, depending on the target:

- TriCore: 6.x and older versions
- C166: 4.x and older versions
- ARM: 5.x and older versions
- RH850: 2.x and older versions

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.

- To override the macro definition, use the option `Preprocessor definitions (-D)`.
- To undefine a macro, use the option `Disabled preprocessor definitions (-U)`.

## Tips

- Polyspace does not support some constructs specific to the TASKING compiler.

  For the list of unsupported constructs, see `codeprover_limitations.pdf` in *`polyspaceroot`*`\polyspace\verifier\code_prover_desktop`. Here, *`polyspaceroot`* is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2019a`.
- The CPU used is TC1793. If you use a different CPU, set the following analysis options in your project:

  - `Disabled preprocessor definitions (-U)`: Undefine the macro `__CPU_TC1793B__`.

- `Preprocessor definitions (-D)`: Define the macro `__CPU__`. Enter `__CPU__=`*`xxx`*, where *`xxx`* is the name of your CPU.

  Additionally, define the equivalent of the macro `__CPU_TC1793B__` for your CPU. For instance, enter `__CPU_TC1793A__`.

  Instead of manually specifying your compiler, if you trace your build command (makefile), Polyspace can detect your CPU and add the required definitions in your project.
- For some errors related to TASKING compiler-specific constructs, see solutions in “Fix Polyspace Compilation Errors Related to TASKING Compiler”.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## Command-Line Information

**Parameter:** `-compiler tasking -target`
**Value:** `tricore | c166 | rh850 | arm`
**Default:** `tricore`
**Example (Bug Finder):** `polyspace-bug-finder -compiler tasking -target tricore`
**Example (Code Prover):** `polyspace-code-prover -compiler tasking -target tricore`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler tasking -target tricore`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler tasking -target tricore`

# Texas Instruments Compiler (-compiler ti)

Specify Texas Instruments compiler

## Description

Specify `ti` for `Compiler (-compiler)` if you compile your code using a Texas Instruments compiler. By specifying your compiler, you can avoid compilation errors from syntax that is not part of the Standard but comes from language extensions.

Then, specify your target processor type. If you select `ti` for **Compiler**, in the user interface of the Polyspace desktop products, you see only the processors allowed for a Texas Instruments compiler. Your choice of target processor determines the size of fundamental data types, the endianness of the target machine and certain keyword definitions.

If you specify the `ti` compiler, you must specify the path to your compiler header files. See “Provide Standard Library Headers for Polyspace Analysis”.

## Settings

To see the default sizes in bits for the fundamental types that the targets use, see the online documentation.

Your compiler specification also determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.

- To override the macro definition, use the option `Preprocessor definitions (-D)`.
- To undefine a macro, use the option `Disabled preprocessor definitions (-U)`.

## Tips

Polyspace does not support some constructs specific to the Texas Instruments compiler.

For the list of unsupported constructs, see `codeprover_limitations.pdf` in *`polyspaceroot`*`\polyspace\verifier\code_prover_desktop`. Here, *`polyspaceroot`* is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2019a`.

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## Command-Line Information

**Parameter:** `-compiler ti -target`
**Value:** `c28x | c6000 | arm | msp430`
**Default:** `c28x`
**Example (Bug Finder):** `polyspace-bug-finder -compiler ti -target msp430`
**Example (Code Prover):** `polyspace-code-prover -compiler ti -target msp430`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler ti -target msp430`

# Generic target options

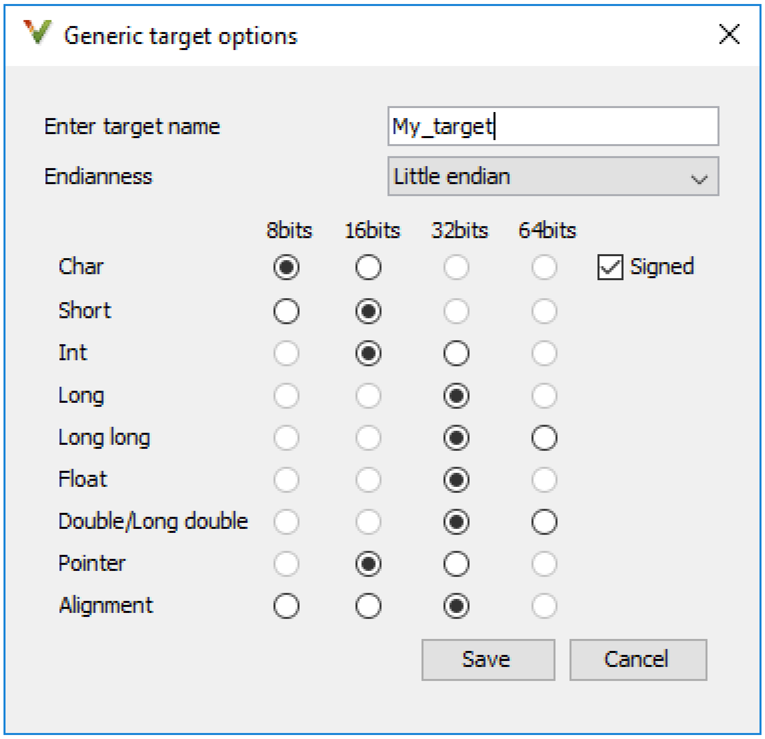
Specify size of data types and endianness by creating your own target processor

## Description

If a target processor is not directly supported by Polyspace, you can create your own target. You specify the target mcpu representing a generic "Micro Controller/Processor Unit" and then explicitly specify sizes of fundamental data types, endianness and other characteristics.

## Settings

In the user interface of the Polyspace desktop products, the **Generic target options** dialog box opens when you set the **Target processor type** to mcpu. The **Target processor type** option is available on the **Target & Compiler** node in the **Configuration** pane.



Generic target options

Enter target name: My_target

Endianness: Little endian

| | 8bits | 16bits | 32bits | 64bits | |
|---|---|---|---|---|---|
| Char | ● | ○ | ○ | ○ | ☑ Signed |
| Short | ○ | ● | ○ | ○ | |
| Int | ○ | ● | ○ | ○ | |
| Long | ○ | ○ | ● | ○ | |
| Long long | ○ | ○ | ● | ○ | |
| Float | ○ | ○ | ● | ○ | |
| Double/Long double | ○ | ○ | ● | ○ | |
| Pointer | ○ | ● | ○ | ○ | |
| Alignment | ○ | ○ | ● | ○ | |

Use the dialog box to specify the name of a new mcpu target, for example My_target. That new target is added to the **Target processor type** option list.

**Default characteristics of a new target:** listed as *type* [size]

- *char* [8]
- *short* [16]
- *int* [16]

- *long* `[32]`
- *long long* `[32]`
- *float* `[32]`
- *double* `[32]`
- *long double* `[32]`
- *pointer* `[16]`
- *alignment* `[32]`
- *char* is signed
- *endianness* is little-endian

## Dependency

A custom target can only be created when `Target processor type (-target)` is set to `mcpu`.

A custom target is not available when `Compiler (-compiler)` is set to one of the `visual*` options.

## Command-Line Options

When using the command line, use `-target mcpu` along with these target specification options.

| Option | Description | Available With | Example |
|---|---|---|---|
| `-little-endian` | Little-endian architectures are Less Significant byte First (LSF). For example: i386.<br>Specifies that the less significant byte of a short integer (e.g. 0x00FF) is stored at the first byte (0xFF) and the most significant byte (0x00) at the second byte. | All targets | `polyspace-bug-finder -target mcpu -little-endian` |

| Option | Description | Available With | Example |
|---|---|---|---|
| `-big-endian` | Big-endian architectures are Most Significant byte First (MSF). For example: SPARC, m68k.<br>Specifies that the most significant byte of a short integer (e.g. 0x00FF) is stored at the first byte (0x00) and the less significant byte (0xFF) at the second byte. | All targets | `polyspace-bug-finder -target mcpu -big-endian` |
| `-default-sign-of-char [signed \| unsigned]` | Specify default sign of `char`.<br>`signed`: Specifies that `char` is signed, overriding target's default.<br>`unsigned`: Specifies that `char` is unsigned, overriding target's default. | All targets | `polyspace-bug-finder -default-sign-of-char unsigned -target mcpu` |
| `-char-is-16bits` | `char` defined as 16 bits and all objects have a minimum alignment of 16 bits<br>Incompatible with `-short-is-8bits` and `-align 8` | `mcpu` | `polyspace-bug-finder -target mcpu -char-is-16bits` |
| `-short-is-8bits` | Define `short` as 8 bits, regardless of sign | `mcpu` | `polyspace-bug-finder -target mcpu -short-is-8bits` |
| `-int-is-32bits` | Define `int` as 32 bits, regardless of sign. Alignment is also set to 32 bits. | `mcpu`, `hc08`, `hc12`, `mpc5xx` | `polyspace-bug-finder -target mcpu -int-is-32bits` |
| `-long-is-32bits` | Define `long` as 32 bits, regardless of sign. Alignment is also set to 32 bits.<br>If your project sets `int` to 64 bits, you cannot use this option. | All targets | `polyspace-bug-finder -target mcpu -long-is-32bits` |

| Option | Description | Available With | Example |
|---|---|---|---|
| `-long-long-is-64bits` | Define `long long` as 64 bits, regardless of sign. Alignment is also set to 64 bits. | `mcpu` | `polyspace-bug-finder -target mcpu -long-long-is-64bits` |
| `-double-is-64bits` | Define `double` and `long double` as 64 bits, regardless of sign. | `mcpu`, `sharc21x61`, `hc08`, `hc12`, `mpc5xx` | `polyspace-bug-finder -target mcpu -double-is-64bits` |
| `-pointer-is-24bits` | Define pointer as 24 bits, regardless of sign. | `c18` | `polyspace-bug-finder -target c18 -pointer-is-24bits` |
| `-pointer-is-32bits` | Define pointer as 32 bits, regardless of sign. | `mcpu` | `polyspace-bug-finder -target mcpu -pointer-is-32bits` |
| `-align [128\|64\|32\|16\|8]` | Specifies the largest alignment of struct or array objects to the 128, 64, 32, 16, or 8 bit boundaries.<br>For instance, if the alignment of basic types in an array or struct is always 8, the array or struct storage is strictly determined by the size of the individual data objects without member and end padding. | All targets | `polyspace-bug-finder -target mcpu -align 16` |

See also:

- `Management of wchar_t (-wchar-t-type-is)`
- `Management of size_t (-size-t-type-is)`
- `Enum type definition (-enum-type-definition)`

You can also use the option `-custom-target` to specify sizes in bytes of fundamental data types, signedness of plain `char`, alignment of structures and underlying types of standard `typedef`-s such as `size_t`, `wchar_t` and `ptrdiff_t`.

## Examples

### GCC Toolchains

If you use any of these GCC toolchains for your software development, you can setup your Polyspace analysis so that your code will compile with Polyspace:

- ARM Ltd's GNU Arm Embedded Toolchain

- HighTec EDV-Systeme
- Linaro® GNU cross-toolchain
- Melexis®
- MENTOR® Embedded Sourcery CodeBench
- QNX® Software Development Platform
- Rowley Associates' CrossWorks
- STMicroelectronics® TrueSTUDIO® for STM32
- Texas Instruments Code Composer Studio™
- Wind River GNU Compiler

Use `polyspace-configure` on a build command that uses one of these toolchains and extract information about your compiler configuration. The command creates a Polyspace project by default. To generate an options file that you then pass to Polyspace at the command line, run `polyspace-configure` with the option `-output-options-file`.

Alternatively, if you prefer to set the details of your compiler configuration manually:

- Select the `gnu#.x` compiler that corresponds to your compiler version for `Compiler (-compiler)`.
- Specify your target by using the “Command-Line Options” on page 2-46. For an example of targets you can specify, see “Targets for GCC Based Compilers” on page 2-49.
- Specify your compiler macro definitions with `Preprocessor definitions (-D)`.

### Targets for GCC Based Compilers

If you select one of the `gnu#.x` compilers for `Compiler (-compiler)`, you can specify one of the supported target processor types. See `Target processor type (-target)`. If a target processor type is not directly listed as supported, you can create the target by using this option.

For instance, you can create these targets:

- **Tricore**: Use these options:

  ```
  -target mcpu
  -int-is-32bits
  -long-long-is-64bits
  -double-is-64bits
  -pointer-is-32bits
  -enum-type-definition auto-signed-first
  -wchar-t-type-is signed-int
  ```
- **PowerPC**: Use these options:

  ```
  -target mcpu
  -int-is-32bits
  -long-long-is-64bits
  -double-is-64bits
  -pointer-is-32bits
  -wchar-t-type-is signed-int
  ```
- **ARM**: Use these options:

  ```
  -target mcpu
  -int-is-32bits
  ```

```
-long-long-is-64bits
-double-is-64bits
-pointer-is-32bits
-enum-type-definition auto-signed-first
-wchar-t-type-is unsigned-int
```

- **MSP430**: Use these options:

```
-target mcpu
-long-long-is-64bits
-double-is-64bits
-wchar-t-type-is signed-long
-align 16
```

### Emulate Microchip MPLAB XC16 and XC32 Compilers

If you build your source code using Microchip MPLAB XC16 or XC32 compilers, you can set up your Polyspace analysis so that your code will compile with Polyspace. Enter these options at the command line or specify them in the **Configuration** pane of the Polyspace desktop user interface.

| Compile r | Target Processor Families | Options |
|---|---|---|
| MPLAB XC16 | PIC24<br>dsPIC | -compiler gnu4.6<br>-D__XC__<br>-D__XC16__<br>-target=mcpu<br>-wchar-t-type-is unsigned-int<br>-align 16<br>-long-long-is-64bits |
| MPLAB XC32 | PIC32 | -compiler gnu4.8<br>-custom-target true,8,2,4,-1,4,8,4,4,8,4,8,1,<br>big,unsigned_long,long,int<br>-D__PIC32M<br>-D__PIC32MX<br>-D__PIC32MX__<br>-D__XC32<br>-D__XC32__<br>-D__XC<br>-D__XC__<br>-D__mips=32<br>-D__mips__<br>-D_mips |

The set of macros specified with the option `Preprocessor definitions (-D)` is a minimal set. Specify additional macros as needed to ensure your code compiles with Polyspace.

## Tips

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

# Sfr type support (`-sfr-types`)

Specify sizes of `sfr` types for code developed with Keil or IAR compilers

## Description

Specify sizes of `sfr` types (types that define special function registers).

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. See “Dependency” on page 2-52 for other options you must also enable.

**Command line and options file**: Use the option `-sfr-types`. See “Command-Line Information” on page 2-52.

### Why Use This Option

Use this option if you have statements such as `sfr addr = 0x80;` in your code. `sfr` types are not standard C types. Therefore, you must specify their sizes explicitly for the Polyspace analysis.

## Settings

**No Default**

List each sfr name and its size in bits.

## Dependency

This option is available only when `Compiler (-compiler)` is set to `keil` or `iar`.

## Command-Line Information

**Syntax:** `-sfr-types` *`sfr_name=size_in_bits`*`,...`
**No Default**
**Name Value:** an sfr name such as `sfr16`.
**Size Value:** `8 | 16 | 32`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -compiler iar -sfr-types sfr=8,sfr16=16 ...`
**Example (Code Prover):** `polyspace-code-prover -lang c -compiler iar -sfr-types sfr=8,sfr16=16 ...`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -compiler iar -sfr-types sfr=8,sfr16=16 ...`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang c -compiler iar -sfr-types sfr=8,sfr16=16 ...`

“Supported Keil or IAR Language Extensions”

# Division round down (`-div-round-down`)

Round down quotients from division or modulus of negative numbers instead of rounding up

## Description

Specify whether quotients from division and modulus of negative numbers are rounded up or down.

**Note** `a = (a / b) * b + a % b` is always true.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option `-div-round-down`. See “Command-Line Information” on page 2-55.

### Why Use This Option

Use this option to emulate your compiler.

The option is relevant only for compilers following C90 standard (ISO/IEC 9899:1990). The standard stipulates that "*if either operand of / or % is negative, whether the result of the / operator, is the largest integer less or equal than the algebraic quotient or the smallest integer greater or equal than the quotient, is implementation defined, same for the sign of the % operator*". The standard allows compilers to choose their own implementation.

For compilers following the C99 standard ((ISO/IEC 9899:1999), this option is not required. The standard enforces division with rounding towards zero (section 6.5.5).

## Settings

☑ On

If either operand of `/` or `%` is negative, the result of the / operator is the largest integer less than or equal to the algebraic quotient. The result of the `%` operator is deduced from `a % b = a - (a / b) * b`.

*Example*: `assert(-5/3 == -2 && -5%3 == 1);` is true.

□ Off (default)

If either operand of `/` or `%` is negative, the result of the `/` operator is the smallest integer greater than or equal to the algebraic quotient. The result of the `%` operator is deduced from `a % b = a - (a / b) * b`.

This behavior is also known as rounding towards zero.

*Example*: `assert(-5/3 == -1 && -5%3 == -2);` is true.

## Command-Line Information

**Parameter:** `-div-round-down`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -div-round-down`
**Example (Code Prover):** `polyspace-code-prover -div-round-down`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -div-round-down`
**Example (Code Prover Server):** `polyspace-code-prover-server -div-round-down`

## See Also

# Enum type definition (-enum-type-definition)

Specify how to represent an enum with a base type

## Description

Allow the analysis to use different base types to represent an enumerated type, depending on the enumerator values and the selected definition. When using this option, each enum type is represented by the smallest integral type that can hold its enumeration values.

This option is available on the **Target & Compiler** node in the **Configuration** pane.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option -enum-type-definition. See “Command-Line Information” on page 2-57.

### Why Use This Option

Your compiler represents enum variables as constants of a base integer type. Use this option so that you can emulate your compiler.

To check your compiler settings:

1 Compile this code using the compiler settings that you typically use:

```
enum { MAXSIGNEDBYTE=127 } mysmallenum_t;

int dummy[(int)sizeof(mysmallenum_t) - (int)sizeof(int)];
```

   If compilation fails, you have to use one of auto-signed-first or auto-unsigned-first.

2 Compile this code using the compiler settings that you typically use:

```
#include <limits.h>

enum { MYINTMAX = INT_MAX } myintenum_t;

int dummy[(MYINTMAX + 1) < 0 ? -1:1];
```

   If compilation fails, use auto-signed-first for this option, otherwise use auto-unsigned-first.

## Settings

**Default:** defined-by-compiler

defined-by-compiler

   Uses the signed integer type for all compilers except gnu, clang and tasking.

For the gnu and clang compilers, it uses the first type that can hold all of the enumerator values from this list: `unsigned int`, `signed int`, `unsigned long`, `signed long`, `unsigned long long` and `signed long long`.

For the tasking compiler, it uses the first type that can hold all of the enumerator values from this list: `char`, `unsigned char`, `short`, `unsigned short`, `int`, and `unsigned int`.

`auto-signed-first`

Uses the first type that can hold all of the enumerator values from this list: `signed char`, `unsigned char`, `signed short`, `unsigned short`, `signed int`, `unsigned int`, `signed long`, `unsigned long`, `signed long long`, and `unsigned long long`.

`auto-unsigned-first`

Uses the first type that can hold all of the enumerator values from these lists:

- If enumerator values are positive: `unsigned char`, `unsigned short`, `unsigned int`, `unsigned long`, and `unsigned long long`.
- If one or more enumerator values are negative: `signed char`, `signed short`, `signed int`, `signed long`, and `signed long long`.

## Command-Line Information

**Parameter:** `-enum-type-definition`
**Value:** `defined-by-compiler | auto-signed-first | auto-unsigned-first`
**Default:** `defined-by-compiler`
**Example (Bug Finder):** `polyspace-bug-finder -enum-type-definition auto-signed-first`
**Example (Code Prover):** `polyspace-code-prover -enum-type-definition auto-signed-first`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -enum-type-definition auto-signed-first`
**Example (Code Prover Server):** `polyspace-code-prover-server -enum-type-definition auto-signed-first`

# Signed right shift (-logical-signed-right-shift)

Specify how to treat the sign bit for logical right shifts on signed variables

## Description

Choose between arithmetic and logical shift for right shift operations on negative values.

This option does not modify compile-time expressions. For more details, see "Limitation" on page 2-58.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option `-logical-signed-right-shift`. See "Command-Line Information" on page 2-59.

### Why Use This Option

The C99 Standard (sec 6.5.7) states that for a right-shift operation `x1>>x2`, if `x1` is signed and has negative values, the behavior is implementation-defined. Different compilers choose between arithmetic and logical shift. Use this option to emulate your compiler.

## Settings

**Default:** `Arithmetical`

`Arithmetical`

The sign bit remains:

```
(-4) >> 1 = -2
(-7) >> 1 = -4
  7  >> 1 = 3
```

`Logical`

0 replaces the sign bit:

```
(-4) >> 1 = (-4U) >> 1 = 2147483646
(-7) >> 1 = (-7U) >> 1 = 2147483644
  7  >> 1 = 3
```

## Limitation

In compile-time expressions, this Polyspace option does not change the standard behavior for right shifts.

For example, consider this right shift expression:

```
int arr[ ((-4) >> 20) ];
```

The compiler computes array sizes, so the expression `(-4) >> 20` is evaluated at compilation time. Logically, this expression is equivalent to 4095. However, arithmetically, the result is -1. This statement causes a compilation error (arrays cannot have negative size) because the standard right-shift behavior for signed integers is arithmetic.

## Command-Line Information

When using the command line, arithmetic is the default computation mode. When this option is set, logical computation is performed.
**Parameter:** `-logical-signed-right-shift`
**Default:** Arithmetic signed right shifts
**Example (Bug Finder):** `polyspace-bug-finder -logical-signed-right-shift`
**Example (Code Prover):** `polyspace-code-prover -logical-signed-right-shift`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -logical-signed-right-shift`
**Example (Code Prover Server):** `polyspace-code-prover-server -logical-signed-right-shift`

# Block char16/32_t types (-no-uliterals)

Disable Polyspace definitions for char16_t or char32_t

## Description

Specify that the analysis must not define char16_t or char32_t types.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node. See “Dependencies” on page 2-60 for other options you must also enable.

**Command line and options file**: Use the option -no-uliterals. See “Command-Line Information” on page 2-61.

### Why Use This Option

If your compiler defines char16_t and/or char32_t through a typedef statement or by using includes, use this option to turn off the standard Polyspace definition of char16_t and char32_t.

To check if your compiler defines these types, save the following code in a C++ file and compile this code using the compiler settings that you typically use:

```
typedef unsigned short char16_t;
typedef unsigned long char32_t;
```

See if there is a compilation error.

- If the file fails to compile with an error such as redeclaration of C++ built-in type, it means that your compiler has the types char16_t and char32_t defined as built-in types. Enable this Polyspace option to emulate your compiler behavior.
- If the file compiles, it means that your compiler defines these types through typedef-s in includes. If you have already added those includes to your project, you do not need to enable this Polyspace option.

## Settings

☑ On

The analysis does not allow char16_t and char32_t types.

□ Off (default)

The analysis allows char16_t and char32_t types.

## Dependencies

You can select this option only when these conditions are true:

- Source code language (-lang) is set to CPP or C-CPP.

- `Compiler (-compiler)` is set to `generic` or a `gnu` version.

## Command-Line Information

**Parameter:** `-no-uliterals`
*Default:* off
**Example (Bug Finder):** `polyspace-bug-finder -lang cpp -compiler gnu4.7 -cpp-version cpp11 -no-uliterals`
**Example (Code Prover):** `polyspace-code-prover -compiler gnu4.7 -lang cpp -cpp-version cpp11 -no-uliterals`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang cpp -compiler gnu4.7 -cpp-version cpp11 -no-uliterals`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler gnu4.7 -lang cpp -cpp-version cpp11 -no-uliterals`

## See Also

`Compiler (-compiler)`

### Topics

# Pack alignment value (`-pack-alignment-value`)

Specify default structure packing alignment for code developed in Visual C++

## Description

Specify the default packing alignment (in bytes) for structures, unions, and class members.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option `-pack-alignment-value`. See “Command-Line Information” on page 2-62.

### Why Use This Option

If you use compiler options to specify how members of a structure are packed into memory, use this option to emulate your compiler.

For instance, if you use the Visual Studio option /Zp to specify an alignment, use this option for your Polyspace analysis.

If you use `#pragma pack` directives in your code to specify alignment, and also specify this option for analysis, the `#pragma pack` directives take precedence.

## Settings

**Default**: 8

You can enter one of these values:

- 1
- 2
- 4
- 8
- 16

## Command-Line Information

**Parameter:** `-pack-alignment-value`
**Value:** `1 | 2 | 4 | 8 | 16`
**Default:** 8
**Example (Bug Finder):** `polyspace-bug-finder -compiler visual10 -pack-alignment-value 4`
**Example (Code Prover):** `polyspace-code-prover -compiler visual10 -pack-alignment-value 4`

**Example (Bug Finder Server):** `polyspace-bug-finder-server -compiler visual10 -pack-alignment-value 4`
**Example (Code Prover Server):** `polyspace-code-prover-server -compiler visual10 -pack-alignment-value 4`

"Code Prover Assumptions About #pragma Directives" (Polyspace Code Prover)

# Ignore pragma pack directives (-ignore-pragma-pack)

Ignore #pragma pack directives

## Description

Specify that the analysis must ignore #pragma pack directives in the code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option -ignore-pragma-pack. See “Command-Line Information” on page 2-64.

### Why Use This Option

Use this option if #pragma pack directives in your code cause linking errors.

For instance, you have two structures with the same name in your code, but one declaration follows a #pragma pack(2) statement. Because the default alignment is 8 bytes, the different packing for the two structures causes a linking error. Use this option to avoid such errors.

## Settings

☑ On

The analysis ignores the #pragma directives.

☐ Off (default)

The analysis takes into account specifications in the #pragma directives.

## Command-Line Information

**Parameter:** -ignore-pragma-pack
**Default**: Off
**Example (Bug Finder):** polyspace-bug-finder -ignore-pragma-pack
**Example (Code Prover):** polyspace-code-prover -ignore-pragma-pack
**Example (Bug Finder Server):** polyspace-bug-finder-server -ignore-pragma-pack
**Example (Code Prover Server):** polyspace-code-prover-server -ignore-pragma-pack

# Management of size_t (-size-t-type-is)

Specify the underlying data type of size_t

## Description

Specify the underlying data type of size_t explicitly: unsigned char, unsigned short, unsigned int, unsigned long or unsigned long long. If you do not specify this option, your choice of compiler determines the underlying type.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option -size-t-type-is. See “Command-Line Information” on page 2-66.

### Why Use This Option

The analysis associates a data type with size_t when you specify your compiler using the option Compiler (-compiler). In most cases, you do not have to explicitly use this option and specify an underlying type for size_t.

In some situations, when building your code, you might be using a compiler option that changed the compiler's default definition of size_t. In these cases, emulate your compiler option by using this Polyspace analysis option. Otherwise, you might see an error message related to size_t during Polyspace analysis. If you see such an error message, to probe further and determine the underlying type of size_t, compile this code with your compiler using the options that you typically use:

```
/* Header defines malloc as void* malloc (size_t size)
#include <stlib.h>

void* malloc (unsigned int size);
```

If the file does not compile, your compiler (along with compiler options) defines size_t using a type different from unsigned int. Replace unsigned int with another type such as unsigned long and try again till you determine the underlying type of size_t.

## Settings

**Default:** defined-by-compiler

defined-by-compiler
: Your specification for Compiler (-compiler) determines the underlying type of size_t.

unsigned-int
: The analysis considers unsigned int as the underlying type of size_t.

unsigned-long
: The analysis considers unsigned long as the underlying type of size_t.

`unsigned-long-long`

The analysis considers `unsigned long long` as the underlying type of `size_t`.

`unsigned-char`

The analysis considers `unsigned char` as the underlying type of `size_t`.

`unsigned-short`

The analysis considers `unsigned short` as the underlying type of `size_t`.

## Tips

Compilation errors from incorrect definition of `size_t` can appear in unexpected ways. For instance, you might see an error like this:

```
first parameter of allocation function must be of type "size_t"
```

on a declaration of an allocation function such as:

```
void * operator new(size_t size);
```

This error appears because Polyspace internally declares the allocation function with the `size_t` definition from your Polyspace analysis configuration, but your declaration might be using a different `size_t` definition from a compiler header. The mismatch in the `size_t` definitions leads to a mismatch in the declarations of the allocation functions and shows up as an error message about the allocation functions.

## Command-Line Information

**Parameter:** `-size-t-type-is`
**Value:** `defined-by-compiler` | `unsigned-char` | `unsigned-int` | `unsigned-short` | `unsigned-long` | `unsigned-long-long`
**Default:** `defined-by-compiler`
**Example (Bug Finder):** `polyspace-bug-finder -size-t-type-is unsigned-long`
**Example (Code Prover):** `polyspace-code-prover -size-t-type-is unsigned-long`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -size-t-type-is unsigned-long`
**Example (Code Prover Server):** `polyspace-code-prover-server -size-t-type-is unsigned-long`

# Management of wchar_t (-wchar-t-type-is)

Specify the underlying data type of `wchar_t`

## Description

Specify the underlying data type of `wchar_t` explicitly. If you do not specify this option, your choice of compiler determines the underlying type.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Target & Compiler** node.

**Command line and options file**: Use the option `-wchar-t-type-is`. See “Command-Line Information” on page 2-67.

### Why Use This Option

The analysis associates a data type with `wchar_t` when you specify your compiler. If you use a compiler option that changes this default type, emulate your compiler option by using this analysis option.

## Settings

**Default:** `defined-by-compiler`

`defined-by-compiler`

Your specification for `Compiler (-compiler)` determines the underlying type of `wchar_t`.

`signed-short`

The analysis considers `signed short` as the underlying type of `wchar_t`.

`unsigned-short`

The analysis considers `unsigned short` as the underlying type of `wchar_t`.

`signed-int`

The analysis considers `signed int` as the underlying type of `wchar_t`.

`unsigned-int`

The analysis considers `unsigned int` as the underlying type of `wchar_t`.

`signed-long`

The analysis considers `signed long` as the underlying type of `wchar_t`.

`unsigned-long`

The analysis considers `unsigned long` as the underlying type of `wchar_t`.

## Command-Line Information

**Parameter:** `-wchar-t-type-is`

**Value:** `defined-by-compiler | signed-short | unsigned-short | signed-int | unsigned-int | signed-long | unsigned-long`
**Default:** `defined-by-compiler`
**Example (Bug Finder):** `polyspace-bug-finder -wchar-t-type-is signed-int`
**Example (Code Prover):** `polyspace-code-prover -wchar-t-type-is signed-int`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -wchar-t-type-is signed-int`
**Example (Code Prover Server):** `polyspace-code-prover-server -wchar-t-type-is signed-int`

# Ignore link errors (-no-extern-C)

Ignore certain linking errors

## Description

Specify that the analysis must ignore certain linking errors.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Environment Settings** node. See "Dependency" on page 2-69 for other options that you must also enable.

**Command line and options file**: Use the option `-no-extern-C`. See "Command-Line Information" on page 2-69.

### Why Use This Option

Some functions may be declared inside an `extern "C" { }` block in some files and not in others. Then, their linkage is not the same and it causes a link error according to the ANSI standard.

Applying this option will cause Polyspace to ignore this error. This permissive option may not resolve all the extern C linkage errors.

## Settings

☑ On

Ignore linking errors if possible.

□ Off (default)

Stop analysis for linkage errors.

## Dependency

This option is available only if you set `Source code language (-lang)` to `CPP` or `C-CPP`.

## Command-Line Information

**Parameter:** `-no-extern-C`
**Default:** off
**Example (Bug Finder):** `polyspace-bug-finder -lang cpp -no-extern-C`
**Example (Code Prover):** `polyspace-code-prover -lang cpp -no-extern-C`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang cpp -no-extern-C`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang cpp -no-extern-C`

## See Also

### Topics

"Specify Polyspace Analysis Options"

# Preprocessor definitions (-D)

Replace macros in preprocessed code

## Description

Replace macros with their definitions in preprocessed code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Macros** node.

**Command line and options file**: Use the option `-D`. See “Command-Line Information” on page 2-72.

### Why Use This Option

Use this option to emulate your compiler behavior. For instance, if your compiler considers a macro `_WIN32` as defined when you build your code, it executes code in a `#ifdef _WIN32` statement. If Polyspace does not consider that macro as defined, you must use this option to replace the macro with 1.

Depending on your settings for `Compiler (-compiler)`, some macros are defined by default. Use this option to define macros that are not implicitly defined.

Typically, you recognize from compilation errors that a certain macro is not defined. For instance, the following code does not compile if the macro `_WIN32` is not defined.

```
#ifdef _WIN32
  int env_var;
#endif

void set() {
  env_var=1;
}
```

The error message states that `env_var` is undefined. However, the definition of `env_var` is in the `#ifdef _WIN32` statement. The underlying cause for the error is that the macro `_WIN32` is not defined. You must define `_WIN32`.

## Settings

### No Default

Using the ✚ button, add a row for the macro you want to define. The definition must be in the format *`Macro`*`=`*`Value`*. If you want Polyspace to ignore the macro, leave the *`Value`* blank.

For example:

- name1=name2 replaces all instances of name1 by name2.
- name= instructs the software to ignore name.
- name with no equals sign or value replaces all instances of name by 1. To define a macro to execute code in a #ifdef *macro_name* statement, use this syntax.

## Tips

- If Polyspace does not support a non-ANSI keyword and shows a compilation error, use this option to replace all occurrences of the keyword with a blank string in preprocessed code. The replacement occurs only for the purposes of the analysis. Your original source code remains intact.

  For instance, if your compiler supports the __far keyword, to avoid compilation errors:

  - In the user interface (desktop products only), enter __far=.
  - On the command line, use the flag -D __far=.

  The software replaces the __far keyword with a blank string during preprocessing. For example:

  ```
  int __far* pValue;
  ```

  is converted to:

  ```
  int * pValue;
  ```
- Polyspace recognizes keywords such as restrict and does not allow their use as identifiers. If you use those keywords as identifiers (because your compiler does not recognize them as keywords), replace the disallowed name with another name using this option. The replacement occurs only for the purposes of the analysis. Your original source code remains intact.

  For instance, to allow use of restrict as identifier:

  - In the user interface, enter restrict=my_restrict.
  - On the command line, use the flag -D restrict=my_restrict.
- Your compiler specification determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option -dump-preprocessing-info.

  - To override the macro definition coming from a compiler specification, use this option.
  - To undefine a macro, use the option Disabled preprocessor definitions (-U).

## Command-Line Information

You can specify only one flag with each -D option. However, you can specify the option multiple times.
**Parameter:** -D
**No Default**
**Value:** *flag=value*
**Example (Bug Finder):** polyspace-bug-finder -D HAVE_MYLIB -D int32_t=int
**Example (Code Prover):** polyspace-code-prover -D HAVE_MYLIB -D int32_t=int
**Example (Bug Finder Server):** polyspace-bug-finder-server -D HAVE_MYLIB -D int32_t=int
**Example (Code Prover Server):** polyspace-code-prover-server -D HAVE_MYLIB -D int32_t=int

## See Also

`Disabled preprocessor definitions (-U)`

### Topics

"Specify Polyspace Analysis Options"

# Disabled preprocessor definitions (-U)

Undefine macros in preprocessed code

## Description

Undefine macros in preprocessed code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Macros** node.

**Command line and options file**: Use the option -U. See “Command-Line Information” on page 2-75.

### Why Use This Option

Use this option to emulate your compiler behavior. For instance, your compiler might consider a macro _WIN32 as undefined and execute the code in a #ifndef _WIN32 block. To emulate this behavior when running a Polyspace analysis, use this option to specify _WIN32 as undefined.

This option undefines these macros:

- Macros you defined by using the -D option. See Preprocessor definitions (-D).
- Macros that might be implicitly defined by the compiler.
- Macros that Polyspace enables by default to emulate compiler behavior. See Compiler (-compiler).

If you define a macro by using a #define statement in your source code, this option cannot undefine it.

Typically, you recognize from compilation errors that a certain macro must be undefined. For instance, the following code does not compile if the macro _WIN32 is defined.

```
#ifndef _WIN32
  int env_var;
#endif

void set() {
  env_var=1;
}
```

The error message states that env_var is undefined. However, the definition of env_var is in the #ifndef _WIN32 statement. The underlying cause for the error is that the macro _WIN32 is defined. You must undefine _WIN32.

## Settings

**No Default**

Using the ✚ button, add a new row for each macro being undefined.

## Tips

Your compiler specification determines the values of many compiler-specific macros. In case you want to know how Polyspace defines a specific macro, use the option `-dump-preprocessing-info`.

- To override a macro definition coming from a compiler specification, use the option `Preprocessor definitions (-D)`.
- To undefine the macro, use this option.

## Command-Line Information

You can specify only one flag with each `-U` option. However, you can specify the option multiple times.
**Parameter:** `-U`
**No Default**
**Value:** *`macro`*
**Example (Bug Finder):** `polyspace-bug-finder -U HAVE_MYLIB -U USE_COM1`
**Example (Code Prover):** `polyspace-code-prover -U HAVE_MYLIB -U USE_COM1`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -U HAVE_MYLIB -U USE_COM1`
**Example (Code Prover Server):** `polyspace-code-prover-server -U HAVE_MYLIB -U USE_COM1`

## See Also

`Preprocessor definitions (-D)`

### Topics

"Specify Polyspace Analysis Options"

# Source code encoding (`-sources-encoding`)

Specify the encoding of source files

## Description

Specify the encoding of the source files that you analyze with Polyspace.

Use this option only if you see compilation errors or display issues from non-ASCII characters in your source files. The option forces an internal conversion of your source files from the specified encoding to an UTF-8 encoding and might help resolve the issue.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Environment Settings** node.

**Command line and options file**: Use the option `-sources-encoding`. See “Command-Line Information” on page 2-77.

### Why Use This Option

The analysis uses the default encoding of your operating system as the source code encoding. In most cases, if your source code contains non-ASCII characters, for instance, Japanese or Korean characters, the Polyspace analysis can interpret the characters and later display the source code correctly.

If you still have compilation errors or display issues from non-ASCII characters, you might be using an encoding that is different from the default encoding. You can then specify your source code encoding explicitly using this option.

## Settings

**Default:** `system`

`system`

The analysis uses the default encoding of the operating system.

`shift-jis`

The analysis uses the Shift JIS (Shift Japanese Industrial Standards) encoding, a character encoding for the Japanese language.

`iso-8859-1`

The analysis uses the ISO/IEC 8859-1:1998 encoding, a character encoding that encodes what it refers to as "Latin alphabet no.1", consisting of 191 characters from the Latin script.

`windows-1252`

The analysis uses the Windows-1252 encoding, a single-byte character encoding of the Latin alphabet, used by default in the legacy components of Windows for English and some other Western languages.

`UTF-8`

The analysis uses the UTF-8 encoding, a variable width character encoding capable of encoding all valid code points in Unicode.

Polyspace supports many more encodings. To specify an encoding that is not in the above list in the Polyspace user interface, enter `-sources-encoding` *`encodingname`* in the `Other` field. In particular, if your source files contain a mix of different encodings, you can use `-sources-encoding auto`. In this mode, the analysis uses internal heuristics to determine the encoding of your source files from their contents.

For the full list of supported encodings, at the command line, enter:

```
-list-all-values -sources-encoding
```

with the `polyspace-bug-finder`, `polyspace-code-prover`, `polyspace-bug-finder-server` or `polyspace-code-prover-server` command. Pipe the output to a file and search the file for the encoding that you are using.

## Command-Line Information

**Parameter:** `-sources-encoding`
**Default:** `system`
**Value:** `auto` | `system` | `shift-jis` | `iso-8859-1` | `windows-1252` | `UTF-8`
**Example (Bug Finder):** `polyspace-bug-finder -sources-encoding windows-1252`
**Example (Code Prover):** `polyspace-code-prover -sources-encoding windows-1252`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources-encoding windows-1252`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources-encoding windows-1252`

Polyspace supports many more encodings besides the above list. For the full list of supported encodings, at the command line, enter:

```
-list-all-values -sources-encoding
```

with the `polyspace-bug-finder`, `polyspace-code-prover`, `polyspace-bug-finder-server` or `polyspace-code-prover-server` command. Pipe the output to a file and search the file for the encoding that you are using.

### Topics

“Specify Polyspace Analysis Options”

# Code from DOS or Windows file system (-dos)

Consider that file paths are in MS-DOS style

## Description

Specify that DOS or Windows files are provided for analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Environment Settings** node.

**Command line and options file**: Use the option `-dos`. See "Command-Line Information" on page 2-78.

### Why Use This Option

Use this option if the contents of the **Include** or **Source** folder come from a DOS or Windows file system. The option helps you resolve case sensitivity and control character issues.

## Settings

☑ On (default)

Analysis understands file names and include paths for Windows/DOS files

For example, with this option,

```
#include "..\mY_TEst.h"^M
```

```
#include "..\mY_other_FILE.H"^M
```

resolves to:

```
#include "../my_test.h"
```

```
#include "../my_other_file.h"
```

In this mode, you see an error if your include folder has header files whose names differ only in case.

□ Off

Characters are not controlled for files names or paths.

## Command-Line Information

**Parameter:** `-dos`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -dos -I ./my_copied_include_dir -D test=1`

**Example (Code Prover):** `polyspace-code-prover -dos -I ./my_copied_include_dir -D test=1`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -dos -I ./my_copied_include_dir -D test=1`
**Example (Code Prover Server):** `polyspace-code-prover-server -dos -I ./my_copied_include_dir -D test=1`

## See Also

### Topics

"Specify Polyspace Analysis Options"

# Stop analysis if a file does not compile (`-stop-if-compile-error`)

Specify that a compilation error must stop the analysis

## Description

Specify that even a single compilation error must stop the analysis.

### Set Option

**User interface** (desktop products only): In the **Configuration** pane, the option is on the **Environment Settings** node.

**Command line and options file**: Use the option `-stop-if-compile-error`. See “Command-Line Information” on page 2-81.

### Why Use This Option

Use this option to first resolve all compilation errors and then perform the Polyspace analysis. This sequence ensures that all files are analyzed.

Otherwise, only files without compilation errors are fully analyzed. The analysis might return some results for files that do not compile. If a file with compilation errors contains a function definition, the analysis considers the function undefined. This assumption can sometimes make the analysis less precise.

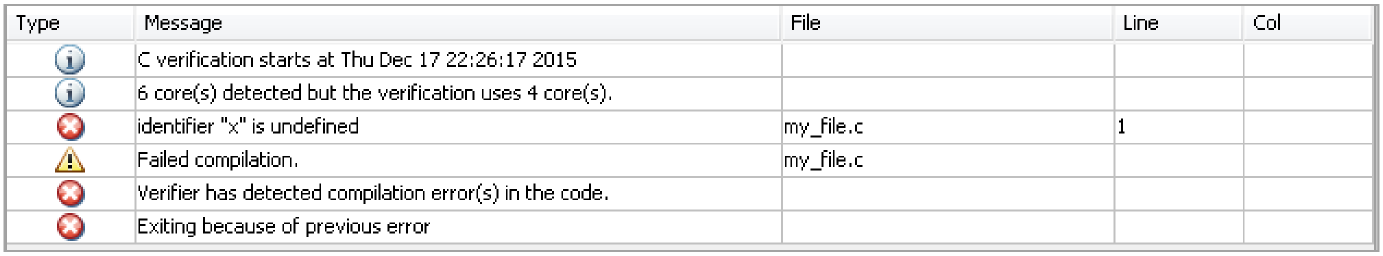
The option is more useful for a Code Prover analysis because the Code Prover run-time checks rely more heavily on range propagation across functions.

## Settings

☑ On

The analysis stops even if a single compilation error occurs.

In the user interface of the Polyspace desktop products, you see the compilation errors on the **Output Summary** pane.



| Type | Message | File | Line | Col |
|---|---|---|---|---|
| ⓘ | C verification starts at Thu Dec 17 22:26:17 2015 | | | |
| ⓘ | 6 core(s) detected but the verification uses 4 core(s). | | | |
| ⊗ | identifier "x" is undefined | my_file.c | 1 | |
| ⚠ | Failed compilation. | my_file.c | | |
| ⊗ | Verifier has detected compilation error(s) in the code. | | | |
| ⊗ | Exiting because of previous error | | | |

For information on how to resolve the errors, see “Troubleshoot Compilation Errors”.

You can also see the errors in the analysis log, a text file generated during the analysis. The log is named `Polyspace_R20##n_ProjectName_date-time.log` and contains lines starting with `Error:` indicating compilation errors. To view the log from the analysis results:

- In the user interface of the Polyspace desktop products, select **Window** > **Show/Hide View** > **Run Log**.
- In the Polyspace Access web interface, open the **Review** tab. Select **Window** > **Run Log**.

Despite compilation errors, you can see some analysis results, for instance, coding rule violations.

□ Off (default)

The analysis does not stop because of compilation errors, but only files without compilation errors are analyzed. The analysis does not consider files that do not compile. If a file with compilation errors contains a function definition, the analysis considers the function undefined. If the analysis needs the definition of such a function, it makes broad assumptions about the function.

- The function return value can take any value in the range allowed by its data type.
- The function can modify arguments passed by reference so that they can take any value in the range allowed by their data types.

If the assumptions are too broad, the analysis can be less precise. For instance, a run-time check can flag an operation in orange even though it does not fail in practice.

If compilation errors occur, in the user interface of the Polyspace desktop products, the **Dashboard** pane has a link, which shows that some files failed to compile. You can click the link and see the compilation errors on the **Output Summary** pane.

You can also see the errors in the analysis log, a text file generated during the analysis. The log is named `Polyspace_R20##n_ProjectName_date-time.log` and contains lines starting with `Error:` indicating compilation errors. To view the log from the analysis results:

- In the user interface of the Polyspace desktop products, select **Window** > **Show/Hide View** > **Run Log**.
- In the Polyspace Access web interface, open the **Review** tab. Select **Window** > **Run Log**.

## Command-Line Information

**Parameter:**`-stop-if-compile-error`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources filename -stop-if-compile-error`
**Example (Code Prover):** `polyspace-code-prover -sources filename -stop-if-compile-error`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources filename -stop-if-compile-error`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources filename -stop-if-compile-error`

# Version History

### Topics

"Specify Polyspace Analysis Options"

# Command/script to apply to preprocessed files (`-post-preprocessing-command`)

Specify command or script to run on source files after preprocessing phase of analysis

## Description

Specify a command or script to run on each source file after preprocessing.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Environment Settings** node.

**Command line and options file**: Use the option `-post-preprocessing-command`. See "Command-Line Information" on page 2-85.

### Why Use This Option

You can run scripts on preprocessed files to work around compilation errors or imprecisions of the analysis while keeping your original source files untouched. For instance, suppose Polyspace does not recognize a compiler-specific keyword. If you are certain that the keyword is not relevant for the analysis, you can run a Perl script to remove all instances of the keyword. When you use this option, the software removes the keyword from your preprocessed code but keeps your original code untouched.

Use a script only if the existing analysis options do not meet your requirements. For instance:

- For direct replacement of one keyword with another, use the option `Preprocessor definitions (-D)`.

  However, the option does not allow search and replacement involving regular expressions. For regular expressions, use a script.
- For mapping your library function to a standard library function, use the option `-code-behavior-specifications`.

  However, the option supports mapping to only a subset of standard library functions. To map to an unsupported function, use a script.

*If you are unsure about removing or replacing an unsupported construct, do not use this option.* Contact MathWorks® Support for guidance.

## Settings

**No Default**

Enter full path to the command or script or click 📁 to navigate to the location of the command or script. This script is executed before verification.

## Tips

- Your script must be designed to process the standard output from preprocessing and produce its results in accordance with that standard output.
- Your script must preserve the number of lines in the preprocessed file. In other words, it must not add or remove entire lines to or from the file.

  Adding a line or removing one can potentially result in some unpredictable behavior on the location of checks and macros in the Polyspace user interface.
- For a Perl script, in Windows, specify the full path to the Perl executable followed by the full path to the script.

  For example:

  - To specify a Perl command that replaces all instances of the `far` keyword, enter *`polyspaceroot`*`\sys\perl\win32\bin\perl.exe -p -e "s/far//g"`.
  - To specify a Perl script `replace_keyword.pl` that replaces all instances of a keyword, enter *`polyspaceroot`*`\sys\perl\win32\bin\perl.exe` *`absolute_path`* `\replace_keyword.pl`.

  Here, *`polyspaceroot`* is the location of the current Polyspace installation such as `C:\Program Files\Polyspace\R2019a\` and *`absolute_path`* is the location of the Perl script. If the paths contain spaces, use quotes to enclose the full path names.
- Use this Perl script as template. The script removes all instances of the `far` keyword.

```
#!/usr/bin/perl

binmode STDOUT;

# Process every line from STDIN until EOF
while ($line = <STDIN>)
{

  # Remove far keyword
  $line =~ s/far//g;

  # Print the current processed line to STDOUT
  print $line;
}
```

  You can use Perl regular expressions to perform substitutions. For instance, you can use the following expressions.

| Expression | Meaning |
|---|---|
| `.` | Matches any single character except newline |
| `[a-z0-9]` | Matches any single letter in the set `a-z`, or digit in the set `0-9` |
| `[^a-e]` | Matches any single letter not in the set `a-e` |
| `\d` | Matches any single digit |
| `\w` | Matches any single alphanumeric character or _ |
| `x?` | Matches 0 or 1 occurrence of `x` |

| Expression | Meaning |
|---|---|
| x* | Matches 0 or more occurrences of x |
| x+ | Matches 1 or more occurrences of x |

For complete list of regular expressions, see Perl documentation.

## Command-Line Information

**Parameter:** `-post-preprocessing-command`
**Value:** Path to executable file or script in quotes
**No Default**
**Example in Linux® (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-post-preprocessing-command `pwd`/replace_keyword.pl`
**Example in Linux (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-post-preprocessing-command `pwd`/replace_keyword.pl`
**Example in Linux (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-post-preprocessing-command `pwd`/replace_keyword.pl`
**Example in Linux (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-post-preprocessing-command `pwd`/replace_keyword.pl`
**Example in Windows:** `polyspace-bug-finder -sources` *`file_name`* `-post-preprocessing-command "C:\Program Files\MATLAB\R2015b\sys\perl\win32\bin\perl.exe" "C:\My_Scripts\replace_keyword.pl"`

You can specify an absolute path to a file or a path relative to the location from which you run the `polyspace-bug-finder` or `polyspace-code-prover` command. Note that if you are running Perl scripts, in Windows, enter the full path to the Perl executable.

### Topics

“Specify Polyspace Analysis Options”
“Remove or Replace Keywords Before Compilation”

# Include (`-include`)

Specify files to be `#include`-ed by each C file in analysis

## Description

Specify files to be `#include`-ed by each C file involved in the analysis. The software enters the `#include` statements in the preprocessed code used for analysis, but does not modify the original source code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Environment Settings** node.

**Command line and options file**: Use the option `-include`. See “Command-Line Information” on page 2-86.

### Why Use This Option

There can be many reasons why you want to `#include` a file in all your source files.

For instance, you can collect in one header file all workarounds for compilation errors. Use this option to provide the header file for analysis. Suppose you have compilation issues because Polyspace does not recognize certain compiler-specific keywords. To work around the issues, `#define` the keywords in a header file and provide the header file with this option.

## Settings

### No Default

Specify the file name to be included in every file involved in the analysis.

Polyspace still acts on other directives such as `#include <include_file.h>`.

## Command-Line Information

**Parameter:** `-include`
**Default:** None
**Value:** *`file`* (Use `-include` multiple times for multiple files)
**Example (Bug Finder):** `polyspace-bug-finder -include `pwd`/sources/a_file.h -include /inc/inc_file.h`
**Example (Code Prover):** `polyspace-code-prover -include `pwd`/sources/a_file.h -include /inc/inc_file.h`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -include `pwd`/sources/a_file.h -include /inc/inc_file.h`
**Example (Code Prover Server):** `polyspace-code-prover-server -include `pwd`/sources/a_file.h -include /inc/inc_file.h`

# Include folders (`-I`)

View include folders used for analysis

## Description

*This option is relevant only for the user interface of the Polyspace desktop products.*

View the include folders used for analysis.

### Set Option

This is not an option that you set in your project configuration. You can only view the include folders in the configuration associated with a result. For instance, in the user interface:

- To add include folders, on the **Project Browser**, right-click your project. Select **Add Source**.
- To view the include folders that you used, with your results open, select **Window** > **Show/Hide View** > **Configuration**. Under the node **Environment Settings**, you see the folders listed under **Include folders**.

## Settings

This is a read-only option available only when viewing results in the user interface of the Polyspace desktop products. Unlike other options, you do not specify include folders on the **Configuration** pane. Instead, you add your include folders on the **Project Browser** pane.

## See Also

`Include (-include)` | `-I`

# Constraint setup (-data-range-specifications)

Constrain global variables, function inputs and return values of stubbed functions

## Description

Specify constraints (also known as data range specifications or DRS) for global variables, function inputs and return values of stubbed functions using a **Constraint Specification** template file. The template file is an XML file that you can generate in the Polyspace user interface.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-data-range-specifications`. See “Command-Line Information” on page 2-90.

### Why Use This Option

Use this option to constrain certain objects in your code whose values are known only at run time, for instance, user inputs or sensor values. Using correctly constrained objects might reduce false positives or orange checks in Polyspace results.

Based on your source code, Polyspace makes assumptions about items such as variable ranges and allowed buffer size for pointers. Sometimes these assumptions are broader than what you expect because:

- You have not provided the complete code. For example, you did not provide some of the function definitions.
- Some of the information about variables is available only at run time. For example, some variables in your code obtain values from the user at run time.

For instance, an `int` variable representing a real life speed cannot have a value that is smaller than zero or greater than the speed of light. Polyspace might assume that the variable has a range `[-2^32... 2^32-1]`. Because of such broad assumptions:

- Code Prover might consider more execution paths than those paths that occur at run time. If an operation fails along one of the execution paths, Polyspace places an orange check on the operation. If that execution path does not occur at run time, the orange check indicates a false positive.
- Bug Finder might produce false positives.

To reduce the number of such false positives, specify applicable constraints on global variables, function inputs, and return values of stubbed functions.

After you specify your constraints, save them as an XML file to use them for subsequent analyses. If your source code changes, update the previous constraints. Creating a new constraint template is not necessary.

## Settings

**No Default**

Enter full path to the template file. Alternately, click Edit to open a **Constraint Specification** wizard. This wizard allows you to generate a template file or navigate to an existing template file.

For more information, see “Specify External Constraints for Polyspace Analysis”.

## Command-Line Information

**Parameter:** `-data-range-specifications`
**Value:** *`file`*
**No Default**
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-data-range-specifications "C:\DRS\range.xml"`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-data-range-specifications "C:\DRS\range.xml"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-data-range-specifications "C:\DRS\range.xml"`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-data-range-specifications "C:\DRS\range.xml"`

You can specify an absolute path to the constraints file or a path relative to the location from which you run the `polyspace-bug-finder` or `polyspace-code-prover` command.

## Examples

### Specify Range of Runtime Variable to Reduce Orange Checks

In this code, the multiplication operation in the definition of `tmp` has an orange overflow check. This check appears because Polyspace assumes that the return value of the function `getSpeed()` has a range `-2^32... 2^32-1`.

```
//file1.c
extern int getSpeed(); //Returns the reading of speedometer
int main(){
    //...
    int tmp = 2* getSpeed();
    //...
    return 0;
}
```

To resolve this orange check, constrain the return value of `getSpeed()` with a range `[0..30000000]`. Create an XML file `drs.xml` that has this content:

```
<?xml version="1.0" encoding="UTF-8"?>
<!--EDRS Version 2.0-->
<global>
    <file name="C:\\Users\\example.c">
            <function name="getSpeed" line="1" attributes="extern" main_generator_called="disable
                <scalar name="return" line="1" base_type="int32" complete_type="int32" init_mode=
            </function>
    </file>
</global>
```

After specifying the data range, run the verification again. Use the command:

```
polyspace-code-prover file1.c -data-range-specifications drs.xml -lang c
```

The orange check is replaced by a green check.

```
extern int getSpeed(); //Returns the reading of speedometer
int main(){
    //...
    int tmp = 2* getSpeed();
    //...
    return 0;
}
```

Functions to stub (-functions-to-stub) | Ignore default initialization of global variables (-no-def-init-glob)

### Topics

"Specify Polyspace Analysis Options"
"Specify External Constraints for Polyspace Analysis"

# Ignore default initialization of global variables (-no-def-init-glob)

Consider global variables as uninitialized unless explicitly initialized in code

## Description

*This option applies to Code Prover only. It does not affect a Bug Finder analysis.*

Specify that Polyspace must not consider global and static variables as initialized unless they are explicitly initialized in the code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-no-def-init-glob`. See “Command-Line Information” on page 2-93.

### Why Use This Option

The C99 Standard specifies that global variables are implicitly initialized. The default analysis follows the Standard and considers this implicit initialization.

If you want to initialize specific global variables explicitly, use this option to find the instances where global variables are not explicitly initialized.

## Settings

☑ On

Polyspace ignores implicit initialization of global and static variables. The verification generates a red **Non-initialized variable** error if your code reads a global or static variable before writing to it.

If you enable this option, global variables are considered uninitialized unless you explicitly initialize them in the code. Note that this option overrides the option `Variables to initialize (-main-generator-writes-variables)`. Even if you initialize variables with the generated `main`, this option forces the analysis to ignore the initialization.

□ Off (default)

Polyspace considers global variables and static variables to be initialized according to C99 or ISO C++ standards. For instance, the default values are:

- 0 for `int`
- 0 for `char`
- 0.0 for `float`

## Tips

Static local variables have the same lifetime as global variables even though their visibility is limited to the function where they are defined. Therefore, the option applies to static local variables.

## Command-Line Information

**Parameter:** `-no-def-init-glob`
**Default:** Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-no-def-init-glob`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-no-def-init-glob`

## See Also

`Non-initialized variable`

### Topics

"Specify Polyspace Analysis Options"

# Functions to stub (`-functions-to-stub`)

Specify functions to stub during analysis

## Description

Specify functions to stub during analysis.

For specified functions, Polyspace :

- Ignores the function definition even if it exists.
- Assumes that the function inputs and outputs have full range of values allowed by their type.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-functions-to-stub`. See “Command-Line Information” on page 2-96.

### Why Use This Option

If you want the analysis to ignore the code in a function body, you can stub the function.

For instance:

- Suppose you have not completed writing the function and do not want the analysis to consider the function body. You can use this option to stub the function and then specify constraints on its return value and modifiable arguments.
- Suppose the analysis of a function body is imprecise. The analysis assumes that the function returns all possible values that the function return type allows. You can use this option to stub the function and then specify constraints on its return value.

## Settings

**No Default**

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

When entering function names, use either the basic syntax or, to differentiate overloaded functions, the argument syntax. For the argument syntax, separate function arguments with semicolons. See the following code and table for examples.

```
//simple function
```

```
void test(int a, int b);

//C++ template function

Template <class myType>
myType test(myType a, myType b);

//C++ class method

class A {
    public:
    int test(int var1, int var2);
};

//C++ template class method

template <class myType> class A
{
    public:
    myType test(myType var1, myType var2);
};
```

| **Function Type** | **Basic Syntax** | **Argument Syntax** |
|---|---|---|
| Simple function | `test` | `test(int; int)` |
| C++ template function | `test` | `test(myType; myType)` |
| C++ class method | `A::test` | `A::test(int;int)` |
| C++ template class method | `A<myType>::test` | `A<myType>::test(myType;myType)` |

## Tips

- Code Prover makes assumptions about the arguments and return values of stubbed functions. For example, Polyspace assumes that the return values of stubbed functions are full range. These assumptions can affect checks in other sections of the code. See “Code Prover Assumptions About Stubbed Functions” (Polyspace Code Prover).
- If you stub a function, you can constrain the range of function arguments and return value. To specify constraints, use the analysis option `Constraint setup (-data-range-specifications)`.
- When you use this option, you might see a change in file-level code complexity metrics such as number of lines and comment density because one or more function bodies are no longer analyzed.
- For C functions, these special characters are allowed:`( ) < > ; _`

  For C++ functions, these special characters are allowed : `( ) < > ; _ * & [ ]`

  Space characters are allowed for C++, but are not allowed for C functions.
- You cannot use this option to stub the following C++ functions:
  - `constexpr` functions
  - Function-try-blocks that associate a `catch` clause with an entire function body, for instance:

```
Class()
    try : Class( 0.0 ) //delegate constructor
    {
        // ...
    }
    catch (...)
    {
        // exception occurred on initialization
    }
```

- Template functions with a parameter pack, for instance:

```
template <class T, class... T2>
    X(T n, T n2, T2... rest): X(rest...) {
        v.insert(v.begin(), n);
        v.insert(v.begin(), n2);
    }
```

- Functions with `auto` return type, for instance:

```
template <typename F, typename... Args>
inline decltype(auto) invoke(F&& func, Args&&... args)
{
  return invoke_impl(eastl::forward<F>(func), eastl::forward<Args>(args)...);
}
```

## Command-Line Information

**Parameter:** `-functions-to-stub`
**No Default**
**Value:** *`function1`*`[,`*`function2`*`[,...]]`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-functions-to-stub function_1,function_2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-functions-to-stub function_1,function_2`

`Constraint setup (-data-range-specifications)`

### Topics

"Specify Polyspace Analysis Options"

# Libraries used (-library)

Specify libraries that you use in your program

## Description

Specify libraries that you use in your program.

The analysis uses smart stubs for functions from those libraries instead of generic stubs and does not attempt to check the function implementations. Using this option enables faster analysis without losing precision and triggers library-specific checks on function calls.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-library`. See "Command-Line Information" on page 2-98.

### Why Use This Option

For faster and library-aware analysis, use this option. Unless you use this option, the analysis either attempts to check the library implementation or if the implementation is not available, uses generic stubs for library functions. Checking the function bodies can increase analysis time significantly while using generic stubs can lead to loss of precision.

The option also triggers library-specific checks on function arguments. For instance, if you select the option value `autosar`, a Bug Finder or Code Prover analysis checks arguments to functions from the AUTOSAR RTE API for compliance with the AUTOSAR Standard.

## Settings

**Default:** `none`

`none`

The analysis uses smart stubs only for functions from the C Standard Library.

`autosar`

The analysis uses smart stubs for AUTOSAR RTE API functions even if their implementations are available.

The option also triggers AUTOSAR-specific checks on function arguments. For more information, see the corresponding checkers:

- Bug Finder: `Non-compliance with AUTOSAR specification`

  Besides setting the option, you must also explicitly enable the above checker (or enable all checkers).
- Code Prover: `Non-compliance with AUTOSAR specification`

Setting the option is sufficient to enable the checker.

`stdlibcxx`

The analysis uses smart stubs for methods from C++ Standard Library containers even if their implementations are available.

The containers whose methods are stubbed include `std::map`, `std::unordered_map`, `std::deque`, `std::vector`, `std::set`, `std::unordered_set`, and `std::list`. If you use this option and your code contains C++ container methods, the analysis log contains a message:

```
n methods stubbed for better performance
```

where *n* is the number of methods stubbed.

Note that unlike functions from the C Standard Library, the stubs of C++ container methods are not used to check for domain errors and other error conditions. The methods are stubbed to avoid the unnecessary performance costs from analyzing their implementation. As a result, if you invoke a C++ container method with incorrect arguments, you do not see errors that refer to the incorrect invocation. But in some cases, you might see other errors that indirectly follow from the incorrect invocation. For instance, if you invoke the `std::stack::top()` method on an empty stack, you see a `Non-initialized variable` error even though the stack itself is initialized.

This option has effect only on a Code Prover analysis. A Bug Finder analysis discards implementations of C++ container methods immediately after compilation and does not require the smart stubbing.

### Command-Line Information

**Parameter:** `-library`
**No Default**
**Value:** `autosar | stdlibcxx`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-library autosar -checkers autosar_lib_non_compliance`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-library autosar`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-library autosar -checkers autosar_lib_non_compliance`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-library autosar`

# Generate stubs for Embedded Coder lookup tables (`-stub-embedded-coder-lookup-table-functions`)

Stub autogenerated functions that use lookup tables and model them more precisely

## Description

*This option is available only for model-generated code. The option is relevant only if you generate code from a Simulink® model that uses Lookup Table blocks using MathWorks code generation products.*

Specify that the verification must stub autogenerated functions that use certain kinds of lookup tables in their body. The lookup tables in these functions use linear interpolation and do not allow extrapolation. That is, the result of using the lookup table always lies between the lower and upper bounds of the table.

### Set Option

If you are running verification from Simulink, use the option “Stub lookup tables” (Polyspace Code Prover) in Simulink Configuration Parameters, which performs the same task.

**User interface** (desktop products only): In your Polyspace project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-stub-embedded-coder-lookup-table-functions`. See “Command-Line Information” on page 2-100.

### Why Use This Option

If you use this option, the verification is more precise and has fewer orange checks. The verification of lookup table functions is usually imprecise. The software has to make certain assumptions about these functions. To avoid missing a run-time error, the verification assumes that the result of using the lookup table is within the full range allowed by the result data type. This assumption can cause many unproven results (orange checks) when a lookup table function is called. By using this option, you narrow down the assumption. For functions that use lookup tables with linear interpolation and no extrapolation, the result is at least within the bounds of the table.

The option is relevant only if your model has Lookup Table blocks. In the generated code, the functions corresponding to Lookup Table blocks also use lookup tables. The function names follow specific conventions. The verification uses the naming conventions to identify if the lookup tables in the functions use linear interpolation and no extrapolation. The verification then replaces such functions with stubs for more precise verification.

## Settings

☑ On (default)

For autogenerated functions that use lookup tables with linear interpolation and no extrapolation, the verification:

- Does not check for run-time errors in the function body.
- Calls a function stub instead of the actual function at the function call sites. The stub ensures that the result of using the lookup table is within the bounds of the table.

To identify if the lookup table in the function uses linear interpolation and no extrapolation, the verification uses the function name. In your analysis results, you see that the function is not analyzed. If you place your cursor on the function name, you see the following message:

```
Function has been recognized as an Embedded Coder Lookup-Table function.
It was stubbed by Polyspace to increase precision.
Unset the -stub-embedded-coder-lookup-table-functions option to analyze
   the code below.
```

□ Off

The verification does not stub autogenerated functions that use lookup tables.

## Tips

- The option applies to only autogenerated functions. If you integrate your own C/C++ S-Function using lookup tables with the model, these functions do not follow the naming conventions for autogenerated functions. The option does not cause them to be stubbed. If you want the same behavior for your handwritten lookup table functions as the autogenerated functions, use the option `-code-behavior-specifications` and map your function to the `__ps_lookup_table_clip` function.
- If you run verification from Simulink, the option is on by default. For certification purposes, if you want your verification tool to be independent of the code generation tool, turn off the option.

## Command-Line Information

**Parameter:** `-stub-embedded-coder-lookup-table-functions`
**Default**: On
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-stub-embedded-coder-lookup-table-functions`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-stub-embedded-coder-lookup-table-functions`

# Version History

**Introduced in R2016b**

## See Also

### Topics

"Specify Polyspace Analysis Options"

# Generate results for sources and (`-generate-results-for`)

Specify files on which you want analysis results

## Description

*This option affects a Bug Finder analysis only.*

Specify files on which you want analysis results.

By default, results appear on source files and header files in the same folder as the source files. You can use this option to see results in other header files. If you use the option `Do not generate results for (-do-not-generate-results-for)` to suppress entire folders, you can use this option to unsuppress some subfolders or files in those folders.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-generate-results-for`. See "Command-Line Information" on page 2-102.

### Why Use This Option

Use this option to see results in header files that are most relevant to you.

For instance, by default, results are generated on header files that are located in the same folder as the source files. Often, other header files belong to a third-party library. Though these header files are required for a precise analysis, you are not interested in reviewing findings in those headers. Therefore, by default, results are not generated for those headers. If you *are interested* in certain headers from third-party libraries, change the default value of this option.

Note that in Polyspace as You Code, you cannot see results in headers `#include`-d through a source file *at all*. The default behavior is to consider the headers in the same folder as the source file (or subfolders) for analysis but suppress results found in the headers. You can use this option only to expand the scope of which headers are considered during analysis. See also "Analysis Scope of Polyspace as You Code".

## Settings

**Default**: `source-headers`

`source-headers`

Results appear on source files and header files in the same folder as the source files or in subfolders of source file folders.

The source files are the files that you add to the **Source** folder of your Polyspace project (or use with the argument `-sources` at the command line).

`all-headers`

Results appear on source files and all header files. The header files can be in the same folder as source files, in subfolders of source file folders or in include folders.

The source files are the files that you add to the **Source** folder of your Polyspace project (or use with the argument `-sources` at the command line).

The include folders are the folders that you add to the **Include** folder of your Polyspace project (or use with the argument `-I` at the command line).

`custom`

Results appear on source files and the files that you specify. If you enter a folder name, results appear on header files in that folder (and its subfolders).

Click ✚ to add a field. Enter a file or folder name.

## Tips

1 Use this option in combination with appropriate values for the option `Do not generate results for (-do-not-generate-results-for)`.

If you choose `custom` and the values for the two options conflict, the more specific value determines the display of results. For instance, in the following examples, the value for the option **Generate results for sources and** is more specific.

| Generate results for sources and | Do not generate results for | Final Result |
|---|---|---|
| `custom`:<br>`C:\Includes\Custom_Library\` | `custom`:<br>`C:\Includes` | Results are displayed on header files in `C:\Includes\Custom_Library\` and its subfolders but not generated for other header files in `C:\Includes`. |
| `custom`:<br>`C:\Includes\my_header.h` | `custom`:<br>`C:\Includes\` | Results are displayed on the header file `my_header.h` in `C:\Includes\` but not generated for other header files in `C:\Includes\` and its subfolders. |

Using these two options together, you can suppress results from all files in a certain folder but unsuppress select files in those folders.

2 If you choose `all-headers` for this option, results are displayed on all header files irrespective of what you specify for the option **Do not generate results for**.

## Command-Line Information

**Parameter:** `-generate-results-for`
**Value:** `source-headers` | `all-headers` | `custom=`*file1*`[,`*file2*`[,...]]` | `custom=`*folder1*`[,`*folder2*`[,...]]`

**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-misra2 required-rules -generate-results-for custom="C:\usr\include"`
**Example (Code Prover):** `polyspace-code-prover -lang c -sources` *`file_name`* `-misra2 required-rules -generate-results-for custom="C:\usr\include"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-misra2 required-rules -generate-results-for custom="C:\usr\include"`
**Example (Code Prover Server):** `polyspace-code-prover-server -lang c -sources` *`file_name`* `-misra2 required-rules -generate-results-for custom="C:\usr\include"`

## Version History

**Introduced in R2016a**

### See Also

**Topics**
"Specify Polyspace Analysis Options"

# Do not generate results for (`-do-not-generate-results-for`)

Specify files on which you do not want analysis results

## Description

*This option affects a Bug Finder analysis only.*

Specify files on which you do not want analysis results.

By default, results do not appear on header files (unless they are in the same folder as the source files). You can use this option to suppress results from some source files too (or from header files in the same folders as source files). If you use the option `Generate results for sources and (-generate-results-for)` to show results on some include folders, you can use this option to suppress results from some subfolders or files in those include folders.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Inputs & Stubbing** node.

**Command line and options file**: Use the option `-do-not-generate-results-for`. See "Command-Line Information" on page 2-107.

### Why Use This Option

Use this option to see results in header files that are most relevant to you.

For instance, by default, results are generated on header files that are located in the same folder as the source files. If you are not interested in reviewing the findings in those headers, change the default value of this option.

Note that in Polyspace as You Code, the default behavior is to not even analyze the headers in non-source folders. You can use this option to expand the scope of not analyzed files to all headers or a different subset of headers. See also "Analysis Scope of Polyspace as You Code".

## Settings

**Default**: `include-folders`

`include-folders`

Results are not generated for header files in include folders (and their subfolders).

The include folders are the folders that you add to the **Include** folder of your Polyspace project (or use with the argument `-I` at the command line).

If an include folder is a subfolder of a source folder, results are generated for files in that include folder even if you specify the option value `include-folders`. In this situation, use the option value `custom` and explicitly specify the include folders to ignore.

`all-headers`

Results are not generated for all header files. The header files can be in the same folder as source files, in subfolders of source file folders or in include folders.

The source files are the files that you add to the **Source** folder of your Polyspace project (or use with the argument `-sources` at the command line).

The include folders are the folders that you add to the **Include** folder of your Polyspace project (or use with the argument `-I` at the command line).

`custom`

Results are not generated for the files that you specify. If you enter a folder name, results are suppressed from files in that folder (and its subfolders).

Click ✚ to add a field. Enter a file or folder name.

## Tips

1 Use this option appropriately in combination with appropriate values for the option `Generate results for sources and (-generate-results-for)`.

If you choose `custom` and the values for the two options conflict, the more specific value determines the display of results. For instance, in the following examples, the value for the option **Generate results for sources and** is more specific.

| Generate results for sources and | Do not generate results for | Final Result |
|---|---|---|
| `custom`:<br>`C:\Includes\Custom_Library\` | `custom`:<br>`C:\Includes` | Results are displayed on header files in `C:\Includes\Custom_Library\` and its subfolders but not generated for other header files in `C:\Includes`. |
| `custom`:<br>`C:\Includes\my_header.h` | `custom`:<br>`C:\Includes\` | Results are displayed on the header file `my_header.h` in `C:\Includes\` but not generated for other header files in `C:\Includes\` and its subfolders. |

Using these two options together, you can suppress results from all files in a certain folder but unsuppress select files in those folders.

2 If you choose `all-headers` for this option, results are suppressed from all header files irrespective of what you specify for the option **Generate results for sources and**.

3 If a defect or coding rule violation involves two files and you do not generate results for one of the files, the defect or rule violation still appears. For instance, if you define two variables with similar-looking names in files `myFile.cpp` and `myFile.h`, you get a violation of the MISRA™ C ++ rule 2-10-1, even if you do not generate results for `myFile.h`. MISRA C++ rule 2-10-1 states that different identifiers must be typographically unambiguous.

The following results can involve more than one file:

### MISRA C: 2004 Rules

- MISRA C: 2004 Rule 5.1 — Identifiers (internal and external) shall not rely on the significance of more than 31 characters.
- MISRA C: 2004 Rule 5.2 — Identifiers in an inner scope shall not use the same name as an identifier in an outer scope, and therefore hide that identifier.
- MISRA C: 2004 Rule 8.8 — An external object or function shall be declared in one file and only one file.
- MISRA C: 2004 Rule 8.9 — An identifier with external linkage shall have exactly one external definition.

### MISRA C: 2012 Directives and Rules

- MISRA C: 2012 Directive 4.5 — Identifiers in the same name space with overlapping visibility should be typographically unambiguous.
- MISRA C: 2012 Rule 5.2 — Identifiers declared in the same scope and name space shall be distinct.
- MISRA C: 2012 Rule 5.3 — An identifier declared in an inner scope shall not hide an identifier declared in an outer scope.
- MISRA C: 2012 Rule 5.4 — Macro identifiers shall be distinct.
- MISRA C: 2012 Rule 5.5 — Identifiers shall be distinct from macro names.
- MISRA C: 2012 Rule 8.5 — An external object or function shall be declared once in one and only one file.
- MISRA C: 2012 Rule 8.6 — An identifier with external linkage shall have exactly one external definition.

### MISRA C++ Rules

- MISRA C++ Rule 2-10-1 — Different identifiers shall be typographically unambiguous.
- MISRA C++ Rule 2-10-2 — Identifiers declared in an inner scope shall not hide an identifier declared in an outer scope.
- MISRA C++ Rule 3-2-2 — The One Definition Rule shall not be violated.
- MISRA C++ Rule 3-2-3 — A type, object or function that is used in multiple translation units shall be declared in one and only one file.
- MISRA C++ Rule 3-2-4 — An identifier with external linkage shall have exactly one definition.
- MISRA C++ Rule 7-5-4 — Functions should not call themselves, either directly or indirectly.
- MISRA C++ Rule 15-4-1 — If a function is declared with an exception-specification, then all declarations of the same function (in other translation units) shall be declared with the same set of type-ids.

### JSF C++ Rules

- JSF C++ Rule 46 — User-specified identifiers (internal and external) will not rely on significance of more than 64 characters.
- JSF C++ Rule 48 — Identifiers will not differ by only a mixture of case, the presence/absence of the underscore character, the interchange of the letter `O` with the number 0 or the letter `D`, the interchange of the letter `I` with the number 1 or the letter `l`, the interchange of the letter `S` with the number 5, the interchange of the letter `Z` with the number 2 and the interchange of the letter `n` with the letter `h`.

- JSF C++ Rule 137 — All declarations at file scope should be static where possible.
- JSF C++ Rule 139 — External objects will not be declared in more than one file.

**Polyspace Bug Finder Defects**

- `Variable shadowing` — Variable hides another variable of same name with nested scope.
- `Declaration mismatch` — Mismatch occurs between function or variable declarations.

4 If a result (coding rule violation or Bug Finder defect) is inside a macro, Polyspace typically shows the result on the macro definition instead of the macro occurrences so that you review the result only once. Even if the macro is used in a suppressed file, the result is still shown on the macro definition, *if the definition occurs in an unsuppressed file*.

## Command-Line Information

**Parameter:** `-do-not-generate-results-for`
**Value:** `all-headers` | `include-folders` | `custom=`*`file1`*`[,`*`file2`*`[,...]]` | `custom=`*`folder1`*`[,`*`folder2`*`[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-misra2 required-rules -do-not-generate-results-for custom="C:\usr\include"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-misra2 required-rules -do-not-generate-results-for custom="C:\usr\include"`

### Topics

“Specify Polyspace Analysis Options”

# External multitasking configuration

Enable setup of multitasking configuration from external file definitions

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify whether you want to use definitions from external files to set up the multitasking configuration of your Polyspace project. The supported external file formats are:

- ARXML files for AUTOSAR projects
- OIL files for OSEK projects

### Set Option

**User interface:** In the **Configuration** pane, the option is available on the **Multitasking** node.

**Command line and options file**: See "Command-Line Information" on page 2-108.

### Why Use This Option

If your AUTOSAR project includes ARXML files with ECU configuration parameters, or if your OSEK project includes OIL files, Polyspace can parse these files. The software sets up tasks, interrupts, cyclical tasks, and critical sections. You do not have to set them up manually.

## Settings

☑ On

Polyspace parses the external files that you provide in the format that you specify to set up the multitasking configuration of your project.

`osek`

Look for and parse OIL files to extract multitasking description.

`autosar`

Look for and parse AUTOSAR XML files to extract multitasking description.

□ Off (default)

Polyspace does not set up the multitasking configuration of your project.

## Command-Line Information

There is no single command-line option to turn on external multitasking configuration. By using the `-osek-multitasking` option or the `-autosar-multitasking` option, you enable external multitasking configuration.

# Version History

**Introduced in R2018a**

## See Also

`ARXML files selection (-autosar-multitasking)` | `OIL files selection (-osek-multitasking)`

### Topics

"Specify Polyspace Analysis Options"
"Analyze Multitasking Programs in Polyspace"

# OIL files selection (`-osek-multitasking`)

Set up multitasking configuration from OIL file definition

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify the OIL files that Polyspace parses to set up the multitasking configuration of your OSEK project.

### Set Option

**User interface:** In the **Configuration** pane, the option is available on the **Multitasking** node. See Dependencies on page 2-114 for other options you must also enable.

**Command line: and options file** Use the option `-osek-multitasking`. See “Command-Line Information” on page 2-114.

### Why Use This Option

If your project includes OIL files, Polyspace can parse these files to set up tasks, interrupts, cyclical tasks, and critical sections. You do not have to set them up manually.

## Settings

☑ On

Polyspace looks for and parses OIL files to set up your multitasking configuration.

`auto`

Look for OIL files in your project source and include folders, but not in their subfolders.

`custom`

Look for OIL files on the specified path and the path subfolders. You can specify a path to the OIL files or to the folder containing the files.

When you select this option, in your source code, Polyspace supports these OSEK multitasking keywords:

- `TASK`
- `DeclareTask`
- `ActivateTask`
- `DeclareResource`
- `GetResource`
- `ReleaseResource`
- `ISR`
- `DeclareEvent`

- DeclareAlarm

Polyspace parses the OIL files that you provide for TASK, ISR, RESOURCE, and ALARM definitions. The analysis uses these definitions and the supported multitasking keywords to configure tasks, interrupts, cyclical tasks, and critical sections.

### Example: Analyze Your OSEK Multitasking Project

This example shows how to set up the multitasking configuration of an OSEK project and run an analysis on this project. To try the steps in this example, use the demo files in the folder *polyspaceroot*/help/toolbox/bugfinder/examples/External_multitasking/OSEK or *polyspaceroot*/help/toolbox/codeprover/examples/External_multitasking/OSEK. *polyspaceroot* is the Polyspace installation folder. The analysis results apply to this example code.

```
#include <assert.h>
#include "include/example_osek_multi.h"

int var1;
int var2;
int var3;

DeclareAlarm(Cyclic_task_activate);
DeclareResource(res1);
DeclareTask(init);
TASK(afterinit1);

TASK(init) // task
{

  var2++;
  ActivateTask(afterinit1);
  var3++;
  GetResource(res1); // critical section begins
  var1++;
  ReleaseResource(res1); // critical section ends
}

TASK(afterinit1) // task
{
  var3++;
  var2++;
  GetResource(res1); // critical section begins
  var1++;
  ReleaseResource(res1); // critical section ends

}
int var4;
void func()
{
  var4++;
}

TASK(Cyclic_task) // cyclic task
{
  func();
}

void main()
{}
```

To set up your multitasking configuration and analyze the code:

1. Copy the contents of *polyspaceroot*/help/toolbox/bugfinder/examples/External_multitasking/OSEK or *polyspaceroot*/help/toolbox/codeprover/examples/External_multitasking/OSEK to your machine, for instance in C:\Polyspace_worskpace\OSEK.
2. Run an analysis on your OSEK project by using the command:

   - Bug Finder:

```
polyspace-bug-finder -sources ^
C:\Polyspace_workspace\OSEK\example_osek_multitasking.c ^
-osek-multitasking auto
```

- Code Prover:

  ```
  polyspace-code-prover -sources ^
  C:\Polyspace_workspace\OSEK\example_osek_multitasking.c ^
  -osek-multitasking auto
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -sources ^
  C:\Polyspace_workspace\OSEK\example_osek_multitasking.c ^
  -osek-multitasking auto
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -sources ^
  C:\Polyspace_workspace\OSEK\example_osek_multitasking.c ^
  -osek-multitasking auto
  ```

Bug Finder detects a data race on variable `var3` because of multiple read and write operation from tasks `init` and `afterinit1`. See `Data race`.

```
#include <assert.h>
#include "include/example_osek_multi.h"

int var1;
int var2;
int var3;
```

There is no defect on `var2` since `afterinit1` goes to an active state (`ActivateTask()`) after `init` increments `var2`. Similarly, there is no defect on `var1` because it is protected by the `GetResource()` and `ReleaseResource()` calls.

Code Prover detects that `var3` is a potentially unprotected global variable because it is used in tasks `init` and `afterinit1` with no protection from interruption during the read and write operations. The analysis also shows that the cyclic task operation on `var4` can potentially cause an overflow. See `Potentially unprotected variable` and `Overflow`.

```
#include <assert.h>
#include "include/example_osek_multi.h"

int var1;
int var2;
int var3;

...
void func()
{
  var4++;
}
```

Variable `var2` is not shared because `afterinit1` goes to an active state (`ActivateTask()`) after `init` increments `var2`. Variable `var1` is a protected variable (Polyspace Code Prover) through the critical sections from the `GetResource()` and `ReleaseResource()` calls.

To see how Polyspace models the `TASK`, `ISR`, and `RESOURCE` definitions from your OIL files, open the **Concurrency window** from the **Dashboard** pane.

□ Off (default)

Polyspace does not set up a multitasking configuration for your OSEK project.

#### Additional Considerations

- Make sure that you declare all tasks by using the `DeclareTask` or `TASK` keywords before you pass those tasks as parameters to functions or macros that expect a task. For example , if you pass task `foo` to `ActivateTask` without using `DeclareTask(foo);` first, Polyspace considers task `foo` undefined which results in a compilation error.
- The analysis ignores `TerminateTask()` declarations in your source code and considers that subsequent code is executed.
- Polyspace ignores syntax elements of your OIL files that do not follow the syntax defined here.

### Dependencies

To enable this option in the user interface of the desktop products, first select the option `External multitasking configuration`.

### Command-Line Information

**Parameter:** `-osek-multitasking`
**Value:** `auto` | `custom='`*`file1 [,file2, dir1,...]`*`'`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`source_path`* `-I` *`include_path`* `-osek-multitasking custom='path\to\file1.oil, path\to\dir'`
**Example (Code Prover):** `polyspace-code-prover -sources` *`source_path`* `-I` *`include_path`* `-osek-multitasking custom='path\to\file1.oil, path\to\dir'`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`source_path`* `-I` *`include_path`* `-osek-multitasking custom='path\to\file1.oil, path\to\dir'`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`source_path`* `-I` *`include_path`* `-osek-multitasking custom='path\to\file1.oil, path\to\dir'`

# ARXML files selection (-autosar-multitasking)

Set up multitasking configuration from ARXML file definitions

## Description

*To detect data races in large AUTOSAR applications, use this option with Polyspace Bug Finder.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify the ARXML files that Polyspace parses to set up the multitasking configuration of your AUTOSAR project.

### Set Option

**User interface:** In the **Configuration** pane, the option is available on the **Multitasking** node. See Dependencies on page 2-116 for other options you must also enable.

**Command line: and options file** Use the option `-autosar-multitasking`. See “Command-Line Information” on page 2-114.

### Why Use This Option

If your project includes ARXML files with `<ECUC-CONTAINER-VALUE>` elements, Polyspace can parse these files to set up tasks, interrupts, cyclical tasks, and critical sections. You do not have to set them up manually.

## Settings

☑ On

Polyspace looks for and parses ARXML files to set up your multitasking configuration.

When you select this option, the software assumes that you use the OSEK multitasking API in your source code to declare and define tasks and interrupts. Polyspace supports these OSEK multitasking keywords:

- `TASK`
- `DeclareTask`
- `ActivateTask`
- `DeclareResource`
- `GetResource`
- `ReleaseResource`
- `ISR`
- `DeclareEvent`
- `DeclareAlarm`

Polyspace parses the ARXML files that you provide for `OsTask`, `OsIsr`, `OsResource`, `OsAlarm`, and `OsEvent` definitions. The analysis uses these definitions and the supported multitasking keywords to configure tasks, interrupts, cyclical tasks, and critical sections.

To see how Polyspace models the `OsTask`, `OsIsr`, and `OsResource` definitions from your ARXML files, open the **Concurrency window** from the **Dashboard** pane. In that window, under the **Entry points** column, the names of the elements are extracted from their `<SHORT-NAME>` values in the ARXML files.

☐ Off (default)

Polyspace does not set up a multitasking configuration for your AUTOSAR project.

### Additional Considerations

- The analysis ignores `TerminateTask()` declarations in your source code and considers that subsequent code is executed.
- Polyspace supports multitasking configuration only from ARXML files for AUTOSAR specification version 4.0 and later.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `External multitasking configuration`.

## Command-Line Information

**Parameter:** `-autosar-multitasking`
**Value:** `file1 [,file2, dir1,...]`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources source_path -I include_path -autosar-multitasking C:\Polyspace_Workspace\AUTOSAR\myFile.arxml`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources source_path -I include_path -autosar-multitasking C:\Polyspace_Workspace\AUTOSAR\myFile.arxml`

# Version History

**Introduced in R2018a**

## See Also

# Configure multitasking manually

Consider that code is intended for multitasking

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify whether your code is a multitasking application. This option allows you to manually configure the multitasking structure for Polyspace.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node.

**Command line and options file**: See “Command-Line Information” on page 2-118.

### Why Use This Option

By default, Bug Finder determines your multitasking model from your use of multithreading functions. In Code Prover, you have to enable automatic concurrency detection with the option `Enable automatic concurrency detection for Code Prover (-enable-concurrency-detection)`. However, in some cases, using automatic concurrency detection can slow down the Code Prover analysis.

In cases where automatic concurrency detection is not supported, you can explicitly specify your multitasking model by using this option. Once you select this option, you can explicitly specify your entry point functions, cyclic tasks, interrupts and protection mechanisms for shared variables, such as critical section details.

A Code Prover verification uses your specifications to determine:

- Whether a global variable is shared.

  See “Global Variables” (Polyspace Code Prover).
- Whether a run-time error can occur.

  For instance, if the operation `var++` occurs in the body of a cyclic task and you do not impose a limit on `var`, the operation can overflow. The analysis detects the possible overflow.

A Bug Finder analysis uses your specifications to look for concurrency defects. For more information, see “Concurrency Defects”.

## Settings

☑ On

The code is intended for a multitasking application.

You have to explicitly specify your multitasking configuration using other Polyspace options. See “Configuring Polyspace Multitasking Analysis Manually”.

□ Off (default)

The code is not intended for a multitasking application.

Disabling the option has this additional effect in Code Prover:

- If a `main` exists, Code Prover verifies only those functions that are called by the `main`.
- If a `main` does not exist, Polyspace verifies the functions that you specify. To verify the functions, Polyspace generates a `main` function and calls functions from the generated `main` in a sequence that you specify. For more information, see `Verify module or library (-main-generator)`.

## Tips

If you run a file by file verification in Code Prover, your multitasking options are ignored. See `Verify files independently (-unit-by-unit)`.

## Command-Line Information

There is no single command-line option to turn on multitasking analysis. By using any of the options `Tasks (-entry-points)`, `Cyclic tasks (-cyclic-tasks)` or `Interrupts (-interrupts)`, you turn on multitasking analysis.

## See Also

`-preemptable-interrupts` | `-non-preemptable-tasks` | `Tasks (-entry-points)` | `Cyclic tasks (-cyclic-tasks)` | `Critical section details (-critical-section-begin -critical-section-end)` | `Temporally exclusive tasks (-temporal-exclusions-file)`

# Enable automatic concurrency detection for Code Prover (`-enable-concurrency-detection`)

Automatically detect certain families of multithreading functions

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify whether the analysis must automatically detect POSIX®, VxWorks®, Windows, µC/OS II and other multithreading functions.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” (Polyspace Code Prover) for other options that you must enable or disable.

**Command line and options file**: Use the option `-enable-concurrency-detection`. See “Command-Line Information” on page 2-120.

### Why Use This Option

If you use this option, Polyspace determines your multitasking model from your use of multithreading functions. In Bug Finder, automatic concurrency detection is enabled by default. In Code Prover, you have to explicitly enable automatic concurrency detection.

In some cases, using automatic concurrency detection can slow down the Code Prover analysis. In those cases, you can choose to not enable this option and explicitly specify your multitasking model. See “Configuring Polyspace Multitasking Analysis Manually”.

## Settings

☑ On

If you use one of the supported functions for multitasking, the analysis automatically detects your multitasking model from your code.

For a list of supported multitasking functions and limitations in auto-detection of threads, see “Auto-Detection of Thread Creation and Critical Section in Polyspace”.

□ Off (default)

The analysis does not attempt to detect the multitasking model from your code.

If you want to manually configure your multitasking model, see “Configuring Polyspace Multitasking Analysis Manually”.

## Dependencies

If you enable this option, your code must contain a `main` function. You cannot use the Code Prover options to generate a `main`.

## Command-Line Information

**Parameter:** `-enable-concurrency-detection`
**Default:** Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-enable-concurrency-detection`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-enable-concurrency-detection`

## See Also

`Show global variable sharing and usage only (-shared-variables-mode)`

# Tasks (`-entry-points`)

Specify functions that serve as tasks to your multitasking application

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify functions that serve as tasks to your code. If the function does not exist, the verification warns you and continues the verification.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-122 for other options you must also enable.

**Command line and options file**: Use the option `-entry-points`. See “Command-Line Information” on page 2-122.

### Why Use This Option

Use this option when your code is intended for multitasking.

To specify cyclic tasks and interrupts, use the options `Cyclic tasks (-cyclic-tasks)` and `Interrupts (-interrupts)`. Use this option to specify other tasks.

A Code Prover analysis uses your specifications to determine:

- Whether a global variable is shared.

  See “Global Variables” (Polyspace Code Prover).
- Whether a run-time error can occur.

  For instance, if the operation `var++` occurs in the body of a cyclic task and you do not impose a limit on `var`, the operation can overflow. The analysis detects the possible overflow.

A Bug Finder analysis uses your specifications to look for concurrency defects. For more information, see “Concurrency Defects”.

## Settings

**No Default**

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `Configure multitasking manually`.

## Tips

- In Code Prover, the functions representing entry points must have the form

  ```
  void functionName (void)
  ```
- If a function `func` takes arguments or returns a value, you cannot use it directly as an entry point. To use `func` as an entry point:, call `func` from a wrapper `void-void` function and specify the wrapper as an entry point. See “Configuring Polyspace Multitasking Analysis Manually”.
- If you specify a function as a task, you must provide its definition. Otherwise, a Code Prover verification stops with the error message:

  ```
  task func_name must be a userdef function without parameters
  ```

  A Bug Finder analysis continues but does not consider the function as an entry point.
- If you run a file by file verification in Code Prover, your multitasking options are ignored. See `Verify files independently (-unit-by-unit)`.
- The Polyspace multitasking analysis assumes that a task cannot interrupt itself.

## Command-Line Information

**Parameter:** `-entry-points`
**No Default**
**Value:** `*function1*[,*function2*[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -sources *file_name* -entry-points func_1,func_2`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -entry-points func_1,func_2`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources *file_name* -entry-points func_1,func_2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -entry-points func_1,func_2`

# Cyclic tasks (-cyclic-tasks)

Specify functions that represent cyclic tasks

## Description

*The option is not available for code generated from MATLAB code or Simulink models.*

Specify functions that represent cyclic tasks. The analysis assumes that operations in the function body:

- Can execute any number of times.
- Can be interrupted by noncyclic tasks, other cyclic tasks and interrupts. Noncyclic tasks are specified with the option `Tasks (-entry-points)` and interrupts are specified with the option `Interrupts (-interrupts)`.

  To model a cyclic task that cannot be interrupted by other cyclic tasks, specify the task as nonpreemptable. See `-non-preemptable-tasks`. For examples, see “Define Task Priorities for Data Race Detection in Polyspace”.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-124 for other options you must also enable.

**Command line and options file**: Use the option `-cyclic-tasks`. See “Command-Line Information” on page 2-125.

### Why Use This Option

Use this option to specify cyclic tasks in your multitasking code. The functions that you specify must have the prototype:

```
void function_name(void);
```

A Bug Finder analysis uses your specifications to look for concurrency defects. For the `Data race` defect, the software establishes the following relations between preemptable tasks and other tasks.

- *Data race between two preemptable tasks*:

  Unless protected, two operations in different preemptable tasks can interfere with each other. If the operations use the same shared variable without protection, a data race can occur.

  If both operations are atomic, to see the defect, you have to enable the checker **Data race including atomic operations**.
- *Data race between a preemptable task and a nonpreemptable task or interrupt*:
  - An atomic operation in a preemptable task cannot interfere with an operation in a nonpreemptable task or an interrupt. Even if the operations use the same shared variable without protection, a data race cannot occur.

  - A nonatomic operation in a preemptable task also cannot interfere with an operation in a nonpreemptable task or an interrupt. However, the latter operation can interrupt the former. Therefore, if the operations use the same shared variable without protection, a data race can occur.

For more information, see:

- “Define Task Priorities for Data Race Detection in Polyspace”
- “Concurrency Defects”

A Code Prover verification uses your specifications to determine:

- Whether a global variable is shared.

  See “Global Variables” (Polyspace Code Prover).
- Whether a run-time error can occur.

  For instance, if the operation `var++` occurs in the body of a cyclic task and you do not impose a limit on `var`, the operation can overflow. The analysis detects the possible overflow.

## Settings

**No Default**

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `Configure multitasking manually`.

## Tips

- In Code Prover, the functions representing cyclic tasks must have the form

  ```
  void functionName (void)
  ```
- If a function `func` takes arguments or returns a value, you cannot use it directly as a cyclic task. To use `func` as a cyclic task:, call `func` from a wrapper `void-void` function and specify the wrapper as a cyclic task. See “Configuring Polyspace Multitasking Analysis Manually”.
- If you specify a function as a cyclic task, you must provide its definition. Otherwise, a Code Prover verification stops with the error message:

  ```
  task func_name must be a userdef function without parameters
  ```

  A Bug Finder analysis continues but does not consider the function as a cyclic task.
- If you run a file by file verification in Code Prover, your multitasking options are ignored. See `Verify files independently (-unit-by-unit)`.

- The Polyspace multitasking analysis assumes that a task cannot interrupt itself.
- Code Prover interprets this option with some limitations. The reason is that Code Prover considers all operations as potentially non-atomic and interruptible. This overapproximation leads to situations where the option might appear to be ignored. For an example, see "Effect of Task Priorities in Code Prover" (Polyspace Code Prover).

### Command-Line Information

**Parameter:** `-cyclic-tasks`
**No Default**
**Value:** `*function1*[,*function2*[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -sources *file_name* -cyclic-tasks func_1,func_2`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -cyclic-tasks func_1,func_2`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources *file_name* -cyclic-tasks func_1,func_2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -cyclic-tasks func_1,func_2`

## Version History

**Introduced in R2016b**

# Interrupts (-interrupts)

Specify functions that represent nonpreemptable interrupts

## Description

*The option is not available for code generated from MATLAB code or Simulink models.*

Specify functions that represent nonpreemptable interrupts. The analysis assumes that operations in the function body:

- Can execute any number of times.
- Cannot be interrupted by noncyclic tasks, cyclic tasks or other interrupts. Noncyclic tasks are specified with the option `Tasks (-entry-points)` and cyclic tasks are specified with the option `Cyclic tasks (-cyclic-tasks)`.

  You can also make interrupts preemptable.

  - To model an interrupt that can be interrupted by other interrupts, specify the interrupt as preemptable. See `-preemptable-interrupts`. For examples, see “Define Task Priorities for Data Race Detection in Polyspace”.
  - To make only a section of an interrupt preemptable, call a routine enabling all interrupts before that section and call another routine disabling all interrupts after the section is complete. For instance, if you specify the routine `isr()` as an interrupt, it is nonpreemptable by default. However, within `isr()`, if you call a routine enabling all interrupts, the section following the call is preemptable till you call another routine disabling all interrupts:

    ```
    void isr() {
       x++; //Nonpreemptable
       enable_all_interrupts(); //Routine enabling interrupts
       y++; //Preemptable
       disable_all_interrupts(); //Routine disabling interrupts
       z++; //Nonpreemptable
    }
    ```

    For information on how to enable and disable all interrupts, see `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-127 for other options you must also enable.

**Command line and options file**: Use the option `-interrupts`. See “Command-Line Information” on page 2-128.

### Why Use This Option

Use this option to specify interrupts in your multitasking code. The functions that you specify must have the prototype:

```
void function_name(void);
```

A Bug Finder analysis uses your specifications to look for concurrency defects. For the `Data race` defect, the analysis establishes the following relations between interrupts and other tasks:

- *Data race between two interrupts*:

  Two operations in different interrupts cannot interfere with each other (unless one of the interrupts is preemptable). Even if the operations use the same shared variable without protection, a data race cannot occur.
- *Data race between an interrupt and another task*:

  - An operation in an interrupt cannot interfere with an atomic operation in any other task. Even if the operations use the same shared variable without protection, a data race cannot occur.
  - An operation in an interrupt can interfere with a nonatomic operation in any other task unless the other task is also a nonpreemptable interrupt. Therefore, if the operations use the same shared variable without protection, a data race can occur.

For more information, see:

- “Define Task Priorities for Data Race Detection in Polyspace”
- “Concurrency Defects”

A Code Prover verification uses your specifications to determine:

- Whether a global variable is shared.

  See “Global Variables” (Polyspace Code Prover).
- Whether a run-time error can occur.

  For instance, if the operation `var=INT_MAX;` occurs in an interrupt and `var++` occurs in the body of a task, an overflow can occur if the interrupt executes before the operation in the task. The analysis detects the possible overflow.

## Settings

**No Default**

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `Configure multitasking manually`.

## Tips

- In Code Prover, the functions representing interrupts must have the form

  ```
  void functionName (void)
  ```

- If a function `func` takes arguments or returns a value, you cannot use it directly as an interrupt. To use `func` as an interrupt, call `func` from a wrapper `void-void` function and specify the wrapper as an interrupt. See “Configuring Polyspace Multitasking Analysis Manually”.
- If you specify a function as an interrupt, you must provide its definition. Otherwise, a Code Prover verification stops with the error message:

  ```
  task func_name must be a userdef function without parameters
  ```

  A Bug Finder analysis continues but does not consider the function as an interrupt.
- If you run a file by file verification in Code Prover, your multitasking options are ignored. See `Verify files independently (-unit-by-unit)`.
- The Polyspace multitasking analysis assumes that an interrupt cannot interrupt itself.
- Code Prover interprets this option with some limitations. The reason is that Code Prover considers all operations as potentially non-atomic and interruptible. This overapproximation leads to situations where the option might appear to be ignored. For an example, see “Effect of Task Priorities in Code Prover” (Polyspace Code Prover).

### Command-Line Information

**Parameter:** `-interrupts`
**No Default**
**Value:** `*function1*[,*function2*[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -sources *file_name* -interrupts func_1,func_2`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -interrupts func_1,func_2`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources *file_name* -interrupts func_1,func_2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -interrupts func_1,func_2`

## Version History

**Introduced in R2016b**

# Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)

Specify routines that disable and reenable interrupts.

## Description

*This option affects a Bug Finder analysis only. The option is not available for code generated from MATLAB code or Simulink models.*

Specify a routine that disables all tasks and interrupts other than the current one, and a routine that reenables them.

The routine that you specify for the option disables preemption by all:

- Non-cyclic tasks.

  See `Tasks (-entry-points)`.
- Cyclic tasks.

  See `Cyclic tasks (-cyclic-tasks)`.
- Interrupts.

  See `Interrupts (-interrupts)`.

In other words, the analysis considers that the body of operations between the disabling routine and the enabling routine is atomic and not interruptible at all.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-130 for other options you must also enable.

**Command line and options file**: Use the option `-routine-disable-interrupts` and `-routine-enable-interrupts`. See “Command-Line Information” on page 2-131.

### Why Use This Option

A Bug Finder analysis uses the information when looking for data race defects. For instance, in the following code, the function `disable_all_interrupts` disables all interrupts until the function `enable_all_interrupts` is called. Even if `task`, `isr1` and `isr2` run concurrently, the operations `x=0` or `x=1` cannot interrupt the operation `x++`. There are no data race defects.

```
int x;

void isr1() {
   x = 0;
}

void isr2() {
   x = 1;
}

void task() {
   disable_all_interrupts();
   x++;
   enable_all_interrupts();
}
```

## Settings

**No Default**

- In **Disabling routine**, enter the routine that disables all interrupts.
- In **Enabling routine**, enter the routine that reenables all interrupts.

Enter function names or choose from a list.

- Click ➕ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `Configure multitasking manually`.

## Tips

- Protection via disabling interrupts is conceptually different from protection via critical sections.

  In the Polyspace multitasking model, to protect two sections of code *from each other* via critical sections, you have to embed them in the same critical section. In other words, you have to place the two sections between calls to the same lock and unlock function.

  For instance, suppose you use critical sections as follows:

  ```
  void isr1() {
     begin_critical_section();
     x = 0;
     end_critical_section();
  }

  void isr2() {
     x = 1;
  }

  void task() {
     begin_critical_section();
     x++;
     end_critical_section();
  }
  ```

Here, the operation x++ is protected from the operation x=0 in isr1, but not from the operation x=1 in isr2. If the function begin_critical_section disabled *all interrupts*, calling it before x++ would have been sufficient to protect it.

Typically, you use one pair of routines in your code to disable and reenable interrupts, but you can have many pairs of lock and unlock functions that implement critical sections.

- The routines that disable and enable interrupts must be functions. For instance, if you define a function-like macro:

  ```
  #define disable_interrupt() interrupt_flag=0
  ```

  You cannot use the macro disable_interrupt() as routine disabling interrupts.
- You can use this option to make sections of nonpreemptable interrupts preemptable. To make only a section of an interrupt preemptable, call a routine enabling all interrupts before that section and call another routine disabling all interrupts after the section is complete.

  For instance, if you specify the routine isr() as an interrupt, it is nonpreemptable by default. However, within isr(), if you call a routine enabling all interrupts, the section following the call is preemptable till you call another routine disabling all interrupts:

  ```
  void isr() {
     x++; //Nonpreemptable
     enable_all_interrupts(); //Routine enabling interrupts
     y++; //Preemptable
     disable_all_interrupts(); //Routine disabling interrupts
     z++; //Nonpreemptable
  }
  ```

## Command-Line Information

**Parameter:** -routine-disable-interrupts | -routine-enable-interrupts
**No Default**
**Value:** *function_name*
**Example (Bug Finder):** polyspace-bug-finder -sources *file_name* -routine-disable-interrupts atomic_section_begins -routine-enable-interrupts atomic_section_ends
**Example (Bug Finder Server):** polyspace-bug-finder-server -sources *file_name* -routine-disable-interrupts atomic_section_begins -routine-enable-interrupts atomic_section_ends

# Version History

# Critical section details (-critical-section-begin -critical-section-end)

Specify functions that begin and end critical sections

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

When verifying multitasking code, Polyspace considers that a critical section lies between calls to a lock function and an unlock function.

```
lock();
/* Critical section code */
unlock();
```

Specify the lock and unlock function names for your critical sections (for instance, `lock()` and `unlock()` in above example).

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-134 for other options you must also enable.

**Command line and options file**: Use the option `-critical-section-begin` and `-critical-section-end`. See “Command-Line Information” on page 2-135.

### Why Use This Option

When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait till `my_task` calls the corresponding unlock function. Therefore, critical section operations in the other tasks cannot interrupt critical section operations in `my_task`.

For instance, the operation `var++` in `my_task1` and `my_task2` cannot interrupt each other.

```
int var;

void my_task1() {
   my_lock();
   var++;
   my_unlock();
}

void my_task2() {
   my_lock();
   var++;
   my_unlock();
}
```

Using your specifications, a Code Prover verification checks if your placement of lock and unlock functions protects all shared variables from concurrent access. When determining values of those variables, the verification accounts for the fact that critical sections in different tasks do not interrupt each other.

A Bug Finder analysis uses the critical section information to look for concurrency defects such as data race and deadlock.

## Settings

**No Default**

Click ✚ to add a field.

- In **Starting routine**, enter name of lock function.
- In **Ending routine**, enter name of unlock function.

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products, first select the option `Configure multitasking manually`.

## Tips

- You can also use primitives such as the POSIX functions `pthread_mutex_lock` and `pthread_mutex_unlock` to begin and end critical sections. For a list of primitives that Polyspace can detect automatically, see “Auto-Detection of Thread Creation and Critical Section in Polyspace”.
- For function calls that begin and end critical sections, Polyspace ignores the function arguments.

  For instance, Polyspace treats the two code sections below as the same critical section.

| **Starting routine**: `my_lock` | |
|---|---|
| **Ending routine**: `my_unlock` | |
| `void my_task1() {`<br>`   my_lock(1);`<br>`   /* Critical section code */`<br>`   my_unlock(1);`<br>`}` | `void my_task2() {`<br>`   my_lock(2);`<br>`   /* Critical section code */`<br>`   my_unlock(2);`<br>`}` |

  To work around the limitation, see “Define Critical Sections with Functions That Take Arguments”.
- The functions that begin and end critical sections must be functions. For instance, if you define a function-like macro:

  ```
  #define init() num_locks++
  ```

  You cannot use the macro `init()` to begin or end a critical section.
- When you use multiple critical sections, you can run into issues such as:

  - Deadlock: A sequence of calls to lock functions causes two tasks to block each other.
  - Double lock: A lock function is called twice in a task without an intermediate call to an unlock function.

  Use Polyspace Bug Finder to detect such issues. See "Concurrency Defects".

  Then, use Polyspace Code Prover™ to detect if your placement of lock and unlock functions actually protects all shared variables from concurrent access. See "Global Variables" (Polyspace Code Prover).

- When considering possible values of shared variables, a Code Prover verification takes into account your specifications for critical sections.

  However, if the shared variable is a pointer or array, the software uses the specifications only to determine if the variable is a shared protected global variable. For run-time error checking, the software does not take your specifications into account and considers that the variable can be concurrently accessed.

## Command-Line Information

**Parameter:** `-critical-section-begin` | `-critical-section-end`
**No Default**
**Value:** `*function1*:cs1[,*function2*:cs2[,...]]`
**Example (Bug Finder):** `polyspace-bug_finder -sources *file_name* -critical-section-begin func_begin:cs1 -critical-section-end func_end:cs1`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -critical-section-begin func_begin:cs1 -critical-section-end func_end:cs1`
**Example (Bug Finder Server):** `polyspace-bug_finder-server -sources *file_name* -critical-section-begin func_begin:cs1 -critical-section-end func_end:cs1`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -critical-section-begin func_begin:cs1 -critical-section-end func_end:cs1`

# Temporally exclusive tasks (`-temporal-exclusions-file`)

Specify entry point functions that cannot execute concurrently

## Description

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify entry point functions that cannot execute concurrently. The execution of the functions cannot overlap with each other.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Multitasking** node. See “Dependencies” on page 2-136 for other options you must also enable.

**Command line and options file**: Use the option `-temporal-exclusions-file`. See “Command-Line Information” on page 2-137.

### Why Use This Option

Use this option to implement temporal exclusion in multitasking code.

A Code Prover verification checks if specifying certain tasks as temporally exclusive protects all shared variables from concurrent access. When determining possible values of those shared variables, the verification accounts for the fact that temporally exclusive tasks do not interrupt each other. See “Global Variables” (Polyspace Code Prover).

A Bug Finder analysis uses the temporal exclusion information to look for concurrency defects such as data race. See “Concurrency Defects”.

## Settings

**No Default**

Click ✚ to add a field. In each field, enter a space-separated list of functions. Polyspace considers that the functions in the list cannot execute concurrently.

Enter the function names manually or choose from a list.

- Click ✚ to add a field and enter the function names.
- Click 🔍 to list functions in your code. Choose functions from the list.

## Dependencies

To enable this option in the user interface of the desktop products:

- Select the option Configure multitasking manually .
- Specify function names for Tasks (-entry-points), Cyclic tasks (-cyclic-tasks) and Interrupts (-interrupts).

You can then specify some of these functions as temporally exclusive tasks. Alternatively, if you specify your multitasking configuration using external files with the option External multitasking configuration, some of the functions from your external files can be specified as temporally exclusive.

The ability to specify temporally exclusive tasks is not supported for automatically detected thread creation routines such as pthread_create. These routines can be invoked at different points in the code to create separate threads. However, the temporal exclusion option does not support specifying two separate invocations of the same routine at different points in the code.

## Tips

When considering possible values of shared variables, a Code Prover verification takes into account your specifications for temporally exclusive tasks.

However, if the shared variable is a pointer or array, the software uses the specifications only to determine if the variable is a shared protected global variable. For run-time error checking in Code Prover, the software does not take your specifications into account and considers that the variable can be concurrently accessed.

## Command-Line Information

For the command-line option, create a temporal exclusions file in the following format:

- On each line, enter one group of temporally excluded tasks.
- Within a line, the tasks are separated by spaces.

To enter comments, begin with #. For an example, see the file *polyspaceroot*\polyspace\examples\cxx\Code_Prover_Example\sources\temporal_exclusions.txt. Here, *polyspaceroot* is the Polyspace installation folder, for example C:\Program Files\Polyspace\R2019a.
**Parameter:** -temporal-exclusions-file
**No Default**
**Value:** Name of temporal exclusions file
**Example (Bug Finder):** polyspace-bug-finder -sources *file_name* -temporal-exclusions-file "C:\exclusions_file.txt"
**Example (Code Prover):** polyspace-code-prover -sources *file_name* -temporal-exclusions-file "C:\exclusions_file.txt"
**Example (Bug Finder Server):** polyspace-bug-finder-server -sources *file_name* -temporal-exclusions-file "C:\exclusions_file.txt"
**Example (Code Prover Server):** polyspace-code-prover-server -sources *file_name* -temporal-exclusions-file "C:\exclusions_file.txt"

# Set checkers by file (`-checkers-selection-file`)

Define a custom set of coding standards checks for your analysis

## Description

Specify the full path of a configuration XML file where you define custom selections of coding standards checkers. In the same XML file, you can specify a custom selection of checkers for each of these coding standards:

- MISRA C:2004
- MISRA C:2012
- MISRA C++
- JSF AV C++
- AUTOSAR C++14 *(Bug Finder only)*
- CERT® C *(Bug Finder only)*
- CERT C++ *(Bug Finder only)*
- ISO/IEC TS 17961 *(Bug Finder only)*
- Polyspace Guidelines *(Bug Finder only)*

You can also define custom rules to match identifiers in your code to text patterns you specify.

If you use a selection XML file generated by using a previous version of Polyspace, previously unimplemented checkers might become implemented. Polyspace warns if the file XML file lists an implemented checker as `'notimplemented'`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node.

**Command line and options file**: Use the option `-checkers-selection-file`. See “Command-Line Information” on page 2-141.

When you enable this option, set the coding standards that you select to `from-file` to use the specified configuration file.

### Why Use This Option

Use this option to define a selection of coding standard checkers specific to your organization. The configuration of different coding standards is consolidated in a single XML file that you can reuse across projects to enforce common coding standards.

## Settings

☑ On

Polyspace checks your code against the selection of coding standard checkers, or the custom rules, defined in the configuration file that you specify.

To create a configuration file by using the Polyspace Desktop, in the **Configuration**, select **Coding Standards & Code Metrics**. To open the **Checkers selection** interface, click the folder (📁) on the right pane. Choose the coding standards that you want to configure in the left pane, and then select the rules that you want to activate in the right pane.

To create a configuration file by using Polyspace As you Code IDE plugins, refer to the documentation of your specific plugin.

To use or update an existing file, enter the full path to the file in the in the **Select file** field of the **Checkers selection** dialog box. Alternatively, click **Browse** in the **Checkers selection** window and browse to the existing file.

⊞ ■ 9 Initialization

⊞ ☑ 10 The essential type model

☐ Off (default)

Polyspace does not check your code against the selection of coding standard checkers, or the custom rules, defined in the configuration file you specify.

## Tips

- For the Polyspace desktop products, specify the coding standard configuration in the Polyspace User Interface. When you save the configuration, an XML file is created for use in the current and other projects.
- To create a custom coding standard classification, or to tag coding rule checkers of interest, enter text in the **Comment** column of the **Checkers selection** window. Polyspace displays that text in the **Results Details** pane and in the **Detail** column of the **Results List** (if available) when you review results in the desktop interface, in Polyspace Access, or in the Polyspace as You Code plugins.

- For the Polyspace Server products, you have to create a coding standard XML. Depending on the standard that you want to enable, make a writeable copy of one of the files in *polyspaceserverroot*\help\toolbox\bugfinder\examples\coding_standards_XML. Enable specific rules by using entries in the XML file (all rules from a standard are disabled in the template). Here, *polyspaceserverroot* is the root installation folder for the Polyspace Server products, for instance, C:\Program Files\Polyspace Server\R2023a.

  For instance, to turn off MISRA C:2012 rule 8.1, in the file misra_c_2012_rules.xml, use this entry:

  ```
  <standard name="MISRA C:2012">
    ...
    <section name="8 Declarations and definitions">
        ...
        <check id="8.1" state="off">
        </check>
        ...
    </section>
    ...
  </standard>
  ```

  For a full list of rule IDs and section names, see:

  - “AUTOSAR C++14 Rules”
  - “CERT C Rules and Recommendations”
  - “CERT C++ Rules”
  - “ISO/IEC TS 17961 Rules”
  - “Custom Coding Rules”
  - “JSF C++ Rules”
  - “MISRA C:2004 Rules”
  - “MISRA C:2012 Directives and Rules”
  - “MISRA C++:2008 Rules”
  - “Guidelines”

**Note** The XML format of the checker configuration file might change in future releases.

## Command-Line Information

Use the command -checkers-selection-file in the command line to select a custom set of coding standards checks for your analysis.
**Parameter:** -checkers-selection-file
**Value:** Full path of XML configuration file
**Default:** Off
**Example (Bug Finder):** polyspace-bug-finder -sources *file_name* -checkers-selection-file "C:\Standards\custom_config.xml" -misra3 from-file
**Example (Bug Finder Server):** polyspace-bug-finder-server -sources *file_name* -checkers-selection-file "C:\Standards\custom_config.xml" -misra3 from-file

Alternatively, activate the custom selection of coding rules and Bug Finder defects in an activation XML file. See -checkers-activation-file.

### Topics

"Specify Polyspace Analysis Options"
"Check for and Review Coding Standard Violations"

# Check MISRA C:2004 (`-misra2`)

Check for violation of MISRA C:2004 rules

## Description

Specify whether to check for violation of MISRA C:2004 rules[1]. Each value of the option corresponds to a subset of rules to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-144 for other options that you must also enable.

**Command line and options file**: Use the option `-misra2`. See “Command-Line Information” on page 2-144.

### Why Use This Option

Use this option to specify the subset of MISRA C:2004 rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding rule violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `required-rules`

`required-rules`

Check required coding rules.

`single-unit-rules`

Check a subset of rules that apply only to single translation units. These rules are checked in the compilation phase of the analysis.

`system-decidable-rules`

Check rules in the `single-unit-rules` subset and some rules that apply to the collective set of program files. The additional rules are the less complex rules that apply at the integration level. These rules can be checked only at the integration level because the rules involve more than one translation unit. These rules are checked in the compilation and linking phases of the analysis.

`all-rules`

Check required and advisory coding rules.

`SQO-subset1`

Check only a subset of MISRA C rules. For more information, see “Software Quality Objective Subsets (C:2004)”.

[1] MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

`SQO-subset2`

Check a subset of rules including `SQO-subset1` and some additional rules. For more information, see “Software Quality Objective Subsets (C:2004)”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

  For projects with mixed C and C++ code, the MISRA C:2004 checker analyzes only `.c` files.
- If you set `Source code language (-lang)` to `C-CPP`, you can activate a C coding rule checker **and** a C++ coding rule checker. When you have both C and C++ coding rule checkers active, to avoid duplicate results, Polyspace does not produce the C coding rules found in the linking phase (such as MISRA C:2012 Rule 8.3).

## Tips

If you select the option `single-unit-rules` or `system-decidable-rules` and choose to detect coding rule violations only, the analysis can complete quicker than checking other rules. For more information, see “Coding Rule Subsets Checked Early in Analysis”.

## Command-Line Information

Use the command `-misra2` in the command line to check for violations of MISRA C:2004 rules.
**Parameter:** `-misra2`
**Value:** `required-rules` | `all-rules` | `SQO-subset1` | `SQO-subset2` | `single-unit-rules` | `system-decidable-rules` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-misra2 all-rules`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-misra2 all-rules`

Alternatively, enable all or specific MISRA C:2004 rules through a checkers activation XML file. See `-checkers-activation-file`.

# Version History

**R2021b: Use of text format for coding rules file not supported**
*Errors starting in R2021b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. Using a text file for this purpose results in an error. You can save custom selections for all the coding standards that Polyspace supports in the same file.

**Desktop interface:**

If you have a project that contains custom coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as *`filename`*`.xml`, where *`filename`* is the name of the first selected file alphabetically. For instance, if you select `foo.conf` and `bar.conf`, they are saved as `bar.conf.xml`.

**Command-line/ IDEs:**

In the command-line or in the IDE extensions, using text files as input to `-misra2` results in an error. To select a custom selection of MISRA C:2004 rules, use an XML file.

Use the file `misra_c_2004_rules.xml` as a template to create the XML file where you define a custom selection of coding standard checkers. This template file is in *`polyspaceroot`*`\help\toolbox\bugfinder\examples\coding_standards_XML` . Here, *`polyspaceroot`* is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace\R2023a`. To update your script, see this table

| Option | Use Instead |
|---|---|
| `-misra2 "custom_standard.conf"` | `-checkers-selection-file misra_c_2004_rules.xml -misra2 from-file` |

See:

- “Configure Coding Rules Checking”
- “Setting Checkers in Polyspace as You Code”

**Note** The XML format of the checker configuration file can change in future releases.

### Example of Configuration File in XML Format

To turn on MISRA C:2012 rule 8.1, use this entry:

```
<standard name="MISRA C:2012">
  ...
  <section name="8 Declarations and definitions">
      ...
      <check id="8.1" state="on">
      </check>
      ...
  </section>
  ...
</standard>
```

For a full list of rule IDs and section names, see:

- “AUTOSAR C++14 Rules”
- “CERT C Rules and Recommendations”
- “CERT C++ Rules”
- “ISO/IEC TS 17961 Rules”
- “Custom Coding Rules”
- “JSF C++ Rules”
- “MISRA C:2004 Rules”
- “MISRA C:2012 Directives and Rules”
- “MISRA C++:2008 Rules”
- “Guidelines”

### R2019b: Use of text format for coding rules file will not be supported

*Warns starting in R2019b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. If you use a text file, Polyspace issues a warning and converts the text file to XML.

# Check MISRA AC AGC (-misra-ac-agc)

Check for violation of MISRA AC AGC rules

## Description

Specify whether to check for violation of rules specified by *MISRA AC AGC Guidelines for the Application of MISRA-C:2004 in the Context of Automatic Code Generation*. Each value of the option corresponds to a subset of rules to check.

To check for MISRA C:2012 rules that apply to generated code, use the option Use generated code requirements (-misra3-agc-mode).

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-148 for other options that you must also enable.

**Command line and options file**: Use the option -misra-ac-agc. See “Command-Line Information” on page 2-148.

### Why Use This Option

Use this option to specify the subset of MISRA C:2004 AC AGC rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding rule violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default**: OBL-rules

OBL-rules

Check required coding rules.

OBL-REC-rules

Check required and recommended rules.

single-unit-rules

Check a subset of rules that apply only to single translation units. These rules are checked in the compilation phase of the analysis.

system-decidable-rules

Check rules in the single-unit-rules subset and some rules that apply to the collective set of program files. The additional rules are the less complex rules that apply at the integration level. These rules can be checked only at the integration level because the rules involve more than one translation unit. These rules are checked in the compilation and linking phases of the analysis.

all-rules

Check required, recommended and readability-related rules.

`SQO-subset1`

Check a subset of rules. For more information, see “Software Quality Objective Subsets (AC AGC)”.

`SQO-subset2`

Check a subset of rules including `SQO-subset1` and some additional rules. For more information, see “Software Quality Objective Subsets (AC AGC)”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

  For projects with mixed C and C++ code, the MISRA AC AGC checker analyzes only `.c` files.
- If you set `Source code language (-lang)` to `C-CPP`, you can activate a C coding rule checker **and** a C++ coding rule checker. When you have both C and C++ coding rule checkers active, to avoid duplicate results, Polyspace does not produce the C coding rules found in the linking phase (such as MISRA C:2012 Rule 8.3).

## Tips

If you select the option `single-unit-rules` or `system-decidable-rules` and choose to detect coding rule violations only, the analysis can complete quicker than checking other rules. For more information, see “Coding Rule Subsets Checked Early in Analysis”.

## Command-Line Information

Use the command `-misra-ac-agc` in the command line to check for violations of MISRA AC AGC rules.
**Parameter:** `-misra-ac-agc`
**Value:** `OBL-rules` | `OBL-REC-rules` | `single-unit-rules` | `system-decidable-rules` | `all-rules` | `SQO-subset1` | `SQO-subset2` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-misra-ac-agc all-rules`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-misra-ac-agc all-rules`

Alternatively, activate the rules in an activation XML file. See `-checkers-activation-file`.

## Version History

**R2021b: Using text format for coding rules file not supported**
*Errors starting in R2021b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. Use of a text file for this porpose results in an error. You can save custom selections for all the coding standards that Polyspace supports in the same file.

In previous releases, you saved your custom selection for each coding standard in separate text files. Polyspace no longer supports custom coding standard files in text format.

**Desktop interface:**

If you have a project that contains custom coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as `*filename*.xml`, where `*filename*` is the name of the first selected file alphabetically. For instance, if you select `foo.conf` and `bar.conf`, they are saved as `bar.conf.xml`.

**Command-line/ IDEs:**

In the command-line or in the IDE extensions, using text files as input to `-misra-ac-agc` results in an error. To select a custom selection of MISRA AC AGC rules, use an XML file.

Use the file `misra_ac_agc_rules.xml` as a template to create the XML file where you define a custom selection of coding standard checkers. This template file is in `*polyspaceroot*\help\toolbox\bugfinder\examples\coding_standards_XML`. Here, *`polyspaceroot`* is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace\R2023a`. To update your script, see this table

| Option | Use Instead |
|---|---|
| `-misra-ac-agc "custom_standard.conf"` | `-checkers-selection-file misra_ac_agc_rules.xml -misra-ac-agc from-file` |

See:

- "Configure Coding Rules Checking"
- "Setting Checkers in Polyspace as You Code"

**Note** The XML format of the checker configuration file can change in future releases.

### Example of Configuration File in XML Format

To turn on MISRA C:2012 rule 8.1, use this entry:

```
<standard name="MISRA C:2012">
  ...
  <section name="8 Declarations and definitions">
      ...
      <check id="8.1" state="on">
      </check>
      ...
  </section>
  ...
</standard>
```

For a full list of rule IDs and section names, see:

- “AUTOSAR C++14 Rules”
- “CERT C Rules and Recommendations”
- “CERT C++ Rules”
- “ISO/IEC TS 17961 Rules”
- “Custom Coding Rules”
- “JSF C++ Rules”
- “MISRA C:2004 Rules”
- “MISRA C:2012 Directives and Rules”
- “MISRA C++:2008 Rules”
- “Guidelines”

### R2019b: Use of text format for coding rules file will not be supported

*Warns starting in R2019b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. If you use a text file, Polyspace issues a warning and converts the text file to XML.

“Specify Polyspace Analysis Options”
“Check for and Review Coding Standard Violations”
“MISRA C:2004 Rules”

# Check MISRA C:2012 (-misra3)

Check for violations of MISRA C:2012 rules and directives

## Description

Specify whether to check for violations of MISRA C:2012 guidelines[2]Each value of the option corresponds to a subset of guidelines to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-152 for other options that you must also enable.

**Command line and options file**: Use the option `-misra3`. See “Command-Line Information” on page 2-153.

### Why Use This Option

Use this option to specify the subset of MISRA C:2012 rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding rule violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `mandatory-required`

`mandatory`

Check for mandatory guidelines.

`mandatory-required`

Check for mandatory and required guidelines.

- Mandatory guidelines: Your code must comply with these guidelines.
- Required guidelines: You may deviate from these guidelines. However, you must complete a formal deviation record, and your deviation must be authorized.

  See Section 5.4 of the MISRA C:2012 guidelines. For an example of a deviation record, see Appendix I of the MISRA C:2012 guidelines.

**Note** To turn off some required guidelines, instead of `mandatory-required` select `custom`. To clear specific guidelines, click Edit. In the **Comment** column, enter your rationale for disabling a guideline. For instance, you can enter the Deviation ID that refers to a deviation record for the guideline. The rationale appears in your generated report.

[2] MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

`single-unit-rules`

Check a subset of rules that apply only to single translation units. These rules are checked in the compilation phase of the analysis.

`system-decidable-rules`

Check rules in the `single-unit-rules` subset and some rules that apply to the collective set of program files. The additional rules are the less complex rules that apply at the integration level. These rules can be checked only at the integration level because the rules involve more than one translation unit. These rules are checked in the compilation and linking phases of the analysis.

`all`

Check for mandatory, required, and advisory guidelines.

`SQO-subset1`

Check for only a subset of guidelines. For more information, see “Software Quality Objective Subsets (C:2012)”.

`SQO-subset2`

Check for the subset `SQO-subset1`, plus some additional rules. For more information, see “Software Quality Objective Subsets (C:2012)”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

  For projects with mixed C and C++ code, the MISRA C:2012 checker analyzes only `.c` files.
- If you set `Source code language (-lang)` to `C-CPP`, you can activate a C coding rule checker **and** a C++ coding rule checker. When you have both C and C++ coding rule checkers active, to avoid duplicate results, Polyspace does not produce the C coding rules found in the linking phase (such as MISRA C:2012 Rule 8.3).

## Tips

- If you select the option `single-unit-rules` or `system-decidable-rules` and choose to detect coding rule violations only, the analysis can complete quicker than checking other rules. For more information, see “Coding Rule Subsets Checked Early in Analysis”.
- In code generated by using Embedded Coder®, there are known deviations from MISRA C:2012. See “Deviations Rationale for MISRA C:2012 Compliance” (Embedded Coder).

## Command-Line Information

Use the command `-misra3` in the command line to check for violations of MISRA C:2012 rules.
**Parameter:** `-misra3`
**Value:** `mandatory` | `mandatory-required` | `single-unit-rules` | `system-decidable-rules` | `all` | `SQO-subset1` | `SQO-subset2` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-misra3 mandatory-required`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-misra3 mandatory-required`

Alternatively, enable all or specific MISRA C:2012 rules through a checkers activation XML file. See `-checkers-activation-file`.

# Version History

### R2021b: Using text format for coding rules file not supported

*Errors starting in R2021b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. Using a text formal file for this purpose results in an error.

**Desktop interface:**

If you have a project that contains custom coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as *`filename`*`.xml`, where *`filename`* is the name of the first selected file alphabetically. For instance, if you select `foo.conf` and `bar.conf`, they are saved as `bar.conf.xml`.

**Command-line/ IDEs:**

In the command-line or in the IDE extensions, using text files as input to `-misra3` results in an error. To select a custom selection of MISRA C:2012 rules and directives, use an XML file.

Use the file `misra_c_2012_rules.xml` as a template to create the XML file where you define the custom selection. This template file is located in *`polyspaceroot`*`\help\toolbox\bugfinder\examples\coding_standards_XML`. Here, *`polyspaceroot`* is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace\R2023a`. To update your script, see this table

| Option | Use Instead |
|---|---|
| `-misra3 "custom_standard.conf"` | `-checkers-selection-file misra_c_2012_rules.xml -misra3 from-file` |

See:

- "Configure Coding Rules Checking"
- "Setting Checkers in Polyspace as You Code"

**Note** The XML format of the checker configuration file can change in future releases.

### Example of Configuration File in XML Format

To turn on MISRA C:2012 rule 8.1, use this entry in the XML file:

```
<standard name="MISRA C:2012">
  ...
  <section name="8 Declarations and definitions">
      ...
      <check id="8.1" state="on">
      </check>
      ...
  </section>
  ...
</standard>
```

For a full list of rule IDs and section names, see:

- "AUTOSAR C++14 Rules"
- "CERT C Rules and Recommendations"
- "CERT C++ Rules"
- "ISO/IEC TS 17961 Rules"
- "Custom Coding Rules"
- "JSF C++ Rules"
- "MISRA C:2004 Rules"
- "MISRA C:2012 Directives and Rules"
- "MISRA C++:2008 Rules"
- "Guidelines"

### R2019b: Use of text format for coding rules file will not be supported

*Warns starting in R2019b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. If you use a text file, Polyspace issues a warning and converts the text file to XML.

### Topics

“Specify Polyspace Analysis Options”
“Check for and Review Coding Standard Violations”
“MISRA C:2012 Directives and Rules”

# Use generated code requirements (-misra3-agc-mode)

Check for violations of MISRA C:2012 rules and directives that apply to generated code

## Description

Specify whether to use the MISRA C:2012 categories for automatically generated code. This option changes which rules are mandatory, required, or advisory.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See "Dependency" on page 2-157 for other options that you must also enable.

**Command line and options file**: Use the option `-misra3-agc-mode`. See "Command-Line Information" on page 2-157.

### Why Use This Option

Use this option to specify that you are checking for MISRA C:2012 rules in generated code. The option modifies the MISRA C:2012 subsets so that they are tailored for generated code.

## Settings

□ Off (default)

Use the normal categories (mandatory, required, advisory) for MISRA C:2012 coding guideline checking.

☑ On (default for analyses from Simulink)

Use the generated code categories (mandatory, required, advisory, readability) for MISRA C:2012 coding guideline checking.

For analyses started from the Simulink plug-in, this option is the default value.

### Category changed to `Advisory`

These rules are changed to advisory:

- 5.3
- 7.1
- 8.4, 8.5, 8.14
- 10.1, 10.2, 10.3, 10.4, 10.6, 10.7, 10.8
- 14.1, 14.4
- 15.2, 15.3
- 16.1, 16.2, 16.3, 16.4, 16.5, 16.6, 16.7

- 20.8

**Category changed to Readability**

These guidelines are changed to readability:

- Dir 4.5
- 2.3, 2.4, 2.5, 2.6, 2.7
- 5.9
- 7.2, 7.3
- 9.2, 9.3, 9.5
- 11.9
- 13.3
- 14.2
- 15.7
- 17.5, 17.7, 17.8
- 18.5
- 20.5

## Dependency

To use this option, activate at least one MISRA C:2012 rule. To activate MISRA C:2012 rules, use either of these:

- Use the option `Check MISRA C:2012 (-misra3)` to activate a preselected subset of the rules.
- Use the option `Set checkers by file (-checkers-selection-file)` alongside `Check MISRA C:2012 (-misra3)` to activate a custom selection that is specified in an XML file.

When using an XML file to specify a custom selection, select at least one MISRA C:2012 rule in the file.

## Command-Line Information

Use the command `-misra3-agc-mode` in the command line to check for violations of MISRA C:2012 rules and directives that apply to generated code.
**Parameter:** `-misra3-agc-mode`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-misra3 all -misra3-agc-mode`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-misra3 all -misra3-agc-mode`

Alternatively, activate the rules and directives in an activation XML file. See `-checkers-activation-file`.

# Effective boolean types (-boolean-types)

Specify data types that coding rule checker must treat as effectively Boolean

## Description

Specify data types that the coding rule checker must treat as effectively Boolean. You can specify a data type as effectively Boolean only if you have defined it through an `enum` or `typedef` statement in your source code.

Polyspace natively supports these boolean types, depending on your language:

- Type `_Bool` in C99 once you include `stdbool.h` in one of your source files.
- Type `bool` in C11 and for all versions of C++.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-160 for other options that you must also enable.

**Command line and options file**: Use the option `-boolean-types`. See “Command-Line Information” on page 2-160.

### Why Use This Option

Use this option to allow Polyspace to check the following coding rules:

- MISRA C: 2004 and MISRA AC AGC

| Rule Number | Rule Statement |
|---|---|
| 12.6 | Operands of logical operators, &&, `||`, and `!`, should be effectively Boolean. Expressions that are effectively Boolean should not be used as operands to other operators. |
| 13.2 | Tests of a value against zero should be made explicit, unless the operand is effectively Boolean. |
| 15.4 | A `switch` expression should not represent a value that is effectively Boolean. |

- MISRA C: 2012

| Rule Number | Rule Statement |
|---|---|
| 10.1 | Operands shall not be of an inappropriate essential type |
| 10.3 | The value of an expression shall not be assigned to an object with a narrower essential type or of a different essential type category |
| 10.5 | The value of an expression should not be cast to an inappropriate essential type |

| Rule Number | Rule Statement |
|---|---|
| 14.4 | The controlling expression of an if statement and the controlling expression of an iteration-statement shall have essentially Boolean type. |
| 16.7 | A switch-expression shall not have essentially Boolean type. |

For example, in the following code, Polyspace detects a violation of MISRA C: 2012 rule 14.4 because `boolean_T` is not recognized as effective boolean. If you rerun the analysis and specify option `-boolean-types boolean_T`, Polyspace considers that the code is compliant with rule 14.4.

```
typedef int boolean_T;

void func1(void);
void func2(void);

void func(boolean_T flag) {
    if(flag) // No misra2012 14.4 violation when you use -boolean-types
        func1();
    else
        func2();
}
```

## Settings

**No Default**

Click + to add a field. Enter a type name that you want Polyspace to treat as Boolean.

## Dependencies

This option is enabled only if you select one of these options:

- `Check MISRA C:2004 (-misra2)`
- `Check MISRA AC AGC (-misra-ac-agc)`.
- `Check MISRA C:2012 (-misra3)`

## Command-Line Information

**Parameter:** `-boolean-types`
**Value:** *type1*[,*type2*[,...]]
**No Default**
**Example (Bug Finder):** `polyspace-bug-finder -sources` *filename* `-misra2 required-rules -boolean-types boolean1_t,boolean2_t`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *filename* `-misra2 required-rules -boolean-types boolean1_t,boolean2_t`

## See Also

`Check MISRA C:2004 (-misra2)` | `Check MISRA AC AGC (-misra-ac-agc)` | `Check MISRA C:2012 (-misra3)`

### Topics

# Allowed pragmas (`-allowed-pragmas`)

Specify pragma directives that are documented

## Description

Specify pragma directives that must not be flagged by MISRA C:2004 rule 3.4 or MISRA C++ rule 16-6-1. These rules require that you document all pragma directives.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-162 for other options that you must also enable.

**Command line and options file**: Use the option `-allowed-pragmas`. See “Command-Line Information” on page 2-163.

### Why Use This Option

MISRA C:2004/MISRA AC AGC rule 3.4 and MISRA C++ rule 16-6-1 require that all pragma directives are documented within the documentation of the compiler. If you list a pragma as documented using this analysis option, Polyspace does not flag use of the pragma as a violation of these rules.

## Settings

**No Default**

Click + to add a field. Enter the pragma name that you want Polyspace to ignore during coding rule checking .

## Dependencies

This option is enabled only if you select one of these options:

- `Check MISRA C:2004 (-misra2)`
- `Check MISRA AC AGC (-misra-ac-agc)`.
- `Check MISRA C++:2008 (-misra-cpp)`

## Tips

Enter the name of the pragma only excluding any argument. For instance, if you use the pragma `pack`:

```
#pragma pack(n)
```

Enter only the name `pack` for this option.

## Command-Line Information

**Parameter:** `-allowed-pragmas`
**Value:** `pragma1[,pragma2[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -sources filename -misra-cpp required-rules -allowed-pragmas pragma_01,pragma_02`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources filename -misra-cpp required-rules -allowed-pragmas pragma_01,pragma_02`

"MISRA C++:2008 Rules"

# Check custom rules (`-custom-rules`)

Follow naming conventions for identifiers

## Description

Define naming conventions for identifiers and check your code against them.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node.

**Command line and options file**: Use the option `-custom-rules`. See “Command-Line Information” on page 2-166.

### Why Use This Option

Use this option to impose naming conventions on identifiers. Using a naming convention allows you to easily determine the nature of an identifier from its name. For instance, if you define a naming convention for structures, you can easily tell whether an identifier represents a structured variable or not.

After analysis, the **Results List** pane lists violations of the naming conventions. On the **Source** pane, for every violation, Polyspace assigns a ▼ symbol to the keyword or identifier relevant to the violation.

For the full list of types on which you can apply naming conventions, see “Custom Coding Rules”.

## Settings

☑ On

Polyspace matches identifiers in your code against text patterns you define. Define the text patterns in a custom coding rules file. To create a coding rules file,

- Use the custom rules wizard:

  1 Click Edit. A **Checkers selection** window opens.

  2 The **Custom** node in the left pane is highlighted. Expand the nodes in the right pane to select custom rule you want to check.

  3 For every custom rule you want to check:

     a Select **On** ☑.

     b In the **Convention** column, enter the error message you want to display if the rule is violated.

       For example, for rule 4.3, **All struct fields must follow the specified pattern**, you can enter `All struct fields must begin with s_`. This message appears on the **Result Details** pane if:

- You specify the **Pattern** as s_[A-Za-z0-9_]+.
- A structure field in your code does not begin with s_.

c In the **Pattern** column, enter the text pattern.

For example, for rule 4.3, **All struct fields must follow the specified pattern**, you can enter s_[A-Za-z0-9_]+. Polyspace reports violation of rule 4.3 if a structure field does not begin with s_.

You can use Perl regular expressions to define patterns. For instance, you can use the following expressions.

| Expression | Meaning |
|---|---|
| . | Matches any single character except newline |
| [a-z0-9] | Matches any single letter in the set a-z, or digit in the set 0-9 |
| [^a-e] | Matches any single letter not in the set a-e |
| \d | Matches any single digit |
| \w | Matches any single alphanumeric character or _ |
| x? | Matches 0 or 1 occurrence of x |
| x* | Matches 0 or more occurrences of x |
| x+ | Matches 1 or more occurrences of x |

For frequent patterns, you can use the following regular expressions:

- (?!__)[a-z0-9_]+(?!__), matches a text pattern that does not start and end with two underscores.

```
int __text; //Does not match
int _text_; //Matches
```

- [a-z0-9_]+_(u8|u16|u32|s8|s16|s32) , matches a text pattern that ends with a specific suffix.

```
int _text_; //Does not match
int _text_s16; //Matches
int _text_s33; // Does not match
```

- [a-z0-9_]+_(u8|u16|u32|s8|s16|s32)(_b3|_b8)? , matches a text pattern that ends with a specific suffix and an optional second suffix.

```
int _text_s16; //Matches
int _text_s16_b8; //Matches
```

If you do not want Polyspace to report a trivial case when you check for a specific pattern, add the pattern for that trivial case to your regular expression.

For example, for rule 8.5, **All floating constants must follow the specified pattern**, the specified pattern might be that all floating point constants must be suffixed with "f" or "F". To ignore the trivial case 0.0, use this regular expression for instance:

```
(.*(f|F))|(^0\.0$)
```

. Polyspace reports violations of this rule for the specified pattern except for 0.0.

```
float arr[] = { 0.0, // No violation reported
                10.05, // Violation reported
                4.00f }; // No violation reported
```

For a complete list of regular expressions, see Perl documentation.

To use or update an existing coding rules file, click Edit to open the **Checkers selection** window then do one of the following:

- Enter the full path to the file in the field provided
- Click **Browse** and navigate to the file location.

☐ Off (default)

Polyspace does not check your code against custom naming conventions.

## Command-Line Information

Use the command `-custom-rules` in the command line to check for violations of predefined naming conventions.
**Parameter:** `-custom-rules`
**Value:** `from-file`, specify the file using `Set checkers by file (-checkers-selection-file)`
**Default**: Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-custom-rules from-file -checkers-selection-file "C:\Standards\custom_config.xml"`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-custom-rules from-file -checkers-selection-file "C:\Standards\custom_config.xml"`

Alternatively, activate the rules in an activation XML file. See `-checkers-activation-file`.

# Version History

**R2021b: Use of text format for coding rules file not supported**
*Errors starting in R2021b*

Since R2019a, the file where you define custom coding rules uses the XML format. Using a text file for this purpose results in an error. You can save selections for custom coding rules and all the coding standards that Polyspace supports in the same file.

**Desktop user interface:**

If you have a project that contains custom coding rules and coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as *filename*.xml, where *filename* is the name of the first selected file alphabetically. For instance, if you select foo.conf and bar.conf, they are saved as bar.conf.xml.

**Command-line:**

In the command-line or in the IDE extensions, using text files as input to -custom-rules results in an error. To select a custom selection of custom rules, use an XML file.

Use the file custom_rules.xml as a template to create the XML file where you define a custom selection of coding standard checkers. This template file is in *polyspaceroot*\help\toolbox\bugfinder\examples\coding_standards_XML. Here, *polyspaceroot* is the root installation folder for the Polyspace products, for instance, C:\Program Files\Polyspace\R2023a. To update your script, replace reference to the old file format with the new XML file format .

### Example of Configuration File in XML Format

To turn on and define custom coding rule 8.1, use this entry:

```
<standard name="CUSTOM RULES">
  ...
  <section name="8 Constants">
      ...
      <check id="8.1" state="on">
       </check>
      ...
  </section>
  ...
</standard>
```

For a full list of rule IDs and section names, see:

- “AUTOSAR C++14 Rules”
- “CERT C Rules and Recommendations”
- “CERT C++ Rules”
- “ISO/IEC TS 17961 Rules”
- “Custom Coding Rules”
- “JSF C++ Rules”
- “MISRA C:2004 Rules”
- “MISRA C:2012 Directives and Rules”
- “MISRA C++:2008 Rules”
- “Guidelines”

### R2019b: Use of text format for coding rules file will not be supported

*Warns starting in R2019b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. If you use a text file, Polyspace issues a warning and converts the text file to XML.

# Check MISRA C++:2008 (`-misra-cpp`)

Check for violations of MISRA C++ rules

## Description

Specify whether to check for violation of MISRA C++:2008 rules [3]. Each value of the option corresponds to a subset of rules to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependency” on page 2-170 for other options that you must also enable.

**Command line and options file**: Use the option `-misra-cpp`. See “Command-Line Information” on page 2-170.

### Why Use This Option

Use this option to specify the subset of MISRA C++ rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding rule violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `required-rules`

`required-rules`

Check required coding rules.

`all-rules`

Check required and advisory coding rules.

`SQO-subset1`

Check only a subset of MISRA C++ rules. For more information, see “Software Quality Objective Subsets (C++)”.

`SQO-subset2`

Check a subset of rules including `SQO-subset1` and some additional rules. For more information, see “Software Quality Objective Subsets (C++)”

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

[3] MISRA is a registered trademark of MIRA Ltd., held on behalf of the MISRA Consortium.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

### Dependency

This option is available only if you set `Source code language (-lang)` to `CPP` or `C-CPP`.

For projects with mixed C and C++ code, the MISRA C++ checker analyzes only `.cpp` files.

### Command-Line Information

Use the command `-misra-cpp` in the command line to check for violations of MISRA C++ rules.
**Parameter:** `-misra-cpp`
**Value:** `required-rules` | `all-rules` | `SQO-subset1` | `SQO-subset2` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-misra-cpp all-rules`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-misra-cpp all-rules`

Alternatively, enable all or specific MISRA C++ rules through a checkers activation XML file. See `-checkers-activation-file`.

## Version History

**R2021b: Use of text format for coding rules file not supported**
*Errors starting in R2021b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. Use of text format for this purpose results in an error. You can save custom selections for all the coding standards that Polyspace supports in the same file.

**Desktop interface:**

If you have a project that contains custom coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as *`filename`*`.xml`, where *`filename`* is the name of the first selected file alphabetically. For instance, if you select `foo.conf` and `bar.conf`, they are saved as `bar.conf.xml`.

**Command-line:**

In the command-line or in the IDE extensions, using text files as input to `-misra-cpp` results in an error. To select a custom selection of MISRA C++:2008 rules, use an XML file.

Use the file `misra_cpp_2008_rules.xml` as a template to create the XML file where you define a custom selection of coding standard checkers. This template file is in `*polyspaceroot*\help\toolbox\bugfinder\examples\coding_standards_XML`. Here, `*polyspaceroot*` is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace\R2023a`. To update your script, see this table

| Option | Use Instead |
|---|---|
| `-misra-cpp "custom_standard.conf"` | `-checkers-selection-file misra_cpp_2008_rules.xml -misra-cpp from-file` |

.

**Note** The XML format of the checker configuration file can change in future releases.

### Example of Configuration File in XML Format

To turn on MISRA C: 2012 rule 8.1, use this entry:

```
<standard name="MISRA C:2012">
  ...
  <section name="8 Declarations and definitions">
      ...
      <check id="8.1" state="on">
      </check>
      ...
  </section>
  ...
</standard>
```

For a full list of rule IDs and section names, see:

- “AUTOSAR C++14 Rules”
- “CERT C Rules and Recommendations”
- “CERT C++ Rules”
- “ISO/IEC TS 17961 Rules”
- “Custom Coding Rules”
- “JSF C++ Rules”
- “MISRA C:2004 Rules”
- “MISRA C:2012 Directives and Rules”
- “MISRA C++:2008 Rules”
- “Guidelines”

### R2019b: Use of text format for coding rules file will not be supported

*Warns starting in R2019b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. You can save custom selections for all the coding standards that Polyspace supports in the same file. If you use a text file, Polyspace issues a warning and converts the text file to XML.

# Check JSF AV C++ rules (`-jsf-coding-rules`)

Check for violations of JSF C++ rules

## Description

Specify whether to check for violation of JSF AV C++ rules (JSF++:2005)[4]. Each value of the option corresponds to a subset of rules to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependency” on page 2-174 for other options that you must also enable.

**Command line and options file**: Use the option `-jsf-coding-rules`. See “Command-Line Information” on page 2-174.

### Why Use This Option

Use this option to specify the subset of JSF C++ rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding rule violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `shall-rules`

`shall-rules`

Check all **Shall** rules. **Shall** rules are mandatory requirements and require verification.

`shall-will-rules`

Check all **Shall** and **Will** rules. **Will** rules are intended to be mandatory requirements but do not require verification.

`all-rules`

Check all **Shall**, **Will**, and **Should** rules. **Should** rules are advisory rules.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

[4] JSF and Joint Strike Fighter® are registered trademarks of Lockheed Martin®.

If you set the option to from-file, enable Set checkers by file (-checkers-selection-file).

## Tips

- If your project uses a setting other than generic for Compiler (-compiler), some rules might not be completely checked. For example, AV Rule 8: “All code shall conform to ISO/IEC 14882:2002(E) standard C++.”

## Dependency

This option is available only if you set Source code language (-lang) to CPP or C-CPP.

For projects with mixed C and C++ code, the JSF C++ checker analyzes only .cpp files.

## Command-Line Information

Use the command -jsf-coding-rules in the command line to check for violations of JSF C++ rules.

**Parameter:** -jsf-coding-rules

**Value:** shall-rules | shall-will-rules | all-rules | from-file

**Example (Bug Finder):** polyspace-bug-finder -sources *file_name* -jsf-coding-rules all-rules

**Example (Bug Finder Server):** polyspace-bug-finder-server -sources *file_name* -jsf-coding-rules all-rules

Alternatively, enable all or specific JSF C++ rules through a checkers activation XML file. See -checkers-activation-file.

# Version History

**R2021b: Using text format for coding rules file will not be supported**

*Errors starting in R2021b*

Since R2019a, the file where you define a custom selection of coding standard checkers uses the XML format. Use of a text file for this purpose results in an error. You can save custom selections for all the coding standards that Polyspace supports in the same file.

**Desktop interface:**

If you have a project that contains custom coding standard selection files in text format, Polyspace automatically updates and consolidates those files into a single XML file. If your project has conflicting configurations that refer to the same custom selection file, the software saves the consolidated coding standard selection for each configuration to separate XML files.

To update your text files to the XML format manually, in the **Coding Standards & Code Metrics** node of the **Configuration** pane, click 📁. In the **Checkers selection** window, select the files then click **Save Changes**. Polyspace consolidates the files into a single XML files, and saves this file as *filename*.xml, where *filename* is the name of the first selected file alphabetically. For instance, if you select foo.conf and bar.conf, they are saved as bar.conf.xml.

**Command-line/ IDEs:**

In the command-line or in the IDE extensions, using text files as input to `-jsf-coding-rules` results in an error. To select a custom selection of JSF C++ rules, use an XML file.

Use the file `jsf_av_cpp.xml` as a template to create the XML file where you define a custom selection of coding standard checkers. This template file is in *`polyspaceroot`*`\help\toolbox\bugfinder\examples\coding_standards_XML`. Here, *`polyspaceserverroot`* is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace\R2023a`. To update your script, see this table

| Option | Use Instead |
|---|---|
| `-jsf-coding-rules "custom_standard.conf"` | `-checkers-selection-file "custom_standard.conf.xml" -jsf-coding-rules from-file` |

See:

- “Configure Coding Rules Checking”
- “Setting Checkers in Polyspace as You Code”

### Example of Configuration File in XML Format

To turn on MISRA C: 2012 rule 8.1, use this entry:

```
<standard name="MISRA C:2012">
  ...
  <section name="8 Declarations and definitions">
      ...
      <check id="8.1" state="on">
      </check>
      ...
  </section>
  ...
</standard>
```

# Check AUTOSAR C++ 14 (`-autosar-cpp14`)

Check for violations of AUTOSAR C++ 14 rules

## Description

*This option affects Bug Finder only.*

Specify whether to check for violations of AUTOSAR C++ 14. Each value of the option corresponds to a subset of guidelines to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-178 for other options that you must also enable.

**Command line and options file**: Use the option `-autosar-cpp14`. See “Command-Line Information” on page 2-178.

### Why Use This Option

Use this option to specify the subset of AUTOSAR C++ 14 rules to check for[5].

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding standard violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `all`

`all`

Check for violations of all AUTOSAR C++ 14 rules supported by Polyspace.

See “AUTOSAR C++14 Rules”.

`required`

Check for violations of *required* rules.

These rules are mandatory requirements placed on your code. This categorization of rules comes from the AUTOSAR C++14 guidelines.

`automated`

Check for violations of *automated* rules.

You can automatically enforce these rules by means of static analysis. This categorization of rules comes from the AUTOSAR C++14 guidelines.

[5] The Polyspace checkers for AUTOSAR C++14 rules supports AUTOSAR C++14 release 18-10 (October 2018). Out of 397 rules from the standard, 308 rules are supported.

Note that all rules in the required category might not be present in the automated category. For rules that AUTOSAR C++14 considers as non-automated, Bug Finder shows only a subset of actual rule violations.

from-file

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to from-file, enable Set checkers by file (-checkers-selection-file).

## Dependencies

- This option is available only if you set Source code language (-lang) to CPP or C-CPP.

## Command-Line Information

Use the command -autosar-cpp14 in the command line to check for violations of AUTOSAR C++ 14 rules.
**Parameter:** -autosar-cpp14
**Value:** all | required | automated | from-file
**Example (Bug Finder):** polyspace-bug-finder -lang cpp -sources *file_name* -autosar-cpp14 required
**Example (Bug Finder Server):** polyspace-bug-finder-server -lang cpp -sources *file_name* -autosar-cpp14 required

Alternatively, enable all or specific AUTOSAR C++ 14 rules through a checkers activation XML file. See -checkers-activation-file.

# Check SEI CERT-C (-cert-c)

Check for violations of CERT C rules and recommendations

## Description

*This option affects Bug Finder only.*

Specify whether to check for violations of CERT C rules and recommendations. Each value of the option corresponds to a subset of the coding standard to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See "Dependencies" on page 2-186 for other options that you must also enable.

**Command line and options file**: Use the option `-cert-c`. See "Command-Line Information" on page 2-186.

### Why Use This Option

Use this option to specify the subset of CERT C rules and recommendations to check in your code.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding standard violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `all`

`all-rules`

Check for violations of CERT C rules only.

See the CERT C website for an explanation of the difference between rules and recommendations.

`all`

Check for violations of all CERT C rules and recommendations supported by Polyspace.

See “CERT C Rules and Recommendations”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

  For projects with mixed C and C++ code, the SEI CERT-C checker analyzes only `.c` files.

## Command-Line Information

Use the command `-cert-c` in the command line to check for violations of CERT C rules and recommendations.
**Parameter:** `-cert-c`
**Value:** `all-rules` | `publish-2016` | `all` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-cert-c all-rules`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-cert-c all-rules`

Alternatively, enable all or specific CERT C rules and recommendations through a checkers activation XML file. See `-checkers-activation-file`.

# Check CWE (-cwe)

Check for weaknesses in your code that are enumerated in CWE

## Description

*This option affects Bug Finder only.*

Specify whether to check for common weaknesses enumerated in CWE. Each value of the option corresponds to a subset of the coding standard to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-186 for other options that you must also enable.

**Command line and options file**: Use the option `-cwe`. See “Command-Line Information” on page 2-186.

### Why Use This Option

Use this option to specify the subset of common weaknesses to check in your code.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding standard violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `all`

`cwe-658-659`

Check for violations of a subset of rules for weaknesses that are specific to C (CWE-658) and C++ (CWE-659) software.

See section *CWE Rules Specific to C and C++ (CWE 658 and CWE 659)* of the “Common Weakness Enumeration (CWE)” category.

`all`

Check for violations of all CWE rules supported by Polyspace.

See section *CWE Rules* of the “Common Weakness Enumeration (CWE)” category.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Command-Line Information

Use the option `-cwe` in the command line to check for common weaknesses enumerated by CWE.
**Parameter:** `-cwe`
**Value:** `all` | `cwe-658-659` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-cwe all`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-cwe all`

Alternatively, enable all or specific CWE rules by using a checkers activation XML file. See `-checkers-activation-file`.

## Tips

Some CWE rule violations that you checked for with a Polyspace product version R2022b or earlier might not be available in version R2023a or later when you use the option `-cwe`. You can use a mapping between CWE rules and Polyspace defect checkers to extend the Polyspace CWE coverage and check for these additional CWE rule violations. See “Extend CWE Coding Standard Coverage Using Polyspace Defect Checkers”.

# Version History

**Introduced in R2023a**

# Check SEI CERT-C++ (`-cert-cpp`)

Check for violations of CERT C++ rules

## Description

*This option affects Bug Finder only.*

Specify whether to check for violations of CERT C++ rules.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-190 for other options that you must also enable.

**Command line and options file**: Use the option `-cert-cpp`. See “Command-Line Information” on page 2-190.

### Why Use This Option

Use this option to specify the subset of CERT C++ rules to check in your code.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding standard violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `all`

`all`

Check for violations of all CERT C++ rules supported by Polyspace.

See “CERT C++ Rules”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set to CPP or C-CPP.

  For projects with mixed C and C++ code, the SEI CERT-C++ checker analyzes only .cpp files.

## Command-Line Information

Use the command -cert-cpp in the command line to check for violations of CERT C++ rules.
**Parameter:** -cert-cpp
**Value:** all | from-file |
**Example (Bug Finder):** polyspace-bug-finder -lang cpp -sources *file_name* -cert-cpp all
**Example (Bug Finder Server):** polyspace-bug-finder-server -lang cpp -sources *file_name* -cert-cpp all

Alternatively, enable all or specific CERT C++ rules through a checkers activation XML file. See -checkers-activation-file.

# Check ISO/IEC TS 17961 (-iso-17961)

Check for violations of ISO/IEC TS 17961 rules

## Description

*This option affects Bug Finder only.*

Specify whether to check for violations of ISO/IEC TS 17961 rules.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node. See “Dependencies” on page 2-192 for other options that you must also enable.

**Command line and options file**: Use the option `-iso-17961`. See “Command-Line Information” on page 2-192.

### Why Use This Option

Use this option to specify the subset of ISO/IEC TS 17961 rules to check for.

After analysis, the **Results List** pane lists the coding standard violations. On the **Source** pane, for every coding standard violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

**Default:** `all`

`decidable`

Check for violations of *decidable* rules. Violations of these rules depend only on compile-time static properties, for instance object type or scope of identifiers.

`all`

Check for violations of all ISO/IEC TS 17961 rules Polyspace supports.

See “ISO/IEC TS 17961 Rules”.

`from-file`

Specify an XML file where you configure a custom selection of checkers for this coding standard.

To create a configuration file, click Edit, then select the rules and recommendations you want to check for this coding standard from the right pane of the **Checkers selection** window. Save the file.

To use or update an existing configuration file, in the **Checkers selection** window, enter the full path to the file in the field provided or click **Browse**.

If you set the option to `from-file`, enable `Set checkers by file (-checkers-selection-file)`.

## Dependencies

- This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

## Command-Line Information

Use the command `-iso-17961` in the command line to check for violations of ISO/IEC TS 17961 rules.
**Parameter:** `-iso-17961`
**Value:**`decidable` | `all` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -lang c -sources` *`file_name`* `-iso-17961 decidable`
**Example:** `polyspace-bug-finder-server -lang c -sources` *`file_name`* `-iso-17961 decidable`
**Example:** `polyspace-code-prover-server -lang c -sources` *`file_name`* `-iso-17961 decidable`

Alternatively, enable all or specific ISO/IEC TS 17961 rules through a checkers activation XML file. See `-checkers-activation-file`.

# Check guidelines (`-guidelines`)

Check for violations of Guidelines

## Description

*This option affects Bug Finder only.*

Specify whether to check for violations of Guidelines. Each option value corresponds to a subset of guidelines to check.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node.

**Command line and options file**: Use the option `-guidelines`. See “Command-Line Information” on page 2-194.

### Why Use This Option

Guidelines are customizable checkers that check for violation of coding best practices. You can use this option to specify the subset of Guidelines rules that matches your requirements.

After analysis, the **Results List** pane lists the violations. On the **Source** pane, for every violation, Polyspace assigns a ▽ symbol to the keyword or identifier relevant to the violation.

## Settings

`all`

Check for violations of all Guidelines rules.

See “Guidelines”.

`his`

Check for violations of software complexity metrics standards specified in the Hersteller Initiative Software (HIS) standard. See “HIS Code Complexity Metrics”.

The HIS standard recommends specific thresholds for a subset of the software complexity checkers. When you use the input `his`, Polyspace activates this subset of software complexity checkers and uses their HIS recommended threshold. Polyspace raises a violation if a software complexity metric exceeds the HIS recommended threshold.

`from-file`

Specify an XML file where you configure a custom selection of Guidelines checkers that have specific thresholds. When running an analysis on Polyspace Desktop, create or edit an XML file that contains your checker configuration by using the Desktop User Interface. When running an analysis on Polyspace Server, edit an existing checker selection file. When running an analysis on Polyspace as You Code, create or edit an XML file that contains your checker configuration by using the Checkers Selection User interface.

When using the value `from-file`, use the option `Set checkers by file (-checkers-selection-file)` to specify the checker selection XML file.

## Tips

- When using an options file, you can activate the guideline checkers and specify a checkers selection file to modify their thresholds. For instance, in an options file, input:

  ```
  -guidelines from-file
  -checkers-selection-file selection_xml
  ```

  You can also use the preceding options together in the command line.
- Alternatively, you can specify a checkers activation file by using the command `-checkers-activation-file`. You do not need to specify the specific options for defects and coding standards. For instance, in the command line or in an options file, input:

  ```
  -checkers-activation-file activation_xml
  ```

  where the file `activation_xml` is a checkers activation file that is created by using the **Checkers Selection** User Interface. Specifying the option `-guidelines` is not needed if the Guidelines checkers are activated in the file `activation_xml`.

## Command-Line Information

Use the command `-guidelines` in the command line to check for violations of code complexity guidelines.
**Parameter:** `-guidelines`
**Value:** `all` | `his` | `from-file`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-guidelines his`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-guidelines from-file -checkers-selection-file` *`path_to_xml`*

Alternatively, enable all or specific code complexity guidelines through a checkers activation XML file. See `-checkers-activation-file`.

# Version History

# Calculate code metrics (-code-metrics)

Compute and display code complexity metrics

## Description

*This option applies to Bug Finder only. See Version History* on page 2-196.

Specify that Polyspace must compute and display code complexity metrics for your source code. The metrics include file metrics such as number of lines and function metrics such as cyclomatic complexity and estimated size of local variables.

For more information, see “Compute Code Complexity Metrics Using Polyspace”.

To maintain an acceptable level of software complexity during the development cycle, use the software complexity checkers. See “Reduce Software Complexity by Using Polyspace Checkers”.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Coding Standards & Code Metrics** node.

**Command line and options file**: Use the option `-code-metrics`. See “Command-Line Information” on page 2-196.

### Why Use This Option

By default, Polyspace does not calculate code complexity metrics. If you want these metrics in your analysis results, before running analysis, set this option.

High values of code complexity metrics can lead to obscure code and increase chances of coding errors. Additionally, if you run a Code Prover verification on your source code, you might benefit from checking your code complexity metrics first. If a function is too complex, attempts to verify the function can lead to a lot of unproven code. For information on how to cap your code complexity metrics, see “Compute Code Complexity Metrics Using Polyspace”.

## Settings

☑ On

Polyspace computes and displays code complexity metrics on the **Results List** pane.

□ Off (default)

Polyspace does not compute complexity metrics.

## Tips

If you want to compute only the code complexity metrics for your code, disable checking of defects. See `Find defects (-checkers)`.

## Command-Line Information

**Parameter:** `-code-metrics`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-code-metrics`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-code-metrics`

# Version History

**R2022a: Higher and lower estimates of local variable size is not computed**
*Warns starting in R2022a*

If you compute code metrics by using Bug Finder, Polyspace issues a warning that these code metrics are not computed:

- `Higher Estimate of Size of Local Variables`
- `Lower Estimate of Size of Local Variables`

To compute these code metrics, use the option `Calculate stack usage (-stack-usage)`.

# Find defects (`-checkers -disable-checkers`)

Enable or disable defect checkers

## Description

*This option affects a Bug Finder analysis only.*

Enable checkers for bugs/coding defects.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Bug Finder Analysis** node.

**Command line and options file**: Use the option `-checkers`. See “Command-Line Information” on page 2-198.

### Why Use This Option

The default set of checkers is designed to find the most meaningful bugs in most software development situations. If you have specific needs, enable or disable individual defect checkers. For instance, if you want to follow a specific security standard, choose a different subset of checkers.

## Settings

**Default:** `default`

`default`

A subset of defects defined by the software.

See “Polyspace Bug Finder Defects Checkers Enabled by Default”.

`all`

All defects.

For a list of all defects checkers, see “Defects”.

Note that the checkers `SQL injection` and `LDAP injection` are disabled even if you specify `all` for this option. You have to explicitly enable these checkers.

`custom`

Choose the defects you want to find by selecting categories of checkers or specific defects.

## Tips

You can use a spreadsheet to keep track of the defect checkers that you enable and add notes explaining why you do not enable the other checkers. A spreadsheet of checkers is provided in *`polyspaceroot`*`\polyspace\resources`. Here, *`polyspaceroot`* is the Polyspace installation folder, such as `C:\Program Files\Polyspace\R2023a`.

## Command-Line Information

Use the command `-checkers` in the command line to enable or disable defect checkers.

Regardless of order, the shell script processes the `-checkers` option, and then `-disable-checkers` option.

For the command-line parameters values, see "Short Names of Bug Finder Defect Groups and Defect Checkers".
**Parameter:** `-checkers`
**Value:** `default | all | none|"Short Names of Bug Finder Defect Groups and Defect Checkers"`
**Default:** `default`
**Parameter:** `-disable-checkers`
**Value:** `"Short Names of Bug Finder Defect Groups and Defect Checkers"`
**Example 1 (Bug Finder):** `polyspace-bug-finder -sources` *`filename`* `-checkers numerical,data_flow -disable-checkers FLOAT_ZERO_DIV`
**Example 2 (Bug Finder):** `polyspace-bug-finder -sources` *`filename`* `-checkers default -disable-checkers concurrency,dead_code`
**Example 1 (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`filename`* `-checkers numerical,data_flow -disable-checkers FLOAT_ZERO_DIV`
**Example 2 (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`filename`* `-checkers default -disable-checkers concurrency,dead_code`

Alternatively, activate the defect checkers in an activation XML file. See `-checkers-activation-file`.

# Version History

### R2023a: The value `CWE` will be removed in a future release

*Warns starting in R2023a*

The value `CWE` for the option `Find defects (-checkers -disable-checkers)` will be removed in a future release. Polyspace emits a warning if you use the option `-checkers CWE` at the command line and continues the analysis using option `-cwe all`. To check your code for CWE violations, use the option `Check CWE (-cwe)` instead.

### R2023a: The value `data_race_all` is removed

*Errors starting in R2023a*

The value `data_race_all` for the option `Find defects (-checkers -disable-checkers)` is removed. Using this option results in an error. To detect data races in atomic operations, use the analysis option `-detect-atomic-data-race`. See:

- `-detect-atomic-data-race`
- "Extend Data Race Checkers to Atomic Operations"

If you use `-checkers all` to run a Bug Finder analysis, you might see a reduced number of defects because this command no longer checks for data races in atomic operations. To mimic the result of `-checkers all` in previous releases, specify the option `-detect-atomic-data-race`.

To use `-detect-atomic-data-race` from the Polyspace user interface, in the **Advanced Settings** node, specify the option in the **Other** field.

# Run stricter checks considering all values of system inputs (-checks-using-system-input-values)

Enable stricter checks and provide examples of values that lead to detected defect

## Description

*This option affects a Bug Finder analysis only. This option is not available for code generated from MATLAB code or Simulink models.*

Enable a stricter analysis mode for a subset of numerical, static memory and data flow related defect and coding standard checkers. If you enable this option:

- The analysis considers all possible values of system inputs when checking for issues.
- When an issue is detected, the analysis provides one example input value that leads to the issue.

For each function `foo` that you specify with `Consider inputs to these functions (-system-inputs-from)`, the following are considered as system inputs:

- Each argument of `foo`.
- Each read of a global variable by `foo` or one of its callees.

  For the `main()` function, the analysis assumes that the global variables are initialized with value 0.
- Each read of a volatile variable by `foo` or one of its callees.
- Each return of a stubbed function. a Bug Finder analysis stubs a function if you do not provide the body of the function in your source code.
- Each read from an absolute address, such as:

  ```
  int value = *((int*)0x1234);
  ```

For information on checkers affected by this option, see “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

You can view examples of values that lead to the detected defects in the **Events** column of the **Results Details** pane on the desktop interface or the Polyspace Access web interface.

### Set Option

**User interface** (desktop products only): In the **Configuration** pane, the option is on the **Bug Finder Analysis** node. See “Dependencies” on page 2-201 for other options that you must also enable.

**Command line and options file**: Use the option `-checks-using-system-input-values`. See “Command-Line Information” on page 2-202.

### Why Use This Option

The default Bug Finder analysis does not flag defects that are caused by specific values of unknown inputs. Since the inputs might be bounded or initialized in a source file that you are not analyzing, or the specific value causing a defect might not occur in practice, the default analysis behavior helps to minimize false positives.

Enable this option to run a stricter analysis on a function whose system inputs might cause sporadic run-time errors during execution. Using this option might result in a longer analysis time.

## Settings

☑ On

Polyspace considers all possible values of system inputs for a subset of numerical and static memory defect checkers and provides examples of values that lead to detected defects.

○ Off (default)

Polyspace considers possible values of a system input only if the input is bounded by constraints in your code such as `assert` or `if`. The analysis provides no examples of values that lead to detected defects.

## Dependencies

- In the desktop interface, this option is enabled only if you enable `Find defects (-checkers)`.
- This option is ignored if you enable `Use fast analysis mode for Bug Finder (-fast-analysis)`.

## Tips

- If you set external constraints on global variables, the analysis shows examples of global variable values causing defects only within these constraints. See `Constraint setup (-data-range-specifications)`.
- If the input is a pointer `p`, the analysis assumes that the pointer is not null and can be safely dereferenced. The example value of the input causing a defect is the value of `*p`. This value is represented as an array in the **Results Details** pane. For instance, in this code snippet:

  ```
  void func(int* x){
      int tmp= *(x+3);

      if(1/(tmp-4))
          return;
  }
  ```

  The example value of the input causing a defect is {0,0,0,4}, where the array represents `*x`, `*(x+1)`, `*(x+2)`, and `*(x+3)`. The value `*(x+3)=4` causes a division by zero.
- The analysis treats these standard library functions that read values from external sources as stubbed functions.
  - `getchar`
  - `getc`
  - `fgetc`
  - `scanf`
- The stricter analysis considers all possible values of system inputs but it is not an exhaustive analysis. If Bug Finder cannot determine whether a particular input causes a defect, no defect is

shown. For more on exhaustive analysis, see “Differences Between Polyspace Bug Finder and Polyspace Code Prover”.

## Command-Line Information

**Parameter:** `-checks-using-system-input-values`
**Default**: Off
**Example (Bug Finder):** `polyspace-bug-finder -sources file_name -checkers numerical,static_memory -checks-using-system-input-values`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources file_name -checkers numerical,static_memory -checks-using-system-input-values`

# Version History

**Introduced in R2020a**

## See Also

“Extend Bug Finder Checkers to Find Defects from Specific System Input Values”

# Consider inputs to these functions (-system-inputs-from)

Specify functions for which the analysis considers all possible input values

## Description

*This option affects a Bug Finder analysis only.*

Specify the functions in your code for which Polyspace considers all possible input values. For each function that you specify with this option, the analysis considers all possible values of these inputs:

- Each argument of the function.
- Each read of a global variable by the function or one of its callees.

  For the `main()` function, the analysis assumes that the global variables are initialized with value 0.
- Each read of a volatile variable by the function or one of its callees.
- Each return of a stubbed function. a Bug Finder analysis stubs a function if you do not provide the body of the function in your source code.
- Each read from an absolute address, such as:

  ```
  int value = *((int*)0x1234);
  ```

### Set Option

**User interface** (desktop products only): In the **Configuration** pane, the option is on the **Bug Finder Analysis** node. See “Dependencies” on page 2-204 for other options that you must also enable.

**Command line and options file**: Use the option `-system-inputs-from`. See “Command-Line Information” on page 2-204.

### Why Use This Option

By default, Polyspace considers all possible input values for the `main()` function and tasks, if any, or uncalled functions with at least one callee if your code has no `main()`. Depending on the issue that you are investigating by running the stricter checks, specify a different subset of functions to analyze.

## Settings

**Default:** `auto`

`auto`

Consider all possible values for inputs to `main()` function and tasks, if any. You specify tasks with these options.

- `Cyclic tasks (-cyclic-tasks)`
- `Tasks (-entry-points)`

- `Interrupts (-interrupts)`

When the analyzed code has no `main()`, the analysis considers all possible values for inputs to uncalled functions with at least one callee.

`uncalled`

Consider all possible values for inputs to all uncalled functions.

`all`

Consider all possible values for inputs to all functions.

`custom`

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

### Dependencies

This option is enabled only if you enable `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

### Tips

- The analysis treats these standard library functions that read values from external sources as stubbed functions.
  - `getchar`
  - `getc`
  - `fgetc`
  - `scanf`

### Command-Line Information

**Parameter:** `-system-inputs-from`
**Value:** `auto | uncalled | all | custom`
**Default**: `auto`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-checks-using-system-input-values -system-inputs-from custom=`*`func1`*`,`*`func2`*
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-checks-using-system-input-values -system-inputs-from custom=`*`func1`*`,`*`func2`*

## Version History

**Introduced in R2020a**

# Class (`-class-analyzer`)

Specify classes that you want to verify

## Description

*This option affects a Code Prover analysis only.*

Specify classes that Polyspace uses to generate a `main`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-206 for other options that you must also enable.

**Command line and options file**: Use the option `-class-analyzer`. See “Command-Line Information” on page 2-207.

### Why Use This Option

If you are verifying a module or library, Code Prover generates a `main` function if one does not exist. If a `main` exists, the analysis uses the existing `main`.

Use this option and the option `Functions to call within the specified classes (-class-analyzer-calls)` to specify the class methods that the generated `main` must call. Unless a class method is called directly or indirectly from `main`, the software does not analyze the method.

## Settings

**Default**: `all`

`all`

To generate a `main` function, Polyspace uses all classes that have at least one method defined outside a header file. The generated `main` calls methods that you specify using the option `Functions to call within the specified classes (-class-analyzer-calls)`.

`none`

The generated `main` cannot call any class method.

`custom`

To generate a `main` function, Polyspace uses classes that you specify. The generated `main` calls methods from classes that you specify using the option `Functions to call within the specified classes (-class-analyzer-calls)`.

## Dependencies

You can use this option only if all of the following are true:

- Your code does not contain a `main` function.

- `Source code language (-lang)` is set to `CPP` or `C-CPP`.
- `Verify module or library (-main-generator)` is selected.

## Tips

- If you select `none` for this option, Polyspace will not verify class methods that you do not call explicitly in your code.
- Polyspace does not verify templates that are not instantiated. To verify a class template, explicitly instantiate a class using the template. See "Template Classes" (Polyspace Code Prover).

## Command-Line Information

**Parameter:** `-class-analyzer`
**Value:** `all` | `none` | `custom=`*`class1`*`[,`*`class2`*`,...]`
**Default:** `all`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2`

## See Also

"Verify C++ Classes" (Polyspace Code Prover)

# Functions to call within the specified classes (-class-analyzer-calls)

Specify class methods that you want to verify

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify class methods that Polyspace uses to generate a `main`. The generated `main` can call static, public and protected methods in classes that you specify using the **Class** option.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-209 for other options that you must also enable.

**Command line and options file**: Use the option `-class-analyzer-calls`. See “Command-Line Information” on page 2-209.

### Why Use This Option

If you are verifying a module or library, Code Prover generates a `main` function if one does not exist. If a `main` exists, the analysis uses the existing `main`.

Use this option and the option `Class (-class-analyzer)` to specify the class methods that the generated `main` must call. Unless a class method is called directly or indirectly from `main`, the software does not analyze the method.

## Settings

**Default**: `unused`

`all`

The generated `main` calls all public and protected methods. It does not call methods inherited from a parent class.

`all-public`

The generated `main` calls all public methods. It does not call methods inherited from a parent class.

`inherited-all`

The generated `main` calls all public and protected methods including those inherited from a parent class.

`inherited-all-public`

The generated `main` calls all public methods including those inherited from a parent class.

`unused`

The generated `main` calls public and protected methods that are not called in the code.

`unused-public`

The generated `main` calls public methods that are not called in the code. It does not call methods inherited from a parent class.

`inherited-unused`

The generated `main` calls public and protected methods that are not called in the code including those inherited from a parent class.

`inherited-unused-public`

The generated `main` calls public methods that are not called in the code including those inherited from a parent class.

`custom`

The generated `main` calls the methods that you specify.

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

If you use the scope resolution operator to specify the function from a particular namespace, enter the fully qualified name, for instance, `myClass::myMethod(int)`. If the function does not have a parameter, use an empty parenthesis, for instance, `myClass::myMethod()`.

## Dependencies

You can use this option only if:

- `Source code language (-lang)` is set to `CPP` or `C-CPP`.
- `Verify module or library (-main-generator)` is selected.

## Command-Line Information

**Parameter:** `-class-analyzer-calls`
**Value:** `all | all-public | inherited-all | inherited-all-public | unused | unused-public | inherited-unused | inherited-unused-public | custom=`*`method1`*`[,`*`method2`*`,...]`
**Default:** `unused`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public`

## See Also

`Verify module or library (-main-generator)` | `Class (-class-analyzer)`

### Topics

"Specify Polyspace Analysis Options"

"Verify C++ Classes" (Polyspace Code Prover)

# Analyze class contents only (`-class-only`)

Do not analyze code other than class methods

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify that Polyspace must verify only methods of classes that you specify using the option `Class (-class-analyzer)`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-211 for other options that you must also enable.

**Command line and options file**: Use the option `-class-only`. See “Command-Line Information” on page 2-212.

### Why Use This Option

Use this option to restrict the analysis to certain class methods only.

You specify these methods through the options:

- `Class (-class-analyzer)`
- `Functions to call within the specified classes (-class-analyzer-calls)`

When you analyze a module or library, Code Prover generates a `main` function if one does not exist. The `main` function calls class methods using these two options and functions that are not class methods using other options. Code Prover analyzes these methods and functions for robustness to all inputs. If you use this option, Code Prover analyzes the methods only.

## Settings

☑ On

Polyspace verifies the class methods only. It stubs functions out of class scope even if the functions are defined in your code.

□ Off (default)

Polyspace verifies functions out of class scope in addition to class methods.

## Dependencies

You can use this option only if all of the following are true:

- Your code does not contain a `main` function.
- `Source code language (-lang)` is set to `CPP` or `C-CPP`.
- `Verify module or library (-main-generator)` is selected.

If you select this option, you must specify the classes using the `Class (-class-analyzer)` option.

## Tips

Use this option:

- For robustness verification of class methods. Unless you use this option, Polyspace verifies methods that you call in your code only for your input combinations.
- In case of scaling.

## Command-Line Information

**Parameter:** `-class-only`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public -class-only`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public -class-only`

## See Also

`Verify module or library (-main-generator)` | `Class (-class-analyzer)` | `Functions to call within the specified classes (-class-analyzer-calls)`

### Topics

“Specify Polyspace Analysis Options”
“Verify C++ Classes” (Polyspace Code Prover)

# Initialization functions (-functions-called-before-main)

Specify functions that you want the generated main to call ahead of other functions

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify functions that you want the generated main to call ahead of other functions.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See "Dependencies" on page 2-214 for other options that you must also enable.

**Command line and options file**: Use the option -functions-called-before-main. See "Command-Line Information" on page 2-214.

### Why Use This Option

If you are verifying a module or library, Code Prover generates a main function if one does not exist. If a main exists, the analysis uses the existing main.

Use this option along with the option Functions to call (-main-generator-calls) to specify which functions the generated main must call. Unless a function is called directly or indirectly from main, the software does not analyze the function.

## Settings

**No Default**

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

If the function or method is not overloaded, specify the function name. Otherwise, specify the function prototype with arguments. For instance, in the following code, you must specify the prototypes func(int) and func(double).

```
int func(int x) {
 return(x * 2);
}
double func(double x) {
 return(x * 2);
}
```

For C++, if the function is:

- A class method: The generated `main` calls the class constructor before calling this function.
- Not a class method: The generated `main` calls this function before calling class methods.

If you use the scope resolution operator to specify the function from a particular namespace, enter the fully qualified name, for instance, `myClass::init(int)`. If the function does not have a parameter, use an empty parenthesis, for instance, `myClass::init()`.

## Dependencies

This option is enabled only if you select **Verify module or library** under **Code Prover Verification** and your code does not contain a `main` function.

## Tips

Although these functions are called ahead of other functions, they can be called in arbitrary order. If you want to call your initialization functions in a specific order, manually write a `main` function to call them.

## Command-Line Information

**Parameter:** `-functions-called-before-main`
**Value:** `*function1*[,*function2*[,...]]`
**No Default**
**Example 1 (Code Prover):** `polyspace-code-prover -sources *file_name* -main-generator -functions-called-before-main myfunc`
**Example 2 (Code Prover):** `polyspace-code-prover -sources *file_name* -main-generator -functions-called-before-main myClass::init(int)`
**Example 1 (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -main-generator -functions-called-before-main myfunc`
**Example 2 (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -main-generator -functions-called-before-main myClass::init(int)`

## See Also

# Verify initialization section of code only (-init-only-mode)

Check initialization code alone for run-time errors and other issues

## Description

*This option affects a Code Prover analysis only.*

Specify that Polyspace must check only the section of code marked as initialization code for run-time errors and other issues.

To indicate the end of initialization code, you enter the line

```
#pragma polyspace_end_of_init
```

in the `main` function (only once). The initialization code starts from the beginning of `main` and continues up to this pragma.

Since compilers ignore unrecognized pragmas, the presence of this pragma does not affect program execution.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node.

**Command line and options file**: Use the option `-init-only-mode`. See “Command-Line Information” on page 2-217.

### Why Use This Option

Often, issues in the initialization code can invalidate the analysis of the remaining code. You can use this option to check the initialization code alone and fix the issues, and then disable this option to verify the remaining program.

For instance, in this example:

```
#include <limits.h>

int aVar;
const int aConst = INT_MAX;
int anotherVar;

int main() {
      aVar = aConst + 1;
#pragma polyspace_end_of_init
      anotherVar = aVar - 1;
      return 0;
}
```

the overflow in the line `aVar = aConst+1` must be fixed first before the value of `aVar` is used in subsequent code.

## Settings

☑ On

Polyspace checks the code from the beginning of `main` and continues up to the pragma `polyspace_end_of_init`.

○ Off (default)

Polyspace checks the complete application beginning from the `main` function.

## Dependencies

You can use this option and designate a section of code as initialization code only if:

- Your program contains a `main` function and you use the option `Verify whole application` (implicitly set by default at command line).
- You set `Source code language (-lang)` to `C`.

Note that the pragma must appear only once in the `main` function. The pragma can appear before or after variable declarations but must appear after type definitions (`typedef`-s).

You cannot use this option with the following options:

- `Verify files independently (-unit-by-unit)`
- `Show global variable sharing and usage only (-shared-variables-mode)`

## Tips

- Use this option along with the option `Check that global variables are initialized after warm reboot (-check-globals-init)` to thoroughly check the initialization code before checking the remaining program. If you use both options, the verification checks for the following:

  - Definite or possible run-time errors in the initialization code.
  - Whether all non-`const` global variables are initialized along all execution paths through the initialization code.
- Multitasking options are disabled if you check initialization code only because the initialization of global variables is expected to happen before the tasks (threads) begin. As a result, task bodies are not verified.

  See also “Multitasking” (Polyspace Code Prover).
- If you check initialization code only, the analysis truncates execution paths containing the pragma at the location of the pragma but continues to check other execution paths.

  For instance, in this example, the `pragma` appears in an `if` block. A red non-initialized variable check appears on the line `int a = var` because the path containing the initialization stops at the location of the pragma. On the only other remaining path that bypasses the `if` block, the variable `var` is not initialized.

  ```
  int var;

  int func();
  ```

```
int main() {
    int err = func();
    if(err) {
        var = 0;
 #pragma polyspace_end_of_init
    }
    int a = var;
    return 0;
}
```

To avoid these situations, try to place the pragma outside a block. See other suggestions for placement of the pragma in the reference for `Check that global variables are initialized after warm reboot (-check-globals-init)`.

- To determine the initialization of a structure, a regular Code Prover analysis only considers fields that are used.

  If you check initialization code only using this option, the analysis covers only a portion of the code and cannot determine if a variable is used beyond this portion. Therefore, the checks for initialization consider all structure fields, whether used or not.

### Command-Line Information

**Parameter:** `-init-only-mode`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-init-only-mode`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-init-only-mode`

## Version History

**Introduced in R2020a**

#### Topics

“Specify Polyspace Analysis Options”
“Code Prover Assumptions About Global Variable Initialization” (Polyspace Code Prover)

# Verify whole application

Stop verification if sources files are incomplete and do not contain a `main` function

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify that Polyspace verification must stop if a `main` function is not present in the source files.

If you select a Visual C++ setting for `Compiler (-compiler)`, you can specify which function must be considered as `main`. See `Main entry point (-main)`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node.

**Command line and options file**: There is no corresponding command-line option. See “Command-Line Information” on page 2-218.

## Settings

● On

Polyspace verification stops if it does not find a `main` function in the source files.

○ Off (default)

Polyspace continues verification even when a `main` function is not present in the source files. If a `main` is not present, it generates a file `__polyspace_main.c` that contains a `main` function.

## Tips

If you use this option, your code must contain a `main` function. Otherwise you see the error:

```
Error: required main procedure not found
```

If your code does not contain a `main` function, use the option `Verify module or library (-main-generator)` to generate a `main` function.

## Command-Line Information

Unlike the user interface, by default, a verification from the command line stops if it does not find a `main` function in the source files. If you specify the option `-main-generator`, Polyspace generates a `main` if it cannot find one in the source files.

# Show global variable sharing and usage only (`-shared-variables-mode`)

Compute global variable sharing and usage without running full analysis

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify this option to run a less extensive analysis that computes the global variable sharing and usage in your entire application. The analysis does not verify your code for run-time errors. The analysis results also include coding standards violations if you enable coding standards checking, and code metrics if you enable code metrics computation.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node.

**Command line and options file**: Use the option `-shared-variables-mode`. See "Command-Line Information" on page 2-221.

### Why Use This Option

You can see global variable sharing and usage without running a full analysis on your entire application that includes run-time error detection. Run-time error detection on an entire application can take a long time.

## Settings

☑ On

Polyspace computes global variable sharing and usage but does not verify your code for run-time errors.

○ Off (default)

Polyspace runs a full analysis on your code, including run-time error detection.

## Dependencies

- You can use this option only if your program contains a `main` function and you enable the option `Verify whole application` (implicitly set by default at command line).
- When you enable this option, you must also enable at least one of these options.
  - `Enable automatic concurrency detection for Code Prover (-enable-concurrency-detection)`
  - `Tasks (-entry-points)`

- `Cyclic tasks (-cyclic-tasks)`
- `Interrupts (-interrupts)`
- `ARXML files selection (-autosar-multitasking)`
- `OIL files selection (-osek-multitasking)`

## Tips

- After you analyze your complete application to see global variable sharing and usage, run a component-by-component Code Prover analysis to detect run-time errors.
- In the desktop product, you can see all read and write operations on global variables in the "Variable Access in Polyspace Desktop User Interface" (Polyspace Code Prover) pane.
- In this less extensive analysis mode, the analysis checks for most but not all coding standards violations, and computes most but not all code metrics.

## Command-Line Information

**Parameter:** `-shared-variables-mode`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-shared-variables-mode -enable-concurrency-detection`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-shared-variables-mode -enable-concurrency-detection`

# Version History

**Introduced in R2019b**

### Topics

"Specify Polyspace Analysis Options"

# Main entry point (-main)

Specify a Microsoft Visual C++ extensions of `main`

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify the function that you want to use as `main`. If the function does not exist, the verification stops with an error message. Use this option to specify Microsoft Visual C++ extensions of `main`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-222 for other options that you must also enable.

**Command line and options file**: Use the option `-main`. See “Command-Line Information” on page 2-223.

## Settings

**Default:** `_tmain`

`_tmain`
: Use `_tmain` as entry point to your code.

`wmain`
: Use `wmain` as entry point to your code.

`_tWinMain`
: Use `_tWinMain` as entry point to your code.

`wWinMain`
: Use `wWinMain` as entry point to your code.

`WinMain`
: Use `WinMain` as entry point to your code.

`DllMain`
: Use `DllMain` as entry point to your code.

## Dependencies

This option is enabled only if you:

- Set `Source code language (-lang)` to `CPP`.
- Select `Verify whole application`.

## Command-Line Information

**Parameter:** `-main`
**Value:** `_tmain` | `wmain` | `_tWinMain` | `wWinMain` | `WinMain` | `DllMain`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-compiler visual14.0 -main _tmain`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-compiler visual14.0 -main _tmain`

# Functions to call (`-main-generator-calls`)

Specify functions that you want the generated `main` to call after the initialization functions

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify functions that you want the generated `main` to call. The `main` calls these functions after the ones you specify through the option `Initialization functions (-functions-called-before-main)`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-225 for other options that you must also enable.

**Command line and options file**: Use the option `-main-generator-calls`. See “Command-Line Information” on page 2-225.

### Why Use This Option

If you are verifying a module or library, Code Prover generates a `main` function if one does not exist. If a `main` exists, the analysis uses the existing `main`.

Use this option along with the option `Initialization functions (-functions-called-before-main)` to specify which functions the generated `main` must call. Unless a function is called directly or indirectly from `main`, the software does not analyze the function.

## Settings

**Default:** `unused`

`none`

The generated `main` does not call any function.

`unused`

The generated `main` calls only those functions that are not called in the source code. It does not call inlined functions.

`all`

The generated `main` calls all functions except inlined ones.

`custom`

The generated `main` calls functions that you specify.

Enter function names or choose from a list.

- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

If you use the scope resolution operator to specify the function from a particular namespace, enter the fully qualified name, for instance, `myClass::myMethod(int)`. If the function does not have a parameter, use an empty parenthesis, for instance, `myClass::myMethod()`.

## Dependencies

This option is available only if you select `Verify module or library (-main-generator)`.

## Tips

- Select `unused` when you use **Code Prover Verification** > **Verify files independently**.
- If you want the generated `main` to call an inlined function, select `custom` and specify the name of the function.
- To verify a multitasking application without a main, select `none`.
- The generated `main` can call the functions in arbitrary order. If you want to call your functions in a specific order, manually write a `main` function to call them.
- To specify instantiations of templates as arguments, run analysis once with the option argument `all`. Search for the template name in the analysis log and use the template name as it appears in the analysis log for the option argument.

  For instance, to specify this template function instantiation as option argument:

  ```
  template <class T>
  T GetMax (T a, T b) {
    T result;
    result = (a>b)? a : b;
    return (result);
  }
  template int GetMax<int>(int, int); // explicit instantiation
  ```

  Run an analysis with the option `-main-generator-calls all`. Search for `getMax` in the analysis log. You see the function format:

  ```
  T1 getMax<int>(T1, T1)
  ```

  To call only this template instantiation, remove the space between the arguments and use the option:

  ```
  -main-generator-calls custom="T1 getMax<int>(T1,T1)"
  ```

## Command-Line Information

**Parameter:** `-main-generator-calls`
**Value:** `none` | `unused` | `all` | `custom=`*`function1`*`[,`*`function2`*`[,...]]`
**Default:** `unused`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -main-generator-calls all`

**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -main-generator-calls all`

## See Also

`Verify module or library (-main-generator)` | `Initialization functions (-functions-called-before-main)` | `Class (-class-analyzer)` | `Functions to call within the specified classes (-class-analyzer-calls)`

### Topics

"Specify Polyspace Analysis Options"
"Verify C Application Without main Function" (Polyspace Code Prover)

# Variables to initialize (-main-generator-writes-variables)

Specify global variables that you want the generated `main` to initialize

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify global variables that you want the generated `main` to initialize. Polyspace considers these variables to have any value allowed by their type.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-228 for other options that you must also enable.

**Command line and options file**: Use the option `-main-generator-writes-variables`. See “Command-Line Information” on page 2-228.

### Why Use This Option

If you are verifying a module or library, Code Prover generates a `main` function if one does not exist. If a `main` exists, the analysis uses the existing `main`.

A Code Prover analysis of a module without a `main` function makes some default assumptions about global variable initialization. The analysis assumes that global variables that are not explicitly initialized can have the full range of values allowed by their data types upon each entry into an uncalled function. For instance, in the example below, which does not have a `main` function, the variable `glob` is assumed to have *all* possible `int` values both in `foo` and `bar` (despite the modification in `foo`). The assumption is a conservative one since the call context of `foo` and `bar`, including which function gets called earlier, is not known.

```
int glob;

int foo() {
   int locFoo = glob;
   glob++;
   return locFoo;
}

int bar() {
   int locBar = glob;
   return locBar;
}
```

To implement this assumption, the generation `main` initializes such global variables to full-range values before calling each otherwise uncalled function. Use this option to modify this default assumption and implement a different initialization strategy for global variables.

## Settings

**Default:**

- C code — `public`
- C++ Code — `uninit`

`uninit`

C++ Only

The generated `main` only initializes global variables that you have not initialized during declaration.

`none`

The generated `main` does not initialize global variables.

Global variables are initialized according to the C/C+ standard. For instance, `int` or `char` variables are initialized to 0, `float` variables to 0.0, and so on.

`public`

The generated `main` initializes all global variables except those declared with keywords `static` and `const`.

`all`

The generated `main` initializes all global variables except those declared with keyword `const`.

`custom`

The generated `main` only initializes global variables that you specify. Click ✚ to add a field. Enter a global variable name.

## Dependencies

You can use this option only if the following are true:

- Your code does not contain a `main` function.
- `Verify module or library (-main-generator)` is selected.

The option is disabled if you enable the option `Ignore default initialization of global variables (-no-def-init-glob)`. Global variables are considered as uninitialized until you explicitly initialize them in the code.

## Tips

This option only affects global variables that are defined in the project. If a global variable is declared as `extern`, the analysis considers that the variable can have any value allowed by its data type, irrespective of the value of this option.

## Command-Line Information

**Parameter:** `-main-generator-writes-variables`
**Value:** `uninit | none` | `public` | `all` | `custom=`*`variable1`*`[,`*`variable2`*`[,...]]`
**Default:** (C) `public |` (C++) `uninit`

**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -main-generator-writes-variables all`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -main-generator-writes-variables all`

## See Also

`Verify module or library (-main-generator)`

### Topics

“Specify Polyspace Analysis Options”
“Verify C Application Without main Function” (Polyspace Code Prover)

# Skip member initialization check (`-no-constructors-init-check`)

Do not check if class constructor initializes class members

## Description

*This option affects a Code Prover analysis only.*

Specify that Polyspace must not check whether each class constructor initializes all class members.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-230 for other options that you must also enable.

**Command line and options file**: Use the option `-no-constructors-init-check`. See “Command-Line Information” on page 2-231.

### Why Use This Option

Use this option to disable checks for initialization of class members in constructors.

## Settings

☑ On

Polyspace does not check whether each class constructor initializes all class members.

□ Off (default)

Polyspace checks whether each class constructor initializes all class members. It checks for initialization of:

- Integer types such as `int`, `char` and `enum`, both `signed` or `unsigned`.
- Floating-point types such as `float` and `double`.
- Pointers.

The analysis uses built-in functions `__ps_builtin_check_NIV()` and `__ps_builtin_check_NIP()` in the generated `main` to perform these checks. If the Code Prover analysis proves that a class member is not initialized in the constructor, you see a red check on this member in a call to the function `__ps_builtin_check_NIV()`. If the analysis cannot prove definite initialization or non-initialization of a class member in the constructor, you see an orange check.

## Dependencies

You can use this option only if all of the following are true:

- Your code does not contain a `main` function.
- `Source code language (-lang)` is set to `CPP` or `C-CPP`.
- `Verify module or library (-main-generator)` is selected.

If you select this option, you must specify the classes using the`Class (-class-analyzer)` option.

## Command-Line Information

**Parameter:** `-no-constructors-init-check`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public -no-constructors-init-check`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -class-analyzer custom=myClass1,myClass2 -class-analyzer-calls unused-public -no-constructors-init-check`

# Verify files independently (`-unit-by-unit`)

Verify each source file independently of other source files

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify that each source file must be verified independently of other source files. Each file is verified individually, independent of other files in the module. Verification results can be viewed for the entire project or for individual files.

After you open the verification result for one file, in the user interface of the Polyspace desktop products, you can see a summary of results for all files on the **Dashboard** pane. You can open the results for each file directly from this summary table.

Each result file (with name `ps_results.pscp`) is saved in a subfolder of the results folder. The subfolder has the same name as the source file being analyzed.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-232 for other options that you must also enable.

**Command line and options file**: Use the option `-unit-by-unit`. See “Command-Line Information” on page 2-233.

### Why Use This Option

There are many reasons you might want to verify each source file independently of other files.

For instance, if verification of a project takes very long, you can perform a file by file verification to identify which file is slowing the verification.

## Settings

☑ On

Polyspace creates a separate verification job for each source file.

□ Off (default)

Polyspace creates a single verification job for all source files in a module.

## Dependencies

This option is enabled only if you select `Verify module or library (-main-generator)`.

## Tips

- Code Prover requires a `main` function as the starting point of verification. In the file-by-file mode, because most files do not have a `main`, Code Prover generates a `main` function when required. By default, the generated `main` calls uncalled functions (uncalled non-private methods and out-of-class functions in C++). For more information, see:
  - “Verify C Application Without main Function” (Polyspace Code Prover)
  - “Verify C++ Classes” (Polyspace Code Prover)
- If you perform a file by file verification, you cannot specify multitasking options.
- If your verification for the entire project takes very long, perform a file by file verification. After the verification is complete for a file, you can view the results while other files are still being verified.
- You can generate a report of the verification results for each file or for all the files together. To generate a single report for all files, perform the report generation after verification (and not along with verification using analysis options).

  To generate a single report for all the files in the Polyspace user interface (desktop product only):

  1. Open the results for one file.
  2. Select **Reporting** > **Run Report**. Before generating the report, select the option **Generate a single report including all unit results**.

  If you use the product Polyspace Code Prover Server to run a verification, to generate a single report for all files:

  - Upload the results for all files to the Polyspace Access server.
  - Use the `polyspace-report-generator` command with option `-all-units` to generate a single report for all the files.
- When you perform a file-by-file verification, you can see many instances of unused variables. Some of these variables might be used in other files but show as unused in a file-by-file verification.

  If you want to ignore these results, use a review scope (named set of filters) that filters out unused variables. See “Filter and Group Results in Polyspace Desktop User Interface” (Polyspace Code Prover).

## Command-Line Information

**Parameter:** `-unit-by-unit`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file1,file2,...`* `-unit-by-unit`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file1,file2,...`* `-unit-by-unit`

## See Also

### Topics

“Specify Polyspace Analysis Options”

# Common source files (-unit-by-unit-common-source)

Specify files that you want to include with each source file during a file by file verification

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

For a file by file verification, specify files that you want to include with each source file verification. These files are compiled once, and then linked to each verification.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node. See “Dependencies” on page 2-234 for other options that you must also enable.

**Command line and options file**: Use the option `-unit-by-unit-common-source`. See “Command-Line Information” on page 2-235.

### Why Use This Option

There are many reasons you might want to verify each source file independently of other files. For instance, if verification of a project takes very long, you can perform a file by file verification to identify which file is slowing the verification.

If you perform a file by file verification, some of your files might be missing information present in the other files. Place the missing information in a common file and use this option to specify the file for verification. For instance, if multiple source files call the same function, use this option to specify a file that contains the function definition or a function stub. Otherwise, Polyspace uses its own stubs for functions that are called but not defined in the source files. The assumptions behind the Polyspace stubs can be broader than what you want, leading to orange checks.

## Settings

**No Default**

Click ✚ to add a field. Enter the full path to a file. Otherwise, use the 📁 button to navigate to the file location.

## Dependencies

This option is enabled only if you select `Verify files independently (-unit-by-unit)`.

## Command-Line Information

**Parameter:** `-unit-by-unit-common-source`
**Value:** `*file1*[,*file2*[,...]]`
**No Default**
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -unit-by-unit -unit-by-unit-common-source definitions.c`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -unit-by-unit -unit-by-unit-common-source definitions.c`

"Specify Polyspace Analysis Options"

# Verify model generated code (`-main-generator`)

Specify that a `main` function must be generated if it is not present in source files

## Description

*This option is automatically set if you run Polyspace from Simulink or MATLAB on generated code. If you run Polyspace on generated code outside Simulink or MATLAB, set this option manually.*

Specify that Polyspace must generate a `main` function if it does not find one in the source files.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node.

**Command line and options file**: Use the option `-main-generator`. See “Command-Line Information” on page 2-236.

## Settings

This option is always enabled for code generated from models.

Polyspace generates a `main` function for the analysis. The generated `main` contains cyclic code that executes in a loop. The loop can run an unspecified number of times.

The `main` performs the following functions before the loop begins:

- Initializes variables specified by `Parameters (-variables-written-before-loop)`.
- Calls the functions specified by `Initialization functions (-functions-called-before-loop)`.

The `main` then performs the following functions in the loop:

- Calls the functions specified by `Step functions (-functions-called-in-loop)`.
- Writes to variables specified by `Inputs (-variables-written-in-loop)`.

Finally, the `main` calls the functions specified by `Termination functions (-functions-called-after-loop)`.

## Command-Line Information

**Parameter:** `-main-generator`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-main-generator ...`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-main-generator ...`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-main-generator ...`

**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator ...`

# Initialization functions (`-functions-called-before-loop`)

Specify functions that the generated `main` must call before the cyclic code loop

## Description

*This option is automatically set if you run Polyspace from Simulink or MATLAB on generated code. If you run Polyspace on generated code outside Simulink or MATLAB, set this option manually.*

Specify functions that the generated `main` must call before the cyclic code begins.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Code Prover Verification** node. You see this option only if you open a project configuration from Simulink.

**Command line and options file**: Use the option `-functions-called-before-loop`. See “Command-Line Information” on page 2-238.

## Settings

**No Default** if you run the analysis outside Simulink. If you run from Simulink, the option uses the initialize functions from the generated code by default. See also “How Polyspace Analysis of Generated Code Works”.

Click ✚ to add a field. Enter function name.

If you use the scope resolution operator to specify the function from a particular namespace, enter the fully qualified name, for instance, `myClass::init(int)`. If the function does not have a parameter, use an empty parenthesis, for instance, `myClass::init()`.

## Tips

- If you specify a function for the option `Termination functions (-functions-called-after-loop)`, you cannot specify it for this option.

## Command-Line Information

**Parameter:** `-functions-called-before-loop`
**No Default**
**Value:** `*function1*[,*function2*[,...]]`
**Example (Bug Finder):** `polyspace-bug-finder -sources *file_name* -main-generator -functions-called-before-loop myfunc`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -main-generator -functions-called-before-loop myfunc`

**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-main-generator -functions-called-before-loop myfunc`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-main-generator -functions-called-before-loop myfunc`

# Step functions (`-functions-called-in-loop`)

Specify functions that the generated `main` must call in the cyclic code loop

## Description

*This option is automatically set if you run Polyspace from Simulink or MATLAB on generated code. If you run Polyspace on generated code outside Simulink or MATLAB, set this option manually.*

Specify functions that the generated `main` must call in each cycle of the cyclic code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Code Prover Verification** node. You see this option only if you open a project configuration from Simulink.

**Command line and options file**: Use the option `-functions-called-in-loop`. See “Command-Line Information” on page 2-241.

## Settings

**Default:** `none` if you run the analysis outside Simulink. If you run from Simulink, the option uses the step functions from the generated code by default. See also “How Polyspace Analysis of Generated Code Works”.

`none`

The generated `main` does not call functions in the cyclic code.

`all`

The generated `main` calls all functions except inlined ones. If you specify certain functions for the options **Initialization functions** or **Termination functions**, the generated `main` does not call those functions in the cyclic code.

`custom`

The generated `main` calls functions that you specify. Click ✚ to add a field. Enter function name.

If you use the scope resolution operator to specify the function from a particular namespace, enter the fully qualified name, for instance, `myClass::myMethod(int)`. If the function does not have a parameter, use an empty parenthesis, for instance, `myClass::myMethod()`.

## Tips

If you have specified a function for the option `Initialization functions (-functions-called-before-loop)` or `Termination functions (-functions-called-after-loop)`, to call it inside the cyclic code, use `custom` and specify the function name.

## Command-Line Information

**Parameter:** `-functions-called-in-loop`
**Value:** `none` | `all` | `custom=`*`function1`*`[,`*`function2`*`[,...]]`
**Default:** `none`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-main-generator -functions-called-in-loop all`

# Verify module or library (`-main-generator`)

Generate a `main` function if source files are modules or libraries that do not contain a `main`

## Description

*This option affects a Code Prover analysis only.*

Specify that Polyspace must generate a `main` function if it does not find one in the source files.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Code Prover Verification** node.

**Command line and options file**: Use the option `-main-generator`. See “Command-Line Information” on page 2-249.

For the analogous option for model generated code, see `Verify model generated code (-main-generator)`.

### Why Use This Option

Use this option if you are verifying a module or library. A Code Prover analysis requires a `main` function. When verifying a module or library, your code might not have a `main`.

When you use this option, Code Prover generates a `main` function if one does not exist. If a `main` exists, the analysis uses the existing `main`.

## Settings

● On (default)

Polyspace generates a `main` function if it does not find one in the source files. The generated `main`:

1. Initializes variables specified by `Variables to initialize (-main-generator-writes-variables)`.
2. Before calling other functions, calls the functions specified by `Initialization functions (-functions-called-before-main)`.
3. In all possible orders, calls the functions specified by `Functions to call (-main-generator-calls)`.
4. (C++ only) Calls class methods specified by `Class (-class-analyzer)` and `Functions to call within the specified classes (-class-analyzer-calls)`.

If you do not specify the function and variable options above, the generated `main`:

- Initializes all global variables except those declared with keywords `const` and `static`.
- In all possible orders, calls all functions that are not called anywhere in the source files. Polyspace considers that global variables can be written between two consecutive function

calls. Therefore, in each called function, global variables initially have the full range of values allowed by their type.

○ Off

Polyspace stops if a main function is not present in the source files.

## Tips

- If a main function is present in your source files, the verification uses that main function, irrespective of whether you enable or disable this option.

  The option is relevant only if a main function is not present in your source files.
- If you use the option Verify whole application (default on the command line), your code must contain a main function. Otherwise you see the error:

  ```
  Error: required main procedure not found
  ```

  If your code does not contain a main function, use this option to generate a main function.
- If you specify multitasking options, the verification ignores your specifications for main generation. Instead, the verification introduces an empty main function.

  For more information on the multitasking options, see “Configuring Polyspace Multitasking Analysis Manually”.

## Command-Line Information

**Parameter:** -main-generator
**Default:** Off
**Example (Code Prover):** polyspace-code-prover -sources *file_name* -main-generator
**Example (Code Prover Server):** polyspace-code-prover-server -sources *file_name* -main-generator

“Specify Polyspace Analysis Options”
“Verify C Application Without main Function” (Polyspace Code Prover)
“Verify C++ Classes” (Polyspace Code Prover)

# Consider environment pointers as unsafe (-stubbed-pointers-are-unsafe)

Specify that environment pointers can be unsafe to dereference unless constrained otherwise

## Description

*This option affects a Code Prover analysis only.*

*This option is not available for code generated from MATLAB code or Simulink models.*

Specify that the verification must consider environment pointers as unsafe unless otherwise constrained. Environment pointers are pointers that can be assigned values outside your code.

Environment pointers include:

- Global or `extern` pointers.
- Pointers returned from stubbed functions.

  A function is stubbed if your code does not contain the function definition or you override a function definition by using the option `Functions to stub (-functions-to-stub)`.
- Pointer parameters of functions whose calls are generated by the software.

  A function call is generated if you verify a module or library and the module or library does not have an explicit call to the function. You can also force a function call to be generated with the option `Functions to call (-main-generator-calls)`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Verification Assumptions** node.

**Command line and options file**: Use the option `-stubbed-pointers-are-unsafe`. See “Command-Line Information” on page 2-252.

### Why Use This Option

Use this option so that the verification makes more conservative assumptions about pointers from external sources.

If you specify this option, the verification considers that environment pointers can have a `NULL` value. If you read an environment pointer without checking for `NULL`, the **Illegally dereferenced pointer** check shows a potential error in orange. The message associated with the orange check shows the pointer can be `NULL`.

## Settings

☑ On

The verification considers that environment pointers can have a `NULL` value.

☐ Off (default)

The verification considers that environment pointers:

- Cannot have a `NULL` value.
- Points within allowed bounds.

## Tips

- Enable this option during the integration phase. In this phase, you provide complete code for verification. Even if an orange check originates from external sources, you are likely to place protections against unsafe pointers from such sources. For instance, if you obtain a pointer from an unknown source, you check the pointer for `NULL` value.

  Disable this option during the unit testing phase. In this phase, you focus on errors originating from your unit.
- If you are verifying code implementation of AUTOSAR runnables, Code Prover assumes that pointer arguments to runnables and pointers returned from `Rte_` functions are not `NULL`. You cannot use this option to change the assumption. See “Run Polyspace on AUTOSAR Code with Conservative Assumptions” (Polyspace Code Prover).
- If you enable this option, the number of orange checks in your code might increase.

| Environment Pointers Safe | Environment Pointers Unsafe |
|---|---|
| The **Illegally dereferenced pointer** check is green. The verification assumes that `env_ptr` is not NULL and any dereference is within allowed bounds. The verification assumes that the result of the dereference is full range. For instance, in this case, the return value has the full range of type `int`.<br>`int func (int *env_ptr) {`<br>`    return *env_ptr;`<br>`}` | The **Illegally dereferenced pointer** check is orange. The verification assumes that `env_ptr` can be NULL.<br>`int func (int *env_ptr) {`<br>`    return *env_ptr;`<br>`}` |

  If you enable this option, the number of gray checks might decrease.

| Environment Pointers Safe | Environment Pointers Unsafe |
|---|---|
| The verification assumes that `env_ptr` is not NULL. The `if` condition is always true and the `else` block is unreachable.<br>`#include <stdlib.h>`<br>`int func (int *env_ptr) {`<br>`    if(env_ptr!=NULL)`<br>`            return *env_ptr;`<br>`    else`<br>`            return 0;`<br>`}` | The verification assumes that `env_ptr` can be NULL. The `if` condition is not always true and the `else` block can be reachable.<br>`#include <stdlib.h>`<br>`int func (int *env_ptr) {`<br>`    if(env_ptr!=NULL)`<br>`            return *env_ptr;`<br>`    else`<br>`            return 0;`<br>`}` |

- Instead of considering all environment pointers as safe or unsafe, you can individually constrain some of the environment pointers. See the description of **Initialize Pointer** in “External Constraints for Polyspace Analysis”.

When you individually constrain a pointer, you first specify an **Init Mode**, and then specify through the **Initialize Pointer** option whether the pointer is `Null`, `Not Null`, or `Maybe Null`. Depending on the **Init Mode**, you can either override the global specification for all environment pointers or not.

- If you set the **Init Mode** of the pointer to `INIT` or `PERMANENT`, your selection for **Initialize Pointer** overrides your specification for this option. For instance, if you specify `Not NULL` for an environment pointer `ptr`, the verification assumes that `ptr` is not NULL even if you specify that environment pointers must be considered unsafe.
- If you set the **Init Mode** to `MAIN GENERATOR`, the verification uses your specification for this option.

  For pointers returned from stubbed functions, the option `MAIN GENERATOR` is not available. If you override the global specification for such a pointer through the **Initialize Pointer** option in constraints, you cannot toggle back to the global specification without changing the **Initialize Pointer** option too.

- If you disable this option, the verification considers that dereferences at all pointer depths are valid.

  For instance, all the dereferences are considered valid in this code:

```
int*** stub(void);

void func2() {
        int ***ptr = stub();
        int **ptr2 = *ptr;
        int *ptr3 = *ptr2;
}
```

## Command-Line Information

**Parameter:** `-stubbed-pointers-are-unsafe`
**Default**: Off
**Example (Code Prover)**: `polyspace-code-prover -sources` *`file_name`* `-stubbed-pointers-are-unsafe`
**Example (Code Prover Server)**: `polyspace-code-prover-server -sources` *`file_name`* `-stubbed-pointers-are-unsafe`

# Consider volatile qualifier on fields (-consider-volatile-qualifier-on-fields)

Assume that `volatile` qualified structure fields can have all possible values at any point in code

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must take into account the `volatile` qualifier on fields of a structure.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Verification Assumptions** node.

**Command line and options file**: Use the option `-consider-volatile-qualifier-on-fields`. See "Command-Line Information" on page 2-255.

### Why Use This Option

The `volatile` qualifier on a variable indicates that the variable value can change between successive operations even if you do not explicitly change it in your code. For instance, if `var` is a `volatile` variable, the consecutive operations `res = var; res =var;` can result in two different values of `var` being read into `res`.

Use this option so that the verification emulates the `volatile` qualifier for structure fields. If you select this option, the software assumes that a `volatile` structure field has a full range of values at any point in the code. The range is determined only by the data type of the structure field.

## Settings

☑ On

The verification considers the `volatile` qualifier on fields of a structure.

In the following example, the verification considers that the field `val1` can have all values allowed for the `int` type at any point in the code.

```
struct myStruct {
   volatile int val1;
   int val2;
};
```

Even if you write a specific value to `val1` and read the variable in the next operation, the variable read results in any possible value.

```
struct myStruct myStructInstance;
myStructInstance.val1 = 1;
assert (myStructInstance.val1 == 1); // Assertion can fail
```

□ Off (default)

The verification ignores the `volatile` qualifier on fields of a structure.

In the following example, the verification ignores the qualifier on field `val1`.

```
struct myStruct {
   volatile int val1;
   int val2;
};
```

If you write a specific value to `val1` and read the variable in the next operation, the variable read results in that specific value.

```
struct myStruct myStructInstance;
myStructInstance.val1 = 1;
assert (myStructInstance.val1 == 1); // Assertion passes
```

## Tips

- If your volatile fields do not represent values read from hardware and you do not expect their values to change between successive operations, disable this option. You are using the `volatile` qualifier for some other reason and the verification does not need to consider full range for the field values.
- If you enable this option, the number of red, gray, and green checks in your code can decrease. The number of orange checks can increase.

  In the following example, a red or green check changes to orange or a gray check goes away when the option is used. Considering the `volatile` qualifier changes the check color. These examples use the following structure definition:

```
struct myStruct {
   volatile int field1;
   int field2;
};
```

| Color Without Option | Result Without Option | Result With Option |
|---|---|---|
| Green | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   assert(structVal.field1 == 1);`<br>`}` | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   assert(structVal.field1 ==1);`<br>`}` |
| Red | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   assert(structVal.field1 != 1);`<br>`}` | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   assert(structVal.field1 !=1);`<br>`}` |

| Color Without Option | Result Without Option | Result With Option |
|---|---|---|
| Gray | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   if (structVal.field1 != 1)`<br>`   {`<br>`   /* Perform operation */`<br>`   }`<br>`}` | `void main(){`<br>`   struct myStruct structVal;`<br>`   structVal.field1 = 1;`<br>`   if (structVal.field1 != 1)`<br>`   {`<br>`   /* Perform operation */`<br>`   }`<br>`}` |

- In C++ code, the option also applies to class members.

## Command-Line Information

**Parameter:** `-consider-volatile-qualifier-on-fields`
**Default**: Off
**Example (Code Prover)**: `polyspace-code-prover -sources` *`file_name`* `-consider-volatile-qualifier-on-fields`

### Topics

"Specify Polyspace Analysis Options"

# Float rounding mode (`-float-rounding-mode`)

Specify rounding modes to consider when determining the results of floating point arithmetic

## Description

*This option affects a Code Prover analysis only.*

Specify the rounding modes to consider when determining the results of floating-point arithmetic.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Verification Assumptions** node.

**Command line and options file**: Use the option `-float-rounding-mode`. See “Command-Line Information” on page 2-258.

### Why Use This Option

The default verification uses the round-to-nearest mode.

Use the rounding mode `all` if your code contains routines such as `fesetround` to specify a rounding mode other than round-to-nearest. Although the verification ignores the `fesetround` specification, it considers all rounding modes including the rounding mode that you specified. Alternatively, for targets that can use extended precision (for instance, using the flag `-mfpmath=387`), use the rounding mode `all`. However, for your Polyspace analysis results to agree with run-time behavior, you must prevent use of extended precision through a flag such as `-ffloat-store`.

Otherwise, continue to use the default rounding mode `to-nearest`. Because all rounding modes are considered when you specify `all`, you can have many orange **Overflow** checks resulting from overapproximation.

## Settings

**Default:** `to-nearest`

`to-nearest`

The verification assumes the round-to-nearest mode.

`all`

The verification assumes all rounding modes for each operation involving floating-point variables. The following rounding modes are considered: round-to-nearest, round-towards-zero, round-towards-positive-infinity, and round-towards-negative-infinity.

## Tips

- The Polyspace analysis uses floating-point arithmetic that conforms to the IEEE® 754 standard. For instance, the arithmetic uses floating point instructions present in the SSE instruction set. The GNU C flag `-mfpmath=sse` enforces use of this instruction set. If you use the GNU C compiler with this flag to compile your code, your Polyspace analysis results agree with your run-time behavior.

However, if your code uses extended precision, for instance using the GNU C flag `-mfpmath=387`, your Polyspace analysis results might not agree with your run-time behavior in some corner cases. See some examples of these corner cases in `codeprover_limitations.pdf` in *`polyspaceroot`*`\polyspace\verifier\code_prover_desktop`. Here, *`polyspaceroot`* is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2019a`.

To prevent use of extended precision, on targets without SSE support, you can use a flag such as `-ffloat-store`. For your Polyspace analysis, use `all` for rounding mode to account for double rounding.

- The **Overflow** check uses the rounding modes that you specify. For instance, the following table shows the difference in the result of the check when you change your rounding modes.

<table>
<tr><th>Rounding mode: <code>to-nearest</code></th><th>Rounding mode: <code>all</code></th></tr>
<tr>
<td>
If results of floating-point operations are rounded to nearest values:
<ul>
<li>In the first addition operation, <code>eps1</code> is just large enough that the value nearest to <code>FLT_MAX + eps1</code> is greater than <code>FLT_MAX</code>. The <b>Overflow</b> check is red.</li>
<li>In the second addition operation, <code>eps2</code> is just small enough that the value nearest to <code>FLT_MAX + eps2</code> is <code>FLT_MAX</code>. The <b>Overflow</b> check is green.</li>
</ul>
<pre>
#include &lt;float.h&gt;
#define eps1 0x1p103
#define eps2 0x0.FFFFFFp103

float func(int ch) {
    float left_op = FLT_MAX;
    float right_op_1 = eps1, \
right_op_2 = eps2;
    switch(ch) {
    case 1:
        return (left_op +\
right_op_1);
    case 2:
        return (left_op +\
right_op_2);
    default:
        return 0;
    }
}
</pre>
</td>
<td>
Besides to-nearest mode, the <b>Overflow</b> check also considers other rounding modes.
<ul>
<li>In the first addition operation, in to-nearest mode, the value nearest to <code>FLT_MAX + eps1</code> is greater than <code>FLT_MAX</code>, so the addition overflows. But if rounded towards negative infinity, the result is <code>FLT_MAX</code>, so the addition does not overflow. Combining these two rounding modes, the <b>Overflow</b> check is orange.</li>
<li>In the second addition operation, in to-nearest mode, the value nearest to <code>FLT_MAX + eps2</code> is <code>FLT_MAX</code>, so the addition does not overflow. But if rounded towards positive infinity, the result is greater than <code>FLT_MAX</code>, so the addition overflows. Combining these two rounding modes, the <b>Overflow</b> check is orange.</li>
</ul>
<pre>
#include &lt;float.h&gt;
#define eps1 0x1p103
#define eps2 0x0.FFFFFFp103

float func(int ch) {
    float left_op = FLT_MAX;
     float right_op_1 = eps1, \
 right_op_2 = eps2;
    switch(ch) {
    case 1:
        return (left_op +\
right_op_1);
    case 2:
        return (left_op +\
right_op_2);
    default:
        return 0;
    }
}
</pre>
</td>
</tr>
</table>

If you set the rounding mode to `all` and obtain an orange **Overflow** check, to determine how the overflow can occur, consider all rounding modes.

## Command-Line Information

**Parameter:** `-float-rounding-mode`
**Value:** `to-nearest` | `all`
**Default:** `to-nearest`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-float-rounding-mode all`

**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-float-rounding-mode all`

### Topics

"Specify Polyspace Analysis Options"

# Ignore assembly code (`-ignore-assembly-code`)

Specify that assembly instructions in C/C++ code cannot modify C/C++ variables

## Description

*This option affects a Code Prover analysis only.*

Enable an analysis mode that ignores assembly instructions in C/C++ code. In this mode, the analysis assumes that assembly instructions in a C/C++ function cannot modify local variables of the function.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **analysis Assumptions** node.

**Command line and options file**: Use the option `-ignore-assembly-code`. See “Command-Line Information” on page 2-261.

### Why Use This Option

Use this option to reduce orange checks from overapproximations around assembly instructions in C/C++ code.

By default, Code Prover makes the conservative assumption that following assembly instructions in a function, local variables can take any value allowed by their data types. This assumption can lead to many orange checks following assembly instructions. If you use assembly instructions primarily for no-ops such as introducing delays or for loading global variables, you can enable an analysis mode that ignores the assembly instructions.

## Settings

☑ On

The analysis considers that assembly instructions in a function cannot modify local variables of the function. Use this option if assembly instructions in your project do not modify local variables of a function.

Consider these examples:

- The analysis assumes that the assembly instructions cannot modify the local variable `val1`. Therefore, the results show a red **Non-initialized variable** check when `val1` is returned.

  ```
  int func(void) {
      int val1;
      asm("NOP");
      //Instructions that do not modify val1
      //...
      return val1;
  }
  ```

- The analysis assumes that the assembly instructions cannot modify the local variables `val1` and `val2`. Therefore, the results show a green **Overflow** check when the two variables are added.

  ```
  int func(void) {
      int val1 = 0, val2 = 0;
      asm("NOP");
      //Instructions that do not modify val1 and val2
      //...
      return (val1+val2);
  }
  ```

□ Off (default)

The analysis considers that assembly instructions in a function can modify local variables of the function. Use this option if assembly instructions in your project can modify local variables of a function.

Consider these examples:

- The analysis assumes that the assembly instructions can potentially modify the local variable `val1`. Therefore, the results show an orange **Non-initialized variable** check when `val1` is returned.

  ```
  int func(void) {
      int val1;
      asm("mov 4%0,%%eax"::"m"(val1));
      //Instructions that do not modify val1
      //...
      return val1;
  }
  ```
- The analysis assumes that the assembly instructions can modify the local variables `val1` and `val2` (and write any possible value allowed by their data types). Therefore, the results show an orange **Overflow** check when the two variables are added.

  ```
  int func(void) {
      int val1 = 0, val2 = 0;
      asm("mov 4%0,%%eax"::"m"(val1));
      //Instructions that do not modify val1 and val2
      //...
      return (val1+val2);
  }
  ```

## Command-Line Information

**Parameter:** `-ignore-assembly-code`
**Default**: Off
**Example (Code Prover)**: `polyspace-code-prover -sources` *`file_name`* `-ignore-assembly-code`
**Example (Code Prover Server)**: `polyspace-code-prover-server -sources` *`file_name`* `-ignore-assembly-code`

# Version History

# Allow negative operand for left shifts (-allow-negative-operand-in-shift)

Allow left shift operations on a negative number

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must allow left shift operations on a negative number.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-allow-negative-operand-in-shift`. See “Command-Line Information” on page 2-263.

### Why Use This Option

According to the C99 standard (sec 6.5.7), the result of a left shift operation on a negative number is undefined. Following the standard, the verification produces a red check on left shifts of negative numbers.

If your compiler has a well-defined behavior for left shifts of negative numbers, set this option. Note that allowing left shifts of negative numbers can reduce the cross-compiler portability of your code.

## Settings

☑ On

The verification allows shift operations on a negative number, for instance, `-2 << 2`.

☐ Off (default)

If a shift operation is performed on a negative number, the verification generates an error.

## Command-Line Information

**Parameter:** `-allow-negative-operand-in-shift`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-allow-negative-operand-in-shift`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-allow-negative-operand-in-shift`

# Consider non finite floats (-allow-non-finite-floats)

Enable an analysis mode that incorporates infinities and NaNs

## Description

Enable an analysis mode that incorporates infinities and NaNs for floating point operations.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-allow-non-finite-floats`. See “Command-Line Information” on page 2-267.

### Why Use This Option

#### Code Prover

By default, the analysis does not incorporate infinities and NaNs. For instance, the analysis terminates the execution thread where a division by zero occurs and does not consider that the result could be infinite.

If you use functions such as `isinf` or `isnan` and account for infinities and NaNs in your code, set this option. When you set this option and a division by zero occurs for instance, the execution thread continues with infinity as the result of the division.

Set this option alone if you are sure that you have accounted for infinities and NaNs in your code. Using the option alone effectively disables many numerical checks on floating point operations. If you have generally accounted for infinities and NaNs, but you are not sure that you have considered all situations, set these additional options:

- `Infinities (-check-infinite)`: Use `warn-first`.
- `NaNs (-check-nan)`: Use `warn-first`.

#### Bug Finder

If the analysis flags comparisons using `isinf` or `isnan` as dead code, use this option. By default, a Bug Finder analysis does not incorporate infinities and NaNs.

## Settings

☑ On

The analysis allows infinities and NaNs. For instance, in this mode:

- The analysis assumes that floating-point operations can produce results such as infinities and NaNs.

  By using options `Infinities (-check-infinite)` and `NaNs (-check-nan)`, you can choose to highlight operations that produce nonfinite results and stop the execution threads where the nonfinite results occur. These options are not available for a Bug Finder analysis.

- The analysis assumes that floating-point variables with unknown values can have any value allowed by their type, including infinite or NaN. Floating-point variables with unknown values include volatile variables and return values of stubbed functions.

□ Off (default)

The analysis does not allow infinities and NaNs. For instance, in this mode:

- The Code Prover analysis produces a red check on a floating-point operation that produces an infinity or a NaN as the only possible result on all execution paths. The verification produces an orange check on a floating-point operation that can potentially produce an infinity or NaN.
- The Code Prover analysis assumes that floating-point variables with unknown values are full-range but finite.
- The Bug Finder analysis shows comparisons with infinity using `isinf` as dead code.

## Tips

- The IEEE 754 Standard allows special quantities such as infinities and `NaN` so that you can handle certain numerical exceptions without aborting the code. Some implementations of the C standard support infinities and `NaN`.

  - If your compiler supports infinities and `NaN`s and you account for them explicitly in your code, use this option so that the verification also allows them.

    For instance, if a division results in infinity, in your code, you specify an alternative action. Therefore, you do not want the verification to highlight division operations that result in infinity.
  - If your compiler supports infinities and `NaN`s but you are not sure if you account for them explicitly in your code, use this option so that the verification incorporates infinities and `NaN`s. Use the options `-check-nan` and `-check-infinite` with argument `warn` so that the verification highlights operations that result in infinities and `NaN`s, but does not stop the execution thread. These options are not available for a Bug Finder analysis.
- If you run a Code Prover analysis and use this option, checkers for overflow, division by zero and other numerical run-time errors are disabled. See “Numerical Checks” (Polyspace Code Prover).

  If you run a Bug Finder analysis and use this option:

  - These checkers are disabled:

    - Bug Finder defects: `Float conversion overflow`, `Float division by zero`, `Invalid use of standard library floating point routine`, `Float overflow`.
    - CERT C rules and recommendation: ,`CERT C: Rule FLP34-C`, `CERT C: Rule FLP32-C`, `CERT C: Rec. FLP03-C`, `CERT C: Rec. FLP06-C`.
    - CERT C++ rules: `CERT C++: FLP34-C`, `CERT C++: FLP32-C`.
    - AUTOSAR C++14 rule: `AUTOSAR C++14 Rule A0-4-4`.
    - MISRA C:2004 rule: MISRA C:2004 rule 20.3.
  - These checker might show less violations: `MISRA C:2012 Dir 4.1`

  - These checkers might show false positives: `Floating point comparison with equality operators`, `AUTOSAR C++14 Rule M6-2-2`, `MISRA C:2012 Dir 1.1`.

- If you select this option, the number and type of Code Prover checks in your code can change.

  For instance, in the following example, when you select the option, the results have one less red check and three more green checks.

<table>
<tr><th>Infinities and NaNs Not Allowed</th><th>Infinities and NaNs Allowed</th></tr>
<tr><td>Code Prover produces a <b>Division by zero</b> error and stops verification.
<pre>
double func(void) {
    double x=1.0/0.0;
    double y=1.0/x;
    double z=x-x;
    return z;
}
</pre></td><td>If you select this option, Code Prover does not check for a <b>Division by zero</b> error.
<pre>
double func(void) {
    double x=1.0/0.0;
    double y=1.0/x;
    double z=x-x;
    return z;
}
</pre>
The analysis assumes that dividing by zero results in:<br>• Value of <code>x</code> equal to <code>Inf</code><br>• Value of <code>y</code> equal to 0.0<br>• Value of <code>z</code> equal to <code>NaN</code><br>In your analysis results in the Polyspace user interface, if you place your cursor on <code>y</code> and <code>z</code>, you can see the nonfinite values <code>Inf</code> and <code>NaN</code> respectively in the tooltip.</td></tr>
</table>

## Command-Line Information

**Parameter:** `-allow-non-finite-floats`
**Default**: Off
**Example (Bug Finder):** `polyspace-bug-finder -sources *file_name* -allow-non-finite-floats`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -allow-non-finite-floats`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources *file_name* -allow-non-finite-floats`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -allow-non-finite-floats`

# Version History

# Infinities (-check-infinite)

Specify how to handle floating-point operations that result in infinity

## Description

*This option affects a Code Prover analysis only.*

Specify how the analysis must handle floating-point operations that result in infinities.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node. See “Dependencies” on page 2-270 for other options you must also enable.

**Command line and options file**: Use the option `-check-infinite`. See “Command-Line Information” on page 2-270.

### Why Use This Option

Use this option to enable detection of floating-point operations that result in infinities.

If you specify that the analysis must consider nonfinite floats, by default, the analysis does not flag these operations. Use this option to detect these operations while still incorporating nonfinite floats.

## Settings

**Default:** `allow`

`allow`

The verification does not produce a check on the operation.

For instance, in the following code, there is no **Overflow** check.

```
double func(void) {
    double x=1.0/0.0;
    return x;
}
```

`warn-first`

The verification produces a check on the operation. The check determines if the result of the operation is infinite when the operands themselves are not infinite. The verification does not terminate the execution thread that produces infinity.

If the verification detects an operation that produces infinity as the only possible result on all execution paths and the operands themselves are never infinite, the check is red. If the operation can potentially result in infinity, the check is orange.

For instance, in the following code, there is a nonblocking **Overflow** check for infinity.

```
double func(void) {
    double x=1.0/0.0;
    return x;
}
```

Even though the **Overflow** check on the / operation is red, the verification continues. For instance, a green **Non-initialized local variable** check appears on x in the return statement.

forbid

The verification produces a check on the operation and terminates the execution thread that produces infinity.

If the check is red, the verification does not continue for the remaining code in the same scope as the check. If the check is orange, the verification continues but removes from consideration the variable values that produced infinity.

For instance, in the following code, there is a blocking **Overflow** check for infinity.

```
double func(void) {
    double x=1.0/0.0;
    return x;
}
```

The verification stops because the **Overflow** check on the / operation is red. For instance, a **Non-initialized local variable** check does not appear on x in the return statement.

### Dependencies

To use this option, you must enable the verification mode that incorporates infinities and NaNs. See Consider non finite floats (-allow-non-finite-floats).

### Command-Line Information

**Parameter:** -check-infinite
**Value:** allow | warn-first | forbid
**Default:** allow
**Example (Code Prover):** polyspace-code-prover -sources *file_name* -check-infinite forbid
**Example (Code Prover Server):** polyspace-code-prover-server -sources *file_name* -check-infinite forbid

## Version History

Overflow

**Topics**
“Specify Polyspace Analysis Options”

“Modify or Disable Code Prover Run-Time Checks” (Polyspace Code Prover)

# Check that global variables are initialized after warm reboot (`-check-globals-init`)

Check that global variables are assigned values in designed initialization code

## Description

*This option affects a Code Prover analysis only.*

Specify that Polyspace must check whether all non-const global variables (and local static variables) are explicitly initialized at declaration or within a section of code marked as initialization code.

To indicate the end of initialization code, you enter the line

```
#pragma polyspace_end_of_init
```

in the `main` function (only once). The initialization code starts from the beginning of `main` and continues up to this pragma.

Since compilers ignore unrecognized pragmas, the presence of this pragma does not affect program execution.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-check-globals-init`. See “Command-Line Information” on page 2-275.

### Why Use This Option

In a warm reboot, to save time, the bss segment of a program, which might hold variable values from a previous state, is not loaded. Instead, the program is supposed to explicitly initialize all non-const variables without default values before execution. You can use this option to delimit the initialization code and verify that all non-const global variables are indeed initialized in a warm reboot.

For instance, in this simple example, the global variable `aVar` is initialized in the initialization code section but the variable `anotherVar` is not.

```
int aVar;
const int aConst = -1;
int anotherVar;

int main() {
      aVar = aConst;
#pragma polyspace_end_of_init
      return 0;
}
```

## Settings

☑ On

Polyspace checks whether all global variables are initialized in the designated initialization code. The initialization code starts from the beginning from `main` and continues up to the pragma `polyspace_end_of_init`.

The results are reported using the check `Global variable not assigned a value in initialization code`.

○ Off (default)

Polyspace does not check for initialization of global variables in a designated code section.

However, the verification continues to check if a variable is initialized at the time of use. The results are reported using the check `Non-initialized variable`.

## Dependencies

You can use this option and designate a section of code as initialization code only if:

- Your program contains a `main` function and you use the option `Verify whole application` (implicitly set by default at command line).
- You set `Source code language (-lang)` to `C`.

Note that the pragma must appear only once in the `main` function. The pragma can appear before or after variable declarations but must appear after type definitions (`typedef`-s).

You cannot use this option with the following options:

- `Disable checks for non-initialization (-disable-initialization-checks)`
- `Verify files independently (-unit-by-unit)`
- `Show global variable sharing and usage only (-shared-variables-mode)`

## Tips

- You can use this option along with the option `Verify initialization section of code only (-init-only-mode)` to check the initialization code before checking the remaining program.

  This approach has the following benefits compared to checking the entire code in one run:

  - Run-time errors in the initialization code can invalidate analysis of the remaining code. You can run a comparatively quicker check on the initialization code before checking the remaining program.
  - You can review results of the checker `Global variable not assigned a value in initialization code` relatively easily.

    Consider this example. There is an orange check on `var` because `var` might remain uninitialized when the `if` and `else if` statements are skipped.

    ```
    int var;
    ```

```
int checkSomething(void);
int checkSomethingElse(void);

int main() {
    int local_var;
    if(checkSomething())
    {
        var=0;
    }
    else if(checkSomethingElse()) {
        var=1;
    }
    #pragma polyspace_end_of_init
    var=2;
    local_var = var;
    return 0;
}
```

To review this check and understand when x might be non-initialized, you have to browse through all instances of x on the **Variable Access** pane. If you check the initialization code alone, only the code in bold gets checked and you have to browse through only the instances in the initialization code.

- The check is only as good as your placement of the pragma polyspace_end_of_init. For instance:

  - Place the pragma only after initialization code ends.

    Otherwise, a variable might appear falsely uninitialized.
  - Try to place the pragma directly in the main function, that is, outside a block. If you place the pragma in a block, the check considers only those paths that end in the block.

    All paths that end in the block might have a variable initialized but paths that skip the block might let the variable go uninitialized. If you do place the pragma in a block, make sure that it is okay if a variable stays uninitialized outside the block.

    For instance, in this example, the variable var is initialized on all paths that end at the location of the pragma. The check is green despite the fact that the if block might be skipped, letting the variable go uninitialized.

```
int var;

int func();

int main() {
    int err = func();
    if(err) {
        var = 0;
 #pragma polyspace_end_of_init
    }
    int a = var;
    return 0;
}
```

The issue is detected by the checker if you place the pragma after the if block ends.

- Do not place the pragma in a loop.

  If you place the pragma in a loop, you can see results that are difficult to interpret. For instance, in this example, both `aVar` and `anotherVar` are initialized in one iteration of the loop. However, the pragma only considers the first iteration of the loop when it shows a green check for initialization. If a variable is initialized on a later iteration, the check is orange.

  ```
  int aVar;
  int anotherVar;

  void main() {
      for(int i=0; i<=1; i++) {
          if(i == 0)
              aVar = 0;
          else
              anotherVar = 0;
          #pragma polyspace_end_of_init
      }
  }
  ```

  The check is red if you verify initialization code alone and do not initialize a variable in the first loop iteration. To avoid these incorrect red or orange checks, do not place the pragma in a loop.
- To determine the initialization of a structure, a regular Code Prover analysis only considers fields that are used.

  If you check initialization code only using the option `Verify initialization section of code only (-init-only-mode)`, the analysis covers only a portion of the code and cannot determine if a variable is used beyond this portion. Therefore, the checks for initialization consider all structure fields, whether used or not.

## Command-Line Information

**Parameter:** `-check-globals-init`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-check-globals-init`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-check-globals-init`

# Version History

**Introduced in R2020a**

“Code Prover Assumptions About Global Variable Initialization” (Polyspace Code Prover)

# NaNs (-check-nan)

Specify how to handle floating-point operations that result in NaN

## Description

*This option affects a Code Prover analysis only.*

Specify how the analysis must handle floating-point operations that result in NaN.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node. See “Dependencies” on page 2-277 for other options you must also enable.

**Command line and options file**: Use the option `-check-nan`. See “Command-Line Information” on page 2-277.

### Why Use This Option

Use this option to enable detection of floating-point operations that result in NaN-s.

If you specify that the analysis must consider nonfinite floats, by default, the analysis does not flag these operations. Use this option to detect these operations while still incorporating nonfinite floats.

## Settings

**Default:** `allow`

`allow`

The verification does not produce a check on the operation.

For instance, in the following code, there is no **Invalid operation on floats** check.

```
double func(void) {
    double x=1.0/0.0;
    double y=x-x;
    return y;
}
```

`warn-first`

The verification produces a check on the operation. The check determines if the result of the operation is NaN when the operands themselves are not NaN. For instance, the check flags the operation `val1 + val2` only if the result can be NaN when *both* `val1` and `val2` are not NaN. The verification does not terminate the execution thread that produces NaN.

If the verification detects an operation that produces NaN as the only possible result on all execution paths and the operands themselves are never NaN, the check is red. If the operation can potentially result in NaN, the check is orange.

For instance, in the following code, there is a nonblocking **Invalid operation on floats** check for NaN.

```
double func(void) {
    double x=1.0/0.0;
    double y=x-x;
    return y;
}
```

Even though the **Invalid operation on floats** check on the `-` operation is red, the verification continues. For instance, a green **Non-initialized local variable** check appears on `y` in the `return` statement.

`forbid`

The verification produces a check on the operation and terminates the execution thread that produces NaN.

If the check is red, the verification does not continue for the remaining code in the same scope as the check. If the check is orange, the verification continues but removes from consideration the variable values that produced a NaN.

For instance, in the following code, there is a blocking **Invalid operation on floats** check for NaN.

```
double func(void) {
    double x=1.0/0.0;
    double y=x-x;
    return y;
}
```

The verification stops because the **Invalid operation on floats** check on the `-` operation is red. For instance, a **Non-initialized local variable** check does not appear on `y` in the `return` statement.

The **Invalid operation on floats** check for NaN also appears on the `/` operation and is green.

## Dependencies

To use this option, you must enable the verification mode that incorporates infinities and NaNs. See `Consider non finite floats (-allow-non-finite-floats)`.

## Command-Line Information

**Parameter:** `-check-nan`
**Value:** `allow | warn-first | forbid`
**Default:** `allow`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-check-nan forbid`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-check-nan forbid`

# Enable pointer arithmetic across fields (-allow-ptr-arith-on-struct)

Allow arithmetic on pointer to a structure field so that it points to another field

## Description

*This option affects a Code Prover analysis only.*

Specify that a pointer assigned to a structure field can point outside its bounds as long as it points within the structure.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node. See “Dependency” on page 2-280 for other options you must also enable.

**Command line and options file**: Use the option `-allow-ptr-arith-on-struct`. See “Command-Line Information” on page 2-280.

### Why Use This Option

Use this option to relax the check for illegally dereferenced pointers. Once you assign a pointer to a structure field, you can perform pointer arithmetic and use the result to access another structure field.

## Settings

☑ On

A pointer assigned to a structure field can point outside the bounds imposed by the field as long as it points within the structure. For instance, in the following code, unless you use this option, the verification will produce a red `Illegally dereferenced pointer` check:

```
void main(void) {
struct S {char a; char b; int c;} x;
char *ptr = &x.b;
ptr ++;
*ptr = 1; // Red on the dereference, because ptr points outside x.b
}
```

☐ Off (default)

A pointer assigned to a structure field can point only within the bounds imposed by the field.

## Tips

- The verification does not allow a pointer with negative offset values. This behavior occurs irrespective of whether you choose the option **Enable pointer arithmetic across fields**.
- Using this option can slightly increase the number of orange checks. The option relaxes the constraint that a pointer to a structure field cannot point to other fields of the structure. In

exchange for relaxing this constraint, the verification loses precision on the boundary of fields within a structure and treats the structure as a whole. Pointer dereferences that were previously green can now turn orange.

Use this option if you follow a policy of reviewing red checks only and you need to work around red checks from pointer arithmetic within a structure.

- Before using this option, consider the costs of using pointer arithmetic across different fields of a structure.

  Unlike an array, members of a structure can have different data types. For efficient storage, structures use padding to accommodate this difference. When you increment a pointer pointing to a structure member, you might not point to the next member. When you dereference this pointer, you cannot rely on what you are reading or writing to.

## Dependency

This option is available only if you set `Source code language (-lang)` to `C`.

## Command-Line Information

**Parameter:** `-allow-ptr-arith-on-struct`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-allow-ptr-arith-on-struct`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-allow-ptr-arith-on-struct`

# Detect stack pointer dereference outside scope (`-detect-pointer-escape`)

Find cases where a function returns a pointer to one of its local variables

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must detect cases where you access a variable outside its scope via dangling pointers. Such an access can happen, for example, when a function returns a pointer to a local variable and you dereference the pointer outside the function. The dereference causes undefined behavior because the local variable that the pointer points to does not live outside the function.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-detect-pointer-escape`. See “Command-Line Information” on page 2-282.

### Why Use This Option

Use this option to enable detection of pointer escape.

## Settings

☑ On

The **Illegally dereferenced pointer** check performs an additional task, besides its usual specifications. When you dereference a pointer, the check also determines if you are accessing a variable outside its scope through the pointer. The check is:

- Red, if all the variables that the pointer points to are accessed outside their scope.

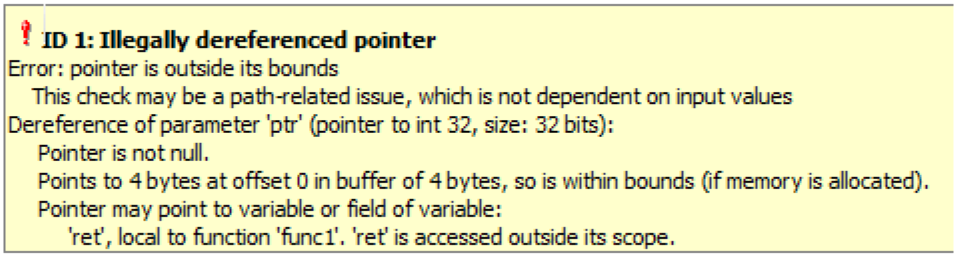
  For instance, you dereference a pointer `ptr` in a function `func` that is called twice in your code. In both calls, when you perform the dereference `*ptr`, `ptr` is pointing to variables outside their scope. Therefore, the **Illegally dereferenced pointer** check is red.
- Orange, if only some of the variables that the pointer points to are accessed outside their scope.
- Green, if none of the variables that the pointer points to are accessed outside their scope, and other requirements of the check are also satisfied.

In the following code, if you enable this option, Polyspace Code Prover produces a red **Illegally dereferenced pointer** check on `*ptr`. Otherwise, the **Illegally dereferenced pointer** check on `*ptr` is green.

```
void func2(int *ptr) {
    *ptr = 0;
}

int* func1(void) {
    int ret = 0;
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

The **Result Details** pane displays a message indicating that `ret` is accessed outside its scope.



**ID 1: Illegally dereferenced pointer**

Error: pointer is outside its bounds

 This check may be a path-related issue, which is not dependent on input values

Dereference of parameter 'ptr' (pointer to int 32, size: 32 bits):

 Pointer is not null.

 Points to 4 bytes at offset 0 in buffer of 4 bytes, so is within bounds (if memory is allocated).

 Pointer may point to variable or field of variable:

  'ret', local to function 'func1'. 'ret' is accessed outside its scope.

□ Off (default)

When you dereference a pointer, the **Illegally dereferenced pointer** check does not check for whether you are accessing a variable outside its scope. The check is green even if the pointer dereference is outside the variable scope, as long as it satisfies these requirements:

- The pointer is not NULL.
- The pointer points within the memory buffer.

## Tips

The detection of stack pointer deference outside scope does not apply to certain types of pointers. For specific limitations, see “Limitations of Polyspace Verification” (Polyspace Code Prover).

## Command-Line Information

**Parameter**: `-detect-pointer-escape`
**Default**: Off

### Topics

“Specify Polyspace Analysis Options”

"Modify or Disable Code Prover Run-Time Checks" (Polyspace Code Prover)

# Disable checks for non-initialization (`-disable-initialization-checks`)

Disable checks for non-initialized variables and pointers

## Description

*This option affects a Code Prover analysis only.*

Specify that Polyspace Code Prover must not check for non-initialization in your code.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-disable-initialization-checks`. See "Command-Line Information" on page 2-285.

### Why Use This Option

Use this option if you do not want to detect instances of non-initialized variables.

## Settings

☑ On

Polyspace Code Prover does not perform the following checks:

- `Non-initialized local variable`: Local variable is not initialized before being read.
- `Non-initialized variable`: Variable other than local variable is not initialized before being read.
- `Non-initialized pointer`: Pointer is not initialized before being read.
- `Return value not initialized`: C function does not return value when expected.

Polyspace assumes that, at declaration:

- Variables have full-range of values allowed by their type.
- Pointers can be `NULL`-valued or point to a memory block at an unknown offset.

□ Off (default)

Polyspace Code Prover checks for non-initialization in your code. The software displays red checks if, for instance, a variable is not initialized and orange checks if a variable is initialized only on some execution paths.

## Tips

- If you select this option, the software does not report most violations of MISRA C:2004 rule 9.1, and `MISRA C:2012 Rule 9.1`.

- If you select this option, the number and type of orange checks in your code can change.

  For instance, the following table shows an additional orange check with the option enabled.

| Checks for Non-initialization Enabled | Checks for Non-initialization Disabled |
|---|---|
| `void func(int flag) {`<br>`    int var1,var2;`<br>`    if( flag==0) {`<br>`        var1=var2;`<br>`    }`<br>`    else {`<br>`        var1=0;`<br>`    }`<br>`    var2=var1 + 1;`<br>`}`<br>In this example, the software produces:<br>• A red **Non-initialized local variable** check on `var2` in the `if` branch. The verification continues as if only the `else` branch of the `if` statement exists.<br>• A green **Non-initialized local variable** check on `var1` in the last statement. `var1` has the assigned value 0.<br>• A green **Overflow** check on the `+` operation. | `void func(int flag) {`<br>`    int var1,var2;`<br>`    if( flag==0) {`<br>`        var1=var2;`<br>`    }`<br>`    else {`<br>`        var1=0;`<br>`    }`<br>`    var2=var1 + 1;`<br>`}`<br>In this example, the software:<br>• Does not produce **Non-initialized local variable** checks. At initialization, the software assumes that `var2` has full range of `int` values. Following the `if` statement, because the software considers both `if` branches, it assumes that `var1` also has full range of `int` values.<br>• Produces an orange **Overflow** check on the `+` operation. For instance, if `var1` has the maximum `int` value, adding 1 to it can cause an overflow. |

## Command-Line Information

**Parameter:** `-disable-initialization-checks`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-disable-initialization-checks`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-disable-initialization-checks`

"Specify Polyspace Analysis Options"
"Modify or Disable Code Prover Run-Time Checks" (Polyspace Code Prover)

# Permissive function pointer calls (`-permissive-function-pointer`)

Allow type mismatch between function pointers and the functions they point to

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must allow function pointer calls where the type of the function pointer does not match the type of the function.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node. See “Dependency” on page 2-288 for other options you must also enable.

**Command line and options file**: Use the option `-permissive-function-pointer`. See “Command-Line Information” on page 2-288.

### Why Use This Option

By default, Code Prover does not recognize calls through function pointers when a type mismatch occurs. Fix the type mismatch whenever possible.

Use this option if:

- You cannot fix the type mismatch, and
- The analysis does not cover a significant portion of your code because calls via function pointers are not recognized.

With sources that use function pointers extensively, enabling this option can cause loss in performance. This loss occurs because the verification has to consider more complex call graphs and more execution paths. In rare cases, the verification can run out of memory.

## Settings

☑ On

The verification must allow function pointer calls where the type of the function pointer does not match the type of the function. For instance, a function declared as `int f(int*)` can be called by a function pointer declared as `int (*fptr)(void*)`.

Only type mismatches between pointer types are allowed. Type mismatches between nonpointer types cause compilation errors. For instance, a function declared as `int f(int)` cannot be called by a function pointer declared as `int (*fptr)(double)`.

□ Off (default)

The verification must require that the argument and return types of a function pointer and the function it calls are identical.

Type mismatches are detected with the check Correctness condition.

## Tips

- Using this option can increase the number of orange checks. Some of these orange checks can reveal a real issue with the code.

  Consider these examples where a type mismatch occurs between the function pointer type and the function that it points to:

  - In this example, the function pointer obj_fptr has an argument that is a pointer to a three-element array. However, it points to a function whose corresponding argument is a pointer to a four-element array. In the body of foo, four array elements are read and incremented. The fourth element does not exist and the ++ operation reads a meaningless value.

```
typedef int array_three_elements[3];
typedef void (*fptr)(array_three_elements*);

typedef int array_four_elements[4];
void foo(array_four_elements*);

void main() {
 array_three_elements arr[3] = {0,0,0};
 array_three_elements *ptr;
 fptr obj_fptr;

 ptr = &arr;
 obj_fptr = &foo;

 //Call via function pointer
 obj_fptr(&ptr);
}

void foo(array_four_elements* x) {
    int i = 0;
    int *current_pos;

    for(i = 0; i< 4; i++) {
      current_pos = (*x) + i;
      (*current_pos)++;
    }
}
```

    Without this option, an orange Correctness condition check appears on the call obj_fptr(&ptr) and the function foo is not verified. If you use this option, the body of foo contains several orange checks. Review the checks carefully and make sure that the type mismatch does not cause issues.

  - In this example, the function pointer has an argument that is a pointer to a structure with three float members. However, the corresponding function argument is a pointer to an unrelated structure with one array member. In the function body, the strlen function is used assuming the array member. Instead the strlen call reads the float members and can read meaningless values, for instance, values stored in the structure padding.

```
#include <string.h>
struct point {
  float x;
  float y;
  float z;
};
struct message {
  char msg[10] ;
};
void foo(struct message*);

void main() {
  struct point pt = {3.14, 2048.0, -1.0} ;
  void (*obj_fptr)(struct point *) ;

  obj_fptr = &foo;

  //Call via function pointer
  obj_fptr(&pt);
}

void foo(struct message* x) {
  int y = strlen(x->msg) ;
}
```

Without this option, an orange check appears on the call `obj_fptr(&pt)` and the function `foo` is not verified. If you use this option, the function contains an orange check on the `strlen` call. Review the check carefully and make sure that the type mismatch does not cause issues.

## Dependency

This option is available only if you set `Source code language (-lang)` to `C`.

## Command-Line Information

**Parameter:** `-permissive-function-pointer`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-lang c -permissive-function-pointer`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-lang c -permissive-function-pointer`

## See Also

`Correctness condition`

# Overflow mode for signed integer (`-signed-integer-overflows`)

Specify whether result of overflow is wrapped around or truncated

## Description

*This option affects a Code Prover analysis only.*

Specify whether Polyspace flags signed integer overflows and whether the analysis wraps the result of an overflow or restricts it to its extremum value.

### Set Option

**User interface** (desktop products only): In the **Configuration** pane, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-signed-integer-overflows`. See “Command-Line Information” (Polyspace Code Prover).

### Why Use This Option

Use this option to specify whether to check for signed integer overflows and to specify the assumptions the analysis makes following an overflow.

## Settings

**Default:** `forbid`

`forbid`

Polyspace flags signed integer overflows. If the **Overflow** check on an operation is:

- Red, Polyspace does not analyze the remaining code in the current scope.
- Orange, Polyspace analyzes the remaining code in the current scope. Polyspace considers that:
  - After a positive **Overflow**, the result of the operation has an upper bound. This upper bound is the maximum value allowed by the type of the result.
  - After a negative **Overflow**, the result of the operation has a lower bound. This lower bound is the minimum value allowed by the type of the result.

This behavior conforms to the ANSI C (ISO C++) standard.

In the following code, `j` has values in the range `[1..`$2^{31}$`-1]` before the orange overflow. Polyspace considers that `j` has even values in the range `[2 .. 2147483646]` after the overflow. Polyspace does not analyze the `printf()` statement after the red overflow.

```
#include<stdio.h>

int getVal();

void func1()
{
    int i = 1;
    i = i << 30;
    // Result of * operation overflows
    i = i * 2;
    // Remaing code in current scope not analyzed
    printf("%d", i);
}
void func2()
{

    int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^31-1]
        // Result of * operation may overflow
        j = j * 2;
        // Range of j: even values in [2 .. 2147483646]
        printf("%d", j);
    }
}
```

Note that tooltips on operations with signed integers show `(result is truncated)` to indicate the analysis mode. The message appears even if the **Overflow** check is green.

`allow`

Polyspace does not flag signed integer overflows. If an operation results in an overflow, Polyspace analyzes the remaining code but wraps the result of the overflow.

In this code, the analysis does not flag any overflow in the code. However, the range of `j` wraps around to even values in the range $[-2^{31}..2]$ or $[2..2^{31}-2]$ and the value of `i` wraps around to $-2^{31}$.

```
#include<stdio.h>

int getVal();

void func1()
{
    int i = 1;
    i = i << 30;
    // i = 2^30
    i = i * 2;
    // i = -2^31
    printf("%d", i);
}
void func2()
{

    int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^31-1]
        j = j * 2;
        // Range of j: even values in [-2^31..2] or [2..2^31-2]
        printf("%d", j);
    }
}
```

Note that tooltips on operations with signed integers show `(result is wrapped)` to indicate the analysis mode. The message appears even if the analysis in this mode does not flag signed integer overflows.

`warn-with-wrap-around`

Polyspace flags signed integer overflows. If an operation results in an overflow, Polyspace analyzes the remaining code but wraps the result of the overflow.

In the following code, `j` has values in the range `[1..`$2^{31}$`-1]` before the orange overflow. Polyspace considers that `j` has even values in the range `[-`$2^{31}$`..2] or [2..`$2^{31}$`-2]` after the overflow.

Similarly, `i` has value $2^{30}$ before the red overflow and value $-2^{31}$ after it .

```
#include<stdio.h>

int getVal();

void func1()
{
    int i = 1;
    i = i << 30;
    // i = 2^30
    // Result of * operation overflows
    i = i * 2;
    // i = -2^31
    printf("%d", i);
}
void func2()
{

    int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^31-1]
        // Result of * operation may overflow
        j = j * 2;
        // Range of j: even values in [-2^31..2] or [2..2^31-2]
        printf("%d", j);
    }
}
```

Note that tooltips on operations with signed integers show `(result is wrapped)` to indicate the analysis mode. The message appears even if the **Overflow** check is green.

In wrap-around mode, an overflowing value propagates and can lead to a similar overflow several lines later. By default, Code Prover shows only the first of similar overflows. To see all overflows, use the option `-show-similar-overflows`.

## Tips

- To check for overflows on conversions from unsigned to signed integers of the same size, set **Overflow mode for unsigned integer** to `forbid` or `warn-with-wrap-around`. If you allow unsigned integer overflows, Polyspace does not flag overflows on conversions and wraps the result of an overflow, even if you check for signed integer overflows.
- In Polyspace Code Prover, overflowing signed constants are wrapped around. This behavior cannot be changed by using the options. If you want to detect overflows with signed constants, use the Polyspace Bug Finder checker `Integer constant overflow`.

## Command-Line Information

**Parameter:** `-signed-integer-overflows`
**Value:** `forbid | allow | warn-with-wrap-around`
**Default:** `forbid`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-signed-integer-overflows allow`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-signed-integer-overflows allow`

## Version History

**Introduced in R2018b**

### Topics

“Specify Polyspace Analysis Options”
“Modify or Disable Code Prover Run-Time Checks” (Polyspace Code Prover)

# Overflow mode for unsigned integer (`-unsigned-integer-overflows`)

Specify whether result of overflow is wrapped around or truncated

## Description

*This option affects a Code Prover analysis only.*

Specify whether Polyspace flags unsigned integer overflows and whether the analysis wraps the result of an overflow or restricts it to its extremum value.

### Set Option

**User interface** (desktop products only): In the **Configuration** pane, the option is on the **Check Behavior** node under **Code Prover Verification**.

**Command line and options file**: Use the option `-unsigned-integer-overflows`. See “Command-Line Information” (Polyspace Code Prover).

### Why Use This Option

Use this option to specify how Polyspace Code Prover reacts to unsigned integer overflows. You can choose to flag an unsigned integer overflow and treat the code following this issue as compromised. Alternatively, you might choose to allow unsigned integer overflows. Depending on the value of this option, Polyspace makes different assumptions when analyzing the code that comes after an unsigned overflow.

## Settings

**Default:** `allow`

`forbid`

Polyspace flags unsigned integer overflows. If the **Overflow** check on an operation is:

- Red, Polyspace does not analyze the remaining code in the current scope.
- Orange, Polyspace analyzes the remaining code in the current scope. Polyspace considers that:
  - After a positive **Overflow**, the result of the operation has an upper bound. This upper bound is the maximum value allowed by the type of the result.
  - After a negative **Overflow**, the result of the operation has a lower bound. This lower bound is the minimum value allowed by the type of the result.

In the following code, `j` has values in the range `[1..`$2^{32}$`-1]` before the orange overflow. Polyspace considers that `j` has even values in the range `[2 .. 4294967294]` after the overflow. Polyspace does not analyze the `printf()` statement after the red overflow.

```
#include<stdio.h>

unsigned int getVal();

void func1()
{
    unsigned int i = 1;
    i = i << 31;
    // Result of * operation overflows
    i = i * 2;
    // Remaing code in current scope not analyzed
    printf("%u", i);
}
void func2()
{

    unsigned int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^32-1]
        // Result of * operation may overflow
        j = j * 2;
        // Range of j: even values in [2 .. 4294967294]
        printf("%u", j);
    }
}
```

Note that tooltips on operations with unsigned integers show `(result is truncated)` to indicate the analysis mode. The message appears even if the **Overflow** check is green.

`allow`

Polyspace does not flag unsigned integer overflows. If an operation results in an overflow, Polyspace analyzes the remaining code but wraps the result of the overflow. For instance, `MAX_INT + 1` wraps to `MIN_INT`. This behavior conforms to the ANSI C (ISO C++) standard.

In this code, the analysis does not flag any overflow in the code. However, the range of `j` wraps around to even values in the range $[0..2^{32}-2]]$ and the value of `i` wraps around to `0`.

```
#include<stdio.h>

unsigned int getVal();

void func1()
{
    unsigned int i = 1;
    i = i << 31;
    // i = 2^31
    i = i * 2;
    // i = 0
    printf("%u", i);
}
void func2()
{

    unsigned int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^32-1]
        j = j * 2;
        // Range of j: even values in [0 .. 4294967294]
        printf("%u", j);
    }
}
```

Note that tooltips on operations with unsigned integers show `(result is wrapped)` to indicate the analysis mode. The message appears even if the analysis does not flag unsigned integer overflows.

`warn-with-wrap-around`

Polyspace flags unsigned integer overflows. If an operation results in an overflow, Polyspace analyzes the remaining code but wraps the result of the overflow. For instance, `INT_MAX + 1` wraps to `0`.

In the following code, `j` has values in the range [1..$2^{32}$-1] before the orange overflow. Polyspace considers that `j` has even values in the range `[0 .. 4294967294]` after the overflow.

Similarly, `i` has value $2^{31}$ before the red overflow and value `0` after it.

```
#include<stdio.h>

unsigned int getVal();

void func1()
{
    unsigned int i = 1;
    i = i << 31;
    // i = 2^31
    i = i * 2;
    // i = 0
    printf("%u", i);
}
void func2()
{

    unsigned int j = getVal();
    if (j > 0) {
        // Range of j: [1..2^32-1]
        j = j * 2;
        // Range of j: even values in [0 .. 4294967294]
        printf("%u", j);
    }
}
```

Note that tooltips on operations with unsigned integers show `(result is wrapped)` to indicate the analysis mode. The message appears even if the **Overflow** check is green.

In wrap-around mode, an overflowing value propagates and can lead to a similar overflow several lines later. By default, Code Prover shows only the first of similar overflows. To see all overflows, use the option `-show-similar-overflows`.

## Tips

- To check for overflows on conversions from unsigned to signed integers of the same size, set **Overflow mode for unsigned integer** to `forbid` or `warn-with-wrap-around`. If you allow unsigned integer overflows, Polyspace does not flag overflows on conversions and wraps the result of an overflow, even if you check for signed integer overflows.
- In Polyspace Code Prover, overflowing unsigned constants are wrapped around. This behavior cannot be changed by using the options. If you want to detect overflows with unsigned constants, use the Polyspace Bug Finder checker `Unsigned integer constant overflow`.
- Code Prover does not show an overflow on bitwise operations on unsigned variables or `sbit`-s, for instance, in this example:

  ```
  volatile unsigned char Y;
  Y = ~Y;
  ```

  The verification considers that such bitwise operations are deliberate on your part and you intend an automatic wrap-around in case the result of the operation overflows.

## Command-Line Information

**Parameter:** `-unsigned-integer-overflows`
**Value:** `forbid` | `allow` | `warn-with-wrap-around`

**Default:** `allow`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-unsigned-integer-overflows allow`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-unsigned-integer-overflows allow`

## Version History

**Introduced in R2018b**

### Topics

"Specify Polyspace Analysis Options"
"Modify or Disable Code Prover Run-Time Checks" (Polyspace Code Prover)

# Allow incomplete or partial allocation of structures (-size-in-bytes)

Allow a pointer with insufficient memory buffer to point to a structure

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must allow dereferencing a pointer that points to a structure but has a sufficient buffer for only some of the structure's fields.

This type of pointer results when a pointer to a smaller structure is cast to a pointer to a larger structure. The pointer resulting from the cast has sufficient buffer for only some fields of the larger structure.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-size-in-bytes`. See "Command-Line Information" on page 2-300.

### Why Use This Option

Use this option to relax the check for illegally dereferenced pointers. You can point to a structure even when the buffer allowed for the pointer is not sufficient for all the structure fields.

## Settings

☑ On

When a pointer with insufficient buffer is dereferenced, Polyspace does not produce an **Illegally dereferenced pointer** error, as long as the dereference occurs within allowed buffer.

For instance, in the following code, the pointer `p` has sufficient buffer for the first two fields of the structure `BIG`. Therefore, with the option on, Polyspace considers that the first two dereferences are valid. The third dereference takes `p` outside its allowed buffer. Therefore, Polyspace produces an **Illegally dereferenced pointer** error on the third dereference.

```
#include <stdlib.h>

typedef struct _little { int a; int b; } LITTLE;
typedef struct _big { int a; int b; int c; } BIG;

void main(void) {
   BIG *p = malloc(sizeof(LITTLE));

   if (p!= ((void *) 0) ) {
      p->a = 0 ;
```

```
          p->b = 0 ;
          p->c = 0 ;   // Red IDP check
         }
    }
```

□ Off (default)

Polyspace does not allow dereferencing a pointer to a structure if the pointer does not have sufficient buffer for all fields of the structure. It produces an **Illegally dereferenced pointer** error the first time you dereference the pointer.

For instance, in the following code, even though the pointer `p` has sufficient buffer for the first two fields of the structure `BIG`, Polyspace considers that dereferencing `p` is invalid.

```
#include <stdlib.h>

typedef struct _little { int a; int b; } LITTLE;
typedef struct _big { int a; int b; int c; } BIG;

void main(void) {
   BIG *p = malloc(sizeof(LITTLE));

   if (p!= ((void *) 0) ) {
      p->a = 0 ;   // Red IDP check
      p->b = 0 ;
      p->c = 0 ;
   }
}
```

## Tips

- If you do not turn on this option, you cannot point to the field of a partially allocated structure.

  For instance, in the preceding example, if you do not turn on the option and perform the assignment

  ```
  int *ptr = &(p->a);
  ```

  Polyspace considers that the assignment is invalid. If you dereference `ptr`, it produces an **Illegally dereferenced pointer** error.
- Using this option can slightly increase the number of orange checks.

## Command-Line Information

**Parameter:** `-size-in-bytes`
**Default**: Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-size-in-bytes`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-size-in-bytes`

# Subnormal detection mode (`-check-subnormal`)

Detect operations that result in subnormal floating-point values

## Description

*This option affects a Code Prover analysis only.*

Specify that the verification must check floating-point operations for subnormal results.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option `-check-subnormal`. See “Command-Line Information” on page 2-304.

### Why Use This Option

Use this option to detect floating-point operations that result in subnormal values.

Subnormal numbers have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the significand. The presence of subnormal numbers indicates loss of significant digits. This loss can accumulate over subsequent operations and eventually result in unexpected values. Subnormal numbers can also slow down the execution on targets without hardware support.

## Settings

**Default:** `allow`

`allow`

The verification does not check operations for subnormal results.

`forbid`

The verification checks for subnormal results.

The verification stops the execution path with the subnormal result and prevents subnormal values from propagating further. Therefore, in practice, you see only the first occurrence of the subnormal value.

`warn-all`

The verification checks for subnormal results and highlights all occurrences of subnormal values. Even if a subnormal result comes from previous subnormal values, the result is highlighted.

The verification continues even if the check is red.

`warn-first`

The verification checks for subnormal results but only highlights first occurrences of subnormal values. If a subnormal value propagates to further subnormal results, those subsequent results are not highlighted.

The verification continues even if the check is red.

For details of the result colors in each mode, see `Subnormal float`.

## Tips

- If you want to see only those operations where a subnormal value originates from non-subnormal operands, use the `warn-first` mode.

  For instance, in the following code, `arg1` and `arg2` are unknown. The verification assumes that they can take all values allowed for the type `double`. This assumption can lead to subnormal results from certain operations. If you use the `warn-first` mode, the first operation causing the subnormal result is highlighted.

| **warn-all** | **warn-first** |
|---|---|
| `void func (double arg1, double arg2)`<br>`{`<br>`      double difference1 = arg1 - arg2;`<br>`      double difference2 = arg1 - arg2;`<br>`      double val1 = difference1 * 2;`<br>`      double val2 = difference2 * 2;`<br>`}`<br>In this example, all four operations can have subnormal results. The four checks for subnormal results are orange. | `void func (double arg1, double arg2)`<br>`{`<br>`      double difference1 = arg1 - arg2;`<br>`      double difference2 = arg1 - arg2;`<br>`      double val1 = difference1 * 2;`<br>`      double val2 = difference2 * 2;`<br>`}`<br>In this example, `difference1` and `difference2` can be subnormal if `arg1` and `arg2` are sufficiently close. The first two checks for subnormal results are orange. `val1` and `val2` cannot be subnormal unless `difference1` and `difference2` are subnormal. The last two checks for subnormal results are green.<br>Through red/orange checks, you see only the first instance where a subnormal value appears. You do not see red/orange checks from those subnormal values propagating to subsequent operations. |

- If you want to see where a subnormal value originates and do not want to see subnormal results arising from the same cause more than once, use the `forbid` mode.

  For instance, in the following code, `arg1` and `arg2` are unknown. The verification assumes that they can take all values allowed for the type `double`. This assumption can lead to subnormal results for `arg1-arg2`. If you use the `forbid` mode and perform the operation `arg1-arg2` twice in succession, only the first operation is highlighted. The second operation is not highlighted because the subnormal result for the second operation arises from the same cause as the first operation.

| **warn-all** | **forbid** |
|---|---|
| `void func (double arg1, double arg2)`<br>`{`<br>`      double difference1 = arg1 - arg2;`<br>`      double difference2 = arg1 - arg2;`<br>`      double val1 = difference1 * 2;`<br>`      double val2 = difference2 * 2;`<br>`}`<br>In this example, all four operations can have subnormal results. The four checks for subnormal results are orange. | `void func (double arg1, double arg2)`<br>`{`<br>`      double difference1 = arg1 - arg2;`<br>`      double difference2 = arg1 - arg2;`<br>`      double val1 = difference1 * 2;`<br>`      double val2 = difference2 * 2;`<br>`}`<br>In this example, `difference1` can be subnormal if `arg1` and `arg2` are sufficiently close. The first check for subnormal results is orange. Following this check, the verification excludes from consideration:<br>• The close values of `arg1` and `arg2` that led to the subnormal value of `difference1`.<br>In the subsequent operation `arg1 - arg2`, the check is green and `difference2` is not subnormal. The result of the check on `difference2 * 2` is green for the same reason.<br>• The subnormal value of `difference1`.<br>In the subsequent operation `difference1 * 2`, the check is green. |

## Command-Line Information

**Parameter:** `-check-subnormal`
**Value:** `allow` | `warn-first` | `warn-all` | `forbid`
**Default:** `allow`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-check-subnormal forbid`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-check-subnormal forbid`

# Detect uncalled functions (-uncalled-function-checks)

Detect functions that are not called directly or indirectly from main or another entry point function

## Description

*This option affects a Code Prover analysis only.*

Detect functions that are not called directly or indirectly from main or another entry point function during run-time.

A function can be uncalled because of several reasons including the following:

- The function is actually not called.
- The call site occurs in dead code.
- The call site follows a red check. See “Code Prover Analysis Following Red and Orange Checks” (Polyspace Code Prover).
- The call occurs via a function pointer and Polyspace is unable to determine which function it points to.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** node.

**Command line and options file**: Use the option -uncalled-function-checks. See “Command-Line Information” on page 2-306.

### Why Use This Option

Typically, after verification, the **Dashboard** pane in the Polyspace user interface shows functions that are not called during verification and therefore not analyzed. However, you do not see them in your analysis results or reports. You cannot comment on them or justify them.

If you want to see these uncalled functions in your analysis results and reports, use this option.

## Settings

**Default:** none

none

The Code Prover analysis excludes checks for uncalled functions.

never-called

The Code Prover analysis checks for functions that are defined but not called.

called-from-unreachable

The Code Prover analysis checks for functions that are defined and called from an unreachable part of the code.

`all`

The Code Prover analysis checks for functions that are:

- Defined but not called
- Defined and called from an unreachable part of the code.

## Command-Line Information

**Parameter:** `-uncalled-function-checks`
**Value:** `none` | `never-called` | `called-from-unreachable` | `all`
**Default**: `none`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-uncalled-function-checks all`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-uncalled-function-checks all`

# Calculate stack usage (`-stack-usage`)

Compute and display the estimates of stack usage

## Description

*This option applies to Code Prover only.*

Specify that Polyspace must estimate and display the stack usage of your source code. The estimates include:

- `Maximum Stack Usage`
- `Minimum Stack Usage`
- `Program Maximum Stack Usage`
- `Program Minimum Stack Usage`
- `Higher Estimate of Size of Local Variables`
- `Lower Estimate of Size of Local Variables`

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Check Behavior** subnode of the **Code Prover Verification** node.

**Command line and options file**: Use the option `-stack-usage`. See “Command-Line Information” on page 2-196.

### Why Use This Option

Estimating the stack usage of your code is necessary because:

- Underestimating the stack usage of your code results in a stack overflow.
- Overestimating the stack usage results in wasted memory.

Obtain the estimated stack usage of your code by using the option `-stack-usage` to avoid a stack overflow or wasted memory. This option is especially important for safety critical applications where the available stack size must accommodate the worst-case stack usage.

## Settings

☑ On

Polyspace computes and displays stack usage metrics on the **Results List** pane.

□ Off (default)

Polyspace does not compute stack usage metrics.

## Tips

- If you want to compute only the stack usage of your code, run verification up to the `Source Compliance Checking` phase. See `Verification level (-to)`.
- A Code Prover analysis computes the stack usage metrics after the source compliance checking phase. If you stop a Code Prover verification before source compliance checking, the stack usage metrics are not reported.
- This option calculates code metrics that are related to stack usage. Use Bug Finder to calculate the other code metrics. See `Calculate code metrics (-code-metrics)`.
- Using this option together with `-code-metrics` option results in an error. The option `-code-metrics` will be removed from Code Prover in a future release. To compute the code metrics, use Bug Finder instead. See "Migrate Code Prover Workflows for Checking Coding Standards and Code Metrics to Bug Finder".
- If a function is not defined, Code Prover considers zero contribution to the stack size when this function is called. You can explicitly specify a stack size contribution from such stubbed functions using the option `-code-behavior-specifications`.

## Command-Line Information

**Parameter:** `-stack-usage`
**Default:** Off
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-stack-usage`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-stack-usage`

# Version History

**Introduced in R2022a**

# Sensitivity context (-context-sensitivity)

Store call context information to identify function call that caused errors

## Description

*This option affects a Code Prover analysis only.*

Specify the functions for which the verification must store call context information. If the function is called multiple times, using this option helps you to distinguish between the different calls.

### Set Option

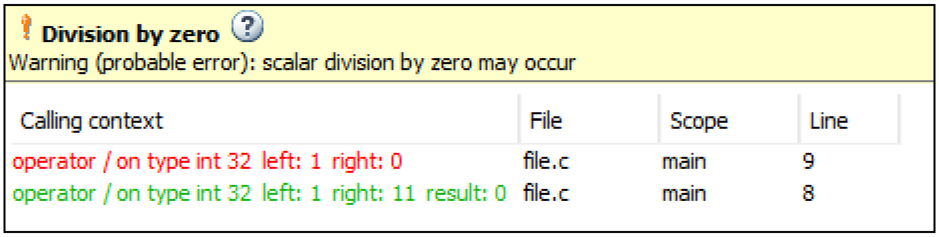
**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node.

**Command line and options file**: Use the option `-context-sensitivity`. See “Command-Line Information” (Polyspace Code Prover).

### Why Use This Option

Suppose a function is called twice in your code. The check color on each operation in the function body is a combined result of both calls. If you want to distinguish between the colors in the two calls, use this option.

For instance, if a function contains a red or orange check and a green check on the same operation for two different calls, the software combines the contexts and displays an orange check on the operation. If you use this option, the check turns dark orange and the result details show the color of the check for each call.



**Division by zero**

Warning (probable error): scalar division by zero may occur

| Calling context | File | Scope | Line |
|---|---|---|---|
| operator / on type int 32 left: 1 right: 0 | file.c | main | 9 |
| operator / on type int 32 left: 1 right: 11 result: 0 | file.c | main | 8 |

## Settings

**Default:** `none`

`none`

The software does not store call context information for functions.

`auto`

The software stores call context information for checks in:

- Functions that form the leaves of the call tree. These functions are called by other functions, but do not call functions themselves.

- Small functions. The software uses an internal threshold to determine whether a function is small.

`custom`

The software stores call context information for functions that you specify. To enter the name of a function, click ✚.

## Tips

- If you select this option, you do not see tooltips in the body of the functions that benefit from this option (and keep the call contexts separate).
- If you select this option, the analysis can show some code operations in grey (unreachable code) even when you can identify execution paths leading to the operations. In this case, the grey code indicates operations that might be unreachable only in a particular call context.

  For instance, suppose this function is called with the arguments -1 and 1 :

  ```
  int isPositive (int num) {
     if(num < 0)
        return 0;
     return 1;
  }
  ```

  If you use the option with this function as argument, there are two unreachable code checks:

  - The check on `if` is grey because when the function is called with argument -1, the `if` condition is always true.
  - The check on the code inside the `if` branch is grey because when the function is called with argument 1, the `if` condition is always false.

  Each unreachable code check indicates code that is unreachable only in a particular call context. You see the call context in the result details.

## Command-Line Information

**Parameter:** `-context-sensitivity`
**Value:** `*function1*[,*function2*,...]`
**Default:** `none`
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -context-sensitivity myFunc1,myFunc2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources *file_name* -context-sensitivity myFunc1,myFunc2`

To allow the software to determine which functions receive call context storage, use the option `-context-sensitivity-auto`.

# Improve precision of interprocedural analysis (-path-sensitivity-delta)

Avoid certain verification approximations for code with fewer lines

## Description

*This option affects a Code Prover analysis only.*

For smaller code, use this option to improve the precision of cross-functional analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node.

**Command line and options file**: Use the option `-path-sensitivity-delta`. See “Command-Line Information” on page 2-311.

### Why Use This Option

Use this option to avoid certain software approximations on execution paths. Avoiding these approximations results in fewer orange checks but a much longer verification time.

For instance, for deep function call hierarchies or nested conditional statements, to complete verification in a reasonable amount of time, the software combines many execution paths and stores less information at each stage of verification. If you use this option, the software stores more information about the execution paths, resulting in a more precise verification.

## Settings

**Default:** Off

Enter a positive integer to turn on this option.

Entering a higher value leads to a greater number of proven results, but also increases verification time exponentially. For instance, a value of 10 can result in very long verification times.

## Tips

Use this option only when you have less than 1000 lines of code.

## Command-Line Information

**Parameter:** `-path-sensitivity-delta`
**Value:** Positive integer
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-path-sensitivity-delta 1`

**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-path-sensitivity-delta 1`

## See Also

### Topics

"Specify Polyspace Analysis Options"
"Improve Verification Precision" (Polyspace Code Prover)

# Precision level (`-O0 | -O1 | -O2 | -O3`)

Specify a precision level for the verification

## Description

*This option affects a Code Prover analysis only.*

Specify the precision level that the verification must use.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node.

**Command line and options file**: Use the option `-O#`, for instance, `-O0` or `-O1`. See “Command-Line Information” on page 2-314.

### Why Use This Option

Higher precision leads to greater number of proven results but also requires more verification time. Each precision level corresponds to a different algorithm used for verification.

In most cases, you see the optimal balance between precision and verification time at level 2.

## Settings

**Default:** 2

`0`

This option corresponds to a static interval verification.

`1`

This option corresponds to a more complex static interval verification.

`2`

This option corresponds to a complex polyhedron model of domain values with additional precision for interprocedural analysis depending on the option `Improve precision of interprocedural analysis (-path-sensitivity-delta)`.

`3`

This option is only suitable for code having less than 1000 lines. Using this option, the percentage of proven results can be very high.

## Tips

- For best results in reasonable time, use the default level 2. If the verification takes a long time, reduce precision. However, the number of unproven checks can increase. Likewise, to reduce orange checks, you can improve your precision. But the verification can take significantly longer time.

- The precision levels 2 and below begin to take effect only from verification levels higher than `Software Safety Analysis level 0`. See also `Verification level (-to)`.

  For instance, to reduce analysis time, you might have reduced the verification level to `Software Safety Analysis level 0`. Do not try to reduce the precision level below 2 to lower the analysis time further.

  Note that algorithms used in precision level 3 can also apply to the verification level `Software Safety Analysis level 0`.

## Command-Line Information

**Parameter:** `-O0` | `-O1` | `-O2` | `-O3`
**Default:** `-O2`
**Example (Code Prover):** `polyspace-code-prover -sources` *file_name* `-O1`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *file_name* `-O1`

`Verification level (-to)` | `Specific precision (-modules-precision)`

### Topics

"Specify Polyspace Analysis Options"
"Improve Verification Precision" (Polyspace Code Prover)

# Specific precision (`-modules-precision`)

Specify source files you want to verify at higher precision than the remaining verification

## Description

*This option affects a Code Prover analysis only.*

Specify source files that you want to verify at a precision level higher than that for the entire verification.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node. See “Dependency” on page 2-315 for other options you must also enable.

**Command line and options file**: Use the option `-modules-precision`. See “Command-Line Information” on page 2-315.

### Why Use This Option

If a specific file is verified imprecisely leading to many orange checks in the file and elsewhere, you can improve the precision for that file.

Note that increasing precision also increases verification time.

## Settings

**Default:** All files are verified with the precision you specified using **Precision** > **Precision level**.

Click ✚ to enter the name of a file without the extension `.c` and the corresponding precision level.

## Dependency

This option is available only if you set `Source code language (-lang)` to `C` or `C-CPP`.

## Command-Line Information

**Parameter:** `-modules-precision`
**Value:** *`file`*`:O0` | *`file`*`:O1` | *`file`*`:O2` | *`file`*`:O3`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-O1 -modules-precision My_File:O2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-O1 -modules-precision My_File:O2`

"Specify Polyspace Analysis Options"
"Improve Verification Precision" (Polyspace Code Prover)

# Verification level (-to)

Specify number of times the verification process runs on your code

## Description

*This option affects a Code Prover analysis only.*

Specify the number of times the Polyspace verification process runs on your source code. Each run can lead to greater number of proven results but also requires more verification time.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node.

**Command line and options file**: Use the option `-to`. See “Command-Line Information” on page 2-318.

### Why Use This Option

There are many reasons you might want to increase or decrease the verification level. For instance, If you see many orange checks after verification, try increasing the verification level. If your analysis takes longer than expected, try decreasing the verification level.

In most cases, the optimal balance between precision and verification time is at level 2.

## Settings

**Default:** `Software Safety Analysis level 2`

`Source Compliance Checking`

Polyspace checks for compilation errors only. Most coding rule violations are found at this level.

`Software Safety Analysis level 0`

The verification process performs some simple analysis. The analysis is designed to reach completion despite complexities in the code.

If the verification gets stuck at a higher level, try running to this level and review the results.

`Software Safety Analysis level 1`

The verification process analyzes each function once with algorithms whose complexity depends on the precision level. See `Precision level (-O)`. The analysis starts from the top of the function call hierarchy (an actual or generated `main` function) and propagates to the leaves of the call hierarchy.

`Software Safety Analysis level 2`

The verification process analyzes each function twice. In the first pass, the analysis propagates from the top of the function call hierarchy to the leaves. In the second pass, the analysis propagates from the leaves back to the top. Each pass uses information gathered from the previous pass.

Use this option for most accurate results in reasonable time.

`Software Safety Analysis level 3`

The verification process runs three times on each function: from the top of the function call hierarchy to the leaves, from the leaves to the top, and from the top to the leaves again. Each pass uses information gathered from the previous pass.

`Software Safety Analysis level 4`

The verification process runs four passes on each function: from the top of the function call hierarchy to the leaves twice. Each pass uses information gathered from the previous pass.

`other`

If you use this option, Polyspace verification will make 20 passes unless you stop it manually.

## Tips

- If the verification takes too long, use a lower **Verification level**. For best results, use the option `Software Safety Analysis level 2`.
- Fix red errors and gray code before rerunning the verification with higher verification levels.
- In some cases, if the results have reached the maximum precision at an earlier level, the verification stops and does not proceed to the level that you specify. If a higher verification level fails because the verification runs out of memory, but results are available at a lower level, Polyspace displays the results from the lower level.
- Use the option `Other` sparingly since it might increase verification time by an unreasonable amount.
- When running Polyspace analyses on a remote server, the source phase takes place on your local computer. If the **Verification Level** is set to `Source Compliance Checking`, do not use `-batch` to submit jobs to a remote server from a desktop. See `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`.
- If you want to see only global variable sharing and usage, use `Show global variable sharing and usage only (-shared-variables-mode)` to run a less extensive analysis.

## Command-Line Information

**Parameter:** `-to`
**Value:** `compile` | `pass0` | `pass1` | `pass2` | `pass3` | `pass4` | `other`
**Default:** `pass2`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-to pass2`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-to pass2`

You can also use these additional values not available in the user interface:

- C projects: `c-to-il` (C to intermediate language conversion phase)
- C++ projects: `cpp-to-il` (C++ to intermediate language conversion phase), `cpp-normalize` (C ++ compilation), `cpp-link` (C++ compilation)

Use these values only if you have specific reasons to do so. For instance, to generate a blank constraints (DRS) template for C++ projects, run an analysis up to the compilation by using `cpp-link` or `cpp-normalize`.

The values `cpp-link` and `cpp-normalize` will be removed in a future release. Use `compile` instead.

## Examples

### Reduce Number of Orange Checks by Increasing Verification Level

Running a Code Prover verification at a higher verification level reduces the number of orange checkers.

Run a Code Prover verification on this code while setting the precision to `Software Safety Analysis level 0`.

```
extern int tab[];

int main() {

    int i = tab[3];
    int j = tab[1];

    if (i > j) {
        int l = i-j;
        assert(l > 0);
     }
}
```

There is an orange check in the `assert` statement.

To resolve the orange check, run the analysis at a higher precision. For instance, run another verification on the preceding code while setting the precision to `Software Safety Analysis level 1`.

```
extern int tab[];

int main() {

    int i = tab[3];
    int j = tab[1];

    if (i > j) {
        int l = i-j;
        assert(l > 0);
     }
}
```

The `assert` statement now has a green check.

"Specify Polyspace Analysis Options"
"Improve Verification Precision" (Polyspace Code Prover)

# Verification time limit (`-timeout`)

Specify a time limit on your verification

## Description

Specify a time limit for the verification in hours. If the verification does not complete within that limit, it stops.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Precision** node.

**Command line and options file**: Use the option `-timeout`. See “Command-Line Information” on page 2-320.

### Why Use This Option

Use this option to impose a time limit on the verification.

By default, if an internal step in the verification lasts for more than 24 hours, the verification stops. You can use this option to reduce the time limit even further. Note that you can have verification results despite the verification timing out. For instance, if a step in Software Safety Analysis level 1 times out, you still get the results from level 0. See `Verification level (-to)`.

The option is useful only in very specific cases. Suppose your code has certain constructs that might slow down the verification. To check this, you can impose a time limit on the verification so that the verification stops if it takes too long.

Typically, Technical Support asks you to use this option as needed.

## Settings

Enter the time in hours. For fractions of an hour, specify decimal form.

## Command-Line Information

**Parameter:** `-timeout`
**Value:** *`time`*
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-timeout 5.75`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-timeout 5.75`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-timeout 5.75`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-timeout 5.75`

“Specify Polyspace Analysis Options”

"Improve Verification Precision" (Polyspace Code Prover)

# Inline (-inline)

Specify functions that must be cloned internally for each function call

## Description

*This option affects a Polyspace Code Prover analysis only.*

Specify the functions that the verification must clone internally for each function call.

### Set Option

**User interface**, in desktop products only: In your project configuration, the `-inline` option is available on the **Scaling** node.

**Command line and options file**: Use the `-inline` option. See "Command-Line Information" on page 2-324.

### Why Use This Option

You use the `-inline` to internally clone a function for each function call. Doing so might reduce the complexity of the analysis in Polyspace Code Prover. Consider this code:

```
void foo(int* p);
void bar(){
    int* intP, intP2;
    foo(intP);
    foo(intP2)
}
```

In this code, Polyspace analyzes the functions `foo()` and `bar()`. When the option `-inline` Is not specified, the analysis keeps track of three objects: the pointers `intP`, `intP2`, and the parameter `p`. If you specify the option `-inline`, Polyspace internally clones `foo` for each function call. The code effectively becomes:

```
void foo_clone1(int* p);
void foo_clone2(int* p);
void bar(){
    int* intP, intP2;
    foo_clone1(intP);
    foo_clone2(intP2)
}
```

Analyzing the function `foo_clone1()` requires Polyspace to keep track of only two objects, `intP` and `p`, instead of three objects. The same is true for the function `foo_clone2()`. By using `-inline`, you reduce the complexity of the analysis and increase the amount of code to analyze.

Using `-inline` might reduce the complexity of your analysis while increasing the amount of code to analyze. This option might help you resolve scaling issues in specific situations. Technical Support might ask you to use this option for certain functions. Using this option changes the meaning of the colors of Polyspace Code Prover checks. See "Settings" (Polyspace Code Prover).

Avoid using this option to distinguish between the Code Prover check colors in the different calls to the same function. Instead, use the option `Sensitivity context (-context-sensitivity)`.

## Settings

**No Default**

Enter function names or choose from a list.

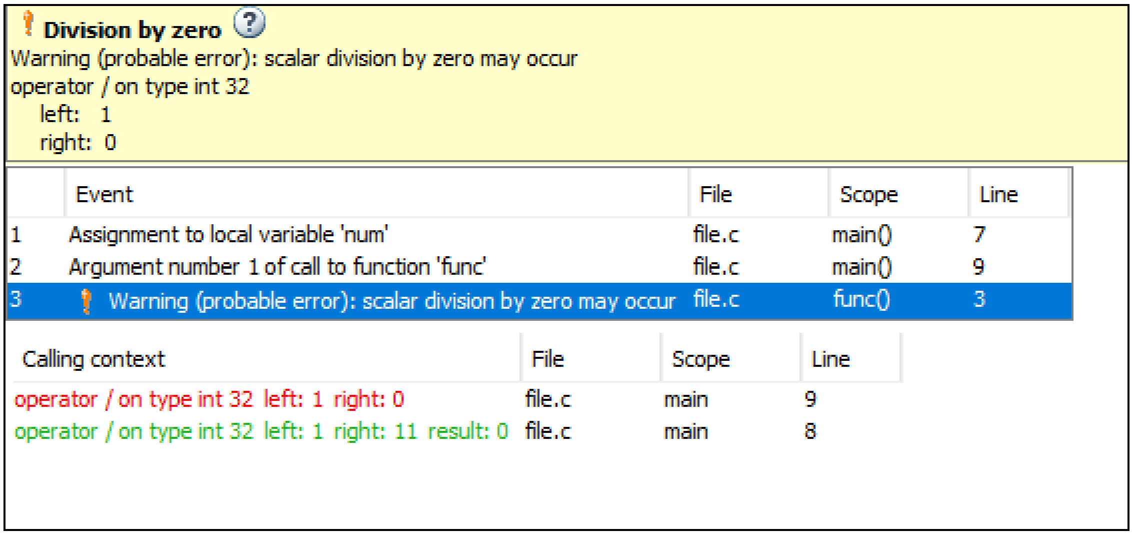
- Click ✚ to add a field and enter the function name.
- Click 🔍 to list functions in your code. Choose functions from the list.

The verification internally clones the function for each call. For instance, if you specify the function `func` for inlining and call `func` twice, the software internally creates two copies of `func` for verification.

However, for each run-time check in the function body, you see only one color in your verification results. The semantics of the check color differ from the normal specification.

| Check Type | Result color without the option `-inline` | Result color with the option `-inline` |
|---|---|---|
| Orange checks | If a function is called twice and an operation causes a definite error in one of the calls, the check color is orange. | If a function is called twice and an operation causes a definite error in one of the calls, the check color is dark orange. The check is shown with an orange exclamation mark in the results list. |
| Gray checks | If a function is called twice and an `if` statement branch is unreachable in one of the calls, the branch does not appear gray. | If a function is called twice and an `if` statement branch is unreachable in one of the calls, the branch appears gray. |

Below each check in an inlined function, you see information specific to each calling context. For instance, if an orange exclamation point appears next to **Division by zero** occurs because a specific function call leads to a definite division by zero, you can identify the call along with values resulting from that call.



**Division by zero**

Warning (probable error): scalar division by zero may occur
operator / on type int 32
left: 1
right: 0

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Assignment to local variable 'num' | file.c | main() | 7 |
| 2 | Argument number 1 of call to function 'func' | file.c | main() | 9 |
| 3 | Warning (probable error): scalar division by zero may occur | file.c | func() | 3 |

| Calling context | File | Scope | Line |
|---|---|---|---|
| operator / on type int 32 left: 1 right: 0 | file.c | main | 9 |
| operator / on type int 32 left: 1 right: 11 result: 0 | file.c | main | 8 |

Do not use this option to understand results. Use this option only if a certain function causes scaling issues.

## Tips

- Choose functions to inline based on hints provided by the alias verification.
- Do not use this option for entry point functions, including `main`.
- Using this option can increase the number of gray **Unreachable code** checks.

  For example, in the following code, if you enter `max` for **Inline**, two **Unreachable code** checks appear for each call to `max`.

  ```
  int max(int a, int b) {
    return a > b ? a : b;
  }

  void main() {
    int i=3, j=1, k;
    k=max(i,j);
    i=0;
    k=max(i,j);
  }
  ```
- If you use the keyword `inline` before a function definition, place the definition in a header file and call the function from multiple source files, the result is the same as using the option **Inline**.
- For C++ code, this option applies to all overloaded methods of a class.

## Command-Line Information

**Parameter:** `-inline`
**Value:** `*function1*[,*function2*[,...]]`
**No Default**
**Example (Code Prover):** `polyspace-code-prover -sources *file_name* -inline func1,func2`

**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-inline func1,func2`

### Topics

"Specify Polyspace Analysis Options"

# Depth of verification inside structures (`-k-limiting`)

Limit the depth of analysis for nested structures

## Description

*This option affects a Code Prover analysis only.*

Specify a limit to the depth of analysis for nested structures.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Scaling** node.

**Command line and options file**: Use the option `-k-limiting`. See “Command-Line Information” on page 2-326.

### Why Use This Option

Use this option if the analysis is slow because your code has a structure that is many levels deep.

Typically, you see a warning message when a structure with a deep hierarchy is slowing down the verification.

## Settings

**Default:** Full depth of nested structures is analyzed.

Enter a number to specify the depth of analysis for nested structures. For instance, if you specify 0, the analysis does not verify a structure inside a structure.

If you specify a number less than 2, the verification could be less precise.

## Command-Line Information

**Parameter:** `-k-limiting`
**Value:** *`positive integer`*
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-k-limiting 3`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-k-limiting 3`

## See Also

“Specify Polyspace Analysis Options”

# Generate report

Specify whether to generate a report after the analysis

## Description

Specify whether to generate a report along with analysis results.

Depending on the format you specify, you can view this report using an external software. For example, if you specify the format `PDF`, you can view the report in a `pdf` reader.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Reporting** node.

**Command line and options file**: See “Command-Line Information” on page 2-328.

### Why Use This Option

You can generate a report from your analysis results for archiving purposes. You can provide this report to your management or clients as proof of code quality.

Using other analysis options, you can tailor the report content and format for your specific needs. See `Bug Finder and Code Prover report (-report-template)` and `Output format (-report-output-format)`.

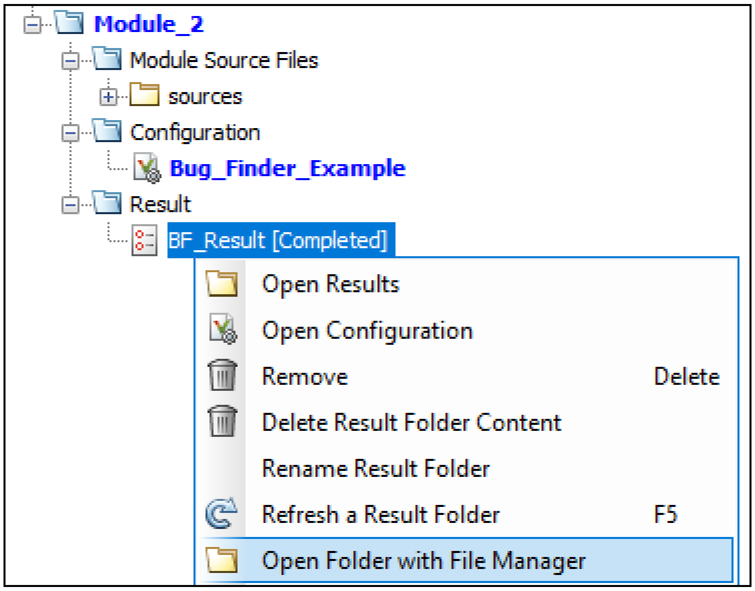
## Settings

☑ On

Polyspace generates an analysis report using the template and format you specify.

The report is stored in the `Polyspace-Doc` subfolder of your results folder.

In Polyspace desktop products, to open your results folder from the user interface, on the **Project Browser** pane, right-click the results node and select **Open Folder with File Manager**.



To change the results folder location, see “Contents of Polyspace Project and Results Folders”.

On the command-line, the results folder is the argument of the option `-results-dir`.

□ Off (default)

Polyspace does not generate an analysis report. You can still view your results in the Polyspace interface.

## Tips

This option allows you to specify report generation before starting an analysis.

To generate a report *after* an analysis is complete, in the user interface of the Polyspace desktop products, select **Reporting** > **Run Report**. Alternatively, at the command line, use the `polyspace-report-generator` command.

After analysis, you can also export the result as a text file for further customization. Use the option `-generate-results-list-file` with the `polyspace-report-generator` command.

## Command-Line Information

There is no command-line option to solely turn on the report generator. However, using the options `-report-template` for template and `-report-output-format` for output format automatically turns on the report generator.

### Topics

“Specify Polyspace Analysis Options”
“Generate Reports from Polyspace Results”

# Bug Finder and Code Prover report (`-report-template`)

Specify template for generating analysis report

## Description

Specify template for generating analysis report.

`.rpt` files for the report templates are available in *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\`. Here, *`polyspaceroot`* is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2023a`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Reporting** node. You have separate options for Bug Finder and Code Prover analysis. See “Dependencies” on page 2-334 for other options you must also enable.

**Command line and options file**: Use the option `-report-template`. See “Command-Line Information” on page 2-335.

### Why Use This Option

Depending on the template that you use, the report contains information about certain types of results from the **Results List** pane. The template also determines what information is presented in the report and how the information is organized. See the template descriptions below.

## Settings – Bug Finder

**Default:** `BugFinderSummary`

`BugFinder`

The report lists:

- **Polyspace Bug Finder Summary**: Number of results in the project. The results are summarized by file. The files that are partially analyzed because of compilation errors are listed in a separate table.
- **Code Metrics**: Summary of the various code complexity metrics. For more information, see “Code Metrics”.
- **Coding Rules**: Coding rule violations in the source code. For each rule violation, the report lists the:
  - Rule number and description.
  - Function containing the rule violation.
  - Review information, such as **Severity**, **Status** and comments.
- **Defects**: Defects found in the source code. For each defect, the report lists the:

  - Function containing the defect.
  - Defect information on the **Result Details** pane.
  - Review information, such as **Severity**, **Status** and comments.
- **Configuration Settings**: List of analysis options that Polyspace uses for analysis. If you configured your project for multitasking, this section also lists the **Concurrency Modeling Summary**. If your project has source files with compilation errors, these files are also listed.

  If you check for coding rules, an additional **Coding Rules Configuration** section states the rules along with the information whether they were enabled or disabled.

`BugFinderSummary`

The report lists:

- **Polyspace Bug Finder Summary**: Number of results in the project. The results are summarized by file. The files that are partially analyzed because of compilation errors are listed in a separate table.
- **Code Metrics**: Summary of the various code complexity metrics. For more information, see “Code Metrics”.
- **Coding Rules Summary**: Coding rules along with number of violations.
- **Defect Summary**: Defects that Polyspace Bug Finder looks for. For each defect, the report lists the:
  - Defect group.
  - Defect name.
  - Number of instances of the defect found in the source code.
- **Configuration Settings**: List of analysis options that Polyspace uses for analysis. If you configured your project for multitasking, this section also lists the **Concurrency Modeling Summary**. For more information, see “Complete List of Polyspace Bug Finder Analysis Engine Options”. If your project has source files with compilation errors, these files are also listed.

  If you check for coding rules, an additional **Coding Rules Configuration** section states the rules along with the information whether they were enabled or disabled.

`CodeMetrics`

The report lists the following:

- **Code Metrics Summary**: Various quantities related to the source code. For more information, see “Code Metrics”.
- **Code Metrics Details**: Various quantities related to the source code with the information broken down by file and function.
- **Configuration Settings**: List of analysis options that Polyspace uses for analysis. If you configured your project for multitasking, this section also lists the **Concurrency Modeling Summary**. If your project has source files with compilation errors, these files are also listed.

  If you check for coding rules, an additional **Coding Rules Configuration** section states the rules along with the information whether they were enabled or disabled.

`CodingStandards`

The report contains separate chapters for each coding standard enabled in the analysis (for instance, MISRA C: 2012, CERT C, custom rules, and so on). Each chapter contains the following information:

- **Summary - Violations by File**: Graph showing each file with number of rule violations.
- **Summary - Violations by Rule**: Graph showing each rule with number of violations. If a rule is not enabled or not violated, it does not appear in the graph.
- **Summary for all Files**: Table showing each file with number of rule violations.
- **Summary for Enabled Guidelines** or **Summary for Enabled Rules**: Table showing each guideline or rule with number of violations.
- **Violations**: Tables listing each rule violation, along with information such as ID, function name, severity, status, and so on. One table is created per file.

An appendix lists the options used in the Polyspace analysis.

`SecurityCWE`

The report contains the same information as the `BugFinder` report. However, in the **Defects** chapter, an additional column lists the CWE™ rules mapped to each defect. The **Configuration Settings** appendix also includes a **Security Standard to Polyspace Result Map**.

`Metrics`

*Only available for results that you upload to the Polyspace Access interface.*

The report lists information useful to quality engineers and available on the Polyspace Access interface, including:

- Information about whether the project satisfies quality objectives
- Metrics about the whole project. For each metric, the report lists the quality threshold and whether the metric satisfies this threshold.
- Coding rule violations in the project. For each rule, the report lists the number of violations justified and whether the justifications satisfy quality objectives.
- Definite as well as possible run-time errors in the project. For each type of run-time error, the report lists the number of errors justified and whether the justifications satisfy quality objectives.

The appendices contain further details of Polyspace configuration settings, code metrics, coding rule violations, and run-time errors.

## Settings – Code Prover

**Default:** `Developer`

`CodeMetrics`

The report contains a summary of code metrics, followed by the complete metrics for an application.

`CodingStandards`

The report contains separate chapters for each coding standard enabled in the analysis (for instance, MISRA C: 2012, custom rules, and so on). Each chapter contains the following information:

- **Summary - Violations by File**: Graph showing each file with number of rule violations.
- **Summary - Violations by Rule**: Graph showing each rule with number of violations. If a rule is not enabled or not violated, it does not appear in the graph.
- **Summary for all Files**: Table showing each file with number of rule violations.
- **Summary for Enabled Guidelines** or **Summary for Enabled Rules**: Table showing each guideline or rule with number of violations.
- **Violations**: Tables listing each rule violation, along with information such as ID, function name, severity, status, and so on. One table is created per file.

An appendix lists the options used in the Polyspace analysis.

`Developer`

The report lists information useful to developers, including:

- Summary of verification results
- Code metrics summary
- Coding rules:
  - Summary of violations by file
  - List of violations
- Run-time errors:
  - List of proven run-time errors or red checks
  - List of unproven run-time errors or orange checks
  - List of unreachable procedures or gray checks
- Global variable usage in code. See "Global Variables" (Polyspace Code Prover).

The report also contains the Polyspace configuration settings and modifiable assumptions used in the analysis. If your project has source files with compilation errors, these files are also listed.

`DeveloperReview`

The report lists the same information as the `Developer` report. However, the reviewed results are sorted by severity and status, and unreviewed results are sorted by file location.

`Developer_withGreenChecks`

The report lists the same information as the `Developer` report. In addition, the report lists code proven to be error-free or green checks.

`Quality`

The report lists information useful to quality engineers, including:

- Summary of results
- Statistics about the code
- Graphs showing distributions of checks per file

The report also contains the Polyspace configuration settings and modifiable assumptions used in the analysis. If your project has source files with compilation errors, these files are also listed.

`VariableAccess`

The report displays the global variable access in your source code. The report first displays the number of global variables of each type. For information on the types, see "Global Variables" (Polyspace Code Prover). For each global variable, the report displays the following information:

- Variable name.

  The entry for each variable is denoted by |.
- Type of the variable.
- Number of read and write operations on the variable.
- Details of read and write operations. For each read or write operation, the table displays the following information:

  - File and function containing the operation in the form *`file_name.function_name`*.

    The entry for each read or write operation is denoted by `||`. Write operations are denoted by < and read operations by >.
  - Line and column number of the operation.

This report captures the information available on the **Variable Access** pane in the Polyspace user interface.

`CallHierarchy`

The report displays the call hierarchy in your source code. For each function call in your source code, the report displays the following information:

- Level of call hierarchy, where the function is called.

  Each level is denoted by |. If a function call appears in the table as `|||->` *`file_name.function_name`*, the function call occurs at the third level of the hierarchy. Beginning from `main` or an entry point, there are three function calls leading to the current call.
- File containing the function call.

  In addition, the line and column is also displayed.
- File containing the function definition.

  In addition, the line and column where the function definition begins is also displayed.

In addition, the report also displays uncalled functions.

This report captures the information available on the **Call Hierarchy** pane in the Polyspace user interface.

`SoftwareQualityObjectives`

The report lists information useful to quality engineers and available on the Polyspace Access interface, including:

- Information about whether the project satisfies quality objectives
- Metrics about the whole project. For each metric, the report lists the quality threshold and whether the metric satisfies this threshold.
- Coding rule violations in the project. For each rule, the report lists the number of violations justified and whether the justifications satisfy quality objectives.
- Definite as well as possible run-time errors in the project. For each type of run-time error, the report lists the number of errors justified and whether the justifications satisfy quality objectives.

The appendices contain further details of Polyspace configuration settings, code metrics, coding rule violations, and run-time errors.

This template is available only if you generate a report from results uploaded to the Polyspace Access web interface. See “Upload Results to Polyspace Access”. In each case, you have to set the objectives explicitly in the web interface and then generate the reports.

For more information on the predefined Software Quality Objectives, see “Evaluate Polyspace Code Prover Results Against Software Quality Objectives” (Polyspace Code Prover).

`SoftwareQualityObjectives_Summary`

The report contains the same information as the `SoftwareQualityObjectives` report. However, it does not have the supporting appendices with details of code metrics, coding rule violations and run-time errors.

This template is available only if you generate a report from results uploaded to the Polyspace Access web interface. See “Upload Results to Polyspace Access”. In each case, you have to set a quality objective level explicitly in the web interface and then generate the reports.

For more information on the predefined Software Quality Objectives, see “Evaluate Polyspace Code Prover Results Against Software Quality Objectives” (Polyspace Code Prover).

## Dependencies

In the user interface of the Polyspace desktop products, this option is enabled only if you select the `Generate report` option.

## Tips

- This option allows you to specify report generation before starting an analysis.

  To generate a report *after* an analysis is complete, in the user interface of the Polyspace desktop products, select **Reporting** > **Run Report**. Alternatively, at the command line, use the `polyspace-report-generator` command.

  After analysis, you can also export the result as a text file for further customization. Use the option `-generate-results-list-file` with the `polyspace-report-generator` command.
- In Bug Finder, the report does not contain the line or column number for a result. Use the report for archiving, gathering statistics and checking whether results have been reviewed and addressed (for certification purposes or otherwise). To review a result in your source code, use the Polyspace desktop interface, the Polyspace Access web interface, or your IDE if you are using a Polyspace plugin.
- If you use the `SoftwareQualityObjectives_Summary` and `SoftwareQualityObjectives` templates to generate reports, the pass/fail status is determined based on all results. For instance, if you use the level SQO-4 which sets a threshold of 60% on orange overflow checks, your project has a **FAIL** status if the percentage of green and justified orange overflow checks is less than 60% of *all green and orange overflow checks*.
- The first chapter of the reports contain a summary of the relevant results. You can enter a Pass/Fail status in that chapter for your project based on the summary. If you use the template `SoftwareQualityObjectives` or `SoftwareQualityObjectives_Summary`, the status is automatically assigned based on your objectives and the verification results. For more information

on enforcing objectives using Polyspace Access, see "Quality Objectives Dashboard in Polyspace Access".

## Command-Line Information

**Parameter:** `-report-template`
**Value:** Full path to *`template`*`.rpt`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-report-template` *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\bug_finder\BugFinder.rpt`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-report-template` *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\Developer.rpt`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-report-template` *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\bug_finder\BugFinder.rpt`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-report-template` *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\Developer.rpt`

## See Also

### Topics

"Specify Polyspace Analysis Options"
"Generate Reports from Polyspace Results"

# Output format (-report-output-format)

Specify output format of generated report

## Description

Specify output format of analysis report.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Reporting** node. See "Dependencies" on page 2-337 for other options you must also enable.

**Command line and options file**: Use the option `-report-output-format`. See "Command-Line Information" on page 2-337.

### Why Use This Option

Use this option to specify whether you want a report in PDF, HTML or another format.

## Settings

**Default:** `Word`

`HTML`

Generate report in `.html` format

`PDF`

Generate report in `.pdf` format

`Word`

Generate report in `.docx` format.

## Tips

- This option allows you to specify report generation before starting an analysis.

  To generate a report *after* an analysis is complete, in the user interface of the Polyspace desktop products, select **Reporting** > **Run Report**. Alternatively, at the command line, use the `polyspace-report-generator` command.

  After analysis, you can also export the result as a text file for further customization. Use the option `-generate-results-list-file` with the `polyspace-report-generator` command.
- If the table of contents or graphics in a `.docx` report appear outdated, select the content of the report and refresh the document. Use keyboard shortcuts **Ctrl+A** to select the content and **F9** to refresh it.

## Dependencies

In the user interface of the Polyspace desktop products, this option is enabled only if you select the `Generate report` option.

## Command-Line Information

**Parameter:** `-report-output-format`
**Value:** `html | pdf | word`
**Default:** `word`
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`file_name`* `-report-output-format pdf`
**Example (Code Prover):** `polyspace-code-prover -sources` *`file_name`* `-report-output-format pdf`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`file_name`* `-report-output-format pdf`
**Example (Code Prover Server):** `polyspace-code-prover-server -sources` *`file_name`* `-report-output-format pdf`

# Run Bug Finder or Code Prover analysis on a remote cluster (`-batch`)

Enable batch remote analysis

## Description

Specify that the analysis must be offloaded to a remote server.

To offload a Polyspace analysis, you need these products:

- A Polyspace product on the client side to submit an analysis job. Typically, you use a desktop product such as Polyspace Bug Finder to submit jobs, but you can also use a server product such as Polyspace Bug Finder Server to offload an analysis from one server to another.
- A Polyspace server product (Polyspace Bug Finder Server or Polyspace Code Prover Server) on the server side to run the analysis.
- MATLAB Parallel Server™ to hold jobs from multiple clients in queue and allocate the jobs as Polyspace Server instances become available.

For details, see “Install Products for Submitting Polyspace Analysis from Desktops to Remote Server”.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Run Settings** node. You have separate options for a Bug Finder and a Code Prover analysis.

**Command line and options file**: Use the option `-batch`. See “Command-Line Information” on page 2-339.

### Why Use This Option

Use this option if you want the analysis to run on a remote cluster instead of your local desktop.

For instance, you can run remote analysis when:

- You want to shut down your local machine but not interrupt the analysis.
- You want to free execution time on your local machine.
- You want to transfer the analysis to a more powerful computer.

## Settings

☑ On

Run batch analysis on a remote computer. In this remote analysis mode, the analysis is queued on a cluster after the compilation phase. Therefore, on your local computer, after the analysis is queued:

- If you are running the analysis from the Polyspace user interface, you can close the user interface.

- If you are running the analysis from the command line, you can close the command-line window.

You can manage the queue from the Polyspace Job Monitor. To use the Polyspace Job Monitor:

- In the Polyspace user interface, select **Tools** > **Open Job Monitor**. See “Send Polyspace Analysis from Desktop to Remote Servers”.
- On the DOS or UNIX® command line, use the `polyspace-jobs-manager` command. For more information, see “Send Polyspace Analysis from Desktop to Remote Servers Using Scripts”.
- On the MATLAB command line, use the `polyspaceJobsManager` function.

**Note** If you use a third-party scheduler instead of the MATLAB Job Scheduler, disable the credentials check by adding the option `-no-credentials-check`. The credentials check performed in the product is compatible only with the MATLAB Job Scheduler and the check outputs an error if you use a different scheduler. In the Polyspace user interface, add this option to the `Other` field.

□ Off (default)

Do not run batch analysis on a remote computer.

## Dependencies

- If you use a Polyspace Server product to offload an analysis from one server to another, the offloading uses the MATLAB Job Scheduler that comes by default with MATLAB Parallel Server. You cannot use a third-party scheduler.

## Tips

- If you run a Code Prover analysis and set the **Verification Level** to `Source Compliance Checking`, the analysis takes place on your local machine even when you enable remote analysis. Therefore, if you run an analysis only up to this verification level, use your local machine.
- In the user interface of the Polyspace desktop products, the results are automatically downloaded after analysis.

  If you run an analysis at the command line, add the options `-wait -download` to automatically download the results after analysis. Otherwise, you can explicitly download the results later with the `polyspace-jobs-manager` command. See “Send Polyspace Analysis from Desktop to Remote Servers Using Scripts”.
- If you use a Polyspace Server product to offload an analysis from one server to another, the results are automatically downloaded after analysis.

## Command-Line Information

To run a remote analysis from the command line, use with the `-scheduler` option.
**Parameter:** `-batch`
**Value:** `-scheduler` *`host_name`* if you have not set the **Job scheduler host name** in the Polyspace user interface

**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -batch -scheduler NodeHost` or `polyspace-bug-finder -batch -scheduler MJSName@NodeHost`
**Example (Code Prover):** `polyspace-code-prover -batch -scheduler NodeHost` or `polyspace-code-prover -batch -scheduler MJSName@NodeHost`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -batch -scheduler NodeHost`
**Example (Code Prover Server):** `polyspace-code-prover-server -batch -scheduler NodeHost`

# Use fast analysis mode for Bug Finder (`-fast-analysis`)

Run analysis using faster local mode

## Description

*This option affects a Bug Finder analysis only.*

Run analysis using faster local mode. The first run analyzes all files, but subsequent runs reanalyze only the files that you edited since the previous analysis.

Fast analysis mode is a faster way to analyze code for localized defects and coding standard violations. When you launch fast analysis, Bug Finder analyzes your code for a subset of defects and coding rules. These defects and coding standard violations are ones that can be found in the early stages of the analysis or can leverage archived information from a previous analysis. The analysis results are also comparatively easier to review and fix because most results can be understood by focusing on two or three lines of code (the line with the defect and one or two previous events).

Because of the simplified nature of the analysis, you might see significantly fewer defects in the fast analysis mode compared to a regular Bug Finder analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is available on the **Run Settings** node.

**Command line and options file**: Use the option `-fast-analysis`. See “Command-Line Information” on page 2-343.

### Why Use This Option

If you use this option, you have to wait less for analysis results from your second analysis onwards. During development, you can frequently run analysis in fast mode and quickly fix new defects or coding standard violations.

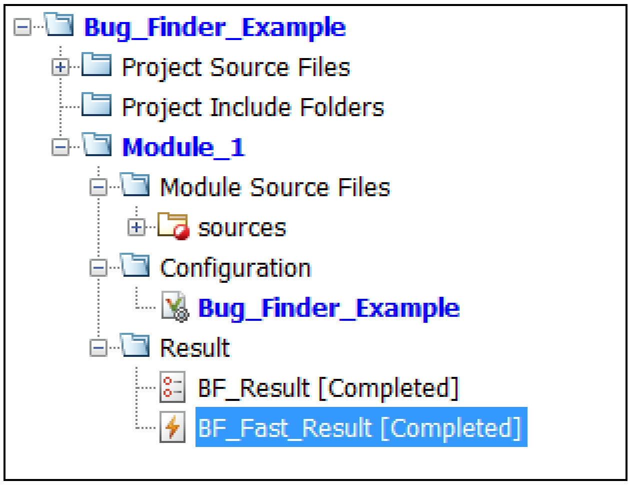
Polyspace produces results quickly because the analysis is localized. When you rerun in fast-analysis mode, Polyspace reanalyzes only those files that need to be reanalyzed, regenerating results even more quickly. These situations trigger a reanalysis.

| Situation | What Is Reanalyzed |
|---|---|
| You modified a source file. | Modified source file |
| You modified a header file. | Source files that include the modified header file (directly or indirectly) |
| You added or removed an analysis option. | All files |
| Previous fast-analysis results were not found.<br>For instance, you deleted the results folder. | All files |

| Situation | What Is Reanalyzed |
|---|---|
| You upgraded to a later release of Polyspace and ran the analysis. | All files<br>Comments from the previous analysis are retained and imported to the current analysis. |

For example, consider a Polyspace project with three `.c` files and you fix a bug in one of the files. When you rerun the analysis, Polyspace reanalyzes only the one file that you changed.

The results of fast analysis appear in a folder separate from the results of normal analysis.



## Settings

**Default:** □ Off

☑ On

Polyspace Bug Finder runs in fast-analysis mode. Polyspace analyzes code for only a subset of defects and coding standard violations. If you have enabled checking of defects or coding standard violations that are not supported by fast-analysis, your code is not checked for those results.

□ Off

Polyspace Bug Finder runs in the normal mode. Analysis checks for all selected defects, coding standard violations, and code metrics.

## Tips

### Comments Import

If you enter comments in your results, the comments are automatically imported to the next analysis in fast mode.

To import the comments from fast mode results to results of a regular Bug Finder analysis, do one of the following:

- Select **Tools** > **Import Comments**. Navigate to the sibling results folder `BF_Fast_Result` and import comments from the fast mode results.
- When reviewing results of fast mode, enter the comments directly into your code. If you run a regular analysis on this code, the comments are imported to your analysis results.

  For details on how to enter code comments, see “Annotate Code and Hide Known or Acceptable Results”.

### Fast Analysis Limitations

In fast analysis mode, you cannot perform these actions:

- You cannot create a new results folder for each run. Even if you choose to create a new result folder, each new run overwrites the previous one.
- You cannot specify constraints using the option `Constraint setup (-data-range-specifications)`.
- You cannot run the analysis on a remote cluster.

## Command-Line Information

**Parameter:** `-fast-analysis`
**Default:** Off
**Example (Bug Finder):** `polyspace-bug-finder -sources` *`filename`* `-fast-analysis`
**Example (Bug Finder Server):** `polyspace-bug-finder-server -sources` *`filename`* `-fast-analysis`

## See Also

“Bug Finder Results Found in Fast Analysis Mode”

# Command/script to apply after the end of the code verification (`-post-analysis-command`)

Specify command or script to be executed after analysis

## Description

Specify a command or script to be executed after the analysis.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Advanced Settings** node.

**Command line and options file**: Use the option `-post-analysis-command`. See “Command-Line Information” on page 2-346.

### Why Use This Option

Create scripts for tasks that you want performed after the Polyspace analysis.

For instance, you want to be notified by email that the Polyspace analysis is over. Create a script that sends an email and use this option to execute the script after the Polyspace analysis.

## Settings

**No Default**

Enter full path to the command or script, or click 📁 to navigate to the location of the command or script. After the analysis, this script is executed.

The script is executed in the Polyspace results folder. In your script, consider the results folder as the current folder for relative paths to other files.

For a Perl script, in Windows, specify the full path to the Perl executable followed by the full path to the script. For example, to specify a Perl script `send_email.pl` that sends an email once the analysis is over, enter *polyspaceroot*`\sys\perl\win32\bin\perl.exe <`*absolute_path*`>\send_email.pl`. Here, *polyspaceroot* is the location of the current Polyspace installation, such as `C:\Program Files\Polyspace\R2019a\`, and <*absolute_path*> is the location of the Perl script.

For example Perl scripts that send emails and other information on writing Perl scripts, see Perl documentation.

## Tips

### Running post analysis commands on the server

If you perform verification on a remote server, after verification, the software executes your command on the server, not on the client desktop. If your command executes a script, the script must be present on the server.

For instance, if you specify the command, `/local/utils/send_mail.sh`, the Shell script `send_email.sh` must be present on the server in `/local/utils/`. The software does not copy the script `send_email.sh` from your desktop to the server before executing the command. If the script is not present on the server, you encounter an error. Sometimes, there are multiple servers that the MATLAB Job Scheduler can run the verification on. Place the script on each of the servers because you do not control which server eventually runs your verification.

### Running post analysis commands in the Polyspace user interface

To test the use of this option, run the following Perl script from a folder containing a Polyspace project (`.psprj` file). The script parses the latest Polyspace log file in the folder `Module_1\CP_Result` and writes the current project name and date to a file `report.txt`. The file is saved in `Module_1\CP_Result`.

```
foreach my $file (`ls Module_1\\CP_Result\\Polyspace_*.log`) {
  open (FH, $file);

while ($line = <FH>) {
    if ($line =~ m/Ending at: (.*)/) {
      $date=$1;
    }
    if ($line =~ m/-prog=(.*)/) {
      $project=$1;
    }
  }
}

my $filename = 'report.txt';
open(my $fh, '>', $filename) or die "Could not open file '$filename' $!";

print $fh "date=$date\n";
print $fh "project=$project\n";

close $fh;
```

In Linux, you can specify the Perl script for this option.

In Windows, instead of specifying the Perl script directly, specify a `.bat` file that invokes Perl and runs this script. For instance, the `.bat` file can contain the following line (assuming that the `.bat` file and `.pl` file are in the Polyspace project folder). Depending on your MATLAB installation, change the path to `perl.exe` appropriately.

```
"C:\Program Files\MATLAB\R2018b\sys\perl\win32\bin\perl.exe" command.pl
```

Run Code Prover. Check that the folder `Module_1\CP_Result` contains the file `report.txt` with the project name and date.

## Command-Line Information

**Parameter:** `-post-analysis-command`
**Value:** Path to executable file or command in quotes
**No Default**
**Example in Linux (Bug Finder):** `polyspace-bug-finder -sources file_name -post-analysis-command `pwd`/send_email.pl`
**Example in Linux (Code Prover) :** `polyspace-code-prover -sources file_name -post-analysis-command `pwd`/send_email.pl`
**Example in Linux (Bug Finder Server):** `polyspace-bug-finder-server -sources file_name -post-analysis-command `pwd`/send_email.pl`
**Example in Linux (Code Prover Server):** `polyspace-code-prover-server -sources file_name -post-analysis-command `pwd`/send_email.pl`
**Example in Windows:** `polyspace-bug-finder -sources file_name -post-analysis-command "C:\Program Files\MATLAB\R2015b\sys\perl\win32\bin\perl.exe" "C:\My_Scripts\send_email"`

Note that in Windows, you use the full path to the Perl executable.

## See Also

`Command/script to apply to preprocessed files (-post-preprocessing-command)`

### Topics

"Specify Polyspace Analysis Options"

# Other

Specify additional flags for analysis

## Description

*This option is useful only if you run an analysis in the user interface of the Polyspace desktop products.*

Enter command-line-style flags such as `-max-processes`.

### Set Option

**User interface** (desktop products only): In your project configuration, the option is on the **Advanced Settings** node. You can enter multiple options in this field. If you enter the same option multiple times with different arguments, the analysis uses your last argument.

### Why Use This Option

Use this option to add nonofficial or command-line only options to the analyzer.

If you have to add several command line options, you can save them in a text file and specify the file using the option `-options-file`. You can reuse the options file across projects.

## Tip

Nonofficial options: In rare circumstances, to work around very specific issues, MathWorks Technical Support might provide you some undocumented options. If you are running verification from the user interface, you use the **Other** field in the **Configuration** pane to enter the options. Sometimes, the options and their arguments have to be preceded by extra flags. When providing you the option, Technical Support will let you know if the extra flags are required.
**Possible Flags:** `-extra-flags | -c-extra-flags | -cpp-extra-flags | -cfe-extra-flags | -il-extra-flags`
**Example (Bug Finder):** `polyspace-bug-finder -extra-flags` *`-option-name`* `-extra-flags` *`option_param`*
**Example (Code Prover):** `polyspace-code-prover -extra-flags` *`-option-name`* `-extra-flags` *`option_param`*
**Example (Bug Finder Server):** `polyspace-bug-finder-server -extra-flags` *`-option-name`* `-extra-flags` *`option_param`*
**Example (Code Prover Server):** `polyspace-code-prover-server -extra-flags` *`-option-name`* `-extra-flags` *`option_param`*

3

# Analysis Options, Command-Line Only

# -asm-begin -asm-end

Exclude compiler-specific `asm` functions from analysis

## Syntax

`-asm-begin "`*`mark1[,mark2,...]`*`" -asm-end "`*`mark1[,mark2,...]`*`"`

## Description

`-asm-begin "`*`mark1[,mark2,...]`*`" -asm-end "`*`mark1[,mark2,...]`*`"` excludes compiler-specific assembly language source code functions from the analysis. You must use these two options together.

Polyspace recognizes most inline assemblers by default. Use the option only if compilation errors occur due to introduction of assembly code. For more information, see “Code Prover Assumptions About Assembly Code” (Polyspace Code Prover).

Mark the offending code block by two `#pragma` directives, one at the beginning of the assembly code and one at the end. In the command usage, give these marks in the same order for `-asm-begin` as they are for `-asm-end`.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

A block of code is delimited by `#pragma start1` and `#pragma end1`. These names must be in the same order for their respective options. Either:

```
-asm-begin "start1" -asm-end "end1"
```

or

```
-asm-begin "mark1,...markN,start1" -asm-end "mark1,...markN,end1"
```

The following example marks two functions for exclusion, `foo_1` and `foo_2`.

Code:

```
#pragma asm_begin_foo
int foo(void) { /* asm code to be ignored by Polyspace */ }
#pragma asm_end_foo

#pragma asm_begin_bar
void bar(void) { /* asm code to be ignored by Polyspace */ }
#pragma asm_end_bar
```

Polyspace Command:

- Bug Finder:

```
polyspace-bug-finder -lang c -asm-begin "asm_begin_foo,asm_begin_bar"
          -asm-end "asm_end_foo,asm_end_bar"
```

- Code Prover:

```
polyspace-code-prover -lang c -asm-begin "asm_begin_foo,asm_begin_bar"
         -asm-end "asm_end_foo,asm_end_bar"
```

- Bug Finder Server:

```
polyspace-bug-finder-server -lang c -asm-begin "asm_begin_foo,asm_begin_bar"
          -asm-end "asm_end_foo,asm_end_bar"
```

- Code Prover Server:

```
polyspace-code-prover-server -lang c -asm-begin "asm_begin_foo,asm_begin_bar"
         -asm-end "asm_end_foo,asm_end_bar"
```

`asm_begin_foo` and `asm_begin_bar` mark the beginning of the assembly source code sections to be ignored. `asm_end_foo` and `asm_end_bar` mark the end of those respective sections.

## Tips

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## See Also

**Topics**
"Specify Polyspace Analysis Options"

# -author

Specify project author

## Syntax

```
-author "value"
```

## Description

`-author "value"` assigns an author to the Polyspace project. The name appears as the project owner on generated reports.

The default value is the user name of the current user, given by the DOS or UNIX command `whoami`.

In the user interface of the Polyspace desktop products, select to specify the Project name, Version, and Author parameters in the **Polyspace Project – Properties** dialog box.

## Examples

Assign a project author to your Polyspace Project.

- Bug Finder:

  ```
  polyspace-bug-finder -author "John Smith"
  ```
- Code Prover:

  ```
  polyspace-code-prover -author "John Smith"
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -author "John Smith"
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -author "John Smith"
  ```

## Tips

This option is not required for a Polyspace as You Code analysis.

## See Also

`-prog` | `-date`

### Topics

“Specify Polyspace Analysis Options”

# -c

Specify path of license file used by the product

## Syntax

`-c licensePath`

## Description

`-c licensePath` specifies the path of the license file that the product uses. When you specify this option, Polyspace looks for only this file to use as a license. Other possible locations such as environment variables `MLM_LICENSE_FILE` and `LM_LICENSE_FILE`, or the `licenses` folder under the Polyspace installation folder are ignored.

By default, Polyspace looks for a license in environment variables, registry keys, user profiles, and the `licenses` folder, in that order. For more details, see What is the license file search path.

Use this option to, for instance, troubleshoot your installation if Polyspace cannot find a license in the default locations, or to use a different license if the currently checked out license has no more seats available.

**Note** When you use this option to specify a Polyspace license, you can specify only a license path. The use of the port and hostname of the license server (For example `-c 27000@lisenseServerHostname`) is not supported.

## Examples

Use license `C:\ps_license\license.lic` when you start the desktop interface or a Polyspace analysis.

- Polyspace desktop interface

  ```
  polypace -c C:\ps_license\license.lic
  ```
- Bug Finder analysis:

  ```
  polypace-bug-finder -c C:\ps_license\license.lic -sources...
  ```
- Code Prover analysis:

  ```
  polypace-code-prover -c C:\ps_license\license.lic -sources...

# -checkers-activation-file

Enable a custom combination of defects and coding rules for a Polyspace Bug Finder analysis

## Syntax

`-checkers-activation-file` *`checkersFile`*`.xml`

## Description

`-checkers-activation-file` *`checkersFile`*`.xml` enables specific defect and coding standards checkers for a Bug Finder analysis. You can create the XML file for checkers activation in one of the following ways:

- Select the checkers in a graphical user interface and save your selection in a file *`checkersFile`*`.xml`. See “Create Checkers Activation File in Graphical User Interface” on page 3-7.
- Open an existing checkers activation XML file in a text editor and turn on checkers. See “Update Checkers Activation File in Text Editor” on page 3-8.

You can specify an absolute path to the XML file or a path relative to the location from which you run the `polyspace-bug-finder` command.

If you use an activation file generated by using a previous version of Polyspace, previously unimplemented checkers might become implemented. Polyspace warns if the file XML file lists an implemented checker as `'notimplemented'`.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

### Create Checkers Activation File in Graphical User Interface

Create a checkers activation file by using the Checkers selection interface. This file is a reusable selection of Bug Finder defects and coding rules that you can use with the option `-checkers-activation-file` in a Bug Finder analysis.

1. Open the Checkers selection interface. At the command line, enter:

   ```
   polyspace-checkers-selection
   ```

   Alternatively, navigate to *`polyspaceroot`*`\polyspace\bin` and launch the binary `polyspace-checkers-selection`. Here, *`polyspaceroot`* is the root installation folder for the Polyspace products, for instance, `C:\Program Files\Polyspace Server\R2023a`.
2. In the Checkers selection interface, select **New**. Select defect checkers and coding rules that you want enabled. Click **Save Changes** to save your selection as an XML file, for instance, *`checkers.xml`*.
3. When running a Bug Finder analysis, specify this XML file as the argument for the option `-checkers-activation-file`.

```
polyspace-bug-finder-access -sources src.c -checkers-activation-file checkers.xml
```

### Update Checkers Activation File in Text Editor

In some cases, you might not have access to the Checkers Selection UI. For instance, you might be using Polyspace in a headless terminal. In this case, create the checkers activation XML file by using the template files in `*polyspaceroot*\help\toolbox\bugfinder\examples\checkers_activation_XML`.

To activate Bug Finder defects or checkers from one of the coding standards, make a writable copy of the corresponding templates. Locate the checker by finding the node that has the correct `check id` attribute. Activate the checker by setting the `state` attribute to `"on"`.

Alternatively, to make a custom XML that activates various coding standards and Bug Finder defects, copy the relevant entries from the corresponding coding standard and defect templates into the `blank.xml` template in `*polyspaceserverroot*\help\toolbox\bugfinder\examples\checkers_activation_XML`. A checkers activation XML file that activates the Bug Finder defect `DATA_RACE` and CERT C coding rule `CON01-C` resembles this example:

```
<?xml version="1.0" encoding="UTF-8"?>
<polyspace_checkers_selection xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="selection_schema.xsd" revision="2.0">
  <standard name="Bug Finder Findings">
      <section name="Concurrency">
        <check id="DATA_RACE" state="on"/>
      </section>
  </standard>

  <standard name="SEI CERT C">
      <section name="Concurrency (CON)">
        <check id="CON01-C" state="on"/>
      </section>
    </standard>
</polyspace_checkers_selection>
```

For a full list of coding rule check IDs, defect checker short names, and section names, see:

- “Defects”
- “AUTOSAR C++14 Rules”
- “CERT C Rules and Recommendations”
- “CERT C++ Rules”
- “ISO/IEC TS 17961 Rules”
- “Custom Coding Rules”
- “JSF C++ Rules”
- “MISRA C:2004 Rules”
- “MISRA C:2012 Directives and Rules”
- “MISRA C++:2008 Rules”
- “Guidelines”

**Note** The XML format of the checker configuration file might change in future releases.

## Tips

- If you use Polyspace as You Code extensions in IDEs, this option is implemented through the IDE extension setting. You do not have to use this option explicitly. If you want to explicitly use this option, enter the option in an analysis options file. See options file.
- To create a custom coding standard classification, or to tag coding rule checkers of interest, enter text in the **Comment** column of the **Checkers selection** window. Polyspace displays that text in the **Results Details** pane and in the **Detail** column of the **Results List** (if available) when you review results in the desktop interface, in Polyspace Access, or in the Polyspace as You Code plugins.

### Topics

"Configure Checkers for Polyspace as You Code at the Command Line"

# -classification

Control precisely which files to include in Polyspace Bug Finder analysis and how to analyze them

## Syntax

`-classification` *`file`*

## Description

`-classification` *`file`* specifies which files to include in a Polyspace Bug Finder analysis and how to analyze them. Here, *`file`* is an XML file that enumerates file sets with specific behaviors.

For instance, you can:

- Skip the definitions of function bodies in third-party libraries.
- Force analysis of all functions in files that you own.

If you run a verification:

- At the command line, specify the absolute path to the XML files or path relative to the folder from which you run the command.
- In the user interface (desktop products only), in the **Other** field, specify the option along with an absolute path to the XML or the path relative to the location of your Polyspace project. See `Other`.

A report generated from the analysis results only show the use of this option and not the details of which behaviors were associated with code elements.

A sample template file `classification-template.xml` shows the XML syntax. The file is in *`polyspaceroot`*`\polyspace\verifier\cxx\` where *`polyspaceroot`* is the Polyspace installation folder.

## Examples

### Excluding Generated Files

Suppose your source code consists of the following files. Both `.c` files contain a comparison that incorrectly uses an = operator instead of an == operator.

- `src\utils.c`:

  ```
  #include "header.h"

  int getEvenElement(int *arr, int size, int idx) {
      int isIndexEven = isEven(idx);
      if(isIndexEven = 0 && idx < size) // Invalid use of = operator
          return arr[idx];
      else
          return -1;
  }
  ```
- `src\utils_generated.c`:

```
#include "header.h"

int isEven(int arg) {
    int rem = arg%2;
    if(rem = 0) { // Invalid use of = operator
        return 1;
    }
    else {
        return 0;
    }
}
```

- `inc\header.h`:

  ```
  int isEven(int);
  ```

Run the default Bug Finder analysis:

```
polyspace-bug-finder -sources src\utils.c,src\utils_generated.c -I inc\
```

You see an `Invalid use of = operator` defect in both `.c` files.

Suppose your generated files follow a naming convention and end with `_generated`. To exclude these files from analysis:

1. Write a classification file that defines a set of files to exclude from analysis.

   ```
   <?xml version="1.0" encoding="UTF-8"?>

   <specification>
       <classification product="bug-finder">
          <fileset name="generated code">
               <files-in-set>
                   <file-pattern>src/**/*_generated.c</file-pattern>
               </files-in-set>
               <behaviors>
                   <do-not-analyze-functions>
                       <function-pattern>*</function-pattern>
                   </do-not-analyze-functions>
                   <show-results value="false"/>
               </behaviors>
           </fileset>
       </classification>
   </specification>
   ```

2. Save the classification file as `exclude_generated_files.xml`. Specify this classification file with the option `-classification`:

   ```
   polyspace-bug-finder -sources src\file.c,src\file_generated.c -I inc\ -classification exclude
   ```

   You no longer see the defect in the file `utils_generated.c`.

# -code-behavior-specifications

Associate behaviors with code elements such as functions

## Syntax

`-code-behavior-specifications *file*`

## Description

`-code-behavior-specifications` *`file`* allows you to associate certain behaviors with elements of your code and modify the results of checks on those elements. Here, *`file`* associates specific behaviors to code elements such as functions, and can be in one of two formats:

- An XML file.

  You can only specify a single XML file as argument. A sample template file `code-behavior-specifications-template.xml` shows the XML syntax. The file is in *`polyspaceroot`*`\polyspace\verifier\cxx\` where *`polyspaceroot`* is the Polyspace installation folder.
- A Datalog (`.dl`) file.

  You can specify multiple Datalog files as comma-separated arguments.

You can specify an absolute path to the XML or Datalog file, or a path relative to the location from which you run the `polyspace-bug-finder` or `polyspace-code-prover` command.

The XML and Datalog format support different code behaviors. For more information, see:

- “Modify Bug Finder Checkers Through Code Behavior Specifications”
- “Modify Code Prover Run-Time Checks Through Code Behavior Specifications” (Polyspace Code Prover)

For instance, you can:

- Map your library functions to corresponding standard functions that Polyspace recognizes. Mapping to standard library functions can help with precision improvement or automatic detection of new threads.
- Specify that a function has a special behavior or must be subjected to special checks.

  For instance, you can specify that a function must only take addresses of initialized variables as arguments, or that a function must not be used altogether.

You can specify this option in the user interface of the Polyspace desktop products, at the command line or in IDE-s:

- If you run verification from the command line, specify the absolute path to the XML files or path relative to the folder from which you run the command.
- If you run verification from the user interface (desktop products only), in the **Other** field, specify the option along with an absolute path to the XML or the path relative to the location of your Polyspace project. See `Other`.

- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

A report generated from the analysis results only show the use of this option and not the details of which behaviors were associated with code elements.

## Examples

### Specify Mapping to Standard Function

You can adapt the sample mapping XML file provided with your Polyspace installation and map your function to a standard function.

Suppose the default verification produces an orange `User assertion` check on this code:

```
double x = acos32(1.0);
assert(x <= 2.0);
```

Suppose you know that the function `acos32` behaves like the function `acos` and the return value is 0. You expect the check on the `assert` statement to be green. However, the verification considers that `acos32` returns any value in the range of type `double` because `acos32` is not precisely analyzed. The check is orange. To map your function `acos32` to `acos`:

1. Copy the file `code-behavior-specifications-template.xml` from *`polyspaceroot`* `\polyspace\verifier\cxx\` to another location, for instance, `"C:\Polyspace_projects\Common\Config_files"`. Change the write permissions on the file.
2. To map your function to a standard function, modify the contents of the XML file. To map your function `acos32` to the standard library function `acos`, change the following code:

   ```
   <function name="my_lib_cos" std="acos"> </function>
   ```

   To:

   ```
   <function name="acos32" std="acos"> </function>
   ```
3. Specify the location of the file for verification:

   - Code Prover:

     ```
     polyspace-code-prover -code-behavior-specifications
       "C:\Polyspace_projects\Common\Config_files
        \code-behavior-specifications-template.xml"
     ```
   - Code Prover Server:

     ```
     polyspace-code-prover-server -code-behavior-specifications
       "C:\Polyspace_projects\Common\Config_files
        \code-behavior-specifications-template.xml"
     ```

### Specify Mapping to Standard Function with Argument Remapping

Sometimes, the arguments of your function do not map one-to-one with arguments of the standard function. In those cases, remap your function argument to the standard function argument. For instance:

- `__ps_lookup_table_clip`:

This function specific to Polyspace takes only a look-up table array as argument and returns values within the range of the look-up table. Your look-up table function might have additional arguments besides the look-up table array itself. In this case, use argument remapping to specify which argument of your function is the look-up table array.

For instance, suppose a function `my_lookup_table` has the following declaration:

```
double my_lookup_table(double u0, const real_T *table,
                                     const double *bp0);
```

The second argument of your function `my_lookup_table` is the look-up table array. In the file `code-behavior-specifications-template.xml`, add this code:

```
<function name="my_lookup_table" std="__ps_lookup_table_clip">
    <mapping std_arg="1" arg="2"></mapping>
</function>
```

When you call the function:

```
res = my_lookup_table(u, table10, bp);
```

The verification interprets the call as:

```
res =__ps_lookup_table_clip(table10);
```

The verification assumes that the value of `res` lies within the range of values in `table10`.

- `__ps_meminit`:

  This function specific to Polyspace takes a memory address as the first argument and a number of bytes as the second argument. The function assumes that the bytes in memory starting from the memory address are initialized with a valid value. Your memory initialization function might have additional arguments. In this case, use argument remapping to specify which argument of your function is the starting address and which argument is the number of bytes.

  For instance, suppose a function `my_meminit` has the following declaration:

```
     void my_meminit(enum InitKind k, void* dest, int is_aligned,
                           unsigned int size);
```

  The second argument of your function is the starting address, and the fourth argument is the number of bytes. In the file `code-behavior-specifications-template.xml`, add this code:

```
<function name="my_meminit" std="__ps_meminit">
    <mapping std_arg="1" arg="2"></mapping>
    <mapping std_arg="2" arg="4"></mapping>
</function>
```

  When you call the function:

```
my_meminit(INIT_START_BY_END, &buffer, 0, sizeof(buffer));
```

  The verification interprets the call as:

```
__ps_meminit(&buffer, sizeof(buffer));
```

  The verification assumes that `sizeof(buffer)` number of bytes starting from `&buffer` are initialized.

- memset: Variable number of arguments.

  If your function has variable number of arguments, you cannot map it directly to a standard function without explicit argument remapping. For instance, say your function is declared as:

  ```
  void* my_memset(void*, int, size_t, ...)
  ```

  To map the function to the memset function, use the following mapping:

  ```
  <function name="my_memset" std="memset">
      <mapping std_arg="1" arg="1"></mapping>
      <mapping std_arg="2" arg="2"></mapping>
      <mapping std_arg="3" arg="3"></mapping>
  </function>
  ```

#### Effect of Mapping on Precision

These examples show the result of mapping certain functions to standard functions:

- my_acos → acos:

  If you use the mapping, the User assertion check turns green. The verification assumes that the return value of my_acos is 0.

  - *Before mapping*:

    ```
    double x = my_acos(1.0);
    assert(x <= 2.0);
    ```
  - *Mapping specification*:

    ```
    <function name="my_acos" std="acos">
    </function>
    ```
  - *After mapping*:

    ```
    double x = my_acos(1.0);
    assert(x <= 2.0);
    ```
- my_sqrt → sqrt:

  If you use the mapping, the Invalid use of standard library routine check turns red. Otherwise, the verification does not check whether the argument of my_sqrt is nonnegative.

  - *Before mapping*:

    ```
    res = my_sqrt(-1.0);
    ```
  - *Mapping specification*:

    ```
    <function name="my_sqrt" std="sqrt">
    </function>
    ```
  - *After mapping*:

    ```
    res = my_sqrt(-1.0);
    ```
- my_lookup_table (argument 2) →__ps_lookup_table_clip (argument 1):

  If you use the mapping, the User assertion check turns green. The verification assumes that the return value of my_lookup_table is within the range of the look-up table array table.

  - *Before mapping*:

    ```
    double table[3] = {1.1, 2.2, 3.3}
    .
    .
    double res = my_lookup_table(u, table, bp);
    assert(res >= 1.1 && res <= 3.3);
    ```

  - *Mapping specification*:

    ```
    <function name="my_lookup_table" std="__ps_lookup_table_clip">
        <mapping std_arg="1" arg="2"></mapping>
    </function>
    ```

  - *After mapping*:

    ```
    double table[3] = {1.1, 2.2, 3.3}
    .
    .
    res_real = my_lookup_table(u, table9, bp);
    assert(res_real >= 1.1 && res_real <= 3.3);
    ```

- `my_meminit` → `__ps_meminit`:

  If you use the mapping, the `Non-initialized local variable` check turns green. The verification assumes that all fields of the structure `x` are initialized with valid values.

  - *Before mapping*:

    ```
    struct X {
      int field1;
      int field2;
    };
    .
    .
    struct X x;
    my_meminit(&x, sizeof(struct X));
    return x.field1;
    ```

  - *Mapping specification*:

    ```
    <function name="my_meminit" std="__ps_meminit">
         <mapping std_arg="1" arg="1"></mapping>
         <mapping std_arg="2" arg="2"></mapping>
    </function>
    ```

  - *After mapping*:

    ```
    struct X {
      int field1 ;
      int field2 ;
    };
    .
    .
    struct X x;
    my_meminit(&x, sizeof(struct X));
    return x.field1;
    ```

- `my_meminit` → `__ps_meminit`:

  If you use the mapping, the `Non-initialized local variable` check turns red. The verification assumes that only the field `field1` of the structure `x` is initialized with valid values.

- *Before mapping*:

  ```
  struct X {
    int field1 ;
    int field2 ;
  };
  .
  .
  struct X x;
  my_meminit(&x, sizeof(int));
  return x.field2;
  ```
- *Mapping specification*:

  ```
  <function name="my_meminit" std="__ps_meminit">
  </function>
  ```
- *After mapping*:

  ```
  struct X {
    int field1 ;
    int field2 ;
  };
  .
  .
  struct X x;
  my_meminit(&x, sizeof(int));
  return x.field2;
  ```

## Limitations

You can map your custom functions to similar standard library functions using the option `-code-behavior-specifications`, subject to the following constraints:

- Your custom function must have the same number of arguments as the standard library function or more. Make sure that every argument of the standard library function is mapped to an argument of the custom function.
- The mapped function arguments must have compatible data types. Likewise, the custom function must have a return type that is compatible with the standard library function. For instance:
  - An integer type (`char`, `int`, etc.) is not compatible with a floating point type (`float`, `double`, etc.)
  - A fundamental type is not compatible with a structure or enumeration.
  - A pointer type is not compatible with a non-pointer type.

# Version History

**Introduced in R2016b**

### Topics

“Specify Polyspace Analysis Options”

# -consider-analysis-perimeter-as-trust-boundary

Consider the analysis perimeter as trust boundary so that data coming from outside the current analysis perimeter is considered tainted

## Syntax

`-checkers tainted_data -consider-analysis-perimeter-as-trust-boundary`

## Description

`-checkers tainted_data -consider-analysis-perimeter-as-trust-boundary` modifies the behavior of the tainted data defects so that data originating from outside the analysis perimeter is considered tainted. For instance, if you are analyzing a single file, then any data that originates outside this file is considered tainted.

By default, these data are considered tainted:

- Objects declared or defined as `volatile`
- External data such as user input, hardware data, network data, and environment variable

See “Sources of Tainted Data”.

If you specify the option `-consider-analysis-perimeter-as-trust-boundary` along with the option `-checkers tainted_data`, data that does not originate in the current scope of Polyspace analysis is considered tainted. Such data might include:

- Formal parameters of externally visible function that do not have a visible caller.
- Return values of stubbed functions.
- Global variables external to the unit.

If you do not trust data that originates from an external module, use this option to detect operations that are vulnerable to this tainted data.

For a list of tainted data checkers that are impacted by this option, see “Polyspace Tainted Data Checkers”.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Example

Consider this code:

```
#include<stdio.h>
double taintedloopboundary(int num, int denum) {
    int count;
    scanf("%d", &count);
    for (int i=0; i<count; ++i) {
        num = num/denum;
    }
    return num;
}
```

The example shows two cases of tainted data: one detected by default and one using this option.

- The variable `count` is obtained from the user. If you perform the default tainted data analysis by using the command:

  ```
  polyspace-bug-finder -checkers tainted_data
  ```

  Polyspace flags the tainted loop variable.
- The variables `num` and `denum` are not defined in the current module. If you modify the tainted data analysis by using the command:

  ```
  polyspace-bug-finder -checkers tainted_data -consider-analysis-perimeter-as-trust-boundary
  ```

  Polyspace flags the division operation between `num` and `denum`.

## Tips

This option is not useful in a Polyspace as You Code analysis.

# -custom-target

Create a custom target processor with specific data type sizes

## Syntax

`-custom-target target_sizes`

## Description

`-custom-target` *`target_sizes`* defines a custom target processor for the Polyspace analysis. The target processor definition includes sizes in bytes of fundamental data types, signedness of plain `char`, alignment of structures and underlying types of standard `typedef`-s such as `size_t`, `ptrdiff_t` and `wchar_t`.

*`target_sizes`* is a comma-separated list specifying these values. From left to right, the values are the following. If a data type is not supported, -1 is used for its size.

| Specification | Possible Values |
|---|---|
| Whether plain `char` is signed | `true` or `false` |
| Size of `char` in bits<br>Other sizes are in bytes. | Number |
| Size of `short` | Number |
| Size of `int` | Number |
| Size of `short long` | Number |
| Size of `long` | Number |
| Size of `long long` | Number |
| Size of `float` | Number |
| Size of `double` | Number |
| Size of `long double` | Number |
| Size of pointer | Number |
| Minimum alignment of all integer types | Number |
| Minimum alignment of variables of type `struct` or `union` | Number |
| Endianness | `little` or `big` |
| Underlying type of `size_t` | `unknown`, `unsigned_char`, `unsigned_short`, `unsigned_int`, `unsigned_long`, or `unsigned_long_long` |
| Underlying type of `ptrdiff_t` | `unknown`, `signed_char`, `short`, `int`, `long`, or `long_long` |
| Underlying type of `wchar_t` | `unknown`, `short`, `unsigned_short`, `int`, `unsigned_int`, `long`, or `unsigned_long` |

Typically, this option is used when the polyspace-configure command creates an options file for the subsequent Polyspace analysis. However, you can directly enter this option when manually writing options files. This option is useful in situations where your target specifications are not covered by one of the predefined target processors. See Target processor type (-target).

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See Other.

## Examples

An usage of the option looks like this:

```
-custom-target false,8,2,4,-1,4,8,4,8,8,4,8,1,little,unsigned_int,int,unsigned_int
```

The option argument translates to the following target specification.

| Specification | Possible Values |
|---|---|
| Whether plain char is signed | false |
| Size of char | 8 bits |
| Size of short | 2 bytes |
| Size of int | 4 bytes |
| Size of short long | short long is not supported. |
| Size of long | 4 bytes |
| Size of long long | 8 bytes |
| Size of float | 4 bytes |
| Size of double | 8 bytes |
| Size of long double | 8 bytes |
| Size of pointer | 4 bytes |
| Maximum alignment of all integer types | 8 bytes |
| Maximum alignment of variables of type struct or union | 1 byte |
| Endianness | little |
| Underlying type of size_t | unsigned_int |
| Underlying type of ptrdiff_t | int |
| Underlying type of wchar_t | unsigned_int |

## Tips

- If your configuration uses both -custom-target and Target processor type (-target) to specify targets, the analysis uses the target that you specify with -custom-target.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## See Also

Target processor type (-target) | Generic target options

**Topics**

"Specify Polyspace Analysis Options"

# -date

Specify date of analysis

## Syntax

`-date "*date*"`

## Description

`-date "date"` specifies the date stamp for the analysis in the format `dd/mm/yyyy`. By default the value is the date the analysis starts.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Assign a date to your Polyspace Project:

- Bug Finder:

  ```
  polyspace-bug-finder -date "15/03/2012"
  ```
- Code Prover:

  ```
  polyspace-code-prover -date "15/03/2012"
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -date "15/03/2012"
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -date "15/03/2012"
  ```

## Tips

This option is not required for a Polyspace as You Code analysis.

## See Also

`-author`

### Topics

“Specify Polyspace Analysis Options”

# -detect-atomic-data-race

Enable detecting data race with atomic operation

## Syntax

`-detect-atomic-data-race`

## Description

`-detect-atomic-data-race` specifies that the analysis must check for data races in atomic operations..

By default, Polyspace does not check for data races in atomic operations. Bug Finder considers an operation as atomic if it can be performed in one machine instruction. For instance:

- The operation:

  ```
  int var = 0;
  ```

  can be performed in one machine instruction on targets where the size of `int` is less than the word size or the pointer size on the target.
- The operation:

  ```
  MYREG = (u32dma0_chbit << 8UL) | u32dma0_chbit;
  ```

  takes more than one cycle to be performed and is nonatomic.

See “Define Atomic Operations in Multitasking Code”. If you do not want to use this definition of atomic operations and want to check every operation for data races, specify the option `-detect-atomic-data-race`.

If you run verification from the user interface (desktop products only), specify the option in the **Other** field. See `Other`.

## Examples

In the code example, the write operation `var=1;` in task `task1` executes concurrently with the read operation `local_var=var;` in task `task2`. By default, Polyspace assumes that the write operation is atomic. Based on your environment, you might want to extend the `data race` checker to include the write operation.

### Code Example

```
#include<stdio.h>

int var;

void begin_critical_section(void);
void end_critical_section(void);
```

```
void task1(void) {
    var = 1;
}

void task2(void) {
    int local_var;
    local_var = var;
    printf("%d", local_var);
}

void task3(void) {
    begin_critical_section();
    /* Operations in task3 */
    end_critical_section();
}
```

To check the atomic operations in this example for data races, at the command line, specify these options:

```
 polyspace-bug-finder -sources SRC -checkers DATA_RACE
   -entry-points task1,task2,task3
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
   -detect-atomic-data-race
```

In the Polyspace user interface, use the options listed in this table.

| Option | Specification | |
|---|---|---|
| Other | -detect-atomic-data-race | |
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2<br>task3 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

## Dependencies

- To detect data races, you have to configure the concurrency options:

  - `Tasks (-entry-points)`
  - `Critical section details (-critical-section-begin -critical-section-end)`

  See “Multitasking”. If you specify the option `-detect-atomic-data-race` without configuring the concurrency options, Polyspace emits a warning.
- This option extends the following checkers and is not useful unless you enable at least one of the checkers:

- `Data race`
- `CERT C: Rule CON43-C`
- `CERT C++: CON43-C`

## Tips

This option is not useful in a Polyspace as You Code analysis.

## See Also

**Topics**
"Extend Data Race Checkers to Atomic Operations"

# -disable-concurrency-detection

Disable automatic detection of multitasking functions

## Syntax

`-disable-concurrency-detection`

## Description

`-disable-concurrency-detection` disables the automatic concurrency detection for supported multitasking functions.

Polyspace can automatically detect multitasking functions from several libraries, including these:

- POSIX
- VxWorks
- Windows
- µC/OS II
- C++11
- C11

See “Multitasking Routines that Polyspace Can Detect”.

Automatic detection of these functions might find too many tasks and slow down a Polyspace analysis. In such cases, use this option to disable automatic detection. Instead, manually configure your multitasking analysis by using analysis options such as `Tasks (-entry-points)`, `Critical section details (-critical-section-begin -critical-section-end)`, `Temporally exclusive tasks (-temporal-exclusions-file)`. See “Configuring Polyspace Multitasking Analysis Manually”.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Disable automatic detection of multitasking functions by using this option. Then, manually configure the multitasking analysis:

```
polyspace-bug-finder -checkers concurrency -disable-concurrency-detection
-entry-points foo1,foo2,foo3
```

## Tips

This option is not useful in a Polyspace as You Code analysis.

## See Also

`Tasks (-entry-points)` | `Critical section details (-critical-section-begin -critical-section-end)` | `Temporally exclusive tasks (-temporal-exclusions-file)`

### Topics

# -doc | -documentation

Display Polyspace documentation in help browser

## Syntax

```
-doc
-documentation
```

## Description

`-doc` and `-documentation` opens the Polyspace web documentation in your default web browser. You can see information such as getting started, workflows and reference pages for commands and analysis options. You can also search through the documentation.

## Examples

Display Polyspace documentation in a help browser:

- Bug Finder:

  ```
  polyspace-bug-finder -doc
  polyspace-bug-finder -documentation
  ```
- Code Prover:

  ```
  polyspace-code-prover -doc
  polyspace-code-prover -documentation
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -doc
  polyspace-bug-finder-server -documentation
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -doc
  polyspace-code-prover-server -documentation
  ```

## See Also

`-h[elp]`

# -dump-preprocessing-info

Show all macros implicitly defined during a particular analysis

## Syntax

`-dump-preprocessing-info`

## Description

`-dump-preprocessing-info` prints all the macros implicitly defined (or undefined) during a particular Polyspace analysis. The macro definitions come from:

- Your specification for the option `Compiler (-compiler)`

  Polyspace emulates a compiler by defining the compiler-specific macros.
- Macros defined (or undefined) in the Polyspace implementation of Standard Library headers
- Macros that you explicitly define (or undefine) using the options `Preprocessor definitions (-D)` and `Disabled preprocessor definitions (-U)`

Use this option only if you want to know how Polyspace defines a specific macro. In case you want to use a different definition for the macro, you can then override the current definition.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`. On the **Output Summary** pane, you can see each macro definition on a separate line. You can search for the macro name in the user interface and click the line with the macro name to see further details in the **Detail** pane.

## Examples

Suppose that you use the ARM v6 compiler for building your source code. For the Polyspace analysis, you use the value `armclang` for the option `Compiler (-compiler)`. Suppose that you want to know what Polyspace uses as definition for the macro `__ARM_ARCH`.

1. Enter the following command and pipe the console output to a file that you can search later:

   ```
   polyspace-bug-finder -sources aFile.c -compiler armclang -dump-preprocessing-info
   ```

   `aFile.c` can be a simple C file. You can also replace `polyspace-bug-finder` with `polyspace-code-prover`, `polyspace-bug-finder-server` or `polyspace-code-prover-server`.
2. Search for `__ARM_ARCH` in the file containing the console output. You can see the line with the macro definition:

   ```
   Remark: Definition of macro __ARM_ARCH (pre-processing __polyspace__stdstubs.c)
   |#define __ARM_ARCH 8
   |defined by syntax extension xml file
   |predefined macro
   ```

In this example, the macro is set to the value 8.

- To override this macro definition, use the option `Preprocessor definitions (-D)`.
- To undefine this macro, use the option `Disabled preprocessor definitions (-U)`.

## See Also

`Compiler (-compiler)`

"Specify Polyspace Analysis Options"

# -generate-launching-script-for

Extract information from project file

## Syntax

`-generate-launching-script-for` *`PRJFILE`*

## Description

`-generate-launching-script-for` *`PRJFILE`* extracts information from a project file *`PRJFILE`* (created in the user interface of the Polyspace desktop products) so that you can run an analysis from the command line. For each project module and each configuration in each module, a folder is created containing the following files::

- `source_command.txt` — List of source files for the `-sources-list-file` option.
- `options_command.txt` — List of the analysis options for the `-options-file` option.
- `temporal_exclusions.txt` — List of temporal exclusions, generated only if you specify the `Temporally exclusive tasks (-temporal-exclusions-file)` option.
- `.polyspace_conf.psprj` — A copy of the project file Polyspace used to generate the scripting files.
- `launchingCommand.sh` (UNIX) or `launchingCommand.bat` (DOS) — shell script that calls the correct commands. The script also calls any options that cannot be given to the `-options-file` command, such as `-batch` or `-add-to-results-repository`. You can give this file additional analysis options as parameters.

After you set up a project in the Polyspace user interface, you can create this script from the resulting project file (with extension `.psprj`). The script that Polyspace generates runs the same analysis as a run in the user interface. If your project runs without errors in the Polyspace user interface, the script runs without errors at the command line.

To generate the script, you must run the command from the same folder as the project file.

## Examples

Extract information to run `myproject` from the command line. Use this option with the desktop binary `polyspace`:

- Bug Finder:

  ```
  polyspace -generate-launching-script-for myproject.psprj -bug-finder
  ```
- Code Prover:

  ```
  polyspace -generate-launching-script-for myproject.psprj
  ```

## See Also

### Topics

"Configure Polyspace Analysis Options in User Interface and Generate Scripts"

# -h | -help

Display list of possible options

## Syntax

```
-h
-help
```

## Description

`-h` and `-help` display the list of possible options in the command window along with option argument syntax.

## Examples

Display the command-line help:

- Bug Finder:

  ```
  polyspace-bug-finder -h
  polyspace-bug-finder -help
  ```
- Code Prover:

  ```
  polyspace-code-prover -h
  polyspace-code-prover -help
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -h
  polyspace-bug-finder-server -help
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -h
  polyspace-code-prover-server -help
  ```

## See Also

`-doc | -documentation`

# -I

Specify include folder for compilation

## Syntax

`-I folder`

## Description

`-I folder` specifies a folder that contains include files required for compiling your sources. You can specify only one folder for each instance of `-I`. However, you can specify this option multiple times.

The analysis looks for include files relative to the folder paths that you specify. For instance, if your code contains the preprocessor directive `#include<../mylib.h>` and you include the folder:

```
C:\My_Project\MySourceFiles\Includes
```

the folder `C:\My_Project\MySourceFiles` must contain a file `mylib.h`.

The analysis automatically includes the `./sources` folder (if it exists) after the include folders that you specify.

## Examples

Include two folders with the analysis:

- Bug Finder:

  ```
  polyspace-bug-finder -I /com1/inc -I /com1/sys/inc
  ```
- Code Prover:

  ```
  polyspace-code-prover -I /com1/inc -I /com1/sys/inc
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -I /com1/inc -I /com1/sys/inc
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -I /com1/inc -I /com1/sys/inc
  ```

The source folder is implicitly included. Include files in the source folder can be found automatically without explicit inclusion of the source folder with the `-I` option.

## Tips

- This option is useful for Polyspace analysis from the command line. In the Polyspace user interface, you add the include folders during project setup. See “Add Source Files for Analysis in Polyspace Desktop User Interface”.
- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

- The option `-I` does not work recursively. If you add a folder path using this option, the analysis only considers include files that are directly in the folder *and not in subfolders of the folder*. If you also want subfolders in the include search path, explicitly add the subfolder paths using their own `-I`-s. For convenience, you can write a script that recursively looks through a folder and generates `-I`-s to subfolders of the folder.

"Specify Polyspace Analysis Options"

# -ignore-code-annotations

Ignore C/C++ code annotations justifying Polyspace results and show all results as unreviewed

## Syntax

```
-ignore-code-annotations
```

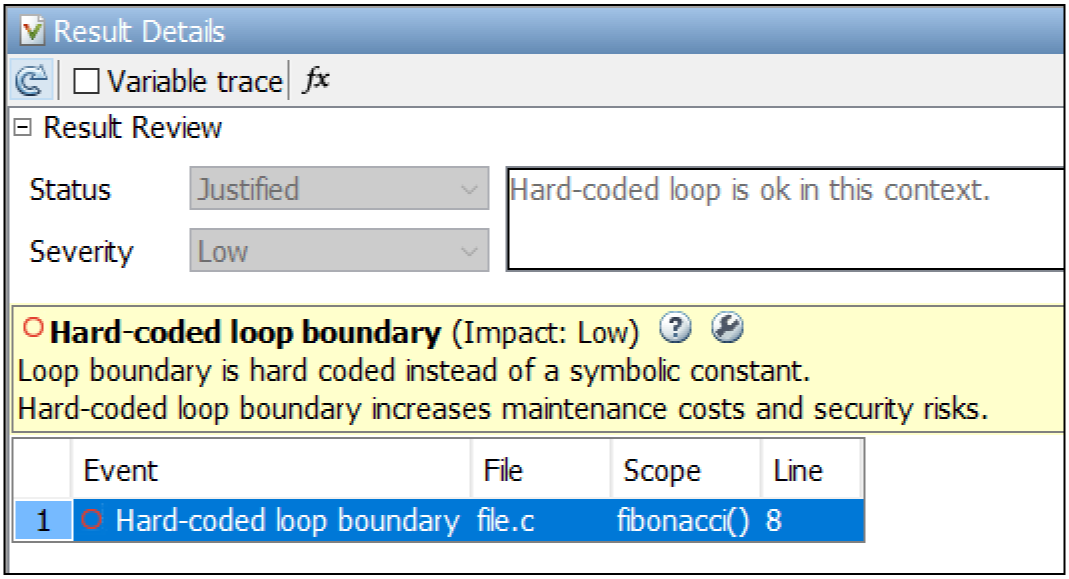
## Description

`-ignore-code-annotations` causes a Polyspace analysis to ignore code annotations justifying Polyspace results and show previously annotated results as unreviewed.

To avoid reviewing a result multiple times, you can add Polyspace-specific annotations to your code with review information such as justification for a result. Later runs take into account these annotations and prepopulate the annotated results with associated review information. However, in some cases, you might want to run a clean analysis as if the results have not been previously reviewed. You can use the option `-ignore-code-annotations` to run such an analysis with no history. The analysis ignores the code annotations and shows all annotated results without any review information taken from the annotations.

For instance, an analysis that takes into account code annotations shows these features:

- The **Results Details** pane for an annotated result is prepopulated with the review information. You can use filters to hide or show these annotated results.



Status: Justified

Severity: Low

Hard-coded loop is ok in this context.

○ **Hard-coded loop boundary** (Impact: Low)

Loop boundary is hard coded instead of a symbolic constant.

Hard-coded loop boundary increases maintenance costs and security risks.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | ○ Hard-coded loop boundary | file.c | fibonacci() | 8 |

- Statistics on the **Dashboard** perspective in Polyspace Access use review information from the annotations. For instance, results that are justified using annotations are counted as **Done**.

If you use the option `-ignore-code-annotations`, both the individual results and the aggregated statistics do not include information from the code annotations.

For details on the code annotations workflow, see “Annotate Code and Hide Known or Acceptable Results”.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

To ignore previous code annotations, use the option `-ignore-code-annotations`.

- Bug Finder:

  ```
  polyspace-bug-finder -sources file.c -ignore-code-annotations
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -sources file.c -ignore-code-annotations
  ```
- Code Prover:

  ```
  polyspace-code-prover -sources file.c -ignore-code-annotations
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -sources file.c -ignore-code-annotations
  ```

## Tips

If you do not want to see any previous review information, you must also make sure that you are not importing review information from previous results. For instance, make sure that:

- You are not using options such as `-import-comments`.
- You have disabled automatic comment import from last results in the Polyspace user interface.

See also “Import Review Information from Previous Polyspace Analysis”.

# Version History

**Introduced in R2022a**

## See Also

### Topics

“Specify Polyspace Analysis Options”
“Annotate Code and Hide Known or Acceptable Results”

# -import-comments

Import review information from previous analysis

## Syntax

```
-import-comments resultsFolderPath
```

## Description

`-import-comments` *`resultsFolderPath`* imports the review information (status, severity and additional notes) from a previous analysis stored in the folder specified by the path *`resultsFolderPath`*.

You can import review information from the same type of results only. For instance:

- You cannot import review information from a results of a Bug Finder checker to a Code Prover run-time check. Even when the checker names sound similar, the underlying semantics of Bug Finder and Code Prover can be different. The only exception is checkers for coding rules. You can import comments between Bug Finder and Code Prover for coding rule violations.
- You cannot import review information from results of a file-by-file verification in Code Prover to results of a regular Code Prover verification.

You can also use this option to create a baseline for the analysis results. In the Polyspace user interface, if you click the **New** button, only the analysis results that are new compared to the baseline remain in the results list.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Import review information from the previous results:

- Bug Finder:

  ```
  polyspace-bug-finder -sources filename -import-comments C:\Results\myProj\1.2
  ```
- Code Prover:

  ```
  polyspace-code-prover -sources filename -import-comments C:\Results\myProj\1.2
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -sources filename -import-comments C:\Results\myProj\1.2
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -sources filename -import-comments C:\Results\myProj\1.2
  ```

## Tips

If you use Polyspace as You Code extensions and you do not use previous analysis results that you downloaded from Polyspace Access, enter this option in an analysis options file. See options file.

## See Also

`-v[ersion]` | `polyspace-comments-import`

### Topics

“Import Review Information from Previous Polyspace Analysis”
“Baselining in Polyspace as You Code”

# -incremental

Enable incremental compilation during an analysis

## Syntax

```
-incremental
```

## Description

*This option affects only a Bug Finder analysis.*

`-incremental` enables an incremental mode during the compilation phase of a Polyspace analysis. Use this option to run faster multi-file analyses.

In this mode, after you run an initial analysis, Polyspace recompiles files during an analysis only if one of the following is true:

- You make edits to a source file. Polyspace recompiles all source files with edits since the last analysis.
- You make edits to a header file. Polyspace recompiles all files that declare a dependency on the edited header file.
- You make changes to the analysis options. Polyspace recompiles all files. Changes to these options are ignored:
  - `-author`
  - `-date`
  - `-prog`
  - `-verif-version`

When you use this option, make sure that you use the same results folder for all your analysis runs.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Example

Enable incremental mode for an analysis where you specify the list of sources in a file `sources.txt` and the list of analysis options in a file `opts.txt`.

- Polyspace Bug Finder

  ```
  polyspace-bug-finder -sources-list-file sources.txt -options-file opts.txt -incremental -results-dir .
  ```

- Polyspace Bug Finder Server

  ```
  polyspace-bug-finder-server -sources-list-file sources.txt -options-file opts.txt -incremental -results-dir .
  ```

## Tip

If you add a header to your project and a header with the same name already exists in a different folder, for instance you add `componentA/myHeader.h` when `componentB/myHeader.h` already exists, the new header does not trigger a recompilation.

# Version History

**Introduced in R2022a**

"Specify Polyspace Analysis Options"

# -list-all-values

Display valid option arguments for a given command-line option

## Syntax

`-list-all-values` *`option`*

## Description

`-list-all-values` *`option`* displays all the valid option arguments for the command-line option *`option`*.

## Examples

Display the valid option arguments for option `-misra3`:

- Polyspace Bug Finder:

  ```
  polyspace-bug-finder -list-all-values -misra3
  ```
- Polyspace Code Prover:

  ```
  polyspace-code-prover -list-all-values -misra3
  ```
- Polyspace Bug Finder Server:

  ```
  polyspace-bug-finder-server -list-all-values -misra3
  ```
- Polyspace Code Prover Server:

  ```
  polyspace-code-prover-server -list-all-values -misra3
  ```

# Version History

**Introduced in R2020a**

### Topics

“Specify Polyspace Analysis Options”

# -max-processes

Specify maximum number of processors for analysis

## Syntax

```
-max-processes num
```

## Description

`-max-processes` *`num`* specifies the maximum number of processes that you want the analysis to use. On a multicore system, the software parallelizes the analysis and creates the specified number of processes to speed up the analysis. The valid range of *`num`* is 1 to 128.

Unless you specify this option, a Code Prover verification uses up to four processes. If you have fewer than four processes, the verification uses the maximum available number. To increase or restrict the number of processes, use this option.

Unless you specify this option, a Bug Finder analysis uses the maximum number of available processes. Use this option to restrict the number of processes used.

To use this option effectively, determine the number of processors available for use. If the number of processes you create is greater than the number of processors available, the analysis does not benefit from the parallelization. Check the system information in your operating system.

Note that when you start a verification, a message states the number of logical processors detected on your system. However, the analysis is parallelized to the physical processor cores on a machine. Multithreading implementations such as hyper-threading is not taken into account.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Disable parallel processing during the analysis:

- Bug Finder:

  ```
  polyspace-bug-finder -max-processes 1
  ```
- Code Prover:

  ```
  polyspace-code-prover -max-processes 1
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -max-processes 1
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -max-processes 1
  ```

## Tips

You must have at least 4 GB of RAM per process for analysis. For instance, if your machine has 16 GB of RAM, do not use this option to specify more than four processes.

This option is not useful in a Polyspace as You Code analysis.

## See Also

### Topics

"Specify Polyspace Analysis Options"

# -non-preemptable-tasks

Specify functions that represent nonpreemptable tasks

## Syntax

```
-non-preemptable-tasks function1[,function2[,...]]
```

## Description

`-non-preemptable-tasks` *`function1`*`[,`*`function2`*`[,...]]` specifies functions that represent nonpreemptable tasks.

The functions cannot be interrupted by other noncyclic tasks and cyclic tasks but can be interrupted by interrupts, preemptable or nonpreemptable. Noncyclic tasks are specified with the option `Tasks (-entry-points)`, cyclic tasks with the option `Cyclic tasks (-cyclic-tasks)` and interrupts with the option `Interrupts (-interrupts)`. For examples, see “Define Task Priorities for Data Race Detection in Polyspace”.

To specify a function as a nonpreemptable cyclic task, you must first specify the function as a cyclic or noncyclic task. The functions that you specify must have the prototype:

```
void function_name(void);
```

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Consider the following program. Suppose that functions `task1` and `task2` represent tasks that can run concurrently.

```
int x;
void task1() {
    x++;
}
void task2() {
    x = 0;
}
void main() {
}
```

To specify that `task1` and `task2` are cyclic tasks, enter the following:

```
polyspace-bug-finder -sources filename -cyclic-tasks task1,task2
```

You see a **Data race** defect because the tasks attempt to concurrently access shared variable `x`.

Specify `task1` as nonpreemptable.

```
polyspace-bug-finder -sources multi.c -cyclic-tasks task1,task2
     -non-preemptable-tasks task1
```

The **Data race** disappears because the operation `x++` in `task1` cannot be interrupted anymore.

## Tips

- This option is not useful in a Polyspace as You Code analysis.
- Code Prover interprets this option with some limitations. The reason is that Code Prover considers all operations as potentially non-atomic and interruptible. This overapproximation leads to situations where the option might appear to be ignored. For an example, see "Effect of Task Priorities in Code Prover" (Polyspace Code Prover).

# -options-file

Run Polyspace using list of options

## Syntax

`-options-file` *`file`*

## Description

`-options-file` *`file`* specifies the file that lists your analysis options. The file must be a text file with each option on a separate line. Use # to add comments to this file.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

When using this option in the user interface, in the **Other** field, specify the absolute path to your options file. For instance:

```
-options-file C:\psconfig\listofoptions.txt
```

When using this option in the command line, you can use relative path of the options file as the input.

## Examples

1 Create an options file called `listofoptions.txt` with your options. For example:

- Bug Finder or Bug Finder Server:

```
#These are the options for MyBugFinderProject
-lang c
-prog MyBugFinderProject
-author jsmith
-sources "mymain.c,funAlgebra.c,funGeometry.c"
-target x86_64
-compiler generic
-dos
-misra2 required-rules
-do-not-generate-results-for all-headers
-checkers default
-disable-checkers concurrency
-results-dir C:\Polyspace\MyBugFinderProject
```

- Code Prover or Code Prover Server:

```
#These are the options for MyCodeProverProject
-lang c
-prog MyCodeProverProject
-author jsmith

"Specify Polyspace Analysis Options"

# -options-for-sources

Specify analysis options specific to a source file

## Syntax

`-options-for-sources` *`filename options`*

## Description

`-options-for-sources` *`filename options`* associates a semicolon-separated list of Polyspace analysis options with the source file specified by *`filename.`*.

This option is primarily used when the `polyspace-configure` command creates an options file for the subsequent Polyspace analysis. The option `-options-for-sources` associates a group of analysis options such as include folders and macro definitions with specific source files.

However, you can directly enter this option when manually writing options files. This option is useful in situations where you want to associate a group of options with a specific source file without applying it to other files.

In the user interface of the Polyspace desktop products, you can create a Polyspace project from your build command. The project uses the option `-options-for-sources` to associate specific Polyspace analysis options with specific files. However, when you open the project in the user interface, you cannot see the use of this option. Open the project in a text editor to see this option.

## Examples

In this sample options file, the include folder `/usr/lib/gcc/x86_64-linux-gnu/6/include` and the macros `__STDC_VERSION__` and `__GNUC__` are associated only with the source file `file.c` and not `fileAnother.c`.

```
-options-for-sources file.c;-I /usr/lib/gcc/x86_64-linux-gnu/6/include;
-options-for-sources file.c;-D __STDC_VERSION__=201112L;-D __GNUC__=6;
-sources file.c
-sources fileAnother.c
```

For the options used in this example, see:

- `-sources`
- `-I`
- `Preprocessor definitions (-D)`

## Tips

When associating multiple options with a source file, if you use an option separator other than semicolon, use a second option `-options-for-sources-delimiter` to explicitly specify this separator. For instance, if you use the separator `@`, specify the additional option:

```
-options-for-sources-delimiter @
```

Otherwise, the analysis assumes a semicolon separator.

`-options-file` | `polyspace-configure`

### Topics

"Specify Polyspace Analysis Options"

# -preemptable-interrupts

Specify functions that represent preemptable interrupts

## Syntax

```
-preemptable-interrupts function1[,function2[,...]]
```

## Description

`-preemptable-interrupts` *`function1`*`[,`*`function2`*`[,...]]` specifies functions that represent preemptable interrupts.

The function acts as an interrupt in every way except that it can be interrupted by other interrupts, preemptable or nonpreemptable. Interrupts are specified with the option `Interrupts (-interrupts)`. For examples, see “Define Task Priorities for Data Race Detection in Polyspace”.

To specify a function as a preemptable interrupt, you must first specify the function as an interrupt. The functions that you specify must have the prototype:

```
void function_name(void);
```

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Consider the following program. Suppose that functions `task1` and `task2` represent interrupts.

```
int x;
void task1() {
    x++;
}
void task2() {
    x = 0;
}
void main() {
}
```

To specify that `task1` and `task2` are cyclic tasks, enter the following:

```
polyspace-bug-finder -sources filename -interrupts task1,task2
```

You do not see a **Data race** defect because the operations in `task1` and `task2` cannot interrupt each other. Functions specified as interrupts are nonpreemptable by default.

Specify `task1` as preemptable.

```
polyspace-bug-finder -sources multi.c -interrupts task1,task2
     -preemptable-interrupts task1
```

A **Data race** now appears because the operation `x++` in `task1` can be interrupted by operations in `task2`.

## Tips

- This option is not useful in a Polyspace as You Code analysis.
- Code Prover interprets this option with some limitations. The reason is that Code Prover considers all operations as potentially non-atomic and interruptible. This overapproximation leads to situations where the option might appear to be ignored. For an example, see “Effect of Task Priorities in Code Prover” (Polyspace Code Prover).

# Version History

**Introduced in R2016b**

# -prog

Specify name of project

## Syntax

`-prog` *`projectName`*

## Description

`-prog` *`projectName`* specifies a name for your Polyspace project. This name must use only letters, numbers, underscores (_), dashes (-), or periods (.).

The name appears in the analysis log and a few other places.

## Examples

Assign a name to your Polyspace project:

- Bug Finder:

  ```
  polyspace-bug-finder -prog MyApp
  ```
- Code Prover:

  ```
  polyspace-code-prover -prog MyApp
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -prog MyApp
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -prog MyApp
  ```

## Tips

This option is not required for a Polyspace as You Code analysis.

“Specify Polyspace Analysis Options”

# -regex-replace-rgx -regex-replace-fmt

Make replacements in preprocessor directives

## Syntax

`-regex-replace-rgx` *`matchFileName`* `-regex-replace-fmt` *`replacementFileName`*

## Description

`-regex-replace-rgx` *`matchFileName`* `-regex-replace-fmt` *`replacementFileName`* replaces tokens in preprocessor directives for the purposes of Polyspace analysis. The original source code is unchanged. You match a token using a regular expression in the file *`matchFileName`* and replace the token using a replacement in the file *`replacementFileName`*.

Use the option only to replace or remove tokens in the preprocessor directives *before preprocessing*. Normally, if a token in your source code causes a compilation error, you can replace or remove the token from the preprocessed code by using the more convenient option `Command/script to apply to preprocessed files (-post-preprocessing-command)`. However, you cannot use the option to replace tokens in preprocessor directives. In this case, use `-regex-replace-rgx -regex-replace-fmt`.

For a complete list of regular expressions available with this option, see Perl documentation. Note that:

- Perl allows the syntax `s/`*`pattern`*`/`*`replacement`*`/`*`modifier`* for replacements. When using this option, you emulate this syntax only partially. You specify the pattern to match, *`pattern`*, in one file and its replacement, *`replacement`*, in another file. Search modifiers, that is, values of *`modifier`* in the Perl syntax, are not supported. For instance, by default, the option makes global replacements (that is, replaces the matched tokens wherever it finds them) and the matches are case-sensitive. You cannot change these defaults using search modifiers.
- The option supports both numbered and named capture groups. You can define a capture group in the match file by including it in parenthesis and use `$1`, `$2`, etc., to refer to those capture groups in the replacement file. Alternatively, you can also name the capture group and refer to the group by name. For an example, see "Replace Multiple Preprocessor Directives with Different Replacements Using Capture Groups" on page 3-57.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

In the user interface, specify absolute paths to the text files with the search and replace patterns.

## Examples

### Replace Undefined Symbols in Preprocessor Directive with Simpler Alternatives

Suppose that you want to modify this `#define` directive:

```
#define ROM_BEG_ADDR (uint16_t)(&_rom_beg)
```

to:

```
#define ROM_BEG_ADDR (0x4000u)
```

The reason for replacement might be that _rom_beg is undefined in the code provided to Polyspace and causes compilation issues. Since the tokens (uint16_t)(&_rom_beg) indicate an address and a Polyspace analysis does not keep track of precise addresses, you can replace (uint16_t)(&_rom_beg) with a simple address such as (0x4000u). To complicate the issue slightly, suppose also that you want to allow for one or more whitespace characters after #define and ROM_BEG_ADDR.

To make the replacement:

1. Specify this regular expression in a file match.txt:

   ```
   ^#define\s+ROM_BEG_ADDR\s+\(uint16_t\)\(\&_rom_beg\)
   ```

   These elements are used in the regular expression:

   - ^ asserts position at the start of a line.
   - \s+ represents one or more whitespace characters.

   The characters *, &, ( and ) are escaped with \.
2. Specify the replacement in a file replace.txt.

   ```
   #define ROM_BEG_ADDR \(0x4000u\)
   ```
3. Specify the two text files during analysis with the options -regex-replace-rgx and -regex-replace-fmt:

   - Bug Finder:

     ```
     polyspace-bug-finder -sources filename
                                 -regex-replace-rgx match.txt
                                 -regex-replace-fmt replace.txt
     ```
   - Code Prover:

     ```
     polyspace-code-prover -sources filename
                                 -regex-replace-rgx match.txt
                                 -regex-replace-fmt replace.txt
     ```
   - Bug Finder Server:

     ```
     polyspace-bug-finder-server -sources filename
                                 -regex-replace-rgx match.txt
                                 -regex-replace-fmt replace.txt
     ```
   - Code Prover Server:

     ```
     polyspace-code-prover-server -sources filename
                                 -regex-replace-rgx match.txt
                                 -regex-replace-fmt replace.txt
     ```

### Replace Multiple Preprocessor Directives with Different Replacements Using Capture Groups

The following example defines two macros bypass_UInt16_ and bypass_UInt32_, both of which contains undefined symbols, UInt16_DO_NOT_EXIST and UInt32_DO_NOT_EXIST.

```
typedef unsigned short UInt16;
typedef signed short Int16;
```

```
typedef unsigned int UInt32;
typedef signed int Int32;

UInt16 x16;
Int16 y16, z16;

UInt32 x32;
Int32 y32, z32;

#define bypass_UInt16_(_var, _value, _add) _var = _value +/*CTO*/(UInt16_DOES_NOT_EXIST) _add
#define bypass_UInt32_(_var, _value, _add) _var = _value +/*CTO*/(UInt32_DOES_NOT_EXIST) _add

void main(void){
    bypass_UInt16_(x16, y16, z16);
    bypass_UInt32_(x32, y32, z32);
}
```

Both undefined symbols follow a comment `/* CTO */`. Since the symbols are undefined, they cause compilation errors. Suppose that you want to modify the macro definitions so that the undefined symbols appear inside the comments instead of just following it. Since you want to perform similar modifications to both definitions but do not want to replace both undefined symbols with one replacement, you can use capture groups to keep the symbol names intact.

To make the replacements:

1 Specify this regular expression in a file `match.txt`:

   ```
   \/\* CTO \*\/(\s+\(.*?\))
   ```

   These elements are used in the regular expression:

   - The characters `/`, `*`, ( and ) are escaped with `\`. For instance, to match against:

     ```
     /* CTO */
     ```

     You enter the escaped sequence:

     ```
     \/\* CTO \*\/
     ```

   - The outer parenthesis in the sequence:

     ```
     (\s+\(.*?\))
     ```

     indicates a capture group. The group includes one or more whitespace characters (indicated with `\s+`) and one or more characters inside a parenthesis. This capture group can capture both the undefined symbols, `(UInt16_DO_NOT_EXIST)` and `(UInt32_DO_NOT_EXIST)`.

     This capture group needs to be referred by number in the replacement file. Alternatively, you can create a named capture group and refer to the group by name in the replacement file. For instance, the following regular expression creates a named capture group `cto_group`:

     ```
     \/\* CTO \*\/(?<cto_group>\s+\(.*?\))
     ```

2 Specify the replacement in a file `replace.txt`.

   ```
   /* CTO $1 */
   ```

   The `$1` refers to the previously captured group. This replacement simply places the captured groups before the `*/` closing the comments.

   If you created a capture group named `cto_group` in the match file, enter this replacement:

   ```
   /* CTO $+{cto_group} */
   ```

The name of the capture group is included in `$+{ }`.

3. Specify the two text files during analysis with the options `-regex-replace-rgx` and `-regex-replace-fmt` (as shown in previous example).

You see the following code in the analysis results with the undefined symbols now included in comments:

```
typedef unsigned short UInt16;
typedef signed short Int16;

typedef unsigned int UInt32;
typedef signed int Int32;

UInt16 x16;
Int16 y16, z16;

UInt32 x32;
Int32 y32, z32;

#define bypass_UInt16_(_var, _value, _add) _var = _value + /* CTO  (UInt16_DO_NOT_EXIST) */ _add
#define bypass_UInt32_(_var, _value, _add) _var = _value + /* CTO  (UInt32_DO_NOT_EXIST) */ _add

void main(void){
    bypass_UInt16_(x16, y16, z16);
    bypass_UInt32_(x32, y32, z32);
}
```

## Tips

- If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.
- To make replacements in multiple kinds of preprocessor directives, enter one regular expression per line in the match file and its replacement on the corresponding line in the replacement file. Each preprocessor line that matches a regular expression in the match file is replaced with the corresponding replacement from the replacement file. You can also enter all the matches and replacements in one line separated by `|`. However, one entry per line improves the readability of the files.

  For instance, the match file can contain two regular expressions such as:

  ```
  ^#define\s+ROM_BEG_ADDR\s+\(uint16_t\)\(\&_rom_beg\)
  ^#define\s+ROM_END_ADDR\s+\(uint16_t\)\(\&_rom_end\)
  ```

  And the replacement file can contain these two replacements:

  ```
  #define ROM_BEG_ADDR \(0x4000u\)
  #define ROM_END_ADDR \(0x8000u\)
  ```

  With these matches and replacements, the following source code:

  ```
  #include <stdint.h>

  #define ROM_BEG_ADDR (uint16_t)(&_rom_beg)
  #define ROM_END_ADDR (uint16_t)(&_rom_end)
  ```

```
void main() {
    uint16_t beg_addr = ROM_BEG_ADDR;
    uint16_t end_addr = ROM_END_ADDR;
}
```

is converted to the following preprocessed code before analysis:

```
#include <stdint.h>

#define ROM_BEG_ADDR (0x4000u)
#define ROM_END_ADDR (0x8000u)

void main() {
    uint16_t beg_addr = ROM_BEG_ADDR;
    uint16_t end_addr = ROM_END_ADDR;
}
```

`Command/script to apply to preprocessed files (-post-preprocessing-command)`

### Topics

"Specify Polyspace Analysis Options"

# -report-output-name

Specify name of report

## Syntax

`-report-output-name` *`reportName`*

## Description

`-report-output-name` *`reportName`* specifies the name of an analysis report.

The default name for a report is *`Prog_Template.Format`*:

- *`Prog`* is the name of the project specified by `-prog`.
- *`TemplateName`* is the type of report template specified by `-report-template`.
- *`Format`* is the file extension for the report specified by `-report-output-format`.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Specify the name of the analysis report:

- Bug Finder:

  ```
  polyspace-bug-finder -report-template Developer
        -report-output-name Airbag_v3.doc
  ```
- Code Prover:

  ```
  polyspace-code-prover -report-template Developer
        -report-output-name Airbag_v3.doc
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -report-template Developer
        -report-output-name Airbag_v3.doc
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -report-template Developer
        -report-output-name Airbag_v3.doc
  ```

## Tips

You cannot generate reports with Polyspace as You Code.

## See Also

`Bug Finder and Code Prover report (-report-template)` | `Output format (-report-output-format)`

**Topics**

“Specify Polyspace Analysis Options”

“Generate Reports from Polyspace Results”

# -results-dir

Specify the results folder

## Syntax

```
-results-dir resultsFolder
```

## Description

`-results-dir resultsFolder` specifies where to save the analysis results. The default location at the command line is the current folder.

Note that the results folder is cleaned up and repopulated at each run. To avoid accidental removal of files during the cleanup, instead of using an existing folder that contains other files, specify a dedicated folder for the Polyspace results.

If you are running analysis in the user interface of the Polyspace desktop products, see “Run Analysis in Polyspace Desktop User Interface”.

## Examples

Specify to store your results in the `RESULTS` folder:

- Bug Finder:

  ```
  polyspace-bug-finder -results-dir RESULTS
  ```
- Code Prover:

  ```
  polyspace-code-prover -results-dir RESULTS
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -results-dir RESULTS
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -results-dir RESULTS
  ```

You can create the name of the results folder based on the verification date and time. For instance, in a Bash shell, enter these commands to create a variable `RESULTS` that begins with `results_` and contains the current date and time:

```
export DATETIME=$(date +%d%B_%HH%M_%A)
export RESULTS=results_$DATE
```

You can then use the variable `RESULTS` as argument of the option `-results-dir`:

```
-results-dir $RESULTS
```

## Tips

If you use Polyspace as You Code extensions in IDEs, this option is implemented through the IDE extension setting. You do not have to use this option explicitly. If you want to explicitly use this option, enter the option in an analysis options file. See options file.

## See Also

### Topics

“Specify Polyspace Analysis Options”

# -scheduler

Specify cluster or job scheduler

## Syntax

`-scheduler` *`schedulingOption`*

## Description

`-scheduler` *`schedulingOption`* specifies the head node of the MATLAB Parallel Server cluster that manages Polyspace analysis submissions from multiple clients and allocates the analysis to worker nodes. You use this option along with the option `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)` to offload an analysis from a desktop to a remote cluster. Note that you use this option with the commands in the desktop products (`polyspace-bug-finder` and `polyspace-code-prover`) and not the commands in the server products (`polyspace-bug-finder-server` and `polyspace-code-prover-server`).

For more information, see "Install Products for Submitting Polyspace Analysis from Desktops to Remote Server".

## Examples

Run a batch analysis on a remote server using one of these syntaxes for the job scheduler:

- Bug Finder:

  ```
  polyspace-bug-finder -batch -scheduler NodeHost
  polyspace-bug-finder -batch -scheduler 192.168.1.124:12400
  polyspace-bug-finder -batch -scheduler MJSName@NodeHost
  ```
- Code Prover:

  ```
  polyspace-code-prover -batch -scheduler NodeHost
  polyspace-code-prover -batch -scheduler 192.168.1.124:12400
  polyspace-code-prover -batch -scheduler MJSName@NodeHost
  ```

For details, see "Send Polyspace Analysis from Desktop to Remote Servers Using Scripts".

You can track the status of the job using the `polyspace-jobs-manager` command:

```
polyspace-jobs-manager listjobs -scheduler NodeHost
```

## Tips

You cannot submit analysis jobs to a remote cluster with Polyspace as You Code.

## See Also

`Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`

### Topics

"Send Polyspace Analysis from Desktop to Remote Servers Using Scripts"

“Send Bug Finder Analysis from Desktop to Locally Hosted Server”
“Install Products for Submitting Polyspace Analysis from Desktops to Remote Server”

# -sources

Specify source files

## Syntax

```
-sources file1[,file2,...]
-sources file1 -sources file2
```

## Description

`-sources file1[,file2,...]` or `-sources file1 -sources file2` specifies the list of source files that you want to analyze. You can use standard UNIX wildcards with this option to specify your sources.

The source files are compiled in the order in which they are specified.

## Examples

Analyze the files `mymain.c`, `funAlgebra.c`, and `funGeometry.c`.

- Bug Finder:

  ```
  polyspace-bug-finder -sources mymain.c
       -sources funAlgebra.c -sources funGeometry.c
  ```
- Code Prover:

  ```
  polyspace-code-prover -sources mymain.c
       -sources funAlgebra.c -sources funGeometry.c
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -sources mymain.c
       -sources funAlgebra.c -sources funGeometry.c
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -sources mymain.c
       -sources funAlgebra.c -sources funGeometry.c
  ```
- Polyspace as You Code:

  ```
  polyspace-bug-finder-access -sources myfile.c
  ```

  Note that you can only analyze one file at a time with Polyspace as You Code. If you use Polyspace as You Code extensions in IDEs, you do not have to specify this option. The analysis runs on the file that is currently active in your IDE.

## Tips

This option is useful for Polyspace analysis from the command line. In the Polyspace user interface, you add the source files during project setup. See “Add Source Files for Analysis in Polyspace Desktop User Interface”.

## See Also

`-sources-list-file` | `polyspace-configure`

### Topics

"Specify Polyspace Analysis Options"

# -sources-list-file

Specify file containing list of sources

## Syntax

`-sources-list-file *file_path*`

## Description

`-sources-list-file` *`file_path`* specifies the absolute path to a text file that lists each file name that you want to analyze.

To specify your sources in the text file, on each line, specify the path to a source file. You can specify an absolute path or a path relative to the folder from which you are running the analysis. For example:

```
C:\Sources\myfile.c
C:\Sources2\myfile2.c
```

## Examples

Run analysis on files listed in `files.txt`:

- Bug Finder:

  ```
  polyspace-bug-finder -sources-list-file "C:\Analysis\files.txt"
  polyspace-bug-finder -sources-list-file "/home/polyspace/files.txt"
  ```
- Code Prover:

  ```
  polyspace-code-prover -sources-list-file "C:\Analysis\files.txt
  polyspace-code-prover -sources-list-file "/home/polyspace/files.txt"
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -sources-list-file "C:\Analysis\files.txt"
  polyspace-bug-finder-server -sources-list-file "/home/polyspace/files.txt"
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -sources-list-file "C:\Analysis\files.txt
  polyspace-code-prover-server -sources-list-file "/home/polyspace/files.txt"
  ```

## Tips

You cannot use this option with Polyspace as You Code.

## See Also

### Topics

“Specify Polyspace Analysis Options”

# -submit-job-from-previous-compilation-results

Specify that the analysis job must be resubmitted without recompilation

## Syntax

```
-submit-job-from-previous-compilation-results
```

## Description

`-submit-job-from-previous-compilation-results` specifies that the Polyspace analysis must start after the compilation phase with compilation results from a previous analysis. The option is primarily useful when offloading a Polyspace analysis from desktops to remote servers. If a remote analysis stops after compilation, for instance because of communication problems between the server and client computers, use this option. Note that you use this option with the commands in the desktop products (`polyspace-bug-finder` and `polyspace-code-prover`) and not the commands in the server products (`polyspace-bug-finder-server` and `polyspace-code-prover-server`).

When you perform a remote analysis:

1. On the local host computer, the Polyspace software performs code compilation and coding rule checking.
2. The analysis job is then submitted to the MATLAB job scheduler on the head node of the MATLAB Parallel Server cluster.
3. The head node of the MATLAB Parallel Server cluster assigns the verification job to a worker node, where the remaining phases of the Polyspace analysis occur.

If an analysis stops after completing the first step and you restart the analysis, use this option to reuse compilation results from the previous analysis. You thereby avoid restarting the analysis from the compilation phase.

If previous compilation results do not exist in the current folder, an error occurs. Remove the option and restart analysis from the compilation phase.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Specify remote analysis with compilation results from a previous analysis:

- Bug Finder:

```
polyspace-bug-finder -batch -scheduler localhost
       -submit-job-from-previous-compilation-results
```

- Code Prover:

```
polyspace-code-prover -batch -scheduler localhost
       -submit-job-from-previous-compilation-results
```

## Tips

You cannot submit analysis jobs to a remote cluster with Polyspace as You Code.

“Install Products for Submitting Polyspace Analysis from Desktops to Remote Server”

# -termination-functions

Specify process termination functions

## Syntax

`-termination-functions` *`function1`*`[,`*`function2`*`[,...]]`

## Description

`-termination-functions` *`function1`*`[,`*`function2`*`[,...]]` specifies functions that behave like the exit function and terminate your program.

Use this option to specify program termination functions that are declared but not defined in your code.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Polyspace detects an **Integer division by zero** defect in the following code because it does not recognize that `my_exit` terminates the program.

```
void my_exit(void);

void main() {
    double ans;
    ans = reciprocal(1);
    ans = reciprocal(0);
}

double reciprocal(int val) {
  if(val==0)
    my_exit();
  return (1/val);
}
```

To prevent Polyspace from flagging the division operation, use the `-termination-functions` option:

```
polyspace-bug-finder -termination-functions my_exit
```

“Run Polyspace Analysis from Command Line”

# -tmp-dir-in-results-dir

Keep temporary files in results folder

## Syntax

```
-tmp-dir-in-results-dir
```

## Description

`-tmp-dir-in-results-dir` specifies that temporary files must be stored in a subfolder of the results folder. Use this option only when the standard temporary folder does not have enough disk space. If the results folder is mounted on a network drive, this option can slow down your processor.

To learn how Polyspace determines the temporary folder location, see “Storage of Temporary Files During Polyspace Analysis”.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

## Examples

Store temporary files in the results folder:

- Bug Finder:

  ```
  polyspace-bug-finder -tmp-dir-in-results-dir
  ```
- Code Prover:

  ```
  polyspace-code-prover -tmp-dir-in-results-dir
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -tmp-dir-in-results-dir
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -tmp-dir-in-results-dir
  ```

## Tips

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

## See Also

### Topics

“Specify Polyspace Analysis Options”

# -v | -version

Display Polyspace version number

## Syntax

```
-v
-version
```

## Description

`-v` or `-version` displays the version number of your Polyspace product.

## Examples

Display the version number and release of your Polyspace product:

- Bug Finder:

  ```
  polyspace-bug-finder -v
  ```
- Code Prover:

  ```
  polyspace-code-prover -v
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -v
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -v
  ```

# -verif-version

Assign a version identifier

## Syntax

`-verif-version` *`id`*

## Description

`-verif-version` *`id`* assigns an identifier, *`id`*, to identify the analysis. You can use this identifier to refer to different analyses at the command line. For example, you can import comments from a previous analysis using the identifier.

## Examples

Assign a verification identifier:

- Bug Finder:

  ```
  polyspace-bug-finder -verif-version 1.3
  ```
- Code Prover:

  ```
  polyspace-code-prover -verif-version 1.3
  ```
- Bug Finder Server:

  ```
  polyspace-bug-finder-server -verif-version 1.3
  ```
- Code Prover Server:

  ```
  polyspace-code-prover-server -verif-version 1.3
  ```

## Tips

This option is not useful for Polyspace as You Code.

## See Also

"Specify Polyspace Analysis Options"

# -xml-annotations-description

Apply custom code annotations to Polyspace analysis results

## Syntax

`-xml-annotations-description` *`file_path`*

## Description

`-xml-annotations-description` *`file_path`* uses the annotation syntax defined in the XML file located in *`file_path`* to interpret code annotations in your source files. You can use the XML file to specify an annotation syntax and map it to the Polyspace annotation syntax. When you run an analysis by using this option, you can justify and hide results with annotations that use your syntax. If you run Polyspace at the command line, *`file_path`* is the absolute path or path relative to the folder from which you run the command. If you run Polyspace through the user interface, *`file_path`* is the absolute path.

If you are running an analysis from the user interface (Polyspace desktop products only), on the **Configuration** pane, you can enter this option in the **Other** field. See `Other`.

If you use Polyspace as You Code extensions in IDEs, enter this option in an analysis options file. See options file.

### Why Use This Option

If you have existing annotations from previous code reviews, you can import these annotations to Polyspace. You do not have to review and justify results that you have already annotated. Similarly, if your code comments must adhere to a specific format, you can map and import that format to Polyspace.

## Examples

### Import Existing Annotations for Coding Rule Violations

Suppose that you have previously reviewed source file `zero_div.c` containing the following code, and justified certain MISRA C: 2012 violations by using custom annotations.

```
#include <stdio.h>

/* Violation of Misra C:2012
rules 8.4 and 8.7 on the next
line of code. */

int func(int p) //My_rule 50, 51
{
    int i;
    int j = 1;

    i = 1024 / (j - p);
    return i;
}

/* Violation of Misra C:2012
rule 8.4 on the next line of
code */

int func2(void){ //My_rule 50
    int x=func(2);
    return x;
}
```

The code comments **`My_rule 50, 51`** and **`My_rule 50`** do not use the Polyspace annotation syntax. Instead, you use a convention where you place all MISRA rules in a single numbered list. In this list, rules 8.4 and 8.7 correspond to the numbers 50 and 51.You can check this code for MISRA C: 2012 violations by typing the command:

- Bug Finder:

  `polyspace-bug-finder -sources *source_path* -misra3 all`
- Code Prover:

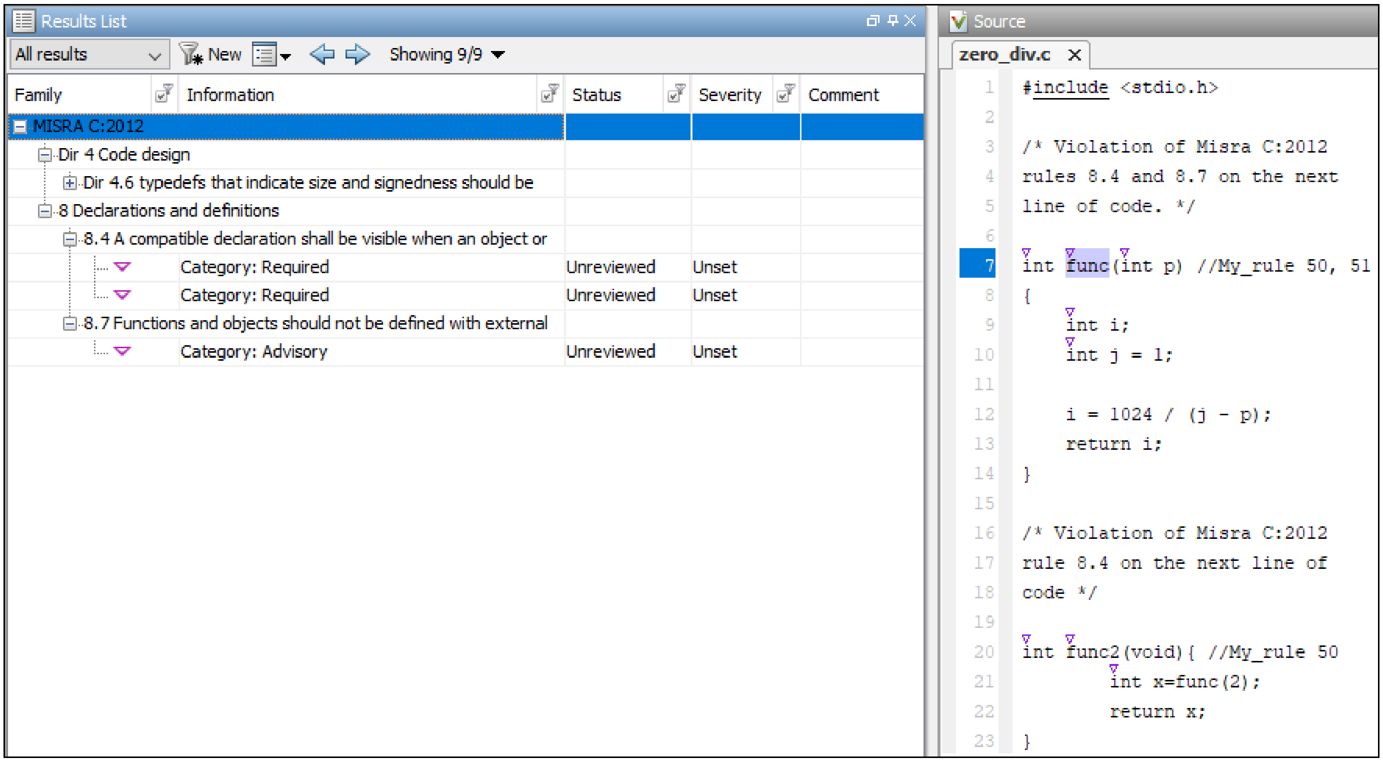
  `polyspace-code-prover -sources *source_path* -misra3 all -main-generator`
- Bug Finder Server:

  `polyspace-bug-finder-server -sources *source_path* -misra3 all`
- Code Prover Server:

  `polyspace-code-prover-server -sources *source_path* -misra3 all -main-generator`

*`source_path`* is the path to `zero_div.c`.

The annotated violations appear in the **Results List** pane. You must review and justify them again.



| Family | Information | Status | Severity | Comment |
|---|---|---|---|---|
| MISRA C:2012 | | | | |
| Dir 4 Code design | | | | |
| Dir 4.6 typedefs that indicate size and signedness should be | | | | |
| 8 Declarations and definitions | | | | |
| 8.4 A compatible declaration shall be visible when an object or | | | | |
| | Category: Required | Unreviewed | Unset | |
| | Category: Required | Unreviewed | Unset | |
| 8.7 Functions and objects should not be defined with external | | | | |
| | Category: Advisory | Unreviewed | Unset | |

```
#include <stdio.h>

/* Violation of Misra C:2012
rules 8.4 and 8.7 on the next
line of code. */

int func(int p) //My_rule 50, 51
{
    int i;
    int j = 1;

    i = 1024 / (j - p);
    return i;
}

/* Violation of Misra C:2012
rule 8.4 on the next line of
code */

int func2(void){ //My_rule 50
        int x=func(2);
        return x;
}
```

This XML example defines the annotation format used in `zero_div.c` and maps it to the Polyspace annotation syntax:

- The format of the annotation is the keyword `My_rule`, followed by a space and one or more comma-separated alphanumeric rule identifiers.
- Rule identifiers 50 and 51 are mapped to MISRA C: 2012 rules 8.4 and 8.7 respectively. The mapping uses the Polyspace annotation syntax.

```
<?xml version="1.0" encoding="UTF-8"?>

<Annotations xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:noNamespaceSchemaLocation="annotations_xml_schema.xsd"
             Group="exampleCustomAnnotation">

  <Expressions Search_For_Keywords="My_rule"
              Separator_Result_Name="," >

    <!-- This section defines the annotation syntax format -->
   <Expression Mode="SAME_LINE"
               Regex="My_rule\s(\w+(\s*,\s*\w+)*)"
               Rule_Identifier_Position="1"
               />

 </Expressions>
  <!-- This section maps the user annotation to the Polyspace
  annotation syntax -->
 <Mapping>
 <Result_Name_Mapping  Rule_Identifier="50" Family="MISRA-C3" Result_Name="8.4"/>
 <Result_Name_Mapping  Rule_Identifier="51" Family="MISRA-C3" Result_Name="8.7"/>
 </Mapping>
</Annotations>
```

To import the existing annotations and apply them to the corresponding Polyspace results:

1 Copy the preceding code example to a text editor and save it on your machine as `annotations_description.xml`, for instance in `C:\Polyspace_workspace\annotations\`.

2 Rerun the analysis on `zero_div.c` by using the command:

- Bug Finder:

```
polyspace-bug-finder -sources source_path -misra3 all ^
-xml-annotations-desription ^
C:\Polyspace_workspace\annotations\annotations_description.xml
```

- Code Prover:

```
polyspace-code-prover -sources source_path -misra3 all ^
-main-generator -xml-annotations-desription ^
C:\Polyspace_workspace\annotations\annotations_description.xml
```

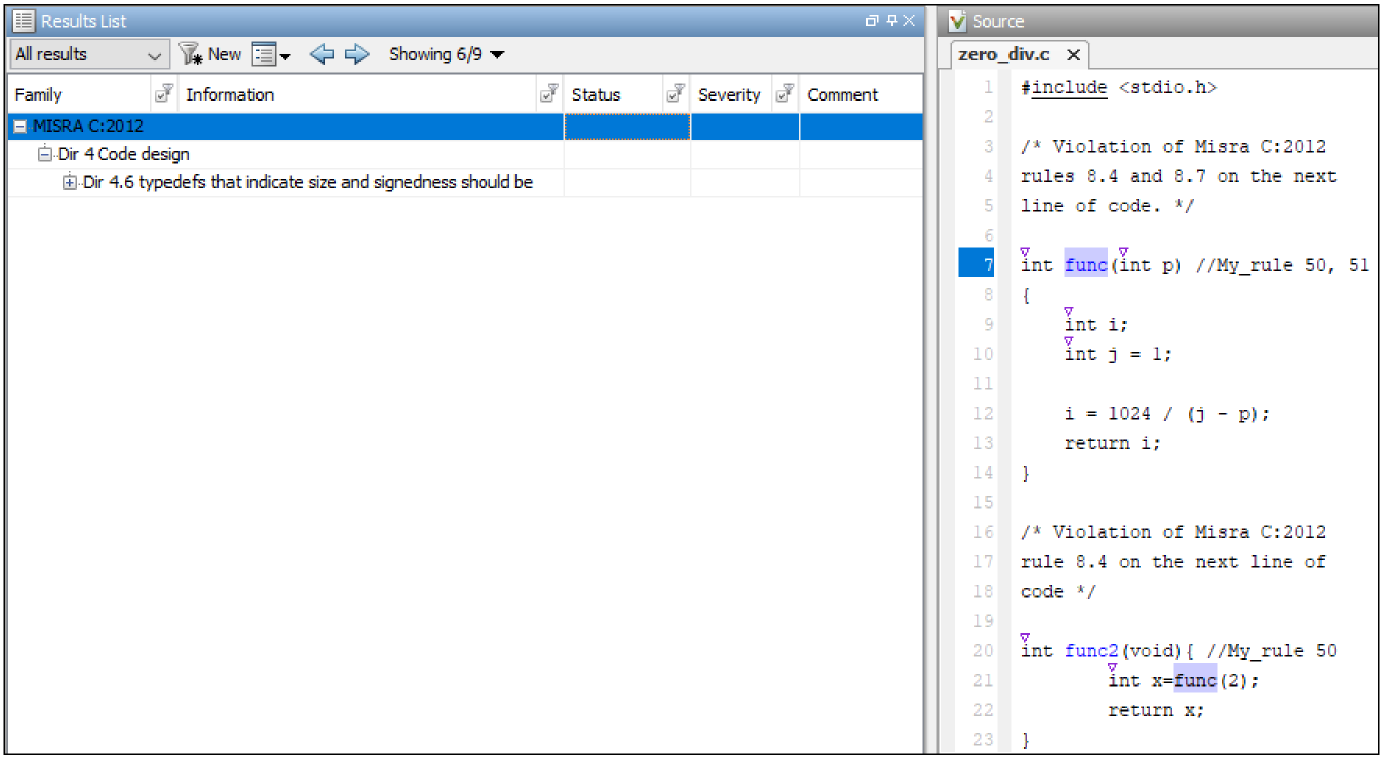
- Bug Finder Server:

```
polyspace-bug-finder-server -sources source_path -misra3 all ^
-xml-annotations-desription ^
C:\Polyspace_workspace\annotations\annotations_description.xml
```

- Code Prover Server:

```
polyspace-code-prover-server -sources source_path -misra3 all ^
-main-generator -xml-annotations-desription ^
C:\Polyspace_workspace\annotations\annotations_description.xml
```

Polyspace considers the annotated results justified and hides them in the **Results List** pane.



| Family | Information | Status | Severity | Comment |
|---|---|---|---|---|
| MISRA C:2012 | | | | |
| Dir 4 Code design | | | | |
| Dir 4.6 typedefs that indicate size and signedness should be | | | | |

```
#include <stdio.h>

/* Violation of Misra C:2012
rules 8.4 and 8.7 on the next
line of code. */

int func(int p) //My_rule 50, 51
{
    int i;
    int j = 1;

    i = 1024 / (j - p);
    return i;
}

/* Violation of Misra C:2012
rule 8.4 on the next line of
code */

int func2(void){ //My_rule 50
        int x=func(2);
        return x;
}
```

# Polyspace DOS/UNIX Commands

# Polyspace DOS/Unix Commands

# admin-docker-agent

(DOS/UNIX) Launch Cluster Admin interface to manage User Manager, Issue Tracker, and Polyspace Access Apps

## Syntax

```
admin-docker-agent [OPTIONS]
```

## Description

`admin-docker-agent [OPTIONS]` starts the **Cluster Admin** interface. If you do not specify additional `OPTIONS`, the Admin agent uses host name `localhost` and starts with the `HTTP` protocol on port `9443`.

## Input Arguments

### `OPTIONS` — Options to manage the Cluster Admin

string

Options to specify and manage the connection settings of the **Cluster Admin**.

**General Options**

| Option | Description |
|---|---|
| `--hostname` *`hostName`* | Specify the fully qualified domain name of the machine on which you run the **Cluster Admin**. This option is required if you use the HTTPS configuration options. *`hostName`* must match the `Common Name (CN)` that you specify to obtain SSL certificates.<br>The default host name is `localhost`. |
| `--port` *`portNumber`* | Specify the server port number that you use to access the **Cluster Admin** web interface.<br>The default port value is 9443. |
| `--data-dir` *`dirPath`* | Specify the absolute path to the folder containing the `settings.json` file.<br>If the file does not exist, the **Cluster Admin** creates it in the specified folder.<br>If the file already exists, the **Cluster Admin** reuses its contents to configure the settings.<br>The default folder is the current folder. |

| Option | Description |
|---|---|
| `--network-name` *`networkName`* | Specify the name of the Docker network that the Polyspace Access, User Manager, and Issue Tracker apps use.<br>Use this option if you do not want the apps to use the default `mathworks` network, for instance, if that network conflicts with an existing network.<br>To check if your docker network conflicts with an existing network, run this command:<br>`docker network inspect` *`networkName`*<br>and inspect the `IPAM.Config` node to view the IP range that is used by the network. You might need to contact your network administrator to determine if the IP range is used by other services. To find *`networkName`*, use the command `docker network ls`.<br>To create a new network, see docker network create. |
| `--force-exposing-ports` | Specify this option to expose the ports of the services when you install all the services on a single node. To specify the Docker host port to which the exposed ports bind, open the **Cluster Admin**, click **Configure Nodes**, then go to the **Services** tab.<br>By default, when you install on a single node, the ports of the services are not exposed .<br>Use this option if you install on a single node but you must communicate with one of the services through a third party tool, for instance if you use PostgreSQL utilities to communicate with the Polyspace Access database. |
| `--reset-password` | Reset the password that you use to log into the **Cluster Admin** web interface. |
| `--version` | Display the version number of the Admin agent. |
| `--help` | Display the help menu. |

**HTTPS Configuration Options**

On Windows systems, all paths must point to local drives.

| Option | Description |
|---|---|
| `--ssl-cert-file` *`absolutePath`* | Specify the absolute path to the SSL certificate `PEM` file. |
| `--ssl-key-file` *`absolutePath`* | Specify the absolute path to the SSL private key `PEM` file that you used to generate the certificate. |

| Option | Description |
|---|---|
| `--ssl-ca-file` *`absolutePath`* | Specify the absolute path to the certificate store where you store trusted certificate authorities. For instance, on a Linux Debian® distribution, `/etc/ssl/certs/ca-certificates.crt` .<br>If you use self-signed certificates, use the same file that you specify for `--ssl-cert-file` |
| `--restart-gateway` | Use this option to restart the **Gateway** service if you restart the `admin-docker-agent` and you make changes to the HTTPS configuration options or you specify a different port.<br>Restart the **Gateway** service by using this option if you make changes to the HTTPS configuration options or specify a different port. |

**New Node Configuration Options**

If you choose to install Polyspace Access on multiple machines, use these options to create nodes on the different machines. In the **Cluster Dashboard**, click **Configure Nodes**, and then select the **Services** tab to select the node on which you want to run the service.

Before you create a node, you must have an instance of the `admin-docker-agent` already running on at least one other machine. This other machine hosts the `primary` node.

| Option | Description |
|---|---|
| `--master-host` *`hostName:port`* | Specify the host name and port number of the machine hosting the `primary` node. |
| `--node-id` *`nodeName`* | Name of the node that you create. After you start the **Cluster Admin**, you see this node listed in the **Node** drop-down lists on the **Services** tab of the **Nodes** settings. |

## Examples

### Configure HTTPS Protocol With Self-Signed Certificate

The **Cluster Admin** uses the HTTP protocol by default. Encrypt the data between the **Cluster Admin** and client machines by configuring the **Cluster Admin** with the HTTPS protocol. This configuration also enables HTTPS for the API Gateway service, which handles communications between all the other services and client machines.

If you install Polyspace Access on multiple nodes, or if you use the `--force-exposing-ports` to start the **Admin** agent, you must configure HTTPS for the User Manager, Issue Tracker, and Polyspace Access services separately. To configure HTTPS for the services, click **Configure Nodes** on the **Cluster Dashboard**.

Create a self-signed SSL certificate and private key file by using the `openssl` toolkit.

```
openssl req -newkey rsa:2048 -new -nodes -x509 -days 365 -keyout self_key.pem -out self_cert.pem
```

After you enter the command, follow the prompts on the screen. You can leave most fields blank, but you must provide a `Common Name` (CN). The CN must match the fully qualified domain name (FQDN) of the machine running the `admin-docker-agent`. The command outputs a certificate file `self_cert.pem` and a private key file `self_key.pem`.

To obtain the FQDN of the machine, use the command `hostname --fqdn` on Linux or `net config workstation | findstr /C:"Full Computer name"` on Windows .

Start the `admin-docker-agent` by using the certificate and private key files that you generated and specify *hostName*, the FQDN of the machine. *hostName* must match the FQDN that you entered for the CN of the SSL certificate. In the command, specify the absolute path to the files.

| | |
|---|---|
| **Windows PowerShell** | admin-docker-agent --hostname *hostName*`<br>--ssl-cert-file *absolutePathTo*\self_cert.pem `<br>--ssl-key-file *absolutePathTo*\self_key.pem.pem `<br>--ssl-ca-file *absolutePathTo*\self_cert.pem |
| **Linux** | ./admin-docker-agent --hostname *hostName* \\<br>--ssl-cert-file *absolutePathTo*/self_cert.pem \\<br>--ssl-key-file *absolutePathTo*/self_key.pem.pem \\<br>--ssl-ca-file *absolutePathTo*/self_cert.pem |

You can now access the **Cluster Admin** web interface from your browser by using https://*hostName*:9443/admin.

## Description

### Manage and View Projects

**Note** This Polyspace command is available in `*polyspaceroot*\polyspace\bin`. Here, *`polyspaceroot`* is the Polyspace Server installation folder, for instance, `C:\Program Files\Polyspace Server\R2023a` (see also “Installation Folder”). To avoid typing the full path to this command, add this location to the `PATH` environment variable in your operating system.

`polyspace-access -create-project folderPath -host hostname [login options]` creates a project folder in the Polyspace Access web interface. The folder can be at the top of the project hierarchy or a subfolder under an existing project folder.

`polyspace-access -move-project sourcePath -to-project-path destinationPath -host hostname [login options]` moves or renames a project or folder. The `sourcePath` and `destinationPath` must be absolute paths of the source and destination projects or folders. You cannot move or rename a project or folder if the path you specify for the destination already exists.

`polyspace-access -delete-project projectToDelete -host hostname [login options]` deletes specified project or folder from the Polyspace Access **Project Explorer**. The project or folder is moved to the **ProjectsWaitingForDeletion** folder, which is visible only to users with a role of **Administrator**. To completely delete the project or folder from the database, see “Delete Project Runs or Entire Projects”.

`polyspace-access -list-project [projectPath] -host hostname [login options]` without the optional argument `projectPath` lists the paths to all projects in the Polyspace Access database and their last run IDs. If you specify the full path to a project with the argument `projectPath`, the command lists the last run ID for only that project.

`polyspace-access -list-runs projectPath -host hostname [login options]` lists all the runs that were uploaded to the specified project. For each run, you see the run ID and any labels associated with that run.

### Upload, Download, or Export Results

`polyspace-access -upload pathToFileOrFolderOrZipFile [upload options] -host hostname [login options]` uploads Polyspace Bug Finder or Code Prover analysis results to the Polyspace Access database from the file (recommended), folder, or zipped file that you specify. You upload results using this command only if those results were generated with Polyspace Bug Finder Server or Polyspace Code Prover Server. You can upload results to an existing Polyspace Access project only if those results were generated by the same type of analysis. For instance, you cannot upload results of a Bug Finder analysis to a project that contains Code Prover results. To upload results generated with the Polyspace desktop interface, see “Upload Results from Polyspace Desktop Client”. Use the “upload options” on page 4-0 to specify a project parent folder or to rename a project.

`polyspace-access -export findingsToExport -output filePath [export options] -host hostname [login options]` exports project results from the Polyspace Access database to a text file whose location you specify with `filePath`. You can specify filters when you export the results or export a comparison between two projects. You specify the project using either the full path in Polyspace Access or the run ID. Use this command to export findings to other tools that you use for custom reports. To get the paths to projects and their last run IDs, use `polyspace-access` with the `-list-project` command.

`polyspace-access -download findingsToDownload -output-folder-path outputFolderPath -host hostname [login options]` downloads results from Polyspace Access project `findingsToDownload` to a folder whose location you specify with `outputFolderPath`. You specify the project using either the full path in Polyspace Access or the run ID.

You cannot open the downloaded results in the Polyspace desktop interface or the Polyspace as You Code IDE extensions. Use this command as part of the workflow to merge review information between projects, or to create a baseline for subsequent Polyspace analyses.

- To merge review information between projects, see “Import Review Information from Existing Polyspace Access Projects”.
- To create a baseline for Polyspace as You Code results at the command-line, see “Baseline Polyspace as You Code Results on Command Line”.

To get the paths to projects and their last run IDs, use `polyspace-access` with the `-list-project` command.

**Manage Review Information for Findings**

`polyspace-access -review fileOrFindingID -project-path projectToReview review options -host hostname [login options]` edits the information in the review fields of the findings in the project `projectToReview`. To review a single finding, pass a finding ID to the `-review` command . To perform a batch review, pass the path of a file where you store the finding IDs of multiple findings to the `-review` command. In this file, list one finding ID per line. You must specify at least one review field with `review options`, such as status, severity, comment, owner, or a bug tracking tool (BTT) ticket number.

You cannot assign a review field to a finding if that review field is set with a code annotation.

`polyspace-access -import-reviews sourceProjectPath -project-path targetProjectPath [-import-strategy never-overwrite-target | always-overwrite-target] -host hostname [login options]` imports review information from source project `sourceProjectPath` to target project `targetProjectPath`. Use this option if you have already reviewed findings in the source project and you reuse the code that contains those findings in the target project.

You can optionally specify one of these import strategies:

- `never-overwrite-target` (default) — If a review field in the target project already has content, do not overwrite that review field with the content from the source project
- `always-overwrite-target` — Always overwrite the content of the review fields in the target project with the content from the source project, even if the target review fields already have content.

See also “Import Review Information from Existing Polyspace Access Projects”.

**Manage Software Quality Objectives (SQO)**

`polyspace-access -set-sqo projectPathWithSQO -level sqoLevel [-name sqoName] -host hostname [login options]` assigns an SQO level to the specified project for the SQO definition that is currently applied to the project. You can optionally apply a different SQO definition to the project by specifying the name of that SQO definition with option `-name`. See also “Manage Software Quality Objectives in Polyspace Access”. You can run this command only on single projects but not on project folders.

`polyspace-access -get-sqo projectPathWithSQO -host hostname [login options]` shows the currently assigned SQO definition and SQO level for the specified project. See also “Manage Software Quality Objectives in Polyspace Access”. You can run this command only on single projects but not on project folders.

`polyspace-access -list-sqo -host hostname [login options]` lists the name of all the available SQO. See also “Manage Software Quality Objectives in Polyspace Access”.

#### Manage Project Run Labels and Unassigned Findings

`polyspace-access -add-label label -run-id runID -host hostname [login options]` adds a label to the project run specified with `runID`. Use labels to identify project runs of interest more easily, or to associate a run with a specific branch or continuous integration build job. See also “Manage Labels at the Command Line”.

`polyspace-access -remove-label label -run-id runID -host hostname [login options]` removes the specified label from the project run with run ID `runID`. If the specified label does not match any of the project run labels, the command is ignored. See also “Manage Labels at the Command Line”.

`polyspace-access -set-unassigned-findings findingsToAssign -owner userToAssign -source-contains pattern [set unassigned findings options] -host hostname [login options]` assigns owners to unassigned results in a project in the Polyspace Access database. You specify the project using either the full path in Polyspace Access or the run ID. Use the `set unassigned findings options` to assign findings from different source files or different groups of source files to different owners. To get the paths to projects and their last run IDs, use `polyspace-access` with the `-list-project` command.

#### Manage User Permissions

`polyspace-access -set-role role -user username -group groupname -project-path folderPathOrProjectPath -host hostname [login options]` assigns a role `role` to `username` or `groupname` for the specified project or project folder. A user or group role set for a project folder applies to all project findings under that folder. All users in a group inherit the role assigned to their parent group. You specify the project using either the full path in Polyspace Access or the last run ID. To get the paths to projects and their last run IDs, use `polyspace-access` command with the `-list-project` command.

`polyspace-access -unset-role -user username -group groupname -project-path folderPathOrProjectPath -host hostname [login options]` removes any role previously assigned to `username` or `groupname` for the specified project or project folder. Unassigning a role for a group unassigns that role for all the users in that group. You specify the project using either the full path in Polyspace Access or the last run ID. To get the paths to projects and their last run IDs, use `polyspace-access` with the `-list-project` command.

#### Migrate Results from Polyspace Web Metrics

`polyspace-access -generate-migration-commands metrics_dir -output-folder-path dir [generate migration commands options]` generates scripts to migrate projects from the path `metrics_dir` in Polyspace Metrics to Polyspace Access. The command stores the scripts in `dir`. To specify which project findings to migrate, use `generate migration commands options`.

`polyspace-access -migrate -option-file-path dir [-dryrun] -host hostname [ login options]` migrates projects from Polyspace Metrics to Polyspace Access using the scripts generated with the `-generate-migration-commands` command. To view which projects are migrated without actually migrating the projects, use the `-dryrun` option.

**Other Commands**

`polyspace-access -ver -host hostname [login options]` displays the version and license number of the Polyspace Access instance that you specify with `hostname`, and the version of the `polyspace-access` binary. You can run this command only with Polyspace Access instances for which you have login credentials.

`polyspace-access -encrypt-password` encrypts the password you use to log into Polyspace Access. Use the output of this command as the argument of the `-encrypted-password` option when you write automation scripts to interact with Polyspace Access.

## Examples

### Encrypt Password and Store Login Options in a Variable

Polyspace Access requires login credentials. You can enter the credentials at the command-line when you execute a command, or you can generate an encrypted password to use with other login options in automation scripts.

To encrypt your password, use the `-encrypt-password` command and enter your Polyspace Access credentials. The command uses the user name and password you enter to generate an encrypted password.

```
polyspace-access -encrypt-password
login: jsmith
password:
CRYPTED_PASSWORD KEAGKAMJMCOPLFKPKOHOJNDJCBACFJBL
Command Completed
```

Store the login and encrypted password in a credentials file and restrict read and write permission on this file. Open a text editor, copy these two lines in the editor, then save the file as `myCredentials.txt` for example.

```
 -login jsmith
 -encrypted-password KEAGKAMJMCOPLFKPKOHOJNDJCBACFJBL
```

To restrict the file permissions, right-click the file and select the **Permissions** tab on Linux or the **Security** tab on Windows.

If you manage your analysis findings through automated scripts, create a variable to store the connection configuration and login credentials. Use this variable in your script, or at the command line to avoid typing your credentials when you execute a command.

```
set LOGIN=-host myAccessServer -port 1234 -credentials-file myCredentials.txt
```

```
polyspace-access %LOGIN% -create-project myProject
```

### Create a Project Folder with Restricted Access and Upload to Folder

Suppose that you want to upload a set of findings to Polyspace Access generated with Polyspace Bug Finder Server or Polyspace Code Prover Server, and authorize only some team members to view these findings.

Create a project folder `restrictedProject` at the top of the project hierarchy.

```
polyspace-access -host myAccessServer -port 1234 ^
-create-project restrictedProject
```

Set roles for users `jsmith` and `rroll`, and group `Authorized Users`, authorizing them to access the project folder as contributors. If a user name or group name contains spaces, enclose it in double quotes.

```
polyspace-access -host myAccessServer ^
-port 1234 -set-role contributor ^
-user jsmith -user rroll -group "Authorized Users" -project-path restrictedProject
```

Aside from the creator of the project folder and the users and group with a role of contributor, no other user can view or access any findings uploaded to `restrictedProject`.

Upload Bug Finder project findings from project "My Example Project" to parent folder `Restricted`.

```
polyspace-access -host myAccessServer -port 1234 ^
-upload "C:\Polyspace_Workspace\My Example Project\Module1\ps_results.psbf" ^
-parent-project Restricted
```

The uploaded findings are stored under `restrictedProject/My_Example_Project (Bug Finder)`. The `-upload` command outputs information about the upload including an `ACCESS URL`. You can use that URL to view the uploaded results in the Polyspace Access interface.

See also “Manage Project Permissions”.

### Assign Results to Component Owners and Export Assigned Results

If you follow a component-based development approach, you can assign analysis findings by component to their respective owners.

Get a list of projects currently stored on the Polyspace Access database. The command outputs a list of project findings paths and their last run ID.

```
polyspace-access -host myAccessServer -list-project

Connecting to https://example-access-server:9443
Connecting as jsmith

Get project list with the last Run Id
Restricted/Code_Prover_Example (Code Prover) RUN_ID 14
multimodule/vxWorks_demo (Code Prover) RUN_ID 16
public/Bug_Finder_Example (Bug Finder) RUN_ID 24
public/CP/Code_Prover_Example (Polyspace Code Prover) RUN_ID 8
public/Polyspace (Code Prover) RUN_ID 28
Command Completed
```

Assign all red and orange run-time error findings to the owner of all the files in `Component_A` of project `vxWorks_demo`. Perform the same assignment for the owner of `Component_B`. To specify the `vxWorks_demo` project, use the run ID.

```
polyspace-access -host myAccessServer ^
-set-unassigned-findings 16 ^
-owner A_owner -source-contains Component_A ^
```

```
-owner B_owner -source-contains Component_B ^
-rte Red -rte Orange
```

`-source-contains Component_A` matches all files with a file path that contains `Component_A`.

`-source-contains Component_B` matches all files with a file path that contains `Component_B`, but excludes files with a file path that contains `Component_A`.

After you assign findings, export the findings and generate `.csv` files for each owner containing the findings assigned to them.

```
polyspace-access -host myAccessServer ^
-export 16 ^
-output C:\Polyspace_Workspace\myResults.csv ^
-output-per-owner
```

The command generates file `myResults.csv` containing all findings from the project with run ID 16. The command also generates files `myResutls.csv.A_owner.csv` and `myResults.csv.B_owner.csv` on the same file path.

### Make Batch Edits to Review Information for New Findings

If you want to make batch edits to the review information of analysis results after you upload those results to Polyspace Access:

1. Export a list of findings that you want to review.
2. Edit the review information for each finding using the finding IDs stored in the file from step 1.

Export a list of findings that you want to review, using the `polyspace-access -export` command. For example, if you want to export all new defects with severity **High** or **Medium** from a project with project path `public/example/Bug_Finder_Example (Bug Finder)` and project ID 129, run this command:

```
polyspace-access $login -export 129 -output newMedHighDefects.txt\
 -resolution new -defects High -defects Medium
```

The command outputs the tab separated values (TSV) file `newMedHighDefects.txt`. The file contains a list of findings that match the filters that you specified, where the first column of the file shows the finding IDs.

Here, `$login` is a variable that stores the login credentials and other connection information. To configure this variable, see “Encrypt Password and Store Login Options in a Variable” on page 4-10.

Extract the finding IDs column from the file that you generated in the previous step to another text file. For instance, you use the `awk` command (BASH command) or a `for` loop (DOS command) to skip the column header and then save the finding IDs to file `findingIDs.txt`.

```
#BASH COMMAND
awk ' NR>1 {print$1} ' newMedHighDefects.txt >> findingIDs.txt

##########################################

REM DOS COMMAND
for /f "skip=1" %i in (newMedHighDefects.txt); do @echo %i >> findingIDs.txt
```

Pass the file `findingIDs.txt` to the `polyspace-access -review` command. Specify the path of the project that contains those findings and the review fields that you want to edit. For instance, you might want to assign a status, owner, and comment to the findings.

```
# BASH COMMAND

 polyspace-access $login -review findingIDs.txt \
 -project-path "public/example/Bug_Finder_Example (Bug Finder)" \
 -set-status "To investigate" -set-owner jsmith \
 -set-comment "Finding assigned automatically"

######################################################

REM DOS COMMAND

polyspace-access %login% -review findingIDs.txt ^
 -project-path "public/example/Bug_Finder_Example (Bug Finder)" ^
 -set-status To investigate" -set-owner jsmith ^
 -set-comment "Finding assigned automatically"
```

The command runs once and performs a batch edit of the specified review fields for all the findings listed in the file `findingsIDs.txt`. Depending on the number of findings and on your network speed, the command might take a few moments to complete.

### Migrate Projects from Metrics to Polyspace Access

If you have projects stored on a Polyspace Metrics server, you can migrate them to the Polyspace Access database. Log in to your Metrics server to complete this operation.

Generate migration scripts for the projects you want to migrate. Specify the folder path of the location where the projects are stored, for example `C:\Users\jsmith\AppData\Roaming\Polyspace_RLDatas\results-repository`

```
polyspace-access -generate-migration-commands ^
C:\Users\jsmith\AppData\Roaming\Polyspace_RLDatas\results-repository ^
-output-folder-path C:\Polyspace_Workspace\toMigrate -project-date-after 2017-06
```

The command generates migration scripts for all projects in the specified metrics folder that were uploaded on or after June 2017. The scripts are stored in folder `C:\Polyspace_Workspace\toMigrate`.

Use the `-dryrun` option to check which projects will be migrated.

```
polyspace-access -host myAccessServer ^
-migrate -option-file-path ^
C:\Polyspace_Workspace\toMigrate -dryrun
```

The command output contains a list of projects. Inspect it to ensure that you are migrating the correct projects.

To perform the migration, rerun the last command without the `-dryrun` option.

## Input Arguments

#### Connection Configuration and Login

### `hostname` — Polyspace Access machine host name

string

`hostname` corresponds to the host name that you specify in the URL of the Polyspace Access interface, for example `https://hostname:port/metrics/index.html`. If you are unsure about which host name to use, contact your Polyspace Access administrator. The default host name is `localhost`. You must specify a host name with all `polyspace-access` commands, except the `-generate-migration-commands` and `-encrypt-password` commands .

Example: `-host myAccessServer`

### `login options` — Options to configure connection to Polyspace Access

string

Options to specify connection configuration and login credentials.

**Connection Options**

| Option | Description |
|---|---|
| `-port portNumber` | `portNumber` corresponds to the port number that you specify in the URL of the Polyspace Access interface, for example `https://hostname:portNumber/metrics/index.html`. If you are unsure about which port number to use, contact your Polyspace Access administrator. The default port number is `9443`. |
| `-protocol http \| https` | HTTP protocol used to access Polyspace Access. The default protocol is `https`. |
| `-credentials-file filePath` | Full path to the text file where you store your login credentials. Use this option if, for instance, you use a command that requires your Polyspace Access credentials in a script but you do not want to store your credentials in that script. While the script runs, someone inspecting currently running processes cannot see your credentials.<br>You can store only one set of credentials in the file, either as `-login` and `-encrypted-password` entries on separate lines, for instance:<br>`-login jsmith`<br>`-encrypted-password LAMMMEACDMKEFELKMNDCONEAPECEEKPL`<br>or as an `-api-key` entry:<br>`-api-key keyValue123`<br>Make sure that you restrict the read and write permissions on the file where you store your credentials. For example, to restrict read and write permissions on file `login.txt` in Linux, use this command:<br>`chmod go-rwx login.txt` |

| Option | Description |
|---|---|
| `-api-key` *`keyValue`* | API key you use as a login credential instead of providing your login and encrypted password. To assign an API key to a user, see “Configure User Manager” or contact your Polyspace Access administrator.<br>Use the API key if, for instance, you use a command that requires your Polyspace Access login credentials as part of an automation script with a CI tool like Jenkins. If a user updates his or her password, you do not need to update the API key associated with that user in your scripts.<br>It is recommended that you store the API key in a text file and pass that file to the command by using `-credentials-file`. See the description for option `-credentials-file`. |
| `-login` *`username`*<br>`-encryted-password` *`ENCRYPTED_PASSWD`* | Login credentials you use to interact with Polyspace Access. The argument of `-encrypted-password` is the output of the `-encrypt-password` command.<br>If you do not use these two options, you are prompted to enter your credentials at the command line, unless you use `-api-key`. |
| `-max-retry` *`retryNumber`* | Number of times the `polyspace-access` command retries to upload results when you upload from a client machine to the server machine that hosts Polyspace Access. Specify this option to retry the upload command in the event of sporadic network outages. The command waits 10 seconds between retries.<br>By default, the command retries 3 times. |

**Miscellaneous Options**

| Option | Description |
|---|---|
| `-output` *`filePath`* | Full path to the file where you store command outputs. |
| `-tmp-dir` *`folderPath`* | Folder path where you store temporary files generated by the `polyspace-access` commands. The default folder path is `tmp/ps_results_server` on Linux and `C:/Users/%username%/AppData/Local/Temp/ps_results_server` on Windows. |
| `-log` *`filePath`* | File path where you store the command output log. By default the command does not generate a log file. |
| `-h` | Display the help information for `polyspace-access` or one of its commands. |

### Manage and View Projects

#### `folderPath` — Absolute path of folder

string

Absolute Project folder path specified as a string. If the name includes spaces, use double quotes. Specify the full path to folders nested under a parent folder.

If your folder path involves a folder that does not already exist, the folder is created.

Example: `-create-project topFolder`

Example: `-create-project "topFolder/subFolder/Folder has spaces"`

#### `sourcePath` — Absolute path of source project or folder
string

Absolute path of project or folder specified as a string. If the name includes spaces, use double quotes. Specify the absolute path of the folder or project that you want to move or rename.

Example: `-move-project old/Folder/Path`

Example: `-move-project "old/Folder/name has spaces"`

#### `destinationPath` — Absolute path of source project or folder
string

Absolute path of project or folder specified as a string. If the name includes spaces, use double quotes. Specify the absolute path of the new folder or project location.

If you move or rename a folder, all subfolders and subprojects are moved to the new parent folder. If you move a project to a different folder, you must specify the absolute path including the project name for the destination path.

Example: `-move-project new/Folder/Path`

Example: `-move-project "new/Folder/name has spaces"`

#### `projectToDelete` — Absolute path of project or folder
string

Absolute path of project or folder specified as a string. If the name includes spaces, use double quotes.

Specify the absolute path of the folder or project that you want to delete. If you delete a folder, all subfolders and subprojects under that folder are also deleted.

Example: `-delete-project public/Folder/projectName`

Example: `-delete-project "public/Folder name has spaces"`

#### `projectPath` — Absolute path of project
string

Absolute path of the project findings. Specify this optional argument with `-list-project` to get the path and the last run ID of the corresponding project, or with `-list-runs` to get run ID and labels of all the runs that you uploaded to the project.

If the path name includes spaces, use double quotes.

Example: `-list-project "public/Examples/Bug_Finder_Example (Bug Finder)"`

Example: `-list-runs public/Examples/Code_Prover_Example`

### Upload, Download, or Export Results

#### `pathToFileOrFolderOrZipFile` — Path to file, folder, or zipped file containing analysis results
string

Path of a Polyspace Bug Finder (PSBF) or Code Prover (PSCP) analysis results file specified as a string. The command uploads copies of the results file and other analysis results files located in the same folder. Alternatively, you can specify the path of a parent folder that contains a single PSBF or PSCP results file, or the path of a zipped results file or folder.

For instance, for the Bug Finder results stored in `C:\Polyspace_Workspace\myProject\Module_1\BF_results\ps_results.psbf`, specify this with the `-upload` command. If the path name includes spaces, enclose the path in double quotes.

For faster uploads, store your analysis results in a dedicated results folder by using option `-results-dir` when you run the analysis. If you store results in a folder that contains a large number of files unrelated to Polyspace analysis results, for example the root folder of your repository, Polyspace Access takes longer to upload the results.

Example: `-upload C:\Polyspace_Workspace\myProject\Module_1\BF_results\ps_results.psbf`

Example: `-upload C:\Polyspace_Workspace\myProject\Module_1\ -project projectFolder`

### `upload options` — Options to specify where to upload results

string

Options to specify path to project folder and name of project where you upload results. These options are not optional.

| Option | Description |
|---|---|
| `-parent-project` *`folderPath`* | Path of the parent folder in the Polyspace Access explorer under which you store uploaded results.<br>If you do not specify a parent folder, uploaded results are stored under the **public** folder. |
| `-project` *`resultsName`* | Name of the uploaded results in the Polyspace Access explorer. Use this option to rename the results that you upload.<br>If you do not specify a results name, the results are stored as `projectName (resultsType)`, where spaces in the `projectName` are replaced with underscores. For instance, if you upload Bug Finder results from project Bug Finder Example, these results are stored as `Bug_Finder_Example (Bug Finder)`. |

### `findingsToExport` — Project findings path or run ID

string

Path or run ID of the project findings that you export. Polyspace assigns a unique run ID to each analysis run you upload. If the path name includes spaces, use double quotes. To get the project findings path or last run ID, use `-list-project`.

Example: `-export "public/Examples/Bug_Finder_Example (Bug Finder)"`

Example: `-export 4`

### `filePath` — Path to file containing command output

string

Path to the file that stores the output of the command when you specify the `-output` option. This option is mandatory with the `-export` command.

Example: `-output C:\Polyspace_Workspace\myResults.txt`

### `export options` — Options to specify which findings to export

string

Options to specify where to export findings, and which subset of findings you export. Use these options to export findings to other tools you use to create custom reports or other custom review templates.

| Option | Description |
|---|---|
| `-output` *`filePath`* | File path where you export the findings. This option is mandatory with the `-export` command. |
| `-resolution New` | Export only new findings compared to the previous analysis (previous upload with the same project name). If the project contains only one run, the command errors out. When there is only one project run, all findings are new and you do not need to specify this option. |
| `-output-per-owner` | Use this option to generate files that only contain findings assigned to a particular user. The files are stored on the path you specify with `-output`.<br>For an example of how to assign findings to owners at the command-line, see “Assign Results to Component Owners and Export Assigned Results” on page 4-11. |
| `-rte` *`All`* `\|` *`Red`* `\|` *`Gray`* `\|` *`Orange`* `\|` *`Green`* | Type of RTE finding to export. Specify `All`, `Red`, `Gray`, `Orange`, or `Green`.<br>To specify more than one argument, call the option for each argument. For example, `-rte Red -rte Orange`. |
| `-defects` *`All`* `\|` *`High`* `\|` *`Medium`* `\|` *`Low`* | Impact of DEFECTS findings to export. Specify `All`, `High`, `Medium`, or `Low`.<br>To specify more than one argument, call the option for each argument. For example, `-defects Medium -defects Low`. |
| `-custom-coding-rules` | Export all custom coding rules findings. |
| `-coding-rules` | Export all coding rules findings. |
| `-code-metrics` | Export all code metrics findings. |
| `-global-variables` | Export all global variables findings. |
| `-status` *`Unreviewed`* `\|` `"`*`To investigate`*`"` `\|` `"`*`To fix`*`"` `\|` *`Justified`* `\|` `"`*`No action planned`*`"` `\|` `"`*`Not a defect`*`"` `\|` *`Other`* | Review status of the findings to export. Specify `Unreviewed` (default), `"To investigate"`, `"To fix"`, `Justified`, `"No action planned"`, `"Not a defect"`, or `Other`.<br>To specify more than one argument, call the option for each argument. For example, `-status Tofix -status Toinvestigate`. |
| `-severity` *`All`* `\|` *`High`* `\|` *`Medium`* `\|` *`Low`* | Severity of the findings to export. Specify `All`, `High`, `Medium`, or `Low`.<br>To specify more than one argument, call the option for each argument. For example, `-severity High -severity Low`. |
| `-unassigned-findings` | Export all unassigned findings. |

| Option | Description |
|---|---|
| `-open-findings-for-sqo` *1 \| 2 \| 3 \| 4 \|5 \| 6* | Software quality objective or SQO level that must be satisfied. Specify a number from 1 to 6 for *`sqo_level`*. If you specify an SQO level, the `polyspace-access` command exports only open findings that must be fixed or justified to satisfy the requirements of this level.<br>The SQO levels 1 to 6 specify an increasingly stricter set of predefined or user-defined requirements in terms of Polyspace results. To customize the requirements in the Polyspace Access web interface, see “Customize Software Quality Objectives”<br>For more information on the SQO levels, see “Evaluate Polyspace Bug Finder Results Against Bug Finder Quality Objectives”.<br>For instance, SQO level 2 in Code Prover requires that you must not have unjustified red checks. This specification means that if you use `-open-findings-for-sqo` with a level higher than 2, all red checks are exported and must be subsequently fixed or justified. If you want to impose this requirement in the earlier SQO level 1, you can customize level 1 in the Polyspace Access web interface. |
| `-resolution` *New \| Fixed \| Unresolved \| Resolved* | Use this option to compare two runs from the same project. The resolution corresponds to the type of comparison that the software performs between the current run and a baseline run that you specify with option `-baseline`. The baseline run must be older than the current run.<br>The resolution types are:<br>• `New` — Findings that are in the current run but not in the baseline run.<br>• `Fixed` — Findings that are fixed in the current run, either because the finding was fixed in the source code, or because the source code containing the finding is deleted or no longer part of the analysis.<br>• `Unresolved` — Findings from the baseline run that are still present in the current run.<br>• `Resolved` — Findings that are `Fixed` in the current run or findings with a status of `Justified`, `No Action Planned`, or `Not A Defect` in the current run.<br>If you do not specify a baseline, the current run is compared to the run that immediately precedes it. If the project contains only one run, you get an error.<br>You can specify only one resolution type at a time. To export a comparison for multiple resolution types, run the `polyspace-access -export` command for each resolution type.<br>See also “Comparison Mode at the Command Line”. |

| Option | Description |
|---|---|
| `-baseline` *`runID`* | Specify the run ID of a run that you use as a baseline for comparison with a current run. This option requires option `-resolution`.<br>This option is not mandatory. If you do not specify a baseline, the current run is compared to the run that immediately precedes it. If the project contains only one run, you get an error.<br>See also “Comparison Mode at the Command Line”. |
| `-imported-reviews` *`Not applied \| Written \| Overwritten \| Unconfirmed`* | Use this option to export a list of findings from a project (target) whose review information was imported from another project (source). Specify one of these types of imports:<br>• `Not applied` — Review information was imported from the source project but the review fields in the target project kept the original values.<br>• `Written` — The Review information from the source project was written to the target project only if the review fields in the target project were previously empty.<br>• `Overwritten` — The Review information from the source project was written to the target project even if the review fields in the target project were not previously empty.<br>• `Unconfirmed` — Use this filter to select findings that where the result of the import operation has not been confirmed by a reviewer. You confirm the result of the import operation in the Polyspace Access interface. See “Confirm Imported Review Information” .<br>See also “Import Review Information from Existing Polyspace Access Projects” |

You can also use a combination of options. For instance, `-coding-rules -severity High` exports coding rule violations that have been assigned a status of `High` in the Polyspace Access web interface.

### `findingsToDownload` — Project findings path or run ID

string

Path or run ID of the project findings that you download. Polyspace assigns a unique run ID to each analysis run that you upload to Polyspace Access. If the path name includes spaces, use double quotes. To get the project findings path or latest run ID, use `-list-project`.

When you specify the project path, the command downloads the latest run of that project. To download an older run, specify the run ID. To obtain the run ID of older runs, in the Polyspace Access interface, select a project in the **Project Explorer**, and then click the **Current** drop-down selection in the toolstrip to view the available run IDs.

Example: `-download "public/Examples/Bug_Finder_Example (Bug Finder)"`

Example: `-download 5113`

### `outputFolderPath` — Path to folder containing downloaded results

string

Path of the folder where you store the downloaded results. If the folder you specify already exists, it must be empty. This option is mandatory with the `-download` command.

Example: `-output-folder-path C:\Polyspace_Workspace\baseline`

#### Manage Review Information for Findings

### `fileOrFindingID` — finding ID or list of finding IDs to review

integer

Specify the ID of the finding to which you want to add review information by using the command `-review`. To perform a batch review, store the finding IDs of multiple findings in a text file (one finding ID per line) and pass that file to `-review` instead.

Polyspace Access assigns unique IDs to each finding that you upload.

Example: `-review 1234`

Example: `-review listOfFindings.txt`

### `projectToReview` — Absolute path of project

string

Specify the absolute path of the project that contains the findings to which you want to add review information. Use option `-project-path` to specify the path. When you use `-review`, this option is mandatory .

Example: `-project-path path/To/Project`

Example: `-project-path "project/path/with spaces"`

### `review options` — Options to specify review fields

string

Options to assign one or more review fields to the finding with the specified finding ID. When you use `polyspace-access -review`, you must specify at least one review option . After you assign review information to the finding, that information is available in the **Result Details** pane in Polyspace Access.

| Option | Description |
|---|---|
| `-set-status` *`Unreviewed \| "To investigate" \| "To fix" \| Justified \| "No action planned" \| "Not a defect" \| Other`* | Assign a status of the finding. Specify `Unreviewed` (default), `"To investigate"`, `"To fix"`, `Justified`, `"No action planned"`, `"Not a defect"`, or `Other`.<br>To reset a finding status, set the status to `Unreviewed`. |
| `-set-severity` *`Unset \| High \| Medium \| Low`* | Assign severity of the finding. Specify `Unset` (default), `High`, `Medium`, or `Low`.<br>To reset a finding severity, set the severity to `Unset`. |
| `-set-comment` *`comment`* | Assign a comment to the finding. |
| `-unset-comment` | Delete the comment currently assigned to the finding. |

| Option | Description |
|---|---|
| `-set-owner` *`username`* | Assign an owner to the finding. Specify the username that the user uses to log into Polyspace Access, not the display name. For instance, specify `jsmith` instead of `John Smith`. |
| `-unset-owner` | Remove the owner currently assigned to the finding. |
| `-set-ticket` *`ticketID`* | Assign an existing BTT ticket to the finding. Specify the ticket ID.<br>You can assign a BTT ticket to a finding only if you integrate a BTT such as Jira Software or Redmine with Polyspace Access. Contact your Polyspace administrator to determine if Polyspace is configured for issue tracking. |
| `-unset-ticket` | Remove the BTT ticket currently applied to the finding. |

**`sourceProjectPath` — Absolute path of project**
string

Specify the absolute path of the project where you have already reviewed the findings. You import the review information from this source project.

Example: `-import-reviews path/To/sourceProject`

Example: `-import-reviews "source project/path/with spaces"`

**`targetProjectPath` — Absolute path of project**
string

Specify the absolute path of the target project to which you import the review information. By default, if a review field already has content, the imported review information from the source project does not overwrite it. Use option `-import-strategy always-overwrite-target` to force the overwrite of the target project review information with the review information imported from the source project.

Example: `-to-project-path path/To/targetProject`

Example: `-import-reviews "target project/path/with spaces"`

**Manage Software Quality Objectives (SQO)**

**`projectPathWithSQO` — Absolute path of project**
string

Specify the absolute path of a project with the command `-set-sqo` to assign an SQO level and optionally an SQO definition. To view the currently applied SQO level and SQO definition for the specified project, use the command `-get-sqo`. You cannot specify a folder path with the commands `-set-sqo` and `-get-sqo`.

If your project path involves a folder that does not already exist, the folder is created.

Example: `-set-sqo path/To/Project`

Example: `-get-sqo "project/path/with spaces"`

**`sqoLevel` — SQO Level to assign**
`1 | 2 | 3 | 4 | 5 | 6 | exhaustive`

Level of the SQO to assign to the specified project for the currently applied SQO definition. Use option `-name` to also assign a different SQO definition.

Example: `-level 3`

Example: `-level exhaustive`

### `sqoName` — Name of SQO definition to assign

string

Specify an SQO definition name (optional) to apply a different SQO definition to the specified project.

To see a lit of available SQO definitions, use the command `-list-sqo`. To view the currently applied SQO definition for the specified project, use the command `-get-sqo`.

If the SQO definition name contains spaces, use double quotes.

Example: `-name Polyspace`

Example: `-name "My Custom SQO"`

#### Manage Project Run Labels and Unassigned Findings

### `label` — Project run label to add or remove

string

Specify a label to add or to remove from the project run that you specify with option `-run-id`. If the label includes spaces, use double quotes.

Example: `-add-label testing_branch`

Example: `-remove-label "testing branch"`

### `runID` — run ID of project run

string

Specify the run ID of the project run to which you add a label or from which you remove a label. To view the latest run IDs for a project, use the command `-list-project`. To view the run IDs of all the project runs for a specific project, use the command `-list-runs`.

Example: `-run-id 1234`

### `findingsToAssign` — Project findings path or run ID

string

Path or run ID of the project findings that you assign to a user. Polyspace assigns a unique run ID to each analysis run you upload. If the path name includes spaces, use double quotes. To get the project findings path or last run ID, use `-list-project`.

Example: `-set-unassigned-findings "public/Examples/Bug_Finder_Example (Bug Finder)"`

Example: `-set-unassigned-findings 4`

### `userToAssign` — Polyspace Access user name

string

User name of user you assign as owner of unassigned findings. To assign multiple owners, call the option for each user.

Each call to `-owner` must be paired with a call to `-source-contains`.

Example: `-owner jsmith`

### `pattern` — Pattern to match against file path

string

Pattern to match against file path of project source files. To match file paths for all source files, use "`-source-contains /`".

Enter a substring from the file path. You cannot use regular expressions.

When you call this option more than once, each instance excludes patterns from previous instances. For example, `-source-contains foo -source-contains bar` matches all file paths that contain `foo`, then all file paths that contain `bar` excluding paths that contain `foo`.

When you assign findings to multiple owners, call this option for each call to `-owner`.

Example: `-source-contains main`

### `set unassigned findings options` — Options to specify which findings to assign

string

Options to assign all findings or only a subset based on component or individual source files. To make an assignment, specify a pattern to match against the folder or file paths to assign.

| Option | Description |
|---|---|
| `-rte` *`All \| Red \| Gray \| Orange \| Green`* | Type of unassigned RTE finding to assign. Specify `All`, `Red`, `Gray`, `Orange`, or `Green`.<br>To specify more than one argument, call the option for each argument. For example, `-rte Red -rte Orange`. |
| `-defects` *`All \| High \| Medium \| Low`* | Impact of unassigned DEFECTS findings to assign. Specify `All`, `High`, `Medium`, or `Low`.<br>To specify more than one argument, call the option for each argument. For example, `-defects Medium -defects Low`. |
| `-custom-coding-rules` | Assign owner to all unassigned custom coding rules findings. |
| `-coding-rules` | Assign owner to all unassigned coding rules findings. |
| `-code-metrics` | Assign owner to all unassigned code metrics findings. |
| `-global-variables` | Assign owner to all unassigned global variables findings. |
| `-resolution New` | Assign owner to unassigned findings that are new compared to previous analysis run. If the project contains only one run, the command errors out. When there is only one project run, all findings are new and you do not need to specify this option. |
| `-status` *`Unreviewed \| "To investigate" \| "To fix" \| Justified \| "No action planned" \| "Not a defect" \| Other`* | Review status of the unassigned findings to assign. Specify `Unreviewed`, `"To investigate"`, `"To fix"`, `Justified`, `"No actionp lanned"`, `"Not a defect"`, or `Other`.<br>To specify more than one argument, call the option for each argument. For example, `-status "To fix" -status "To investigate"`. |

| Option | Description |
|---|---|
| `-severity` *`All \| High \| Medium \| Low`* | Severity of the unassigned findings to assign. Specify `All`, `High`, `Medium`, or `Low`.<br>To specify more than one argument, call the option for each argument. For example, `-severity High -severity Low`. |
| `-dryrun` | Display command output without making any assignment. Use this option to check that your assignments are correct. |

#### Manage User Permissions

### `role` — Level of access permissions for project folder or findings

`owner | contributor | forbidden`

Level of access to project folder and findings for a user.

- **owner**: User can move, rename, or delete specified project folders or findings and review their content.
- **contributor**: User can review content of specified project folder or findings.
- **forbidden**: User cannot access specified project folder or findings. Set this role to restrict the access of a user to a set of project findings inside a project folder that is accessible to the user.

Example: `-set-role contributor`

### `username` — Polyspace Access user name

string

Polyspace Access user name.

Example: `-user jsmith`

### `groupname` — Polyspace Access group name

string

Polyspace Access group name.

Example: `-group "Group UI team"`

### `folderPathOrProjectPath` — Project folder or findings path

string

Path of a project folder or project findings. When `folderPathOrProjectPath` is the path to a project folder, the user role you set applies to all subfolders and project findings under that folder. If the path name includes spaces, use double quotes. To get the project folder or findings path, use `-list-project`.

Example: `-project-path "public/Examples/Bug_Finder_Example (Bug Finder)"`

Example: `-project-path public`

#### Migrate Results from Metrics to Polyspace Access

### `metrics_dir` — Folder path of Polyspace Metrics projects

string

Path of folder containing the Polyspace Metrics projects you want to migrate to Polyspace Access.

Example: `-generate-migration-commands C:\Users\%username%\AppData\Roaming\Polyspace_RLDatas\results-repository`

**`dir` — Output folder for migration scripts**
string

Path to folder that stores the output of `-generate-migration-commands`. Do not specify an existing folder.

Example: `local/Polyspace_Workspace/migration_scripts`

**`generate migration commands options` — Options to specify which projects to migrate**
string

| Option | Description |
|---|---|
| `-output-folder-path` *`folderPath`* | Folder path where you want to store the generated command files. Do not specify an existing folder. |
| `-max-project-runs` *`int`* | Number of most recent analysis runs you want to migrate for each project. For instance, to migrate only the last two analysis runs of a project, specify 2. |
| `-project-date-after` *`YYYY[-MM[-DD]]`* | Only migrate results that were uploaded to Polyspace Metrics on or after the specified date. |
| `-product` *`productName`* | Product used to analyze and produce project findings, specified as `bug-finder`, `code-prover`, or `polyspace-ada`. |
| `-analysis-mode` *`integration \| unit-by-unit`* | Analysis mode use to generate project findings, specified as `integration` or `unit-by-unit`. |

## Version History

**Introduced in R2019a**

# polyspace-bug-finder-access

(DOS/UNIX) Run Polyspace as You Code from Windows, Linux, or other command line

## Syntax

```
polyspace-bug-finder-access -sources sourceFile [options]
```

```
polyspace-bug-finder-access -sources sourceFile -import-comments
baselineFolder [options]
```

```
polyspace-bug-finder-access -sources sourceFile -options-file optFile
```

```
polyspace-bug-finder-access -h[elp]
```

## Description

**Note** This Polyspace command is available in `*polyspaceroot*\polyspace\bin`. Here, *`polyspaceroot`* is the Polyspace as You Code installation folder, for instance, `C:\Program Files\Polyspace as You Code\R2023a` (see also “Run Polyspace as You Code from Command Line and Export Results”). To avoid typing the full path to this command, add this location to the `PATH` environment variable in your operating system.

`polyspace-bug-finder-access -sources sourceFile [options]` runs a Polyspace as You Code analysis on the source file `sourceFile`. You can customize the analysis with additional options.

`polyspace-bug-finder-access -sources sourceFile -import-comments baselineFolder [options]` runs a Polyspace as You Code analysis on the source file `sourceFile` and then imports the review information from a previous run stored in `baselineFolder`. See `-import-comments`.

Use this workflow to compare your results against the results of a previous run that you download from Polyspace Access and focus on new results only or on unreviewed results. See “Baseline Polyspace as You Code Results on Command Line”.

`polyspace-bug-finder-access -sources sourceFile -options-file optFile` runs a Polyspace as You Code analysis on the source file `sourceFile` with the options specified in the option file. When you have many analysis options, an options file makes it easier to run the same analysis again.

`polyspace-bug-finder-access -h[elp]` lists a summary of possible analysis options.

## Examples

### Run Analysis by Directly Specifying Options

Run the `polyspace-bug-finder-access` command by specifying all options directly at the command line.

Run the `polyspace-bug-finder-access` command on a single source file `file.c` in the current folder. Save the results in the folder `polyspaceResults`.

```
polyspace-bug-finder-access -sources file.c -results-dir polyspaceResults
```

### Run Analysis Using Options File

Run the `polyspace-bug-finder-access` command by specifying options in a text file.

Enter the following in a text file `opts.txt`:

```
-results-dir polyspaceResults
-compiler gnu7.x
```

Run the `polyspace-bug-finder-access` command on a single source file `file.c` in the current folder. Use the analysis options in the previously created file `opts.txt`:

```
polyspace-bug-finder-access -sources file.c -options-file opts.txt
```

## Input Arguments

### `sourceFile` — C or C++ file to analyze

source file name or path

C or C++ source file name, specified as a string. If the file is not in the current folder (`pwd`), `sourceFile` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-sources`.

Note that you can only analyze a single source file at a time using Polyspace as You Code.

Example: `myFile.c`

### `options` — Analysis option and corresponding value

command-line flag with optional value

Analysis options and their corresponding values, specified by the option name and if applicable value. For syntax specifications, see the individual analysis option reference pages.

Example: `-lang C-CPP` `-compiler diab`

### `optFile` — Text file listing analysis options and values

options file name or path

Text file listing analysis options and values, specified as a string. If the file is not in the current folder (`pwd`), `optFile` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-options-file`.

Example: `opts.txt`, `"C:\ps_analysis\options.txt"`

### `baselineFolder` — Folder where you download baseline run

folder path

Path of folder where you store the run that you download from Polyspace Access. You use the downloaded run as a baseline for Polyspace as You Code runs. See “Baseline Polyspace as You Code Results on Command Line”.

Example: `"C:\Temp\Results_Folder\baseline"`

"Baseline Polyspace as You Code Results on Command Line"

# polyspace-bug-finder

(DOS/UNIX) Run a Bug Finder analysis from Windows, Linux, or other command line

## Syntax

```
polyspace-bug-finder [options]
polyspace-bug-finder -sources sourceFiles [options]

polyspace-bug-finder -sources-list-file listOfSources [options]

polyspace-bug-finder -options-file optFile

polyspace-bug-finder -h[elp]
```

## Description

**Note** This Polyspace command is available in *polyspaceroot*\polyspace\bin. Here, *polyspaceroot* is the Polyspace installation folder, for instance, C:\Program Files\Polyspace\R2023a (see also "Installation Folder"). To avoid typing the full path to this command, add this location to the PATH environment variable in your operating system.

polyspace-bug-finder [options] runs a Bug Finder analysis if your current folder contains a sources subfolder with source files (.c or .cxx files). The analysis considers files in sources and all subfolders under sources.

polyspace-bug-finder -sources sourceFiles [options] runs a Bug Finder analysis on the source file(s) sourceFiles. You can customize the analysis with additional options.

polyspace-bug-finder -sources-list-file listOfSources [options] runs a Bug Finder analysis on the source files listed in the text file listOfSources. You can customize the analysis with additional options. Using a sources list file is recommended when you have many source files. By keeping the list of sources in a text file, the command is shorter and updates to the list are easier.

polyspace-bug-finder -options-file optFile runs a Bug Finder analysis with the options specified in the option file. When you have many analysis options, an options file makes it easier to run the same analysis again.

polyspace-bug-finder -h[elp] lists a summary of possible analysis options.

## Examples

### Run Analysis by Directly Specifying Options

Run a local Bug Finder analysis by specifying analysis options at the command line itself. This example uses source files from a demo Polyspace Bug Finder example. To run this example, replace *polyspaceroot* with the path to your Polyspace installation, for example C:\Program Files\Polyspace\R2023a.

Run an analysis on `numerical.c` and `programming.c`, checking for MISRA C:2012 mandatory rules, programming and numerical defects, and using GNU 4.7 compiler settings. This example command is split by ^ characters for readability. In practice, you can put all commands on one line.

```
polyspace-bug-finder -sources ^
polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\numerical.c,^
polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\programming.c ^
-compiler gnu4.7 -misra3 mandatory -checkers numerical,programming ^
-author jlittle -prog myProject -results-dir C:\Polyspace_Workspace\Results\
```

Open the results.

```
polyspace C:\Polyspace_Workspace\Results\ps_results.psbf
```

To rerun the analysis, you must rerun it from the command line.

### Run Local Analysis with Options File

Run a local Bug Finder analysis by specifying analysis options with an options. This example uses source files from a demo Polyspace Bug Finder example. To run this example, replace *`polyspaceroot`* with the path to your Polyspace installation, for example `C:\Program Files\Polyspace\R2023a`.

Save this text to a text file called `myOptionsFile.txt`.

```
# Options for analyzing numerical.c and programming.c
-sources polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\numerical.c
-sources polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\programming.c
-compiler gnu4.7
-misra3 mandatory
-checkers numerical,programming
-author jlittle
-prog myProject
-results-dir C:\Polyspace_Workspace\Results\
```

Run the analysis with the options specified in the text file.

```
polyspace-bug-finder -options-file myOptionsFile.txt
```

Open the results.

```
polyspace C:\Polyspace_Workspace\Results\ps_results.psbf
```

To rerun the analysis, you must rerun it from the command line.

## Input Arguments

### `sourceFiles` — Comma-separated names of C or C++ files to analyze

source file name or path

Comma-separated C or C++ source file names, specified as a string. If the files are not in the current folder (pwd), `sourceFiles` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-sources`.

If your current folder contains a `sources` subfolder with the source files, you can omit the `-sources` flag. The analysis considers files in `sources` and all subfolders under `sources`.

Example: `myFile.c`, `"C:\mySources\myFile1.c,C:\mySources\myFile2.c"`

**`listOfSources` — Text file listing names of C or C++ files to analyze**
sources list file name or path

Text file which lists the name of C or C++ files, specified as a string. If the files are not in the current folder (`pwd`), `listOfSources` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-sources-list-file`.

Example: `filename.txt`, `"C:\ps_analysis\source_files.txt"`

**`options` — Analysis option and corresponding value**
command-line flag with optional value

Analysis options and their corresponding values, specified by the option name and if applicable value. For syntax specifications, see the individual analysis option reference pages.

Example: `-lang C-CPP` `-compiler diab`

**`optFile` — Text file listing analysis options and values**
options file name or path

Text file listing analysis options and values, specified as a string. For more information, see `-options-file`.

Example: `opts.txt`, `"C:\ps_analysis\options.txt"`

## Tips

If you run the command as part of a script, check the exit status to confirm a successful analysis. The command returns zero on a successful analysis. A nonzero return value means that the analysis failed and was not completed. For instance, if the analyzed file does not compile, the command returns a nonzero value. If some of the files do not compile when you are analyzing multiple files, the command completes analysis on the files that do compile and returns zero. It is possible to stop analysis if a file does not compile. See `Stop analysis if a file does not compile (-stop-if-compile-error)`.

After running the command, you can check the `%ERRORLEVEL%` variable in Windows command line to confirm a successful analysis.

(DOS/UNIX) Run a Bug Finder analysis on a server from Windows, Linux, or other command line

## Syntax

```
polyspace-bug-finder-server [options]
polyspace-bug-finder-server -sources sourceFiles [options]

polyspace-bug-finder-server -sources-list-file listOfSources [options]

polyspace-bug-finder-server -options-file optFile

polyspace-bug-finder-server -h[elp]
```

## Description

**Note** This Polyspace command is available in *polyspaceroot*\polyspace\bin. Here, *polyspaceroot* is the Polyspace Server installation folder, for instance, C:\Program Files \Polyspace Server\R2023a (see also “Installation Folder”). To avoid typing the full path to this command, add this location to the PATH environment variable in your operating system.

polyspace-bug-finder-server [options] runs a Bug Finder analysis on a server if your current folder contains a sources subfolder with source files (.c or .cxx files). The analysis considers files in sources and all subfolders under sources.

polyspace-bug-finder-server -sources sourceFiles [options] runs a Bug Finder analysis on a server on the source file(s) sourceFiles. You can customize the analysis with additional options.

polyspace-bug-finder-server -sources-list-file listOfSources [options] runs a Bug Finder analysis on a server on the source files listed in the text file listOfSources. You can customize the analysis with additional options. Using a sources list file is recommended when you have many source files. By keeping the list of sources in a text file, the command is shorter and updates to the list are easier.

polyspace-bug-finder-server -options-file optFile runs a Bug Finder analysis on a server with the options specified in the option file. When you have many analysis options, an options file makes it easier to run the same analysis again.

polyspace-bug-finder-server -h[elp] lists a summary of possible analysis options.

## Examples

### Run Analysis by Directly Specifying Options

Run a Bug Finder analysis on a server by specifying analysis options in the run command itself. This example uses source files from a demo Polyspace Bug Finder example. To run this example, replace *polyspaceroot* with the path to your Polyspace installation, for example `C:\Program Files\Polyspace\R2023a`.

Run an analysis on `numerical.c` and `programming.c`, checking for MISRA C:2012 mandatory rules, programming and numerical defects, and using GNU 4.7 compiler settings. This example command is split by ^ characters for readability. In practice, you can put all commands on one line.

```
polyspace-bug-finder-server -sources ^
polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\numerical.c,^
polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\programming.c ^
-compiler gnu4.7 -misra3 mandatory -checkers numerical,programming ^
-author jlittle -prog myProject -results-dir C:\Polyspace_Workspace\Results\
```

After analysis, you can upload the results to the Polyspace Access interface for review. See:

- `polyspace-access`
- “Run Polyspace Bug Finder on Server and Upload Results to Web Interface”

#### Run Analysis with Options File

Run a Bug Finder analysis on a server by specifying analysis options with an options file. This example uses source files from a demo Polyspace Bug Finder example. To run this example, replace *polyspaceroot* with the path to your Polyspace installation, for example `C:\Program Files\Polyspace\R2023a`.

Save this text to a text file called `myOptionsFile.txt`.

```
# Options for analyzing numerical.c and programming.c
-sources polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\numerical.c
-sources polyspaceroot\polyspace\examples\cxx\Bug_Finder_Example\sources\programming.c
-compiler gnu4.7
-misra3 mandatory
-checkers numerical,programming
-author jlittle
-prog myProject
-results-dir C:\Polyspace_Workspace\Results\
```

Run the analysis with the options specified in the text file.

```
polyspace-bug-finder-server -options-file myOptionsFile.txt
```

After analysis, you can upload the results to the Polyspace Access interface for review. See:

- `polyspace-access`
- “Run Polyspace Bug Finder on Server and Upload Results to Web Interface”

## Input Arguments

### `sourceFiles` — Comma-separated names of C or C++ files to analyze

source file name or path

Comma-separated C or C++ source file names, specified as a string. If the files are not in the current folder (pwd), `sourceFiles` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-sources`.

If your current folder contains a `sources` subfolder with the source files, you can omit the `-sources` flag. The analysis considers files in `sources` and all subfolders under `sources`.

Example: `myFile.c`, `"C:\mySources\myFile1.c,C:\mySources\myFile2.c"`

**`listOfSources` — Text file listing names of C or C++ files to analyze**
sources list file name or path

Text file which lists the name of C or C++ files, specified as a string. If the files are not in the current folder (`pwd`), `listOfSources` must include a full or relative path. To avoid errors because of paths with spaces, add quotes `" "` around the path. For more information, see `-sources-list-file`.

Example: `filename.txt`, `"C:\ps_analysis\source_files.txt"`

**`options` — Analysis option and corresponding value**
command-line flag with optional value

Analysis options and their corresponding values, specified by the option name and if applicable value. For syntax specifications, see the individual analysis option reference pages.

Example: `-lang C-CPP` `-compiler diab`

**`optFile` — Text file listing analysis options and values**
options file name or path

Text file listing analysis options and values, specified as a string. For more information, see `-options-file`.

Example: `opts.txt`, `"C:\ps_analysis\options.txt"`

## Tips

If you run the command as part of a script, check the exit status to confirm a successful analysis. The command returns zero on a successful analysis. A nonzero return value means that the analysis failed and was not completed. For instance, if the analyzed file does not compile, the command returns a nonzero value. If some of the files do not compile when you are analyzing multiple files, the command completes analysis on the files that do compile and returns zero. It is possible to stop analysis if a file does not compile. See `Stop analysis if a file does not compile (-stop-if-compile-error)`.

After running the command, you can check the `%ERRORLEVEL%` variable in Windows command line to confirm a successful analysis.

# polyspace-cluster-profile-manager

(DOS/UNIX) Import MATLAB cluster profile to Polyspace Server commands

## Syntax

```
polyspace-cluster-profile-manager -import-profile clusterProfile
```

## Description

**Note** To avoid typing the full path to this command, add *polyspaceroot*\polyspace\bin to your PATH environment variable . Here, *polyspaceroot* is the Polyspace Server installation folder, for instance, C:\Program Files\Polyspace Server\R2023a.

polyspace-cluster-profile-manager -import-profile clusterProfile imports the cluster profile stored in clusterProfile to your Polyspace Server product. This is equivalent to using the **Cluster Profile Manager** to import a profile. See “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox). Use this command to import a profile if you do not have access to the **Cluster Profile Manager** interface, for instance if you are on a server machine with no graphical interface.

Once you import a profile, you can offload a Polyspace analysis to a remote server by specifying only the name of the job scheduler with option -scheduler.

## Examples

### Import Profile of Cluster that Requires a Certificate

When you enable the flag REQUIRE_CLIENT_CERTIFICATE in file *matlabroot*\toolbox\parallel\bin\mjs_def.sh, clients must use a cluster profile that contains the correct certificate to connect to the job scheduler. Here, *matlabroot* is the installation folder of the MATLAB Parallel Server product, for example C:\Program Files\MATLAB\R2023a.

After you configure the MATLAB Parallel Server cluster and create the certificate file, export the cluster profile and then import it to the Polyspace clients that you want to allow to connect to the job scheduler.

To create a certificate file, generate a shared secret file and then use that file to create the certificate. At the command line, navigate to *matlabroot*\toolbox\parallel\bin\ and run the createSharedSecret script to generate file mySecret.

```
createSharedSecret -file mySecret
```

Pass file mySecret to the generateCertificate script to create the certificate.

```
generateCertificate -secretfile mySecret -certfile clusterClientCert
```

The command generates a certificate file clusterClientCert.

Export the cluster profile by using the createProfile script. Specify the name of the cluster, the hostname of the machine where the job scheduler is running, and the path of the certificate file. For instance, if the job scheduler runs on a machine with hostname mjsHost, run this command:

```
createProfile -name clusterName -host mjsHost -certfile clusterClientCert -outfile mjsProfile
```

The command creates a cluster profile XML file mjsProfile. This XML file contains the certificate that the clients need to connect to the job scheduler.

Import the cluster profile mjsProfile to the client machine where you run the Polyspace Server product that offloads the analysis to the MATLAB Parallel Server cluster. On the machine where you run the Polyspace client, run this command:

```
polyspace-cluster-profile-manager -import-profile path/to/mjsProfile
```

The Polyspace client uses the imported cluster profile and can connect to the job scheduler. Once you import the profile, specify the cluster name with option -scheduler when you run a Polyspace Server analysis in -batch mode, for instance -batch -scheduler clusterName.

## Input Arguments

**clusterProfile — XML file**
source file name or path

clusterName.settings XML file that you generate using the **Cluster Profile Manager** or the createProfile script located in the folder *matlabroot*\toolbox\parallel\bin. Here, *matlabroot* is the installation folder of the MATLAB Parallel Server product, for example C:\Program Files\MATLAB\R2023a.

Example: myClusterName.settings

# Version History

**Introduced in R2021b**

### Topics

“Offload Polyspace Analysis from Continuous Integration Server to Another Server”

# polyspace-configure

(DOS/UNIX) Create Polyspace project from your build system at the DOS or UNIX command line

## Syntax

```
polyspace-configure buildCommand
```

```
polyspace-configure [options] buildCommand
```

```
polyspace-configure [options] -compilation-database jsonFile
```

## Description

**Note** This Polyspace command is available in *polyspaceroot*\polyspace\bin. Here, *polyspaceroot* is the Polyspace installation folder, for instance, C:\Program Files\Polyspace\R2023a (see also “Installation Folder” for desktop products or “Installation Folder” for server products). To avoid typing the full path to this command, add this location to the PATH environment variable in your operating system.

polyspace-configure buildCommand traces your build system and creates a Polyspace project with information gathered from your build system. Polyspace creates a project from your build system only if your build commands or makefiles meet certain requirements. For a list of compiler and build command requirements, including a list of compilers that Polyspace supports, see “Requirements for Project Creation from Build Systems”.

polyspace-configure [options] buildCommand traces your build system and uses options to modify the default operation of polyspace-configure. Specify the modifiers before buildCommand, otherwise they are considered as options in the build command itself.

polyspace-configure [options] -compilation-database jsonFile creates a Polyspace project with information gathered from the JSON compilation database file jsonFile that you provide. You do not need to specify a build command or trace your build system. For more on JSON compilation databases, see JSON Compilation Database.

## Examples

### Create Polyspace Project Using Compile Command (gcc, cl, etc.)

This example shows how to use a compile command to create your Polyspace project. The simplest way to run polyspace-configure is to run it directly on the compile command used to build your source code. This example uses the GCC compiler and the compile command gcc. GCC is a standard compiler suite included with Linux based systems. For Windows based systems, MinGW can be installed to support the GCC compiler.

First, ensure that your source code compiles without errors.

```
gcc myFilename.c otherFile.c
```

After confirming that your source code compiles without errors, remove the object files before continuing.

```
rm myFilename.o otherFile.o
```

Create a Polyspace project specifying a unique project name. Run `polyspace-configure` on the compile command as previously tested.

```
polyspace-configure -prog myProject gcc myFilename.c otherFile.c
```

Open the Polyspace project in the Polyspace user interface.

If you use Visual Studio to compile your sources, you can replace `gcc` in the above example with `cl`. You can also run `polyspace-configure` on a full build of your Visual Studio project. See "Create Polyspace Projects from Visual Studio Build" .

Note that `polyspace-configure` creates a new Polyspace project using the sources from your compile command. It is not possible to append to an already existing Polyspace project by using the `polyspace-configure` command. If you use compile options (such as `-D` for `gcc`), `polyspace-configure` sets the equivalent Polyspace options in the project. For more details, see "Algorithms" on page 4-49.

### Create Polyspace Project from Makefile

Typically, in real applications, you do not invoke the compiler directly to build your source code. Your build command runs several commands, one of which is compilation. For instance, you might be running a makefile to build your source code. This example shows how to create a Polyspace project if you use the command `make` *`targetName buildOptions`* to build your source code.

Create a Polyspace project specifying a unique project name. Use the `-B` or `-W` *`makefileName`* option with `make` so that the all prerequisite targets in the makefile are remade.

```
polyspace-configure  -prog myProject \
make -B targetName buildOptions
```

Open the Polyspace project in the Polyspace user interface.

### Create Polyspace Options File from JSON Compilation Database

This example shows how to create a Polyspace options file from a JSON compilation database that you generate with the CMake build system generator. CMake generates build instructions for the build tool you specify, such as a Unix Makefiles for `make` or project files for Microsoft Visual Studio. CMake supports the generation of a JSON compilation database only for Makefile generators and Ninja generator. For more information, see makefile generators.

Generate a JSON compilation database for your CMake project. For an example of a Cmake project, see *`polyspaceroot`*`\help\toolbox\bugfinder\examples\compilation_database` where *`polyspaceroot`* is your Polyspace installation folder.

Navigate to the root of your project source tree. This folder contains the file `CMakeLists.txt` which CMake uses as an input to generate build instructions. Enter these commands:

```
mkdir JSON_cdb
cd JSON_cdb
cmake -G "Unix Makefiles" -DCMAKE_EXPORT_COMPILE_COMMANDS=1 ../
```

The last command generates a Unix makefile with build instructions for the `make` build tool. The command also outputs file `compile_commands.json`. This file lists the compiler calls for every translation unit in your project.

Generate a Polyspace options file from the compilation database that you generated in the previous step.

```
polyspace-configure -compilation-database compile_commands.json \
-output-options-file options.txt
```

You do not need to specify a build command and `polyspace-configure` does not trace your build. Polyspace extracts information about your build system from the JSON compilation database.

Pass the options file to Polyspace to run an analysis, for instance:

```
polyspace-bug-finder -options-file options.txt
```

### Create Projects That Have Different Source Files from Same Build Trace

This example shows how to create different Polyspace projects from the same trace of your build system. You can specify which source files to include for each project.

Trace your build system without creating a Polyspace project by specifying the option `-no-project`. To ensure that all the prerequisite targets in your makefile are remade, use the appropriate `make` build command option, for instance `-B`.

```
polyspace-configure -no-project make -B
```

`polyspace-configure` stores the cache information and the build trace in default locations inside the current folder. To store the cache information and build trace in a different location, specify the options `-cache-path` and `-build-trace`.

Generate Polyspace projects by using the build trace information from the previous step. Specify a project name and use the `-include-sources` or `-exclude-sources` option to select which files to include for each project.

```
polyspace-configure -no-build -prog myProject \
-include-sources "glob_pattern"
```

*`glob_pattern`* is a glob pattern that corresponds to folders or files you filter in or out of your project. To ensure the shell does not expand the glob patterns you pass to `polyspace-configure`, enclose them in double quotes. For more information on the supported syntax for glob patterns, see “Select Files for Polyspace Analysis Using Pattern Matching”.

If you specified the options `-build-trace` and `-cache-path` in the previous step, specify them again.

Delete the trace file and cache folder.

```
rm -r polyspace_configure_cache polyspace_configure_built_trace
```

If you used the options `-build-trace` and `-cache-path`, use the paths and file names from those options.

### Run Command-Line Polyspace Analysis from Makefile

This example shows how to run Polyspace analysis if you use the command `make` *`targetName buildOptions`* to build your source code. In this example, you use `polyspace-configure` to trace your build system but do not create a Polyspace project. Instead you create an options file that you can use to run Polyspace analysis from command-line.

Create a Polyspace options file specifying the `-output-options-file` command. Use the `-B` or `-W` *`makefileName`* option with `make` so that all prerequisite targets in the makefile are remade.

```
polyspace-configure -output-options-file\
 myOptions make -B targetName buildOptions
```

Use the options file that you created to run a Polyspace analysis at the command line:

```
polyspace-bug-finder -options-file myOptions
```

## Input Arguments

### `buildCommand` — Command for full build of source code

string

Build command specified exactly as you use to build your source code.

The build command must perform a full build of your sources and not an incremental build. Typically, build commands such as `make` are set up to only build sources that have changed since the previous build. However, `polyspace-configure` requires a full build to determine which sources to add to a Polyspace project or options file. Add appropriate options to your build command to force a full build. For instance, when using a makefile, append the option `-B` to `make`.

Example: `make -B`, `make -B -W` *`makefileName`*

### `options` — Options for changing default operation of `polyspace-configure`

single option starting with `-`, followed by argument | multiple space-separated option-argument pairs

**Basic Options**

| Option | Argument | Description |
|---|---|---|
| `-prog` | Project name | Project name that appears in the Polyspace user interface. The default is `polyspace`.<br>If you do not use the option `-output-project`, the `-prog` argument also sets the project name.<br>**Example:** `-prog myProject` creates a project that has the name `myProject` in the user interface. If you do not use the option `-output-project`, the project name is also `myProject.psrprj`. |

| Option | Argument | Description |
|---|---|---|
| -author | Author name | Name of project author.<br>**Example:** -author jsmith |
| -output-project | Path | Name and location of Polyspace project. The default is the file polyspace.psprj in the current folder.<br>**Example:** -output-project ../myProjects/project1 creates a project project1.psprj in the folder with the relative path ../myProjects/. |
| -output-options-file | File name | Option to create a Polyspace analysis options file. Use this file for command-line analysis using one of these commands:<br>• polyspace-bug-finder<br>• polyspace-code-prover<br>• polyspace-bug-finder-server<br>• polyspace-code-prover-server<br>• polyspace-bug-finder-access |
| -allow-build-error | None | Option to create a Polyspace project even if an error occurs in the build process.<br>If an error occurs, the build trace log shows the following message:<br>polyspace-configure (polyspaceConfigure)<br>   ERROR: build command<br>   *command_name* fail [status=*status_value*]<br>*command_name* is the build command name that you use and *status_value* is the non-zero exit status or error level that indicates which error occurred in your build process.<br>This option is ignored when you use -compilation-database. |
| -allow-overwrite | None | Option to overwrite a project with the same name, if it exists.<br>By default, polyspace-configure (polyspaceConfigure) throws an error if a project with the same name already exists in the output folder. Use this option to overwrite the project. |
| -no-console-output<br>-silent (default)<br>-verbose | None | Option to suppress or display additional messages from running polyspace-configure (polyspaceConfigure).<br>• -no-console-output – Suppress all outputs including errors and warnings.<br>• -silent (default) – Show only errors and warnings.<br>• -verbose – Show all messages.<br>If you specify more than one of these options, the most verbose option is applied.<br>These options are ignored if they are used in combination with -easy-debug. |

| Option | Argument | Description |
|---|---|---|
| `-help` | None | Option to display the full list of `polyspace-configure (polyspaceConfigure)` commands |
| `-debug` | None | Option to store debug information for use by MathWorks technical support.<br>This option has been superseded by the option `-easy-debug`. |
| `-easy-debug` | Path | Option to store debug information for use by MathWorks technical support.<br>After a `polyspace-configure (polyspaceConfigure)` run, the path provided contains a zipped file ending with `pscfg-output.zip`. If the run fails to create a complete Polyspace project or options file, send this zipped file to MathWorks Technical Support for further debugging. The zipped file does not contain source files traced in the build. See also “Errors in Project Creation from Build Systems”. |

**Options to Create Multiple Modules**

These options are not compatible with `-compilation-database`.

| Option | Argument | Description |
|---|---|---|
| `-module` | None | Option to create a separate options file for each binary you create in build system. You can only create separate options files for different binaries.<br>Use this option only if your build system uses GNU or Visual C++ compilers.<br>See also “Modularize Polyspace Analysis by Using Build Command”. |
| `-output-options-path` | Path name | Location where generated options files are saved. Use this option together with the option `-module`.<br>The options files are named after the binaries created in the build system. |

**Advanced Options**

| Option | Argument | Description |
|---|---|---|
| -compilation-database | Path and file name | Location and name of JSON compilation database (JSON CDB) file. You generate this file from your build system, for instance by using the flag -DCMAKE_EXPORT_COMPILE_COMMANDS=1 with cmake. The file contains compiler calls for all the translation units in you projects. For more information, see JSON Compilation Database. polyspace-configure uses the content of this file to get information about your build system. The extracted compiler paths in the JSON CDB must be accessible from the path where you run polyspace-configure.<br>You do not specify a build command when you use this option.<br>These build systems and compilers support the generation of a JSON CDB:<br>• CMake<br>• Bazel<br>• Clang<br>• Ninja<br>• Qbs<br>• waf<br>This option is not compatible with -no-project and with the options to create multiple modules.<br>The cache control options, -allow-build-error, and -no-build are ignored when you use this option. |
| -compiler-config | Path and file name | Location and name of compiler configuration file.<br>The file must be in a specific format. For guidance, see the existing configuration files in *polyspaceroot*\polyspace\configure\compiler_configuration\. For information on the contents of the file, see “Create Polyspace Projects from Build Systems That Use Unsupported Compilers”.<br>**Example:** -compiler-configuration myCompiler.xml |
| -no-project | None | Option to trace your build system without creating a Polyspace project and save the build trace information.<br>Use this option to save your build trace information for a later run of polyspace-configure (polyspaceConfigure) with the -no-build option.<br>This option is not compatible with -compilation-database. |

| Option | Argument | Description |
|---|---|---|
| `-no-build` | None | Option to create a Polyspace project using previously saved build trace information.<br>To use this option, you must have the build trace information saved from an earlier run of `polyspace-configure (polyspaceConfigure)` with the `-no-project` option.<br>If you use this option, you do not need to specify the `buildCommand` argument.<br>This option is ignored when you use `-compilation-database`. |
| `-no-sources` | None | Option to create a Polyspace options file that does not contain the source file specifications.<br>Use this option when you intend to specify the source files by other means. For instance, you can use this option when:<br>• Running Polyspace on AUTOSAR-specific code.<br>You want to create an options file that traces your build command for the compiler options:<br>`-output-options-file options.txt -no-sources`<br>You later append this options file when extracting source file names from ARXML specifications and running the subsequent Code Prover analysis with `polyspace-autosar`<br>`-extra-options-file options.txt`<br>See also “Run Polyspace on AUTOSAR Code Using Build Command” (Polyspace Code Prover).<br>• Running Polyspace in Eclipse™.<br>Your source files are already specified in your Eclipse project. When running a Polyspace analysis, you want to specify an options file that has the compilation options only. |

| Option | Argument | Description |
|---|---|---|
| `-extra-project-options` | Options to use for subsequent Polyspace analysis. For instance, `"-stubbed-pointers-are-unsafe"`. | Options that are used for subsequent Polyspace analysis.<br>Once a Polyspace project is created, you can change some of the default options in the project. Alternatively, you can pass these options when tracing your build command. The flag `-extra-project-options` allows you to pass additional options.<br>Specify multiple options in a space separated list, for instance `"-allow-negative-operand-in-shift -stubbed-pointers-are-unsafe"`.<br>Suppose you have to set the option `-stubbed-pointers-are-unsafe` for every Polyspace project created. Instead of opening each project and setting the option, you can use this flag when creating the Polyspace project:<br>`-extra-project-options "-stubbed-pointers-are-unsafe"`<br>For the list of options available, see:<br>• "Complete List of Polyspace Bug Finder Analysis Engine Options"<br>• "Complete List of Polyspace Code Prover Analysis Options" (Polyspace Code Prover)<br>If you are creating an options file instead of a Polyspace project from your build command, do not use this flag. Instead, add the extra analysis options manually in the generated options file, in a separate options file, or at the command-line when you start the analysis. |
| `-tmp-path` | Path | Location of folder where temporary files are stored. |
| `-build-trace` | Path and file name | Location and name of file where build information is stored. The default is `./polyspace_configure_build_trace.log`.<br>**Example:** `-build-trace ../build_info/trace.log` |
| `-log` | Path and file name | Location and name of log file where the output of the `polyspace-configure` command is stored. The use of this option does not suppress the console output. |
| `-include-sources`<br>`-exclude-sources` | Glob pattern | Option to specify which source files `polyspace-configure (polyspaceConfigure)` includes in, or excludes from, the generated project. You can combine both options together.<br>A source file is included if the file path matches the glob pattern that you pass to `-include-sources`.<br>A source file is excluded if the file path matches the glob pattern that you pass to `-exclude-sources`. |

| Option | Argument | Description |
|---|---|---|
| -print-included-sources<br>-print-excluded-sources | None | Option to print the list of source files that polyspace-configure (polyspaceConfigure) includes in, or excludes from, the generated project. You can combine both options together. The output displays the full path of each file on a separate line.<br>Use this option to troubleshoot the glob patterns that you pass to -include-sources or -exclude-sources. You can see which files match the pattern that you pass to -include-sources or -exclude-sources. |
| -compiler-cache-path | Folder path | Specify a folder path where polyspace-configure looks for or stores the compiler cache files. If the folder does not exist, polyspace-configure creates it.<br>By default, Polyspace looks for and stores compiler caches under these folder paths:<br>• **Windows**<br>%appdata%\Mathworks\R20xxY\Polyspace<br>• **Linux**<br>~/.matlab/R20xxY/Polyspace<br>• **Mac**<br>~/Library/Application Support/MathWorks/MATLAB/R20xxY/Polyspace<br>*R20xxY* is the release version of your Polyspace product, for instance R2020b. |
| -no-compiler-cache | None | Use this option if you do not want Polyspace to cache your compiler configuration information or to use an existing cache for your compiler configuration.<br>By default, the first time you run polyspace-configure with a particular compiler configuration, Polyspace queries your compiler for the size of fundamental types, compiler macro definitions, and other compiler configuration information then caches this information. Polyspace reuses the cached information in subsequent runs of polyspace-configure for builds that use the same compiler configuration. |
| -reset-compiler-cache-entry | None | Use this option to query the compiler for the current configuration and to refresh the entry in the cache file that corresponds to this configuration. Other compiler configuration entries in the cache are not updated. |
| -clear-compiler-cache | None | Use this option to delete all compiler configurations stored in the cache file.<br>If you also specify a build command or -compilation-database, polyspace-configure computes and caches the compiler configuration information of the current run, except if you specify -no-project or -no-compiler-cache. |

| Option | Argument | Description |
|---|---|---|
| `-import-macro-definitions` | `none`<br>`from-allowlist`<br>`from-source-tokens`<br>`from-compiler` | Typically, you do not need to specify this option.<br>Polyspace attempts to automatically determine the best strategy to query your compiler for macro definitions in this order of priority:<br>1 `from-compiler` — Polyspace uses native compiler options, such as `gcc -dm -E`, to obtain the compiler macro definitions. This strategy does not require Polyspace to trace your build and is available only for compilers that support listing macro definitions.<br>2 `from-source-tokens` — Polyspace uses every non-keyword token in your source code to query your compiler for macro definitions. This strategy is available only if Polyspace can trace your build. The strategy is not available if you use option `-compilation-database`.<br>3 `from-allowlist` — Polyspace uses an internal allow list to query the compiler for macro definitions.<br>If you prefer to specify macro definitions manually, use this option with the `none` flag and use option `Preprocessor definitions (-D)` to specify the macro definitions.<br>If the macro import strategy that Polyspace uses is not the one that you expect, try specifying this option manually to troubleshoot the issue. |
| `-options-for-sources-delimiter` | A single character | Specify an option separator to use when multiple analysis options are associated with one source file using the `-options-for-sources` option. Typically, the `-options-for-sources` option uses a semicolon as separator.<br>See also `-options-for-sources`. |

### Cache Control Options

These options are primarily useful for debugging. Use the options if `polyspace-configure (polyspaceConfigure)` fails and MathWorks Technical Support asks you to use the option and provide the cached files. Starting R2020a, the option `-easy-debug` provides an easier way to provide debug information. See “Contact Technical Support About Issues with Running Polyspace”.

These options are ignored when you use `-compilation-database`.

| Option | Argument | Description |
|---|---|---|
| `-no-cache`<br>`-cache-sources` (default)<br>`-cache-all-text`<br>`-cache-all-files` | None | Option to perform one of the following:<br>• `-no-cache`: Not create a cache<br>• `-cache-sources`: Cache text files temporarily created during build for later use by `polyspace-configure (polyspaceConfigure)`.<br>• `-cache-all-text`: Cache all text files including sources and headers.<br>• `-cache-all-files`: Cache all files including binaries.<br>Typically, you cache temporary files created by your build command to debug issues in tracing the command. |

| Option | Argument | Description |
|---|---|---|
| `-cache-path` | Path | Location of folder where cache information is stored.<br>When tracing a Visual Studio build (`devenv.exe`), if you see the error:<br>`path is too long`<br>try using a shorter path for this option to work around the error.<br>**Example:** `-cache-path ../cache` |
| `-keep-cache`<br>`-no-keep-cache` (default) | None | Option to preserve or clean up cache information after `polyspace-configure (polyspaceConfigure)` completes execution.<br>If `polyspace-configure (polyspaceConfigure)` fails, you can provide this cache information to technical support for debugging purposes. |

## Algorithms

The `polyspace-configure` command creates a Polyspace project or options file from a build command such as `make` using roughly these steps:

1. The build command is first executed. `polyspace-configure` keeps track of the commands that run during this build and the files read or written. One or more of these commands would be the compiler invocation. For instance, if the build command uses a GCC compiler, one or more of these commands would exercise the `gcc`, `g++`, or related executable. Based on the presence of a known compiler executable, `polyspace-configure` picks out the compiler invocation commands from amidst all the commands executed during build.
2. Each compiler invocation command contains these three parts: the compiler executable, some source files and some compiler options. For instance, the following command exercises the GCC compiler on the file `myFile.c` with a compiler option `-std` that triggers C++11-based compilation:

   ```
   gcc -std=c++11 myFile.c
   ```

   `polyspace-configure` reads the source file names from these commands and directly uses them in the Polyspace project or options file. The compiler executable plus compiler options are translated to Polyspace analysis options.

   To determine Polyspace options such as the ones corresponding to sizes of basic types or underlying type of `size_t`, `polyspace-configure` runs the previously read compiler executable plus compiler options on some small source files. Depending on whether a source file compiles successfully or shows errors, `polyspace-configure` can set an appropriate Polyspace option. To determine compiler macro definitions and include paths, `polyspace-configure` also reinvokes the compiler on small sources but thereafter uses a slightly different strategy.

   For a simple example of a source file that can help determine a Polyspace option, see the reference page for the option `Management of size_t (-size-t-type-is)`.

Instead of a build command, `polyspace-configure` can also create a project or options file from a JSON compilation database. When the `polyspace-configure` command runs on a compilation database, the first step above is omitted. A compilation database directly states the compiler invocation command in entries such as this:

```
{
"directory": "/proj/files/
"command": "/usr/local/bin/gcc -std=c++11 -c /proj/files/myFile.c",
"file" : "/proj/files/myFile.c"
}
```

`polyspace-configure` can simply read these compiler invocation commands and continue with the remaining step of reinvoking the compiler on small source files. Since the build command execution step is skipped, running `polyspace-configure` on a compilation database is much faster than running `polyspace-configure` on a build command. However, it is your responsibility to make sure that the compilation database you provide accurately reflects a full build of your source code.

# polyspace-report-generator

(DOS/UNIX) Generate reports for Polyspace analysis results stored locally or on Polyspace Access

## Syntax

```
polyspace-report-generator -template outputTemplate [reporting options]
polyspace-report-generator -generate-results-list-file [-results-dir
resultsFolder] [-set-language-english]
polyspace-report-generator -generate-variable-access-file [-results-dir
resultsFolder] [-set-language-english]
polyspace-report-generator -configure-keystore
```

```
polyspace-report-generator -template outputTemplate -host hostName -run-id
runID [polyspace access options] [reporting options]
polyspace-report-generator -generate-results-list-file -host hostName -run-id
runID [polyspace access options] [-set-language-english]
polyspace-report-generator -generate-variable-access-file -host hostName -
run-id runID [polyspace access options] [-set-language-english]
```

## Description

### Generate Reports from Local Results

**Note** This Polyspace command is available in `*polyspaceroot*\polyspace\bin`. Here, `*polyspaceroot*` is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2023a` (see also “Installation Folder” for desktop products or “Installation Folder” for server products). To avoid typing the full path to this command, add this location to the `PATH` environment variable in your operating system.

`polyspace-report-generator -template outputTemplate [reporting options]` generates a report by using the template `outputTemplate` for the local analysis results that you specify with `reporting options`.

By default, reports for results from `project-name` are stored as `project-name_report-name` in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the results folder of `project-name`.

`polyspace-report-generator -generate-results-list-file [-results-dir resultsFolder] [-set-language-english]` exports the analysis results stored locally in `resultsFolder` to a tab-delimited text file. The file contains the result information available on the **Results List** pane in the user interface. For more information on the exported results list, see “View Exported Results”.

By default, the results file for results from `project-name` is stored in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the results folder of `project-name`.

For exporting results to a tab-delimited text file, the `polyspace-results-export` command is preferred.

`polyspace-report-generator -generate-variable-access-file [-results-dir resultsFolder] [-set-language-english]` exports the list of global variables in your code from the Code Prover analysis stored locally in `FOLDER` to a tab-delimited text file. The file contains the information available on the **Variable Access** pane in the user interface. For more information on the exported variables list, see “View Exported Variable List” (Polyspace Code Prover).

By default, the variables file for results from `project-name` is stored in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the results folder of `project-name`.

`polyspace-report-generator -configure-keystore` configures the report generator to communicate with Polyspace Access over HTTPS.

Run this one-time configuration step if Polyspace Access is configured to use the HTTPS protocol and you do not have a Polyspace Bug Finder desktop license, or you have a desktop license but you have not configured the desktop UI to communicate with Polyspace Access over HTTPS. Before running this command, generate a client keystore to store the SSL certificate that Polyspace Access uses for HTTPS. See “Generate a Client Keystore”.

#### Generate Reports from Polyspace Access Results

`polyspace-report-generator -template outputTemplate -host hostName -run-id runID [polyspace access options] [reporting options]` generates a report by using the template `outputTemplate` for the analysis results corresponding to run `runID` on Polyspace Access. `hostName` is the fully qualified host name of the machine that hosts Polyspace Access.

By default, reports for results from `project-name` are stored as `project-name_report-name` in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the path from which you call the command.

`polyspace-report-generator -generate-results-list-file -host hostName -run-id runID [polyspace access options] [-set-language-english]` exports the analysis results corresponding to run `runID` on Polyspace Access to a tab-delimited text file. The file contains the result information available on the **Results List** pane in the Polyspace Access web interface. `hostName` is the fully qualified host name of the machine that hosts Polyspace Access. For more information on the exported results list, see “Results List in Polyspace Access Web Interface”.

By default, the results file for results from `project-name` is stored in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the path from which you call the command.

For exporting results to a tab-delimited text file, the `polyspace-results-export` command is preferred.

`polyspace-report-generator -generate-variable-access-file -host hostName -run-id runID [polyspace access options] [-set-language-english]` exports the list of global variables in your code from the Code Prover analysis corresponding to run `runID` on Polyspace Access to a tab-delimited text file. The file contains the information available on the **Variable Access** pane in the Polyspace Access web interface. `hostName` is the fully qualified host name of the machine that hosts Polyspace Access. For more information on the exported variables list, see “View Exported Variable List” (Polyspace Code Prover).

By default, the variables file for results from `project-name` is stored in the `PathToFolder\Polyspace-Doc` folder. `PathToFolder` is the path from which you call the command.

## Examples

### Generate PDF Reports for Analysis Results Stored Locally

You can generate multiple reports for analysis results that you store locally.

Create a variable `template_path` to store the path to the report templates and create a variable `report_templates` to store a comma-separated list of templates to use.

```
SET template_path="C:\Program Files"\Polyspace\R2019a\toolbox\polyspace^
\psrptgen\templates\bug_finder
SET report_templates=%template_path%\BugFinder.rpt,^
%template_path%\CodingStandards.rpt
```

Generate the reports from the templates that you specified in `report_templates` for analysis results of Polyspace project `myProject`.

```
 polyspace-report-generator -template %report_templates% ^
-results-dir C:\Polyspace_Workspace\myProject\Module_1\BF_Result ^
-format PDF
```

The command generates two PDF reports, `myProject_BugFinder.PDF` and `myProject_CodingStandards.PDF`. The reports are stored in `C:\Polyspace_Workspace\myProject\Module_1\BF_Result\Polyspace-Doc`. For more information on the content of the reports, see `Bug Finder and Code Prover report (-report-template)`.

### Configure Report Generator with Client Keystore

If you configure Polyspace Access to use the HTTPS protocol, you must generate a client keystore where you store the SSL certificate that Polyspace Access uses, and configure `polyspace-report-generator` to use that keystore. See “Generate a Client Keystore”. This one-time configuration enables the report generator to communicate with Polyspace Access over HTTPS.

To configure the report generator with a client keystore, use the `polyspace-report-generator -configure-keystore` command. Follow the prompts to provide the URL you use to log into Polyspace Access, the full path to the keystore file you generated, and the keystore password.

```
polyspace-report-generator -configure-keystore
Location: US, user name: jsmit, id: 62600@us-jsmith, print mode: false
Enter the Polyspace Access URL using form  http[s]://<host>:<port> :
https://myAccessServer:9443
Enter full path to client keystore file :
C:\R2019b\ssl\client-cert.jks
Enter client keystore password :

The keystore has been configured
```

You must run the keystore configuration command again if:

- The Polyspace Access URL changes, for instance if you use a different port number.
- The path to the keystore file changes.
- The keystore password changes.

### Generate Report and Variables List from Polyspace Access

**Note** To generate reports of results on Polyspace Access at the command line, you must have a Polyspace Bug Finder Server or Polyspace Code Prover Server installation.

Suppose that you want to generate a report and export the variables list for the results of a Code Prover analysis stored on the Polyspace Access database.

To connect to Polyspace Access, provide a host name and your login credentials including your encrypted password. To encrypt your password, use the `polyspace-access` command and enter your user name and password at the prompt.

```
polyspace-access -encrypt-password
login: jsmith
password:
CRYPTED_PASSWORD LAMMMEACDMKEFELKMNDCONEAPECEEKPL
Command Completed
```

Store the login and encrypted password in a credentials file and restrict read and write permission on this file. Open a text editor, copy these two lines in the editor, then save the file as `myCredentials.txt` for example.

```
 -login jsmith
 -encrypted-password LAMMMEACDMKEFELKMNDCONEAPECEEKPL
```

To restrict the file permissions, right-click the file and select the **Permissions** tab on Linux or the **Security** tab on Windows.

To specify project results on Polyspace Access, specify the run ID of the project. To obtain a list of projects with their latest run IDs, use the `polyspace-access` with option `-list-project`.

```
polyspace-access -host myAccessServer -credentials-file myCredentials.txt -list-project
Connecting to https://myAccessServer:9443
Connecting as jsmith
Get project list with the last Run Id
Restricted/Code_Prover_Example (Code Prover) RUN_ID 14
public/Bug_Finder_Example (Bug Finder) RUN_ID 24
public/CP/Code_Prover_Example (Polyspace Code Prover) RUN_ID 16
public/Polyspace (Code Prover) RUN_ID 28
Command Completed
```

For more information on this command, see `polyspace-access`.

Generate a `Developer` report for results with run ID `16` from the Polyspace Access instance with host name `myAccessServer`. The URL of this instance of Polyspace Access is `https://myAccessServer:9443`.

```
SET template_path=^
"C:\Program Files\Polyspace\R2019a\toolbox\polyspace\psrptgen\templates"

polyspace-report-generator -credentials-file myCredentials.txt ^
-template %template_path%\Developer.rpt ^
-host myAccessServer ^
-run-id 16 ^
-output-name myReport
```

The command creates report `myReport.docx` by using the template that you specify. The report is stored in folder `Polyspace-Doc` on the path from which you called the command.

Generate a tab-delimited text file that contains a list of global variables in your code for the specified analysis results.

```
polyspace-report-generator -credentials-file myCredentials.txt^
-generate-variable-access-file ^
-host myAccessServer ^
-run-id 16
```

The list of global variables `Variable_View.txt` is stored in the same folder as the generated report. For more information on the exported variables list, see “View Exported Variable List” (Polyspace Code Prover).

## Input Arguments

### `outputTemplate` — path to report template file

string

Path to the report template that you use to generate an analysis report. To generate multiple reports, specify a comma-separated list of report template paths (do not put a space after the commas). The templates are available in *`polyspaceroot`*`\toolbox\polyspace\psrptgen\templates\` as `.rpt` files. Here, *`polyspaceroot`* is the Polyspace installation folder. The `polyspace-report-generator` command accepts the same templates as the analysis option `-report-template`. For information on the available templates, see `Bug Finder and Code Prover report (-report-template)`.

This option is not compatible with `-generate-variable-access-file` and `-generate-results-list-file`.

Example: `C:\Program Files\Polyspace\R2019a\toolbox\polyspace\psrptgen\templates\Developer.rpt`

Example: `TEMPLATE_PATH\BugFinder.rpt,TEMPLATE_PATH\CodingStandards.rpt`

### `resultsFolder` — Analysis results folder path

string

Path to a folder containing Polyspace analysis results (`.psbf` or `.pscp` file). To generate a report for multiple verifications, specify a comma-separated list of folder paths (do not put a space after the commas). If you do not specify a folder path, the command generates a report for analysis results in the current folder.

Example: `C:\Polyspace_Workspace\My_project\Module_1\results`

Example: `C:\Polyspace_Workspace\My_project\Module_2\results,C:\Polyspace_Workspace\My_project\Module_3\other_results`

### `hostName` — Polyspace Access machine host name

string

Fully qualified host name of the machine that hosts the Polyspace Access **Gateway API** service. You must specify a host name to generate a report for results on the Polyspace Access database.

Example: `my-company-server`

### `runID` — Polyspace Access run ID

integer

Run ID of the project findings for which you generate a report. Polyspace assigns a unique run ID to each analysis run that you upload to the Polyspace Access.

You can see the run ID of a project in the Polyspace Access web interface. To get the run ID, use the command `polyspace-access` with option `-list-project`.

### `reporting options` — Options for generated report

string

| Option | Description |
|---|---|
| `-format` *`HTML`* `\|` *`PDF`* `\|` *`WORD`* | File format of the report that you generate. By default, the command generates a WORD document.<br>To generate reports in multiple formats, specify a comma-separated list of formats. (Do not put a space after the commas). For instance, `-format PDF,HTML`.<br>This option is not compatible with `-generate-variable-access-file` and `-generate-results-list-file`. |
| `-output-name` *`outputName`* | Name of the generated report or folder name if you generate multiple reports.<br>The report or exported file is saved on the path from which you call the command. To save in a different folder, specify the full path to the folder, for instance `-output-name C:\PathTo\OtherFolder`. |
| `-results-dir` *`FOLDER_1,...,FOLDER_N`* | Path to the locally stored results folder. To generate reports for multiple analyses, specify a comma-separated list of folder path. (Do not put a space after the commas). For example:<br>`-results-dir folderPath1,folderPath2`<br>This option is not compatible with Polyspace Access results. |
| `-key-mode` *`file-scope`* `\|` *`function-scope`* | Specify how the entries in the **Key** column of the exported results are calculated:<br>• `file-scope` (default) — The key is calculated from the result name, result type, and file location.<br>• `function-scope` — The key is calculated from the result name, result type, and function location if the results is located inside a function, or file location otherwise. Keys generated in this mode are prefixed with `FN` if the result is inside a function.<br>See also “Enable Function Scope for Exported Keys”.<br>This option applies only in combination with option `-generate-results-list-file`. |

| Option | Description |
|---|---|
| `-set-language-english` | Generate the report in English. Use this option if your display language is set to another language. |
| `-help` | Display the help information. |

**`polyspace access options` — Options for Polyspace Access**
string

| Option | Description |
|---|---|
| `-host` *`HOST_NAME`* | `HOST_NAME` corresponds to the host name that you specify in the URL of the Polyspace Access interface, for example `https://`*`HOST_NAME`*`:`*`port`*`/metrics/index.html`. If you are unsure about which host name to use, contact your Polyspace Access administrator. The default host name is `localhost`.<br>This option is mandatory when you generate reports for results stored on the Polyspace Access database. |
| `-run-id` *`RUN_ID`* | Run ID of the project. Polyspace assigns a unique run ID to each analysis run that you upload. To get the last run ID of a project, use the `-list-project` option of the `polyspace-access` command.<br>For more information on the command, see `polyspace-access`.<br>This option is mandatory when you generate reports for results stored on the Polyspace Access database. |
| `-all-units` | Specify this option to generate a report for all units from a `unit by unit` analysis.<br>When you use this option, specify the run ID of only one unit with `-run-id`. The command includes the other units from the analysis in the report. |
| `-port` *`portNumber`* | `portNumber` corresponds to the port number that you specify in the URL of the Polyspace Access interface, for example `https://`*`hostname`*`:`*`portNumber`*`/metrics/index.html`. If you are unsure about which port number to use, contact your Polyspace Access administrator. The default port number is `9443`. |
| `-protocol` *`http`* `\|` *`https`* | HTTP protocol used to connect to Polyspace Access. Default value is `https`. |

| Option | Description |
|---|---|
| `-credentials-file` *`file_path`* | Full path to the text file where you store your login credentials. Use this option if, for instance, you use a command that requires your Polyspace Access credentials in a script but you do not want to store your credentials in that script. While the script runs, someone inspecting currently running processes cannot see your credentials.<br>You can store only one set of credentials in the file, either as `-login` and `-encrypted-password` entries on separate lines, for instance:<br>`-login jsmith`<br>`-encrypted-password LAMMMEACDMKEFELKMNDCONEAPECEEKPL`<br>or as an `-api-key` entry:<br>`-api-key keyValue123`<br>Make sure that you restrict the read and write permissions on the file where you store your credentials. For example, to restrict read and write permissions on file `login.txt` in Linux, use this command:<br>`chmod go-rwx login.txt` |
| `-api-key` *`keyValue`* | API key you use as a login credential instead of providing your login and encrypted password. To assign an API key to a user, see “Configure User Manager” or contact your Polyspace Access administrator.<br>Use the API key if, for instance, you use a command that requires your Polyspace Access login credentials as part of an automation script with a CI tool like Jenkins. If a user updates his or her password, you do not need to update the API key associated with that user in your scripts.<br>It is recommended that you store the API key in a text file and pass that file to the command by using `-credentials-file`. See the description for option `-credentials-file`. |
| `-login` *`username`*<br>`-encryted-password` *`ENCRYPTED_PASSWD`* | Credentials that you use to log into Polyspace Access. The argument of `-encrypted-password` is the output of the `polyspace-access -encrypt-password` command.<br>For more information on the command, see `polyspace-access`. |

## Tips

- You cannot use the `polyspace-report-generator` command with results generated with Polyspace as You Code. Use the `polyspace-results-export` command instead. See `polyspace-results-export`.
- Report generation can take a long time for result sets containing a very large number of defects or coding rules violations. In some cases, you might run into issues from insufficient memory. If that happens, you can either increase the Java® heap size or use the option `-wysiwyg` to generate multiple filtered reports instead of a single report containing all results. For more information, see “Fix Insufficient Memory Errors During Polyspace Report Generation”.

## Alternative Functionality

Instead of generating reports from existing analysis results, you might want a report to be generated along with the analysis. In this case, use the analysis options `-report-template` and `-report-output-format`. See “Reporting”.

Reports generated along with analysis will only contain review information imported from previous analyses (if any such information is imported). If you add new review information to the results, you will have to regenerate the reports using the `polyspace-report-generator` command.

# Version History

**Introduced in R2013b**

### Topics

“Generate Reports from Polyspace Results”
“Customize Existing Bug Finder Report Template”
“Fix Insufficient Memory Errors During Polyspace Report Generation”

# polyspace-results-export

(DOS/UNIX) Export Polyspace results to external formats such as CSV or JSON

## Syntax

```
polyspace-results-export -format exportFormat -results-dir resultsFolder [
export options]
```

```
polyspace-results-export -format exportFormat -host hostName -run-id runID [
export options] [polyspace access options]
```

## Description

**Note** This Polyspace command is available in *polyspaceroot*\polyspace\bin. Here, *polyspaceroot* is the Polyspace installation folder, for instance, C:\Program Files\Polyspace \R2023a (see also “Installation Folder” for desktop products or “Installation Folder” for server products). To avoid typing the full path to this command, add this location to the PATH environment variable in your operating system.

polyspace-results-export -format exportFormat -results-dir resultsFolder [ export options] exports Polyspace analysis results stored locally in resultsFolder to an external format exportFormat.

polyspace-results-export -format exportFormat -host hostName -run-id runID [ export options] [polyspace access options] exports Polyspace analysis results stored in Polyspace Access to an external format exportFormat. Specify the Polyspace Access instance by using hostName and the project on Polyspace Access by using runID.

## Examples

### Export Polyspace Results Stored Locally

Export results from a project myProject in the Polyspace user interface to JSON format.

Suppose your project is stored in C:\Polyspace_Workspace. To export results from a specific module in the project, specify the path to the folder that directly contains results from the module.

```
polyspace-results-export -format json-sarif ^
    -results-dir C:\Polyspace_Workspace\myProject\Module_1\BF_Result ^
    -output-name C:\Polyspace_Workspace\reports\myProject\myProject.json
```

(The ^ is used to continue the command to the next line in Windows. If using a different operating system, use the appropriate character for continuing on to the next line.)

### Export Results Stored in Polyspace Access

**Note** To generate reports of results on Polyspace Access at the command line, you must have a Polyspace Bug Finder Server or Polyspace Code Prover Server installation.

Suppose that you want to export the results of a project on Polyspace Access to JSON format.

To connect to Polyspace Access, provide a host name and your login credentials including your encrypted password. To encrypt your password, use the `polyspace-access` command and enter your user name and password at the prompt.

```
polyspace-access -encrypt-password
login: jsmith
password:
CRYPTED_PASSWORD LAMMMEACDMKEFELKMNDCONEAPECEEKPL
Command Completed
```

Store the login and encrypted password in a credentials file and restrict read and write permission on this file. Open a text editor, copy these two lines in the editor, then save the file as `myCredentials.txt` for example.

```
 -login jsmith
 -encrypted-password LAMMMEACDMKEFELKMNDCONEAPECEEKPL
```

To restrict the file permissions, right-click the file and select the **Permissions** tab on Linux or the **Security** tab on Windows.

To specify project results on Polyspace Access, specify the run ID of the project. To obtain a list of projects with their latest run IDs, use the `polyspace-access` with option `-list-project`.

```
polyspace-access -host myAccessServer -credentials-file myCredentials.txt -list-project
Connecting to https://myAccessServer:9443
Connecting as jsmith
Get project list with the last Run Id
Restricted/Code_Prover_Example (Code Prover) RUN_ID 14
public/Bug_Finder_Example (Bug Finder) RUN_ID 24
public/CP/Code_Prover_Example (Polyspace Code Prover) RUN_ID 16
public/Polyspace (Code Prover) RUN_ID 28
Command Completed
```

For more information on this command, see `polyspace-access`.

If Polyspace Access uses the HTTPS protocol, use the `polyspace-report-generator` binary to configure `polyspace-results-export` to enable communications with Polyspace Access over HTTPS. See “Configure Report Generator with Client Keystore” on page 4-53.

Export results from the project with run ID 16 to JSON format.

```
polyspace-results-export -credentials-file myCredentials.txt ^
 -format json-sarif ^
 -host myAccessServer ^
 -run-id 16
```

(The ^ is used to continue the command to the next line in Windows. If using a different operating system, use the appropriate character for continuing on to the next line.)

## Input Arguments

### `exportFormat` — Output format for results

`csv` | `json-sarif` | `console`

Format in which the Polyspace results are exported: `csv` for tab separated values (TSV) output or `json-sarif` for JSON output. If you use the `polyspace-bug-finder-access` command for single-file analysis (Polyspace as You Code), you can also export the results to the console using the format `console`.

Each result consists of information such as result name, family, and so on. Both TSV and JSON formats result in almost the same content being exported but the exported content might refer to the same type of information by different names.

- In the TSV format, each result consists of tab-separated information in columns such as `ID`, `Family`, `Group`, `Color`, `Check`, and so on.

  To package and potentially filter your result data, use the `csv` format. For instance, you can import the TSV file to Microsoft Excel® and use Excel filters on the results.
- In the JSON format, each result consists of almost the same information as JSON object properties. The properties shown for a result sometimes use a name that is different from the name used in the CSV format. For instance, to get the full rule checker name for a result, use the `ruleId` property of a result in combination with the `id` and `name` property of a rule. The reason for the difference is that the JSON format follows the standard notation provided by the OASIS Static Analysis Results Interchange Format (SARIF).

  The JSON format contains some additional information such as the checker short name and the full message that accompanies a result. Use the JSON format if you want to use this short name or message. You can also use this format for a more standardized reporting of results. For instance, if you use several static analysis tools and want to report their results in one interface by using a single parsing algorithm, you can export all the results to the standard SARIF JSON format.

The console output is preformatted in a form similar to compiler errors and warnings, and contains less information than the other formats. In particular, if you baseline Polyspace as You Code results using integration results in the Polyspace Access web interface, use the JSON or CSV format for maximum benefits from the baselining. See “Baseline Polyspace as You Code Results on Command Line”.

### `resultsFolder` — Result folder path

string

Path to a folder containing Polyspace analysis results (`.psbf` or `.pscp` file). If you do not specify a folder path, the command generates a report for analysis results in the current folder.

Example: `C:\Polyspace_Workspace\My_project\Module_1\results`

### `hostName` — Polyspace Access machine host name

string

`hostName` corresponds to the host name that you specify in the URL of the Polyspace Access interface, for example `https://`*`hostName`*`:`*`port`*`/metrics/index.html`. If you are unsure about which host name to use, contact your Polyspace Access administrator. The default host name is `localhost`. You must specify a host name to generate a report for results on the Polyspace Access database.

Example: `my-company-server`

### `runID` — Polyspace Access run ID

integer

Run ID of the project findings that you export. A unique run ID is assigned to each analysis run that you upload to Polyspace Access.

You can see the run ID of a project in the Polyspace Access web interface. To get the run ID of a project at the command line, use the command `polyspace-access` with option `-list-project`.

### `export options` — Additional options for exporting results

string

| Option | Description |
|---|---|
| `-output-name` *`outputName`* | Name of the exported file. The default name is `results_list.txt` (TSV) or `results_list.json` (JSON).<br>The file is saved on the path from which you call the command. To save the file in a different folder, specify the full path to the folder, for instance `-output-name C:\PathTo\OtherFolder`.<br>This option is not compatible with the console output format (`-format console`). |
| `-set-language-english` | Use this option if your display language is set to a language other than English but you want the exported results in English. |
| `-key-mode file-scope \| function-scope` | Specify how the entries in the **Key** column of the exported results are calculated:<br>• `file-scope` (default) — The key is calculated from the result name, result type, and file location.<br>• `function-scope` — The key is calculated from the result name, result type, and function location if the results is located inside a function, or file location otherwise. Keys generated in this mode are prefixed with `FN` if the result is inside a function.<br>See also “Enable Function Scope for Exported Keys”. |

To see options available with this command, enter `polyspace-results-export -h`.

### `polyspace access options` — Additional options for exporting results from Polyspace Access

string

| Option | Description |
|---|---|
| `-port` *`portNumber`* | `portNumber` corresponds to the port number that you specify in the URL of the Polyspace Access interface, for example `https://`*`hostname`*`:`*`portNumber`*`/metrics/index.html`. If you are unsure about which port number to use, contact your Polyspace Access administrator. The default port number is `9443`. |
| `-protocol http \| https` | HTTP protocol to connect to Polyspace Access. Default value is `https`. |
| `-credentials-file` *`file_path`* | Full path to the text file where you store your login credentials. Use this option if, for instance, you use a command that requires your Polyspace Access credentials in a script but you do not want to store your credentials in that script. While the script runs, someone inspecting currently running processes cannot see your credentials.<br>You can store only one set of credentials in the file, either as `-login` and `-encrypted-password` entries on separate lines, for instance:<br>`-login jsmith`<br>`-encrypted-password`<br>`  LAMMMEACDMKEFELKMNDCONEAPECEEKPL`<br>or as an `-api-key` entry:<br>`-api-key keyValue123`<br>Make sure that you restrict the read and write permissions on the file where you store your credentials. For example, to restrict read and write permissions on file `login.txt` in Linux, use this command:<br>`chmod go-rwx login.txt` |

| Option | Description |
|---|---|
| `-api-key` *`keyValue`* | API key you use as a login credential instead of providing your login and encrypted password. To assign an API key to a user, see “Configure User Manager” or contact your Polyspace Access administrator.<br>Use the API key if, for instance, you use a command that requires your Polyspace Access login credentials as part of an automation script with a CI tool like Jenkins. If a user updates his or her password, you do not need to update the API key associated with that user in your scripts.<br>It is recommended that you store the API key in a text file and pass that file to the command by using `-credentials-file`. See the description for option `-credentials-file`. |
| `-login` *`username`*<br>`-encryted-password` *`ENCRYPTED_PASSWD`* | Credentials that you use to log into Polyspace Access. The argument of `-encrypted-password` is the output of the `polyspace-access -encrypt-password` command.<br>For more information on the command, see `polyspace-access`. |

## Version History

**Introduced in R2020b**

### R2023a: CWE ID column is removed

The column that lists the CWE rules that are mapped to Bug Finder defects is removed. Polyspace supports the CWE standard natively, and when you export analysis results, violations of CWE rules are reported in the same way as violations of other coding standards, one results per line. See also “Common Weakness Enumeration (CWE)”.

## See Also

`polyspace-report-generator`

# polyspace-comments-import

(DOS/UNIX) Import review information from previous Polyspace analysis

## Syntax

```
polyspace-comments-import -diff-rte prevResultsFolder currentResultsFolder [-print-new-results] [-overwrite-destination-comments]
```

## Description

**Note** This Polyspace command is available in *`polyspaceroot`*`\polyspace\bin`. Here, *`polyspaceroot`* is the Polyspace installation folder, for instance, `C:\Program Files\Polyspace\R2023a` (see also “Installation Folder” for desktop products or “Installation Folder” for server products). To avoid typing the full path to this command, add this location to the `PATH` environment variable in your operating system.

`polyspace-comments-import -diff-rte prevResultsFolder currentResultsFolder [-print-new-results] [-overwrite-destination-comments]` imports review information from a results file in `prevResultsFolder` to `currentResultsFolder`. The review information includes the severity, status and additional notes that you assign to a result.

Besides importing the review information, the command also shows the number of results where review information could not be imported either because the result changed or the result already had new review information. If you use the option `-print-new-results`, you see this information:

- Number of new results in current results folder, that is, results not present in previous results folder
- Number of results removed from previous results folder, that is, results no longer present in the current results folder
- Number of results in current results folder that do not have associated review information

You can also use this command to create a baseline for the analysis results. In the Polyspace user interface, if you click the **New** button, only the analysis results that are new compared to the baseline remain in the results list.

If you use the option `-overwrite-destination-comments`, newer review information on previously existing results are overwritten with previous review information. For instance, if the same result has a different status in the current and previous results folder, after using the `polyspace-comments-import` command:

- Without the option, the result in the current results folder retains its status.
- With the option, the status of the result in the current results folder is overwritten with the status from the previous results folder.

## Examples

### Import Review Information from Previous Polyspace Results

Run Bug Finder on a sample file and add some review information. Then, run Bug Finder a second time and import the information from the previous run.

Copy the file `numerical.c` from *`polyspaceroot`*`\polyspace\examples\cxx\Bug_Finder_Example\sources` to a writable folder. Open a command window and navigate to the folder (using `cd`). Run Bug Finder on the file and save results in the subfolder `Run_1`:

```
polyspace-bug-finder -sources numerical.c -results-dir Run_1/
```

Depending on the product installed, you can also run `polyspace-code-prover`, `polyspace-bug-finder-server` or `polyspace-code-prover-server`.

Open the results file in the `Run_1` subfolder:

```
polyspace Run_1/ps_results.psbf
```

Select a result. On the **Result Details** window, select a **Severity** and **Status** and add some notes. You will import this review information to results from a later analysis.

Run Bug Finder again, but save the results in a different subfolder `Run_2`:

```
polyspace-bug-finder -sources numerical.c -results-dir Run_2/
```

You can open the results file in `Run_2` and see that there is no review information.

Import the review information from the results file in the `Run_1` subfolder to the `Run_2` subfolder. Add the option `-print-new-results` to see the number of new, removed and unreviewed results.

```
polyspace-comments-import -diff-rte Run_1/ Run_2/ -print-new-results
```

Open the results file in the `Run_2` subfolder:

```
polyspace Run_2/ps_results.psbf
```

You see the review information imported from the results file in the `Run_1` subfolder.

## Input Arguments

### `prevResultsFolder` — Folder containing previous Polyspace results with review information

string

Path to a folder containing a Polyspace results file (`.psbf` file for Bug Finder results and `.pscp` file for Code Prover results). The results are presumably from an earlier Polyspace analysis and contain review information that will be imported to a later results file.

Example: `"C:\Polyspace\Project_1_Run_25"`

### `currentResultsFolder` — Folder containing later Polyspace results

string

Path to a folder containing Polyspace results (`.psbf` file for Bug Finder results and `.pscp` file for Code Prover results). The results are presumably from a later Polyspace analysis and have no review information or review information for new results only. You want to import review information from an earlier Polyspace analysis to these results.

Example: `"C:\Polyspace\Project_1_Run_26"`

## Version History

# MATLAB and Simulink Functions, Classes, and Methods

5

# Functions, Properties, Classes, and Apps

# pslinkfun

Manage model analysis at the command line

## Syntax

```
pslinkfun('annotations','type',typeValue,'kind',kindValue,Name,Value)
```

```
pslinkfun('openresults',systemName)
```

```
pslinkfun('settemplate',psprjFile)
prjTemplate = pslinkfun('gettemplate')
```

```
pslinkfun('advancedoptions')
pslinkfun('enablebacktomodel')
pslinkfun('help')
pslinkfun('metrics')
pslinkfun('jobmonitor')
pslinkfun('stop')
```

## Description

`pslinkfun('annotations','type',typeValue,'kind',kindValue,Name,Value)` adds an annotation of type `typeValue` and kind `kindValue` to the selected block in the model. You can specify a different block using a `Name,Value` pair argument. You can also add notes about a severity classification, an action status, or other comments using `Name,Value` pairs.

In the generated code associated with the annotated block, Polyspace adds code comments before and after the lines of code. Polyspace reads these comments and marks Polyspace results of the specified `kind` with the annotated information.

Syntax limitations:

- You can have only one annotation per block. If a block produces both a rule violation and an error, you can annotate only one type.
- Even though you apply annotations to individual blocks, the scope of the annotation can be larger. The generated code from one block can overlap with another, causing the annotation to also overlap.

  For example, consider this model. The first summation block has a Polyspace annotation, but the second does not.

  
  However, the associated generated code adds all three inputs in one line of code.

```
/* polyspace:begin<RTE:OVFL:Medium:To Fix>*/
annotate_y.Out1=(annotate_u.In1+annotate_U.In2)+annotate_U.In3;
/* polyspace:end<RTE:OVFL:Medium:To Fix> */
```

Therefore, the annotation justifies both summations.

`pslinkfun('openresults',systemName)` opens the Polyspace results associated with the model or subsystem `systemName` in the Polyspace environment.

`pslinkfun('settemplate',psprjFile)` sets the configuration file for new verifications.

`prjTemplate = pslinkfun('gettemplate')` returns the template configuration file used for new analyses.

`pslinkfun('advancedoptions')` opens the advanced verification options window to configure additional options for the current model.

`pslinkfun('enablebacktomodel')` enables the back-to-model feature of the Simulink plug-in. If your Polyspace results do not properly link to back to the model blocks, run this command.

`pslinkfun('help')` opens the Polyspace documentation in a separate window. Use this option for only pre-R2013b versions of MATLAB.

`pslinkfun('metrics')` opens the Polyspace Metrics interface.

`pslinkfun('jobmonitor')` opens the Polyspace Job Monitor to display remote verifications in the queue.

`pslinkfun('stop')` kills the code analysis that is currently running. Use this option for local analyses only.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Examples

### Annotate a Block and Run a Polyspace Bug Finder Analysis

Use the Polyspace annotation function to annotate a block and see the annotation in the analysis results.

In the example model WhereAreTheErrors, add an annotation to the switch block for MISRA C rule 13.7 violations with a comment, a severity, and a status.

```
model = 'WhereAreTheErrors';
open(model)
pslinkfun('annotations','type','Misra-C', 'kind', '13.7','block',...
    'WhereAreTheErrors/Switch1','status','to fix','comment','must fix')
```

In the open model, you can see a Polyspace annotation added to the Switch block.

Generate code for the model and run an analysis. After the analysis is finished, open the results in the Polyspace environment:

```
slbuild(model)
opts = pslinkoptions(model);
opts.VerificationMode = 'BugFinder';
opts.VerificationSettings = 'PrjConfigAndMisra';
pslinkrun(model,opts)
pslinkfun('openresults',model)
```

The five MISRA C 13.7 rule violations are annotated with the information you added to the switch block. The annotations appear in the **Status** and **Comment** columns.

### Add Batch Options to Default Configuration Template

Change advanced Polyspace options and set the new configuration as a template.

Load the model `WhereAreTheErrors` and open the advanced options window.

```
model = 'WhereAreTheErrors';
load_system(model)
pslinkfun('advancedoptions')
```

In the **Run Settings** pane, select the options **Run Bug Finder analysis on a remote cluster** and **Upload results to Polyspace Metrics**.

Set the configuration template for new Polyspace analyses to have these options.

```
pslinkfun('settemplate',fullfile(cd,'pslink_config',...
    'WhereAreTheErrors_config.psprj'))
```

View the current Polyspace template.

```
template = pslinkfun('gettemplate')
```

```
template =
C:\ModelLinkDemo\pslink_config\WhereAreTheErrors_config.psprj
```

### View Polyspace Queue and Metrics

Run a remote analysis, view the analysis in the queue, and review the metrics.

Before performing this example, check that your Polyspace configuration is set up for remote analysis and Polyspace Metrics.

Build the model `WhereAreTheErrors`, create a Polyspace options object, set the verification mode, and open the advanced options window.

```
model = 'WhereAreTheErrors';
load_system(model)
slbuild(model)
opts = pslinkoptions(model);
opts.VerificationMode = 'BugFinder';
pslinkfun('advancedoptions')
```

In the **Run Settings** pane, select the options **Run Bug Finder analysis on a remote cluster** and **Upload results to Polyspace Metrics**.

Run Polyspace, then open the Job Monitor to monitor your remote job.

```
pslinkrun(model,opts)
pslinkfun('jobmonitor')
```

After your job is finished, open the metrics server to see your job in the repository.

```
pslinkfun('metrics')
```

## Input Arguments

### typeValue — type of result

'DEFECT' | 'MISRA-C' | 'MISRA-AC-AGC' | 'MISRA-CPP' | 'JSF'

The type of result with which to annotate the block, specified as:

- 'DEFECT' for defects.
- 'MISRA-C' for MISRA C coding rule violations (C code only).
- 'MISRA-AC-AGC' for MISRA C coding rule violations (C code only).
- 'MISRA-CPP' for MISRA C++ coding rule violations (C++ code only).
- 'JSF' for JSF C++ coding rule violations (C++ code only).

Example: 'type','MISRA-C'

### kindValue — specific check or coding rule

check acronym | rule number

The specific check or coding rule specified by the acronym of the check or the coding rule number. For the specific input for each type of annotation, see the following table.

| type Value | kind Values |
|---|---|
| 'DEFECT' | Use the abbreviation associated with the type of defect that you want to annotate. For example, 'int_ovfl' – Integer overflow.<br>For the list of possible checks, see: “Complete List of Polyspace Bug Finder Results”. |
| 'MISRA-C' | Use the rule number that you want to annotate. For example, '2.2'.<br>For the list of supported MISRA C rules and their numbers, see “MISRA C:2004 and MISRA AC AGC Coding Rules”. |
| 'MISRA-AC-AGC' | Use the rule number that you want to annotate. For example, '2.2'.<br>For the list of supported MISRA C rules and their numbers, see “MISRA C:2004 and MISRA AC AGC Coding Rules”. |
| 'MISRA-CPP' | Use the rule number that you want to annotate. For example, '0-1-1'.<br>For the list of supported MISRA C++ rules and their numbers, see “MISRA C++:2008 Rules”. |

| type Value | kind Values |
|---|---|
| 'JSF' | Use the rule number that you want to annotate. For example, '3'.<br>For the list of supported JSF C++ rules and their numbers, see "JSF AV C ++ Coding Rules". |

Example: pslinkfun('annotations','type','MISRA-CPP','kind','1-2-3')

Data Types: char

**systemName — Simulink model**
system | subsystem

Simulink model specified by the system or subsystem name.

Example: pslinkfun('openresults','WhereAreTheErrors')

**psprjFile — Polyspace project file**
standard Polyspace template (default) | absolute path to .psprj file

Polyspace project file specified as the absolute path to the .psprj project file. If psprjFile is empty, Polyspace uses the standard Polyspace template file. New Polyspace projects start with this project configuration.

Example: pslinkfun('settemplate', fullfile(polyspaceroot, 'polyspace', 'examples', 'cxx', 'Bug_Finder_Example', 'Bug_Finder_Example.bf.psprj'));

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose* Name *in quotes.*

Example: 'block','MyModel\Sum', 'status','to fix'

**block — block to be annotated**
gcb (default) | block name

The block you want to annotate specified by the block name. If you do not use this option, the block returned by the function gcb is annotated.

Example: 'block','MyModel\Sum'

**class — severity of the check**
'high' | 'medium' | 'low' | 'unset'

Severity of the check specified as high, medium, low, or unset.

Example: 'class','high'

**status — action status**
'unreviewed' | 'to investigate' | 'to fix' | 'justified' | 'no action planned' | 'not a defect' | 'other'

Action status of the check specified as unreviewed, to investigate, to fix, justified, no action planned, not a defect, or other.

Example: `'status','no action planned'`

**`comment` — additional comments**
character vector

Additional comments specified as a character vector. The comments provide more information about why the results are justified.

Example: `'comment','defensive code'`

## Version History

**Introduced in R2014a**

### See Also

`pslinkrun` | `pslinkoptions` | `gcb`

# pslinkoptions

Create an options object to customize configuration of a Simulink model, generated code or a S-Function block. Use the object to specify configuration options for these Simulink objects in a Polyspace run from the MATLAB command line

## Syntax

```
opts = pslinkoptions(codegen)
opts = pslinkoptions(model)
opts = pslinkoptions(sfunc)
```

## Description

`opts = pslinkoptions(codegen)` returns an options object with the configuration options for code generated by `codegen`.

`opts = pslinkoptions(model)` returns an options object with the configuration options for the Simulink model.

`opts = pslinkoptions(sfunc)` returns an options object with the configuration options for the S-Function.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Examples

### Create generic options object for code generated by Embedded Coder

This example shows how you can create a generic Polyspace options object that is suitable for analyzing code generated by using Embedded Coder. This options object is prepopulated with appropriate Embedded Coder parameters. Edit the options object to modify the generic analysis.

Create a new Polyspace configuration object `new_opt` by calling the function `pslinkoptions` and specify `'ec'` as the input argument.

```
new_opt = pslinkoptions('ec')
```

```
new_opt = 

                    ResultDir: 'results_$ModelName$'
         VerificationSettings: 'PrjConfig'
           OpenProjectManager: 0
         AddSuffixToResultDir: 0
     EnableAdditionalFileList: 0
           AdditionalFileList: {}
             VerificationMode: 'CodeProver'
          EnablePrjConfigFile: 0
```

```
                PrjConfigFile: ''
         AddToSimulinkProject: 0
               InputRangeMode: 'DesignMinMax'
               ParamRangeMode: 'None'
              OutputRangeMode: 'None'
           ModelRefVerifDepth: 'Current model only'
      ModelRefByModelRefVerif: 0
                  AutoStubLUT: 1
      CxxVerificationSettings: 'PrjConfig'
    CheckConfigBeforeAnalysis: 'OnWarn'
        VerifAllSFcnInstances: 0
```

By default, this options object uses the same verification settings that you specify in the Polyspace project. To check MISRA C® 2012 coding rule violations in addition to the existing verifications specified in the project, run this code at the MATLAB command line:

```
new_opt.VerificationSettings = 'PrjConfigAndMisraC2012'
```

```
new_opt = 

                    ResultDir: 'results_$ModelName$'
         VerificationSettings: 'PrjConfigAndMisraC2012'
           OpenProjectManager: 0
         AddSuffixToResultDir: 0
     EnableAdditionalFileList: 0
           AdditionalFileList: {}
             VerificationMode: 'CodeProver'
          EnablePrjConfigFile: 0
                PrjConfigFile: ''
         AddToSimulinkProject: 0
               InputRangeMode: 'DesignMinMax'
               ParamRangeMode: 'None'
              OutputRangeMode: 'None'
           ModelRefVerifDepth: 'Current model only'
      ModelRefByModelRefVerif: 0
                  AutoStubLUT: 1
      CxxVerificationSettings: 'PrjConfig'
    CheckConfigBeforeAnalysis: 'OnWarn'
        VerifAllSFcnInstances: 0
```

When you start the Polyspace analysis of the generated code, you might want to open the Polyspace User Interface to follow the progress of the and to review the results afterwards. To open the Polyspace interface when you start the analysis, run this code:

```
new_opt.OpenProjectManager = true
```

```
new_opt = 

                    ResultDir: 'results_$ModelName$'
         VerificationSettings: 'PrjConfigAndMisraC2012'
           OpenProjectManager: 1
         AddSuffixToResultDir: 0
     EnableAdditionalFileList: 0
           AdditionalFileList: {}
             VerificationMode: 'CodeProver'
          EnablePrjConfigFile: 0
                PrjConfigFile: ''
         AddToSimulinkProject: 0
```

```
               InputRangeMode: 'DesignMinMax'
               ParamRangeMode: 'None'
              OutputRangeMode: 'None'
           ModelRefVerifDepth: 'Current model only'
      ModelRefByModelRefVerif: 0
                  AutoStubLUT: 1
      CxxVerificationSettings: 'PrjConfig'
    CheckConfigBeforeAnalysis: 'OnWarn'
        VerifAllSFcnInstances: 0
```

### Create and edit options object to modify Polyspace configuration

This example shows how you can store the Polyspace configurations of a Simulink model in to an object, and use the object to edit the configuration options.

Load the model `closed_loop_control`.

```
load_system('closed_loop_control');
```

To create an object containing the Polyspace configurations of the model, call `pslinkoptions`.

```
model_opt = pslinkoptions('closed_loop_control')
```

```
model_opt = 

                    ResultDir: 'results_$ModelName$'
         VerificationSettings: 'PrjConfig'
           OpenProjectManager: 0
         AddSuffixToResultDir: 0
     EnableAdditionalFileList: 0
           AdditionalFileList: {}
             VerificationMode: 'CodeProver'
          EnablePrjConfigFile: 0
                PrjConfigFile: ''
         AddToSimulinkProject: 0
               InputRangeMode: 'DesignMinMax'
               ParamRangeMode: 'None'
              OutputRangeMode: 'None'
           ModelRefVerifDepth: 'Current model only'
      ModelRefByModelRefVerif: 0
                  AutoStubLUT: 1
      CxxVerificationSettings: 'PrjConfig'
    CheckConfigBeforeAnalysis: 'OnWarn'
        VerifAllSFcnInstances: 0
```

The model is already configured for Embedded Coder®, so only the Embedded Coder configuration options appear as the fields of the object `model_opt`.

To modify a Polyspace configuration option, set the corresponding field of `model_opt`. For instance, change the results directory and set the verification mode to `CodeProver` by modifying fields : `model_opt.ResultDir` and `model_opt.VerificationMode`, respectively.

```
model_opt.ResultDir = 'results_v1_$ModelName$';
model_opt.VerificationMode = 'CodeProver'
```

```
model_opt = 

                    ResultDir: 'results_v1_$ModelName$'
         VerificationSettings: 'PrjConfig'
           OpenProjectManager: 0
         AddSuffixToResultDir: 0
     EnableAdditionalFileList: 0
           AdditionalFileList: {}
             VerificationMode: 'CodeProver'
          EnablePrjConfigFile: 0
                PrjConfigFile: ''
         AddToSimulinkProject: 0
               InputRangeMode: 'DesignMinMax'
               ParamRangeMode: 'None'
              OutputRangeMode: 'None'
           ModelRefVerifDepth: 'Current model only'
      ModelRefByModelRefVerif: 0
                  AutoStubLUT: 1
      CxxVerificationSettings: 'PrjConfig'
    CheckConfigBeforeAnalysis: 'OnWarn'
        VerifAllSFcnInstances: 0
```

### Create and edit an options object for TargetLink at the command line

Create a Polyspace® options object called `new_opt` with TargetLink® parameters:

```
new_opt = pslinkoptions('tl')
```

```
new_opt = 

                   ResultDir: 'results_$ModelName$'
        VerificationSettings: 'PrjConfig'
          OpenProjectManager: 0
        AddSuffixToResultDir: 0
    EnableAdditionalFileList: 0
          AdditionalFileList: {}
            VerificationMode: 'CodeProver'
         EnablePrjConfigFile: 0
               PrjConfigFile: ''
        AddToSimulinkProject: 0
              InputRangeMode: 'DesignMinMax'
              ParamRangeMode: 'None'
             OutputRangeMode: 'None'
                 AutoStubLUT: 1
```

Set the `OpenProjectManager` option to true to follow the progress in the Polyspace interface. Also change the configuration to check for both run-time errors and MISRA C® coding rule violations:

```
new_opt.OpenProjectManager = true;
new_opt.VerificationSettings = 'PrjConfigAndMisra'
```

```
new_opt = 

                   ResultDir: 'results_$ModelName$'
        VerificationSettings: 'PrjConfigAndMisra'
          OpenProjectManager: 1
        AddSuffixToResultDir: 0
    EnableAdditionalFileList: 0
          AdditionalFileList: {}
            VerificationMode: 'CodeProver'
         EnablePrjConfigFile: 0
               PrjConfigFile: ''
        AddToSimulinkProject: 0
              InputRangeMode: 'DesignMinMax'
              ParamRangeMode: 'None'
             OutputRangeMode: 'None'
                 AutoStubLUT: 1
```

## Input Arguments

### codegen — Code generator
'ec' | 'tl'

Code generator, specified as either `'ec'` for Embedded Coder or `'tl'` for TargetLink®. Each argument creates a Polyspace options object with properties specific to that code generator.

For a description of all configuration options and their values, see pslinkoptions.

Example: `ec_opt = pslinkoptions('ec')`

Example: `tl_opt = pslinkoptions('tl')`

Data Types: `char`

### model — Simulink model name
model name

Simulink model, specified by the model name. Creates a Polyspace options object with the configuration options of that model. If you have not set any options, the object has the default configuration options. If you have set a code generator, the object has the default options for that code generator.

For a description of all configuration options and their values, see pslinkoptions.

Example: `model_opt = pslinkoptions('my_model')`

Data Types: `char`

### sfunc — path to S-Function
character vector

Path to S-Function, specified as a character vector. Creates a Polyspace options object with the configuration options for the S-function. If you have not set any options, the object has the default configuration options.

For a description of all configuration options and their values, see pslinkoptions.

Example: `sfunc_opt = pslinkoptions('path/to/sfunction')`

Data Types: `char`

## Output Arguments

**`opts` — Polyspace configuration options**
options object

Polyspace configuration options, returned as an options object. The object is used with `pslinkrun` to run Polyspace from the MATLAB command line.

For the list of object properties, see pslinkoptions.

Example: `opts= pslinkoptions('ec')`
`opts.VerificationSettings = 'Misra'`

# Version History

**Introduced in R2012a**

## See Also

`pslinkrun` | `pslinkfun` | pslinkoptions

# polyspacesetup

Integrate Polyspace installation with Simulink

## Syntax

```
polyspacesetup('install')
polyspacesetup('install', 'polyspacefolder', folder)
polyspacesetup('install', 'polyspacefolder', folder, 'silent', isSilent)
polyspacesetup('uninstall')
polyspacesetup('showpolyspacefolders')
```

## Description

`polyspacesetup('install')` integrates Polyspace from the default installation folder with MATLAB or Simulink. If you installed Polyspace in a nondefault folder, the function prompts you for the installation folder. See “Installation Folder”.

To run MATLAB scripts for Polyspace analysis, install MATLAB and Polyspace in separate folders, and then integrate them by using this function. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

`polyspacesetup('install', 'polyspacefolder', folder)` integrates Polyspace installed in the folder `folder` with MATLAB or Simulink.

`polyspacesetup('install', 'polyspacefolder', folder, 'silent', isSilent)` integrates Polyspace installed in the folder `folder` with MATLAB or Simulink silently when `isSilent` is `true` or with a prompt if `isSilent` is `false`. When you start MATLAB with the option `-batch`, `isSilent` is set to `true` by default. If you use a nondefault folder to install Polyspace and then do not specify the folder in `folder`, you are prompted to specify the install location even if you use `-batch` to start MATLAB.

`polyspacesetup('uninstall')` unlinks the currently linked installation of Polyspace from MATLAB.

`polyspacesetup('showpolyspacefolders')` lists all Polyspace folders that are linked to your current installation of MATLAB.

## Examples

### Integrate Polyspace with MATLAB or Simulink

To integrate Polyspace with MATLAB or Simulink, use the function `polyspacesetup`.

Open MATLAB with administrator or root privilege.

At the MATLAB command prompt, enter:

```
polyspacesetup('install');
```

If you install Polyspace in the default folder `C:\Program Files\Polyspace\R2023a`, the command integrates Polyspace with MATLAB. You might be prompted that the workspace will be cleared and all open models closed. Click **Yes**. The process might take a few minutes to complete. When you start MATLAB with the `-batch` option, the installation completes without any prompts .

If a Polyspace installation is not detected at the default location, you are prompted for the installation location. Use this command:

```
polyspacesetup('install', 'polyspaceFolder', Folder)
```

where *`Folder`* is the Polyspace installation folder.

Restart MATLAB.

### Integrate Polyspace Noninteractively with MATLAB at Command Line by Using `-batch`

To integrate Polyspace with MATLAB in the command line noninteractively, start MATLAB with the startup option `-batch`. See “Commonly Used Startup Options”.

When you start MATLAB with the startup option `-batch`, `polyspacesetup` is silent by default. That is, the function does not emit any messages unless there is any input error.

1. Open a Windows command-line prompt with administrator or root privilege.
2. To ensure that the integration takes place noninteractively, specify the install folder for Polyspace. At the command-line prompt, enter:

   ```
   matlab -batch "polyspacesetup('install','polyspaceFolder',folder)"
   ```

   where *`folder`* is the installation location of Polyspace.
3. If the integration is successful, this message is displayed:

   ```
   Polyspace plug-in: installation complete.
   Restart MATLAB before using Polyspace plug-in.
   ```

   You can also enter the command in a script. For instance, you might have a script that performs the installations of MATLAB and Polyspace. Append the preceding command to your script to integrate MATLAB and Polyspace noninteractively.

### Silently Integrate Polyspace with MATLAB or Simulink

To integrate Polyspace with MATLAB or Simulink silently, use the function `polyspacesetup`. By default, Polyspace is installed in the folder `C:\Program Files\Polyspace\R2023a`.

Open MATLAB with administrator or root privilege.

At the MATLAB command prompt, enter:

```
polyspacesetup('install', 'polyspaceFolder', Folder, 'silent', true);
```

where *`Folder`* is the Polyspace installation folder. The process might take a few minutes to complete.

Restart MATLAB.

## Input Arguments

### `folder` — Polyspace installation folder

Path to Polyspace installation

Path to the Polyspace installation folder specified as a character vector.

Example: `'C:\Program Files\Polyspace\R2023a'`

Data Types: `char`

### `isSilent` — Indicator for silent integration

`false` (default) | `true`

Whether to perform the integration silently (without prompting for user input), specified as `true` or `false`. When you start MATLAB with the `-batch` option, this argument is set to `true` by default .

Data Types: `logical`

# Version History

**Introduced in R2019a**

# polyspacePackNGo

Generate and package options files to run Polyspace analysis on code generated from Simulink model

## Syntax

```
archivePath = polyspacePackNGo(mdlName)
archivePath = polyspacePackNGo(mdlName,psOpt)
archivePath = polyspacePackNGo(mdlName,psOpt,asModelRef)
```

## Description

`archivePath = polyspacePackNGo(mdlName)` examines the Simulink model `mdlName`, extracts Polyspace options files from it, and packages the options files in the zip file located at `archivePath`. Before using `polyspacePackNGo`, generate code from your Simulink model. Then archive the generated code, for instance, by using `packNGo`. Generate the Polyspace options files from the Simulink model and include them in the code archive by using `polyspacePackNGo`. In a different development environment, when running a Polyspace analysis of the generated code, use the options files included in the code archive to preserve model-specific information, such as design range specifications. You must have Embedded Coder to use `slbuild`.

`archivePath = polyspacePackNGo(mdlName,psOpt)` generates and packages the Polyspace options files that are generated according to the specification in `psOpt`. The object `psOpt` must be a Polyspace options object that is generated by using `pslinkoptions`. Using `psOpt`, modify the options for the Polyspace analysis.

`archivePath = polyspacePackNGo(mdlName,psOpt,asModelRef)` generates and packages the Polyspace options files by using `asModelRef` to specify whether to generate option files for model reference code or standalone code.

## Examples

### Generate and Package Polyspace Options Files

To generate and package Polyspace options files for a Simulink model, use `polyspacePacknGo`.

Open the Simulink model `rtwdemo_counter` and specify a folder for storing the generated code.

```
% Make temporary folders for code genration
[TEMPDIR, CGDIR] = rtwdemodir();
% Open the model
mdlName = 'rtwdemo_counter';
open_system(mdlName);
% Specify a folder for generated code
codegenFolder = 'rtwdemo_counter_ert_rtw';
```

To enable packing the generated code in an archive, set the option `PackageGeneratedCodeAndArtifacts` to `true`. Specify the name of the generated code archive as `genCodeArchive.zip`.

```
configSet = getActiveConfigSet(mdlName);
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
```

To make the model compatible with Polyspace, set `SystemTargetFile` to `ert.tlc`.

```
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate code.

```
slbuild(mdlName)
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

Generate and package Polyspace options files.

```
zipFile = polyspacePackNGo(mdlName);
```

In the code archive `genCodeArchive.zip`, the Polyspace options files are packaged in the `polyspace` folder.

### Package Polyspace Options Files That Have Specific Polyspace Analysis Options

To specify the Polyspace analysis options when packaging and generating options files, use `pslinktoptions`.

Open the Simulink model `rtwdemo_counter` and configure the model for generating a code archive that is compatible with Polyspace.

```
% Make temporary folders for code genration
[TEMPDIR, CGDIR] = rtwdemodir();
% Open the model
mdlName = 'rtwdemo_counter';
open_system(mdlName);
% Specify a folder for generated code
codegenFolder = 'rtwdemo_counter_ert_rtw';
configSet = getActiveConfigSet(mdlName);
% Enable packing the generated code into an archive
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
% Specify a name for the code archive
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
% Configure the model to be Polyspace Compatible
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate code.

```
slbuild(mdlName)
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

To specify the model configuration for the Polyspace analysis, use a `pslinkoptions` object. Create this object by using the function `pslinkoptions`.

```
psOpt = pslinkoptions(mdlName);
```

The object psopt is a structure where the fields are model configurations that you can specify.

Specify the model configuration by using psOpt object. For instance, set InputRangeMode to full range. For a full options list, see the input argument psOpt.

```
psOpt.InputRangeMode = 'FullRange';
```

Generate and package Polyspace options files. Use the psOpt object as the second argument in polyspacePacknGo.

```
zipFile = polyspacePackNGo(mdlName,psOpt);
```

In the code archive genCodeArchive.zip, the Polyspace options files are packaged in the polyspace folder. The file optionsFile.txt contains the specified Polyspace analysis options.

### Package Polyspace Options Files for Code Generated as a Model Reference

To accelerate model simulations, invoke referenced Simulink models as simulation targets. To generate model reference simulation targets from a Simulink model, generate code from the model by using slbuild with the build process specified as ModelReferenceCoderTarget. Then, package the generated code by using packNGo. To generate and package Polyspace options files for analyzing such code, use the function polyspacePacknGo with the optional argument asModelRef set to true.

Open the Simulink model rtwdemo_counter and configure the model for generating a code archive that is compatible with Polyspace.

```
% Make temporary folders for code genration
[TEMPDIR, CGDIR] = rtwdemodir();
% Load model
mdlName = 'rtwdemo_counter';
load_system(mdlName);
configSet = getActiveConfigSet(mdlName);
% Enable packing the generated code into an archive
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', '');
% Configure the model to be Polyspace Compatible
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate a model reference simulation target from it by using the function slbuild. Specify the option ModelReferenceCoderTarget. See slbuild.

```
slbuild(mdlName,'ModelReferenceCoderTarget');
```

The code that is generated is stored in the folder slprj.

To package the code that is generated as a model reference, use the function packNGo. Locate the file buildinfo.mat in <*working folder*>/slprj/ert/rtwdemo_counter and use the full path to it as the input to packNGo. This command generates an archive containing the generated code and the object buildinfo.mat. See packNGo.

```
% Locate buildinfo and generate code archive
buildinfo = fullfile(pwd,'slprj','ert',mdlName,'buildinfo.mat');
packNGo(buildinfo)
```

Generate and package Polyspace options files. Omit the optional second argument. Set the third argument `asModelRef` to `true`.

```
zipFile = polyspacePackNGo(mdlName,[],true);
```

In the code archive `rtwdemo_counter.zip`, the Polyspace options files are packaged in the `polyspace` folder.

## Input Arguments

### `mdlName` — Name of Simulink model for which to generate Polyspace options files

model name

A character array containing the name of the model for which you want to generate and package the Polyspace options files.

Example: `polyspacePackNGo('rtwdemo_roll')`

Data Types: `char`

### `psOpt` — Polyspace options object

options associated with `model` (default) | object created by using `pslinkoptions`

Specifies the model configuration for the Polyspace analysis by using a `pslinkoptions` object. You can modify certain analysis options by modifying `psOpt`, which is a structure where individual fields represent analysis options. For a fill list of options that you can modify, see the table **Polyspace Analysis Options Supported by `polyspacePacknGo`**.

### Polyspace Analysis Options Supported by `polyspacePacknGo`

| Property | Value | Description |
|---|---|---|
| EnableAdditionalFileList: Enable an additional file list to be analyzed, specified as `true` or `false`. Use with the `AdditionalFileList` option. | `true` | Polyspace verifies additional files specified in the `AdditionalFileList` option. |
| | `false` (default) | Polyspace does not verify additional files. |
| AdditionalFileList: List of additional files to be analyzed specified as a cell array of files. To add these files to the analysis, use the `EnableAdditionalFileList` option. | cell array | Polyspace considers the listed files for verification. |
| InputRangeMode: Specifies the range of the input variables. | `'DesignMinMax'` (default) | Polyspace uses the input range defined in the workspace or a block. |
| | `'Fullrange'` | Polyspace uses full range inputs. |
| ParamRangeMode: Specifies the range of the constant parameters. | `'DesignMinmax'` | Polyspace uses the constant parameter range defined in the workspace or in a block. |
| | `'None'` (default) | Polyspace uses the value of parameters specified in the code. |
| OutputRangeMode: Specifies the output assertions. | `'DesignMinMax'` | Polyspace applies assertions to outputs by using a range defined in a block or the workspace. |
| | `'None'` (default) | Polyspace does not apply assertions to the output variables. |
| ModelRefVerifDepth: Specify the depth for analyzing the models that are referenced by the current model. | `'Current model Only'` (default) | Polyspace analyzes only the top model without analyzing the referenced models. Use this option when you refer to models that do not need to be analyzed, such as library models. |

| Property | Value | Description |
|---|---|---|
| | `'1'|'2'|'3'` | Polyspace analyzes referenced models up to the specified depth in the reference hierarchy. To analyze the models that are referenced by the top model, specify the property `ModelRefVerifDepth` as `'1'`. To analyze models that are referenced by the first level of references, specify this property as `'2'`. |
| | `'All'` | Polyspace verifies all referenced models. |
| ModelRefByModelRefVerif: Specify whether you want to analyze all referenced models together or individually. | `true` | Polyspace analyzes the top model and the referenced models together. Use this option to check for integration or scaling issues. |
| | `false` (default) | Polyspace analyzes the top model and the referenced models individually. |
| AutoStubLUT: Specifies how lookup tables are used. | `true` (default) | Polyspace stubs the lookup tables and verifies the model without analyzing the lookup table code. |
| | `false` | Polyspace includes the lookup table code in the analysis. |
| CheckConfigBeforeAnalysis: Specifies the level of configuration checking done before the Polyspace analysis starts. | `'Off'` | Polyspace checks only for errors. The analysis stops if errors are found. |
| | `'OnWarn'` (default) | Polyspace stops the analysis when errors are found and displays a message when warnings are found. |
| | `'OnHalt'` | Polyspace stops the analysis when either errors or warnings are found. |

Example: `polyspacePackNGo('rtwdemo_roll', psOpt)`, where `ps_opt` is an options object created by calling `pslinkoptions`

### `asModelRef` — Indicator for model reference analysis

`false` (default) | `true`

Indicator for model reference analysis, specified as `true` or `false`.

- If `asModelRef` is `false` (default), the function generates options files so that Polyspace analyzes the generated code as standalone code.

- If asModelRef is true, the function generates options files so that Polyspace analyzes the generated code as model reference code.

**Note** If you set asModelRef to true, use slbuild to generate code.

Example: polyspacePackNGo('rtwdemo_roll', psOpt,true)

Data Types: logical

## Output Arguments

**archivePath — The full path to the archive containing the generated options files**
path to archive

A character array containing the path to the generated archive. The options files are located in the polyspace folder in the archive. The polyspace folder contains these options files:

- optionsFile.txt: a text file containing the Polyspace options required to run a Polyspace analysis on the generated code without losing model-specific information, such as design range specification.
- *model*_drs.xml: A file containing the design range specification of the model.
- linksData.xml: A file that links the generated code to the components of the model.

To run a Polyspace analysis on the generated code in an environment that is different than the environment where the code was generated from the Simulink model, use these files.

Data Types: char

pslinkoptions Properties

# pslinkrunCrossRelease

Analyze C/C++ code generated by R2020b or newer Embedded Coder versions by using a different version of Polyspace that is more recent than the Simulink version

## Syntax

```
[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem)
[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem,
psOpt)
[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem,
psOpt,asModelRef)
[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem,
psOpt,asModelRef,OptionsFile)
```

## Description

`[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem)` runs a Polyspace analysis of the code generated from `ModelOrSubsystem` by using Embedded Coder from an earlier release of Simulink.

`[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem, psOpt)` runs a Polyspace analysis of the code generated from `ModelOrSubsystem` through an earlier release of Simulink. The analysis uses the model configuration options that are specified in the `pslinkoptions` object `psOpt`.

`[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem, psOpt,asModelRef)` runs a Polyspace analysis of the code generated as a model reference from `ModelOrSubsystem` through an earlier release of Simulink.The analysis uses `asModelRef` to specify which type of generated code to analyze—standalone code or model reference code.

`[polyspaceFolder, resultsFolder] = pslinkrunCrossRelease(ModelOrSubsystem, psOpt,asModelRef,OptionsFile)` runs a Polyspace analysis of the code generated from `ModelOrSubsystem` through an earlier release of Simulink. The analysis uses the Polyspace analysis options specified in the options file `OptionsFile`.

## Examples

### Analyze Code Generated by Using Earlier Simulink Release

To run a Polyspace analysis on code generated by using an earlier release of Simulink, use the function `pslinkrunCrossRelease`. The analysis uses the configuration options associated with `ModelOrSubsystem`. The Simulink release must be R2020b or later. Before you run an analysis, you must integrate Polyspace with Simulink. See “MATLAB Release Earlier Than Polyspace”.

1 Open the Simulink model `rtwdemo_roll` and configure the model for code generation.

```
% Load the model
model = 'rtwdemo_roll';
load_system(model);
```

```
% Configure the Solver
configSet = getActiveConfigSet(model);
set_param(configSet,'Solver','FixedStepDiscrete');
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

2 To enable packing the generated code in an archive, set the option `PackageGeneratedCodeAndArtifacts` to `true`.

```
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true)
```

3 Create temporary folders for code generation and generate code.

```
[TEMPDIR, CGDIR] = rtwdemodir();
slbuild(model);
```

4 Start a Polyspace analysis.

```
% Run Polyspace analysis
[~,resultsFolder] = pslinkrunCrossRelease(model);
bdclose(model);
```

The character vector `resultsFolder` contains the full path to the results folder.

### Run Polyspace Analysis with Modified Configuration While Analyzing Code Generated by Using Earlier Simulink Release

To run a Polyspace analysis with modified model configurations, use a `pslinkoptions` object. For a list of model configurations related to Polyspace analysis that you can modify, see the table **Polyspace Configuration Parameters Supported by `pslinkrunCrossRelease`** on this page. Before you run an analysis, you must integrate Polyspace with Simulink. See “MATLAB Release Earlier Than Polyspace”.

1 Open the Simulink model `rtwdemo_roll` and configure the model for code generation.

```
% Load the model
model = 'rtwdemo_roll';
load_system(model);
% Configure the Solver
configSet = getActiveConfigSet(model);
set_param(configSet,'Solver','FixedStepDiscrete');
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

2 To enable packing the generated code in an archive, set the option `PackageGeneratedCodeAndArtifacts` to `true`.

```
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true)
```

3 Create temporary folders for code generation and generate code.

```
[TEMPDIR, CGDIR] = rtwdemodir();
slbuild(model);
```

4 To specify the model configurations for the Polyspace analysis, use a `pslinkoptions` object. Create this object by using the function `pslinkoptions`. To run a Bug Finder analysis, set `psOpt.VerificationMode` to `'BugFinder'`. To assert the range defined in a block on its input variables, specify `psOpts.InputRangeMode` as `'DesignMinMax'`.

```
% Create a Polyspace options object from the model.
psOpts = pslinkoptions(model);

% Set model configurtion for the Polyspace analysis.
```

```
psOpts.VerificationMode = 'BugFinder';
psOpts.InputRangeMode = 'DesignMinMax';
```

5. Start a Polyspace analysis. To specify model configuration for the Polyspace analysis, set the object psOpt as the optional second argument in pslinkrunCrossRelease.

   ```
   % Run Polyspace analysis
   [~,resultsFolder] = pslinkrunCrossRelease(model,psOpt);
   bdclose(model);
   ```

   The character vector resultsFolder contains the full path to the results folder.

#### Analyze Code Generated as Model Reference by Using an Earlier Simulink Release

To accelerate model simulations, invoke referenced Simulink models as simulation targets. To generate model reference simulation targets from a Simulink model, generate code from the ModelOrSubsystem by using slbuild with the build process specified as ModelReferenceCoderTarget. Package the generated code by using packNGo. Then, analyze the generated code by running a cross-release Polyspace analysis. Before you run an analysis, you must integrate Polyspace with Simulink. See “MATLAB Release Earlier Than Polyspace”.

1. Open the Simulink model rtwdemo_roll and configure the model for code generation.

   ```
   % Load the model
   model = 'rtwdemo_roll';
   load_system(model);
   % Configure the Solver
   configSet = getActiveConfigSet(model);
   set_param(configSet,'Solver','FixedStepDiscrete');
   set_param(configSet, 'SystemTargetFile', 'ert.tlc');
   set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true)
   ```
2. Create temporary folders for code generation and generate code. Specify the option ModelReferenceCoderTarget. See slbuild.

   ```
   [TEMPDIR, CGDIR] = rtwdemodir();
   slbuild(model,'ModelReferenceCoderTarget');
   ```

   The generated code is stored in the folder slprj
3. To package the code that is generated as a model reference, use the function packNGo. Locate the file buildinfo.mat in <*working folder*>/slprj/ert/rtwdemo_counter and use the full path to it as the input to packNGo. This command generates an archive containing the generated code and the object buildinfo.mat. See packNGo.

   ```
   % Locate buildinfo and generate code archive
   buildinfo = fullfile(pwd,'slprj','ert',model,'buildinfo.mat');
   packNGo(buildinfo)
   ```
4. To specify the Polyspace analysis options, use a pslinkoptions object. Create this object by using the function pslinkoptions. To run a Bug Finder analysis, set psOpt.VerificationMode to 'BugFinder'.

   ```
   % Create a Polyspace options object from the model.
   psOpts = pslinkoptions(model);

   % Set properties that define the Polyspace analysis.
   psOpts.VerificationMode = 'BugFinder';
   ```

```
psOpts.InputRangeMode = 'DesignMinMax';
```

5 Start a Polyspace analysis. To specify Polyspace analysis options, set the object `psOpt` as the optional second argument in `pslinkrunCrossRelease`. To analyze the code as a model reference, set the optional third argument `asModelRef` to true.

```
% Run Polyspace analysis
[~,resultsFolder] = pslinkrunCrossRelease(model,psOpt,true);
bdclose(model);
```

The character vector `resultsFolder` contains the full path to the results folder.

### Specify Polyspace Analysis Options While Analyzing Code Generated by Using an Earlier Simulink Release

1 Open the Simulink model `rtwdemo_roll` and configure the model for code generation.

```
% Load the model
model = 'rtwdemo_roll';
load_system(model);
% Configure the Solver
configSet = getActiveConfigSet(model);
set_param(configSet,'Solver','FixedStepDiscrete');
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

2 To enable packing the generated code in an archive, set the option `PackageGeneratedCodeAndArtifacts` to `true`.

```
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true)
```

3 Create temporary folders for code generation and generate code.

```
[TEMPDIR, CGDIR] = rtwdemodir();
slbuild(model);
```

4 To specify the model configuration for the Polyspace analysis, use a `pslinkoptions` object. Create this object by using the function `pslinkoptions`. To run a Bug Finder analysis, set `psOpt.VerificationMode` to `'BugFinder'`.

```
% Create a Polyspace options object from the model.
psOpts = pslinkoptions(model);

% Set properties that define the Polyspace analysis.
psOpts.VerificationMode = 'BugFinder';
psOpts.InputRangeMode = 'DesignMinMax';
```

5 To specify Polyspace analysis options, create an options file. An options file is a text file that contains Polyspace options in a flat list, one line for each option. For instance, to enable all Bug Finder checkers and AUTOSAR C++14 coding rules, create a text file named *`OptionFile.txt`*. In the text file, enter:

```
-checkers all
-autosarcpp14 all
```

Save the options file. You can save the preceding options in an options file named `Options.txt` in the default work folder.

See “Complete List of Polyspace Bug Finder Analysis Engine Options”.

6 Start a Polyspace analysis.

- To specify the model configurations for the Polyspace analysis run, set the object psOpt as the optional second argument in pslinkrunCrossRelease.
- Because the code is generated as standalone code, set the third argument asModelRef to false.
- To specify the Polyspace analysis options, specify the relative path to the created options file as the fourth argument.

```
%  Locate options file
optionsPath = fullfile(userpath,'Options.txt');
% Run Polyspace analysis
[~,resultsFolder] = pslinkrunCrossRelease(model,psOpts,false,optionsPath);
bdclose(model);
```

The character vector resultsFolder contains the full path to the results folder.

## Input Arguments

### ModelOrSubsystem — Target of the analysis

bdroot (default) | model or system name

Target of the analysis specified as a character vector with the model or system in single quotes. The default value is the system returned by bdroot.

Example: resultsDir = pslinkrunCrossRelease('rtwdemo_roll') where rtwdemo_roll is the name of a model.

Data Types: char

### psOpt — Options object

configuration options associated with ModelOrSubsystem (default) | configuration object created by using pslinkoptions

Specifies the model configuration for the Polyspace analysis by using a pslinkoptions object. You can modify certain analysis options by modifying psOpt, which is an object where individual fields represent model configuration options. For a full list of options that you can modify, see this table.

**Polyspace Configuration Parameters Supported by `pslinkrunCrossRelease`**

| Property | Description | Value | Description |
|---|---|---|---|
| EnableAdditionalFileList | Enable an additional file list to be analyzed, specified as `true` or `false`. Use with the `AdditionalFileList` option. | `true` | Polyspace verifies additional files specified in the `AdditionalFileList` option. |
| | | `false` (default) | Polyspace does not verify additional files. |
| AdditionalFileList | List of additional files to be analyzed, specified as a cell array of files. To add these files to the analysis, use the `EnableAdditionalFileList` option. | cell array | Polyspace considers the listed files for verification. |
| VerificationMode | Polyspace analysis mode specified as `'BugFinder'`, for a Bug Finder analysis, or `'CodeProver'`, for a Code Prover verification. | 'BugFinder' | Polyspace runs a Bug Finder analysis. |
| | | 'CodeProver' (default) | Polyspace runs a Code Prover analysis. |
| InputRangeMode | Specifies the range of the input variables. | `'DesignMinMax'` (default) | Polyspace uses the input range defined in the workspace or a block. |
| | | `'Fullrange'` | Polyspace uses full range inputs. |
| ParamRangeMode | Specifies the range of the constant parameters. | `'DesignMinmax'` | Polyspace uses the constant parameter range defined in the workspace or in a block. |
| | | `'None'` (default) | Polyspace uses the value of parameters specified in the code. |
| OutputRangeMode | Specifies the output assertions. | `'DesignMinMax'` | Polyspace applies assertions to outputs by using a range defined in a block or the workspace. |
| | | `'None'` (default) | Polyspace does not apply assertions to the output variables. |

| Property | Description | Value | Description |
|---|---|---|---|
| ModelRefVerifDepth | Specify the depth for analyzing the models that are referenced by the current model. | `'Current model Only'` (default) | Polyspace analyzes only the top model without analyzing the referenced models. Use this option when you refer to models that do not need to be analyzed, such as library models. |
| | | `'1'\|'2'\|'3'` | Polyspace analyzes referenced models up to the specified depth in the reference hierarchy. To analyze the models that are referenced by the top model, specify the property `ModelRefVerifDepth` as `'1'`. To analyze models that are referenced by the first level of references, specify this property as `'2'`. |
| | | `'All'` | Polyspace verifies all referenced models. |
| ModelRefByModelRefVerif | Specify whether you want to analyze all referenced models together or individually. | `true` | Polyspace analyzes the top model and the referenced models together. Use this option to check for integration or scaling issues. |
| | | `false` (default) | Polyspace analyzes the top model and the referenced models individually. |
| AutoStubLUT | Specifies how lookup tables are used. | `true` (default) | Polyspace stubs the lookup tables and verifies the model without analyzing the lookup table code. |
| | | `false` | Polyspace includes the lookup table code in the analysis. |

| Property | Description | Value | Description |
|---|---|---|---|
| CheckConfigBeforeAnalysis | Specifies the level of configuration checking done before the Polyspace analysis starts. | 'Off' | Polyspace checks only for errors. The analysis stops if errors are found. |
| | | 'OnWarn' (default) | Polyspace stops the analysis when errors are found and displays a message when warnings are found. |
| | | 'OnHalt' | Polyspace stops the analysis when either errors or warnings are found. |

Example: `pslinkrunCrossRelease('rtwdemo_roll', psOpt)`, where `psOpt` is an options object created by calling `pslinkoptions`

**`asModelRef` — Indicator for model reference analysis**
`false` (default) | `true`

Indicator for model reference analysis, specified as `true` or `false`.

- If `asModelRef` is `false` (default), the function generates options files so that Polyspace analyzes the generated code as standalone code.
- If `asModelRef` is `true`, the function generates options files so that Polyspace analyzes the generated code as model reference code.

Example: `pslinkrunCrossRelease('rtwdemo_roll', psOpt,true)`

Data Types: `logical`

**`OptionsFile` — Relative path to a Polyspace options file**
default Polyspace analysis options (default) | relative path to a custom options file

Relative path to a text file that contains a list of Polyspace analysis options. The options file must have each option in a separate line.

Example: `pslinkrunCrossRelease('rtwdemo_roll', psOpt,true,'OptionsFile.txt')`

Data Types: `char`

## Output Arguments

**`polyspaceFolder` — Folder containing Polyspace project and results**
character vector

Name of the folder containing Polyspace projects and results, specified as a character vector. The default value of this variable is `results_$ModelName$`.

To change this value, see “Output folder” on page 6-16.

**`resultsFolder` — Full path to subfolder containing Polyspace results**
character vector

Full path to subfolder containing Polyspace results, specified as a character vector.

The folder `results_$ModelName$` contains your Polyspace project and a subfolder `$ModelName$` containing the analysis results. This variable provides the full path to the subfolder.

To change the parent folder `results_$ModelName$`, see “Output folder” on page 6-16.

# Version History

pslinkoptions Properties

# pslinkrun

Run Polyspace analysis on model, system, or S-Function

## Syntax

```
[polyspaceFolder, resultsFolder] = pslinkrun
[polyspaceFolder, resultsFolder]= pslinkrun(target)
[polyspaceFolder, resultsFolder] = pslinkrun('-slcc',target)
[polyspaceFolder, resultsFolder] = pslinkrun(target, opts)
[polyspaceFolder, resultsFolder] = pslinkrun('-slcc', target, opts)
[polyspaceFolder, resultsFolder] = pslinkrun(target, opts, asModelRef)
[polyspaceFolder, resultsFolder] = pslinkrun('-codegenfolder', codegenFolder,
opts)
```

## Description

`[polyspaceFolder, resultsFolder] = pslinkrun` analyzes code generated from the current system using the configuration options associated with the current system. It returns the location of the results folder. The current system is the system returned by the command `bdroot`.

`[polyspaceFolder, resultsFolder]= pslinkrun(target)` analyzes `target` with the configuration options associated with the model containing `target`. Before you run an analysis, you must:

- Generate code for models and subsystems.
- Compile S-Functions.

`[polyspaceFolder, resultsFolder] = pslinkrun('-slcc',target)` runs Polyspace on C/C++ custom code included in C Caller blocks and Stateflow charts in the model.

`[polyspaceFolder, resultsFolder] = pslinkrun(target, opts)` analyzes `target` using the configuration options specified in the object `opts`. It returns the location of the results folder.

`[polyspaceFolder, resultsFolder] = pslinkrun('-slcc', target, opts)` runs Polyspace on C/C++ custom code included in C Caller blocks and Stateflow charts in the model. The analysis uses the configuration options specified in the object `opts`.

`[polyspaceFolder, resultsFolder] = pslinkrun(target, opts, asModelRef)` uses `asModelRef` to specify which type of generated code to analyze—standalone code or model reference code. This option is useful when you want to analyze code that is generated as model reference. Code that is generated as model reference is intended to be called or used in other models or code.

`[polyspaceFolder, resultsFolder] = pslinkrun('-codegenfolder', codegenFolder, opts)` runs Polyspace on C/C++ code generated from MATLAB code and stored in `codegenFolder`.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Examples

### Analyze Generated Code

Use a Simulink model to generate code, set configuration options, and then run an analysis from the command line.

```
% Generate code from the model WhereAreTheErrors.
model = 'WhereAreTheErrors';
load_system(model);
slbuild(model);

% Create a Polyspace options object from the model.
opts = pslinkoptions(model);

% Set properties that define the Polyspace analysis.
opts.VerificationMode = 'CodeProver';
opts.VerificationSettings = 'PrjConfigAndMisraC2012';

% Run Polyspace using the options object.
[polyspaceFolder, resultsFolder] = pslinkrun(model,opts);
bdclose(model);
```

The results and the corresponding Polyspace project are saved to the `results_WhereAreTheErrors` folder, listed in the `polyspaceFolder` variable. The full path to the results folder is in the `resultsFolder` variable.

### Analyze Referenced Model Code

Use a Simulink model to generate model reference code, set configuration options, and then run an analysis from the command line.

```
% Generate code from the model WhereAreTheErrors.
% Treat WhereAreTheErrors as if referenced by another model.
model = 'WhereAreTheErrors';
load_system(model);
slbuild(model,'ModelReferenceCoderTarget');

% Create a Polyspace options object from the model.
opts = pslinkoptions(model);

% Set properties that define the Polyspace analysis.
opts.VerificationMode = 'CodeProver';
opts.VerificationSettings = 'PrjConfigAndMisraC2012';

% Run Polyspace with the options object.
[polyspaceFolder, resultsFolder] = pslinkrun(model,opts,true);
bdclose(model);
```

The results and corresponding Polyspace project are saved to the `results_mr_WhereAreTheErrors` folder, listed in the `polyspaceFolder` variable. The full path to the results folder is in the `resultsFolder` variable.

### Reuse Analysis Options for Multiple Models

This example shows how to reuse a subset of options for Polyspace analysis of multiple models. Create a generic options object and specify properties that describe the common options. Associate the generic options object with a model-specific options object. Optionally, set some model-specific options and run the Polyspace analysis.

```
% Generate code from the model WhereAreTheErrors.
model = 'psdemo_model_link_sl';
load_system(model);
slbuild(model);

% Create a generic options object to use for multiple model analyses.
opts = polyspace.ModelLinkOptions();
opts.CodingRulesCodeMetrics.EnableMisraC3 = true;
opts.CodingRulesCodeMetrics.MisraC3Subset = 'all';
opts.MergedReporting.ReportOutputFormat = 'PDF';
opts.MergedReporting.EnableReportGeneration = true;

% Create a model-specific options object.
mlopts = pslinkoptions(model);

% Create a project from the generic options object.
% Associate the project with the model-specific options object.
prjfile = opts.generateProject('model_link_opts');
mlopts.EnablePrjConfigFile = true;
mlopts.PrjConfigFile = prjfile;
mlopts.VerificationMode = 'BugFinder';

% Run Polyspace with the model-specific options object.
[polyspaceFolder, resultsFolder] = pslinkrun(model,mlopts);
bdclose(model);
```

After the analysis completes, results open automatically in the Polyspace interface.

### Analyze C/C++ Code Generated from MATLAB Code

This example shows how to analyze C/C++ code generated from MATLAB code.

```
% Generate code
codeName = 'average_filter';
matlabFileName = fullfile(polyspaceroot, 'help',...
    'toolbox','codeprover','examples','matlab_coder','averaging_filter.m');
codegenFolder = fullfile(pwd, 'codegenFolder');
codegen(matlabFileName, '-config:lib', '-c', '-args', ...
   {zeros(1,100,'double')}, '-d', codegenFolder);

% Configure Polyspace analysis
opts = pslinkoptions('ec');
```

```
opts.ResultDir = ['results_',codeName];
opts.OpenProjectManager = 1;

% Run Polyspace
[polyspaceFolder, resultsFolder] = pslinkrun('-codegenfolder', codegenFolder, opts);
```

After the analysis completes, results open automatically in the Polyspace interface.

## Input Arguments

### target — Target of the analysis

bdroot (default) | model or system name | path to S-Function block

Target of the analysis specified as a character vector, with the model, system, or S-function in single quotes. The default value is the system returned by bdroot.

If you analyze custom code in C Caller blocks and Stateflow charts using pslinkrun('-slcc',...), the argument target cannot be an S-Function block.

Example: [polyspaceFolder, resultsFolder] = pslinkrun('demo') where demo is the name of a model.

Example: [polyspaceFolder, resultsFolder] = pslinkrun('path/to/sfunction')

Data Types: char

### opts — Configuration options

configuration options associated with target (default) | object created by pslinkoptions

Specify configuration options of target, specified as a Polyspace options object. The function pslinkoptions creates such an options object. You can customize the options object by changing the pslinkoption properties.

Example: pslinkrun('demo', opts_demo) where demo is the name of a model and opts_demo is an options object.

### asModelRef — Indicator for model reference analysis

false (default) | true

Indicator for model reference analysis, specified as true or false.

- If asModelRef is false (default), Polyspace analyzes the generated code as stand-alone code. This option is equivalent to choosing **Verify Code Generated For** > **Model** in the Simulink Polyspace options.
- If asModelRef is true, Polyspace analyzes the generated code as a model reference code. This option is equivalent to choosing **Verify Code Generated For** > **Referenced Model** in the Simulink Polyspace options. Specifying model reference code indicates that Polyspace must look for the generated code in a different location from the location for standalone code.

Data Types: logical

### codegenFolder — Folder containing generated C/C++ code

character vector

Folder containing C/C++ code generated from MATLAB code, specified as a character vector. You specify this folder with the codegen command using the flag -d.

## Output Arguments

**`polyspaceFolder` — Folder containing Polyspace project and results**
character vector

Name of the folder containing Polyspace project and results, specified as a character vector. The default value of this variable is `results_$ModelName$`.

To change this value, see “Output folder” on page 6-16.

**`resultsFolder` — Full path to subfolder containing Polyspace results**
character vector

Full path to subfolder containing Polyspace results, specified as a character vector.

The folder `results_$ModelName$` contains your Polyspace project and a subfolder `$ModelName$` with the analysis results. This variable gives you the full path to the subfolder. You can use this path with a `polyspace.BugFinderResults` or `polyspace.CodeProverResults` object.

To change the parent folder `results_$ModelName$`, see “Output folder” on page 6-16.

# polyspaceBugFinder

Run Polyspace Bug Finder analysis from MATLAB

**Note** For easier scripting, run Polyspace® analysis using a `polyspace.Project` object.

## Syntax

```
status = polyspaceBugFinder
status = polyspaceBugFinder(projectFile)

status = polyspaceBugFinder(optsObject)
status = polyspaceBugFinder(projectFile, '-nodesktop')

status = polyspaceBugFinder(resultsFile)
status = polyspaceBugFinder('-results-dir',resultsFolder)

status = polyspaceBugFinder('-help')

status = polyspaceBugFinder('-sources',sourceFiles)
status = polyspaceBugFinder('-sources',sourceFiles,Name,Value)
```

## Description

`status = polyspaceBugFinder` opens Polyspace Bug Finder.

`status = polyspaceBugFinder(projectFile)` opens a Polyspace project file in Polyspace Bug Finder.

`status = polyspaceBugFinder(optsObject)` runs an analysis on the Polyspace options object in MATLAB.

`status = polyspaceBugFinder(projectFile, '-nodesktop')` runs an analysis on the Polyspace project file in MATLAB.

`status = polyspaceBugFinder(resultsFile)` opens a Polyspace results file in Polyspace Bug Finder.

`status = polyspaceBugFinder('-results-dir',resultsFolder)` opens a Polyspace results file from `resultsFolder` in Polyspace Bug Finder.

`status = polyspaceBugFinder('-help')` displays options that can be supplied to the `polyspaceBugFinder` command to run a Polyspace Bug Finder analysis.

`status = polyspaceBugFinder('-sources',sourceFiles)` runs a Polyspace Bug Finder analysis on the source files specified in `sourceFiles`.

`status = polyspaceBugFinder('-sources',sourceFiles,Name,Value)` runs a Polyspace Bug Finder analysis on the source files with additional options specified by one or more `Name,Value` pair arguments.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Examples

### Open Polyspace Projects from MATLAB

This example shows how to open a Polyspace project file with extension `.psprj` from MATLAB. In this example, you open the project file `Bug_Finder_Example.psprj` from the folder *`polyspaceroot`*`\polyspace\examples\cxx\Bug_Finder_Example`.

Open the project `Bug_Finder_Example.psprj` in the Polyspace interface.

```
prjFile = fullfile(polyspaceroot, 'polyspace', 'examples', 'cxx', ...
         'Bug_Finder_Example', 'Bug_Finder_Example.psprj');
polyspaceBugFinder(prjFile);
```

### Open Polyspace Results from MATLAB

This example shows how to open a Polyspace results file from MATLAB. In this example, you open the results file from the folder *`polyspaceroot`*`\polyspace\examples\cxx\Bug_Finder_Example\Module_1\BF_Result`.

Open the results of `resFolder`.

```
resFolder = fullfile(polyspaceroot, 'polyspace', 'examples',  ...
         'cxx', 'Bug_Finder_Example', 'Module_1', 'BF_Result');
polyspaceBugFinder('-results-dir',resFolder)
```

### Run Polyspace Analysis with Options Object

This example shows how to run a Polyspace analysis from the MATLAB command-line using objects.

Create an options object and add the source file and include folder to the properties.

```
opts = polyspace.BugFinderOptions;
opts.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
opts.EnvironmentSettings.IncludeFolders = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources')};
opts.ResultsDir = fullfile(pwd,'results');
```

Run the analysis and view the results.

```
polyspaceBugFinder(opts);
polyspaceBugFinder('-results-dir',opts.ResultsDir)
```

### Run Polyspace Analysis from MATLAB with DOS/UNIX Options

This example shows how to run a Polyspace analysis in MATLAB using DOS/UNIX-style options.

Run the analysis and open the results.

```
sourceFiles = fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c');
includeFolders = fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources');
resultsDir = fullfile(pwd,'results');
polyspaceBugFinder('-sources',sourceFiles, ...
             '-I',includeFolders, ...
             '-results-dir',resultsDir);
```

To view the results, enter:

```
polyspaceBugFinder('-results-dir',resultsDir);
```

### Run Polyspace Analysis with Coding Rules Checking

This example shows two different ways to customize an analysis in MATLAB. You can customize as many additional options as you want by changing properties in an options object or by using Name-Value pairs. Here you specify checking of MISRA C 2012 coding rules.

Create variables to save the source file path and results folder path. You can use these variables for either analysis method.

```
sourceFileName = fullfile(polyspaceroot, 'polyspace','examples', 'cxx', ...
    'Bug_Finder_Example','sources','dataflow.c');
resFolder1 = fullfile('Polyspace_Results_1');
resFolder2 = fullfile('Polyspace_Results_2');
```

Analyze coding rules with an options object.

```
opts = polyspace.BugFinderOptions();
opts.Sources = {sourceFileName};
opts.ResultsDir = resFolder1;
opts.CodingRulesCodeMetrics.MisraC3Subset = 'all';
opts.CodingRulesCodeMetrics.EnableMisraC3 = true;
polyspaceBugFinder(opts);
polyspaceBugFinder('-results-dir',resFolder1);
```

Analyze coding rules with DOS/UNIX options.

```
polyspaceBugFinder('-sources',sourceFileName,'-results-dir',resFolder2,...
    '-misra3','all');
polyspaceBugFinder('-results-dir',resFolder2);
```

## Input Arguments

### `optsObject` — Polyspace options object name

object handle

Polyspace options object name, specified as the object handle.

To create an options object, use one of the Polyspace options classes.

Example: `opts`

### `projectFile` — Name of `.psprj` file

character vector

Name of project file with extension `.psprj`, specified as a character vector.

If the file is not in the current folder, `projectFile` must include a full or relative path.

Example: `'C:\Polyspace_Projects\myProject.psprj'`

Data Types: `char`

### `resultsFile` — Name of `.psbf` file

character vector

Name of results file with extension `.psbf`, specified as a character vector.

If the file is not in the current folder, `resultsFile` must include a full or relative path.

Example: `'myResults.psbf'`

Data Types: `char`

### `resultsFolder` — Name of result folder

character vector

Name of result folder, specified as a character vector. The folder must contain the results file with extension `.psbf`. If the results file resides in a subfolder of the specified folder, this command does not open the results file.

If the folder is not in the current folder, `resultsFolder` must include a full or relative path.

Example: `'C:\Polyspace\Results\'`

Data Types: `char`

### `sourceFiles` — Comma-separated names of C or C++ files

character vector

Comma-separated C or C++ source file names, specified as a single character vector.

If the files are not in the current folder, `sourceFiles` must include a full or relative path.

Example: `'myFile.c'`, `'C:\mySources\myFile1.c,C:\mySources\myFile2.c'`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose* `Name` *in quotes.*

Example: `'-target','i386','-compiler','gnu4.6'` specifies that the source code is intended for a i386 target and contains non-ANSI C syntax for GCC 4.6.

For option names and values, see the **Command-Line Information** section in “Complete List of Polyspace Bug Finder Analysis Engine Options”.

## Output Arguments

**`status` — Status indicating whether the Polyspace Bug Finder analysis completed successfully or not**
`true` | `false`

If the Polyspace Bug Finder analysis completes without error, `status` is `false`. Otherwise, it is `true`.

The analysis might fail for multiple reasons, including:

- You provided a source file, project file, or results file that does not exist.
- You specified an invalid path.
- One of your files did not compile.

# Version History

**Introduced in R2013b**

## See Also

`polyspace.BugFinderOptions` | `polyspace.ModelLinkBugFinderOptions`

**Topics**

"Run Polyspace Analysis by Using MATLAB Scripts"

# polyspaceBugFinderServer

Run analysis with Polyspace Bug Finder Server using MATLAB scripts

**Note** For easier scripting, run Polyspace® analysis using a `polyspace.Project` object.

## Syntax

`polyspaceBugFinderServer(optsObject)`

`polyspaceBugFinderServer('-help')`

`polyspaceBugFinderServer('-sources',sourceFiles)`
`polyspaceBugFinderServer('-sources',sourceFiles,Name,Value)`

## Description

`polyspaceBugFinderServer(optsObject)` runs an analysis on the Polyspace options object in MATLAB.

`polyspaceBugFinderServer('-help')` displays options that can be supplied to the `polyspaceBugFinderServer` command to run an analysis with Polyspace Bug Finder Server.

`polyspaceBugFinderServer('-sources',sourceFiles)` runs an analysis with Polyspace Bug Finder Server on the source files specified in `sourceFiles`.

`polyspaceBugFinderServer('-sources',sourceFiles,Name,Value)` runs an analysis with Polyspace Bug Finder Server on the source files with additional options specified by one or more `Name,Value` pair arguments.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace Server Products with MATLAB”.

## Examples

### Run Polyspace Analysis with Options Object

This example shows how to run a Polyspace analysis from the MATLAB command-line. For this example:

- Use the source file `numerical.c` located in the directory *`polyspaceroot`*`/polyspace/examples/cxx/BugFinder_example/sources`.
- Include the headers located in the same directory.

Create an options object and add the source file and include folder to the properties.

```
opts = polyspace.BugFinderOptions;
opts.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};;
opts.EnvironmentSettings.IncludeFolders = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources')};
opts.ResultsDir = 'C:\Polyspace_Results';
```

Polyspace runs on the file `C:\Polyspace_Sources\source.c` and stores the result in `C:\Polyspace_Results`.

Run the analysis with Polyspace Bug Finder Server.

```
polyspaceBugFinderServer(opts);
```

### Run Polyspace Analysis from MATLAB with DOS/UNIX Options

This example shows how to run a Polyspace analysis in MATLAB by using DOS/UNIX Options. For this example:

- Use the source file `numerical.c` located in the directory *`polyspaceroot`*`/polyspace/examples/cxx/BugFinder_example/sources`.
- Include the headers located in the same directory.

Define the location of source and include files.

```
src = fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c');
inc = fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Bug_Finder_Example', 'sources');
res = fullfile(pwd,'results');
```

To analyze `numerical.c`, run the following command.

```
polyspaceBugFinderServer('-sources',src, ...
    '-I',inc, ...
    '-results-dir',res)
```

### Run Polyspace Analysis with Coding Rules Checking

This example shows two different ways to customize an analysis in MATLAB. You can customize as many additional options as you want by changing properties in an options object or by using Name-Value pairs. Here you specify checking of MISRA C 2012 coding rules.

Create variables to save the source file path and results folder path. You can use these variables for either analysis method.

```
sourceFileName = fullfile(polyspaceroot, 'polyspace','examples', 'cxx', ...
    'Bug_Finder_Example','sources','dataflow.c');
resFolder1 = fullfile('Polyspace_Results_1');
resFolder2 = fullfile('Polyspace_Results_2');
```

Analyze coding rules with an options object.

```
opts = polyspace.BugFinderOptions();
opts.Sources = {sourceFileName};
opts.ResultsDir = resFolder1;
opts.CodingRulesCodeMetrics.EnableMisraC3 = true;
opts.CodingRulesCodeMetrics.MisraC3Subset = 'all';
polyspaceBugFinderServer(opts);
```

Analyze coding rules with DOS/UNIX options.

```
polyspaceBugFinderServer('-sources',sourceFileName,'-results-dir',resFolder2,...
    '-misra3','all');
```

## Input Arguments

### `optsObject` — Polyspace options object name

object handle

Polyspace options object name, specified as the object handle.

To create an options object, use one of the Polyspace options classes `polyspace.Options` or `polyspace.Project`.

Example: `opts`

### `sourceFiles` — Comma-separated names of C or C++ files

character vector

Comma-separated C or C++ source file names, specified as a single character vector.

If the files are not in the current folder, `sourceFiles` must include a full or relative path.

Example: `'myFile.c'`, `'C:\mySources\myFile1.c,C:\mySources\myFile2.c'`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose* `Name` *in quotes.*

Example: `'-target','i386','-compiler','gnu4.6'` specifies that the source code is intended for a i386 target and contains non-ANSI C syntax for GCC 4.6.

For option names and values, see the **Command-Line Information** section in “Complete List of Polyspace Bug Finder Analysis Engine Options”.

# Version History

`polyspace.Project`

### Topics

“Integrate Polyspace Server Products with MATLAB”

# polyspaceConfigure

Create Polyspace project from your build system at the MATLAB command line

## Syntax

```
polyspaceConfigure buildCommand
```

```
polyspaceConfigure -option value buildCommand
```

## Description

`polyspaceConfigure buildCommand` traces your build system and creates a Polyspace project with information gathered from your build system. You can run an analysis on a Polyspace project only in the user interface of the Polyspace desktop products.

`polyspaceConfigure -option value buildCommand` traces your build system and uses `-option value` to modify the default operation of `polyspaceConfigure`. Specify the modifiers before `buildCommand`, otherwise they are considered as options in the build command itself.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Examples

### Create Polyspace Project from Makefile

This example shows how to create a Polyspace project if you use the command `make` *`targetName buildOptions`* to build your source code. The example creates a Polyspace project that can be opened only in the user interface of the Polyspace desktop products.

Create a Polyspace project specifying a unique project name. Use the `-B` or `-W` *`makefileName`* option with `make` so that the all prerequisite targets in the makefile are remade.

```
polyspaceConfigure  -prog myProject ...
          make -B targetName buildOptions
```

Open the Polyspace project in the **Project Browser**.

```
polyspaceBugFinder('myProject.psprj')
```

### Create Projects That Have Different Source Files from Same Build Trace

This example shows how to create different Polyspace projects from the same trace of your build system. You can specify which source files to include for each project. The example creates a Polyspace project that can be opened only in the user interface of the Polyspace desktop products.

Trace your build system without creating a Polyspace project by specifying the option `-no-project`. To ensure that all the prerequisite targets in your makefile are remade, use the appropriate `make` build command option, for instance `-B`.

```
polyspaceConfigure -no-project make -B;
```

`polyspace-configure` stores the cache information and the build trace in default locations inside the current folder. To store the cache information and build trace in a different location, specify the options `-cache-path` and `-build-trace`.

Generate Polyspace projects by using the build trace information from the previous step. Specify a project name and use the `-include-sources` or `-exclude-sources` option to select which files to include for each project.

```
polyspaceConfigure -no-build -prog myProject ...
-include-sources "glob_pattern";
```

*`glob_pattern`* is a glob pattern that corresponds to folders or files you filter in or out of your project. To ensure the shell does not expand the glob patterns you pass to `polysapce-configure`, enclose them in double quotes.For more information on the supported syntax for glob patterns, see “Select Files for Polyspace Analysis Using Pattern Matching”.

If you specified the options `-build-trace` and `-cache-path` in the previous step, specify them again.

Delete the trace file and cache folder.

```
rmdir('polyspace_configure_cache', 's');
delete polyspace_configure_built_trace;
```

If you used the options `-build-trace` and `-cache-path`, use the paths and file names from those options.

### Run Command-Line Polyspace Analysis from Makefile

This example shows how to run Polyspace analysis if you use a build command such as `make` *`targetName buildOptions`* to build your source code. In this example, you use `polyspaceConfigure` to trace your build system but do not create a Polyspace project. Instead you create an options file that you can use to run Polyspace analysis from the command-line.

Create a Polyspace options file specifying the `-output-options-file` command. Use the `-B` or `-W` *`makefileName`* option with `make` so that all prerequisite targets in the makefile are remade.

```
polyspaceConfigure -output-options-file ...
         myOptions make -B targetName buildOptions
```

Use the options file that you created to run a Polyspace analysis at the command line:

```
polyspaceBugFinder -options-file myOptions
```

## Input Arguments

### buildCommand — Command for building source code

build command

Build command specified exactly as you use to build your source code.

Example: `make -B`, `make -W *makefileName*`

### -option value — Options for changing default operation of polyspaceConfigure

single option starting with `-`, followed by argument | multiple space-separated option-argument pairs

**Basic Options**

| Option | Argument | Description |
|---|---|---|
| `-prog` | Project name | Project name that appears in the Polyspace user interface. The default is `polyspace`.<br>If you do not use the option `-output-project`, the `-prog` argument also sets the project name.<br>**Example:** `-prog myProject` creates a project that has the name `myProject` in the user interface. If you do not use the option `-output-project`, the project name is also `myProject.psrprj`. |
| `-author` | Author name | Name of project author.<br>**Example:** `-author jsmith` |
| `-output-project` | Path | Name and location of Polyspace project. The default is the file `polyspace.psprj` in the current folder.<br>**Example:** `-output-project ../myProjects/project1` creates a project `project1.psprj` in the folder with the relative path `../myProjects/`. |
| `-output-options-file` | File name | Option to create a Polyspace analysis options file. Use this file for command-line analysis using one of these commands:<br>• `polyspace-bug-finder`<br>• `polyspace-code-prover`<br>• `polyspace-bug-finder-server`<br>• `polyspace-code-prover-server`<br>• `polyspace-bug-finder-access` |

| Option | Argument | Description |
|---|---|---|
| `-allow-build-error` | None | Option to create a Polyspace project even if an error occurs in the build process.<br>If an error occurs, the build trace log shows the following message:<br>`polyspace-configure (polyspaceConfigure)`<br>`   ERROR: build command`<br>`   command_name fail [status=status_value]`<br>*`command_name`* is the build command name that you use and *`status_value`* is the non-zero exit status or error level that indicates which error occurred in your build process.<br>This option is ignored when you use `-compilation-database`. |
| `-allow-overwrite` | None | Option to overwrite a project with the same name, if it exists.<br>By default, `polyspace-configure (polyspaceConfigure)` throws an error if a project with the same name already exists in the output folder. Use this option to overwrite the project. |
| `-no-console-output`<br>`-silent` (default)<br>`-verbose` | None | Option to suppress or display additional messages from running `polyspace-configure (polyspaceConfigure)`.<br>• `-no-console-output` – Suppress all outputs including errors and warnings.<br>• `-silent` (default) – Show only errors and warnings.<br>• `-verbose` – Show all messages.<br>If you specify more than one of these options, the most verbose option is applied.<br>These options are ignored if they are used in combination with `-easy-debug`. |
| `-help` | None | Option to display the full list of `polyspace-configure (polyspaceConfigure)` commands |
| `-debug` | None | Option to store debug information for use by MathWorks technical support.<br>This option has been superseded by the option `-easy-debug`. |
| `-easy-debug` | Path | Option to store debug information for use by MathWorks technical support.<br>After a `polyspace-configure (polyspaceConfigure)` run, the path provided contains a zipped file ending with `pscfg-output.zip`. If the run fails to create a complete Polyspace project or options file, send this zipped file to MathWorks Technical Support for further debugging. The zipped file does not contain source files traced in the build. See also “Errors in Project Creation from Build Systems”. |

### Options to Create Multiple Modules

These options are not compatible with `-compilation-database`.

| Option | Argument | Description |
|---|---|---|
| `-module` | None | Option to create a separate options file for each binary you create in build system. You can only create separate options files for different binaries.<br>Use this option only if your build system uses GNU or Visual C++ compilers.<br>See also “Modularize Polyspace Analysis by Using Build Command”. |
| `-output-options-path` | Path name | Location where generated options files are saved. Use this option together with the option `-module`.<br>The options files are named after the binaries created in the build system. |

**Advanced Options**

| Option | Argument | Description |
|---|---|---|
| `-compilation-database` | Path and file name | Location and name of JSON compilation database (JSON CDB) file. You generate this file from your build system, for instance by using the flag `-DCMAKE_EXPORT_COMPILE_COMMANDS=1` with `cmake`. The file contains compiler calls for all the translation units in you projects. For more information, see JSON Compilation Database. `polyspace-configure` uses the content of this file to get information about your build system. The extracted compiler paths in the JSON CDB must be accessible from the path where you run `polyspace-configure`.<br>You do not specify a build command when you use this option.<br>These build systems and compilers support the generation of a JSON CDB:<br>• CMake<br>• Bazel<br>• Clang<br>• Ninja<br>• Qbs<br>• waf<br>This option is not compatible with `-no-project` and with the options to create multiple modules.<br>The cache control options, `-allow-build-error`, and `-no-build` are ignored when you use this option. |
| `-compiler-config` | Path and file name | Location and name of compiler configuration file.<br>The file must be in a specific format. For guidance, see the existing configuration files in *`polyspaceroot`*`\polyspace\configure\compiler_configuration\`. For information on the contents of the file, see “Create Polyspace Projects from Build Systems That Use Unsupported Compilers”.<br>**Example:** `-compiler-configuration myCompiler.xml` |

| Option | Argument | Description |
|---|---|---|
| `-no-project` | None | Option to trace your build system without creating a Polyspace project and save the build trace information.<br>Use this option to save your build trace information for a later run of `polyspace-configure (polyspaceConfigure)` with the `-no-build` option.<br>This option is not compatible with `-compilation-database`. |
| `-no-build` | None | Option to create a Polyspace project using previously saved build trace information.<br>To use this option, you must have the build trace information saved from an earlier run of `polyspace-configure (polyspaceConfigure)` with the `-no-project` option.<br>If you use this option, you do not need to specify the `buildCommand` argument.<br>This option is ignored when you use `-compilation-database`. |
| `-no-sources` | None | Option to create a Polyspace options file that does not contain the source file specifications.<br>Use this option when you intend to specify the source files by other means. For instance, you can use this option when:<br>• Running Polyspace on AUTOSAR-specific code.<br>You want to create an options file that traces your build command for the compiler options:<br>`-output-options-file options.txt -no-sources`<br>You later append this options file when extracting source file names from ARXML specifications and running the subsequent Code Prover analysis with `polyspace-autosar`<br>`-extra-options-file options.txt`<br>See also “Run Polyspace on AUTOSAR Code Using Build Command” (Polyspace Code Prover).<br>• Running Polyspace in Eclipse.<br>Your source files are already specified in your Eclipse project. When running a Polyspace analysis, you want to specify an options file that has the compilation options only. |

| Option | Argument | Description |
|---|---|---|
| `-extra-project-options` | Options to use for subsequent Polyspace analysis. For instance, `"-stubbed-pointers-are-unsafe"`. | Options that are used for subsequent Polyspace analysis.<br>Once a Polyspace project is created, you can change some of the default options in the project. Alternatively, you can pass these options when tracing your build command. The flag `-extra-project-options` allows you to pass additional options.<br>Specify multiple options in a space separated list, for instance `"-allow-negative-operand-in-shift -stubbed-pointers-are-unsafe"`.<br>Suppose you have to set the option `-stubbed-pointers-are-unsafe` for every Polyspace project created. Instead of opening each project and setting the option, you can use this flag when creating the Polyspace project:<br>`-extra-project-options "-stubbed-pointers-are-unsafe"`<br>For the list of options available, see:<br>• "Complete List of Polyspace Bug Finder Analysis Engine Options"<br>• "Complete List of Polyspace Code Prover Analysis Options" (Polyspace Code Prover)<br>If you are creating an options file instead of a Polyspace project from your build command, do not use this flag. Instead, add the extra analysis options manually in the generated options file, in a separate options file, or at the command-line when you start the analysis. |
| `-tmp-path` | Path | Location of folder where temporary files are stored. |
| `-build-trace` | Path and file name | Location and name of file where build information is stored. The default is `./polyspace_configure_build_trace.log`.<br>**Example:** `-build-trace ../build_info/trace.log` |
| `-log` | Path and file name | Location and name of log file where the output of the `polyspace-configure` command is stored. The use of this option does not suppress the console output. |
| `-include-sources`<br>`-exclude-sources` | Glob pattern | Option to specify which source files `polyspace-configure` (`polyspaceConfigure`) includes in, or excludes from, the generated project. You can combine both options together.<br>A source file is included if the file path matches the glob pattern that you pass to `-include-sources`.<br>A source file is excluded if the file path matches the glob pattern that you pass to `-exclude-sources`. |

| Option | Argument | Description |
|---|---|---|
| `-print-included-sources`<br>`-print-excluded-sources` | None | Option to print the list of source files that `polyspace-configure` `(polyspaceConfigure)` includes in, or excludes from, the generated project. You can combine both options together. The output displays the full path of each file on a separate line.<br>Use this option to troubleshoot the glob patterns that you pass to `-include-sources` or `-exclude-sources`. You can see which files match the pattern that you pass to `-include-sources` or `-exclude-sources`. |
| `-compiler-cache-path` | Folder path | Specify a folder path where `polyspace-configure` looks for or stores the compiler cache files. If the folder does not exist, `polyspace-configure` creates it.<br>By default, Polyspace looks for and stores compiler caches under these folder paths:<br>• **Windows**<br>`%appdata%\Mathworks\R20xxY\Polyspace`<br>• **Linux**<br>`~/.matlab/R20xxY/Polyspace`<br>• **Mac**<br>`~/Library/Application Support/MathWorks/MATLAB/R20xxY/Polyspace`<br>*`R20xxY`* is the release version of your Polyspace product, for instance R2020b. |
| `-no-compiler-cache` | None | Use this option if you do not want Polyspace to cache your compiler configuration information or to use an existing cache for your compiler configuration.<br>By default, the first time you run `polyspace-configure` with a particular compiler configuration, Polyspace queries your compiler for the size of fundamental types, compiler macro definitions, and other compiler configuration information then caches this information. Polyspace reuses the cached information in subsequent runs of `polyspace-configure` for builds that use the same compiler configuration. |
| `-reset-compiler-cache-entry` | None | Use this option to query the compiler for the current configuration and to refresh the entry in the cache file that corresponds to this configuration. Other compiler configuration entries in the cache are not updated. |
| `-clear-compiler-cache` | None | Use this option to delete all compiler configurations stored in the cache file.<br>If you also specify a build command or `-compilation-database`, `polyspace-configure` computes and caches the compiler configuration information of the current run, except if you specify `-no-project` or `-no-compiler-cache`. |

| Option | Argument | Description |
|---|---|---|
| -import-macro-definitions | none<br>from-allowlist<br>from-source-tokens<br>from-compiler | Typically, you do not need to specify this option.<br>Polyspace attempts to automatically determine the best strategy to query your compiler for macro definitions in this order of priority:<br>1 from-compiler — Polyspace uses native compiler options, such as gcc -dm -E, to obtain the compiler macro definitions. This strategy does not require Polyspace to trace your build and is available only for compilers that support listing macro definitions.<br>2 from-source-tokens — Polyspace uses every non-keyword token in your source code to query your compiler for macro definitions. This strategy is available only if Polyspace can trace your build. The strategy is not available if you use option -compilation-database.<br>3 from-allowlist — Polyspace uses an internal allow list to query the compiler for macro definitions.<br>If you prefer to specify macro definitions manually, use this option with the none flag and use option Preprocessor definitions (-D) to specify the macro definitions.<br>If the macro import strategy that Polyspace uses is not the one that you expect, try specifying this option manually to troubleshoot the issue. |
| -options-for-sources-delimiter | A single character | Specify an option separator to use when multiple analysis options are associated with one source file using the -options-for-sources option. Typically, the -options-for-sources option uses a semicolon as separator.<br>See also -options-for-sources. |

### Cache Control Options

These options are primarily useful for debugging. Use the options if polyspace-configure (polyspaceConfigure) fails and MathWorks Technical Support asks you to use the option and provide the cached files. Starting R2020a, the option -easy-debug provides an easier way to provide debug information. See “Contact Technical Support About Issues with Running Polyspace”.

These options are ignored when you use -compilation-database.

| Option | Argument | Description |
|---|---|---|
| -no-cache<br>-cache-sources (default)<br>-cache-all-text<br>-cache-all-files | None | Option to perform one of the following:<br>• -no-cache: Not create a cache<br>• -cache-sources: Cache text files temporarily created during build for later use by polyspace-configure (polyspaceConfigure).<br>• -cache-all-text: Cache all text files including sources and headers.<br>• -cache-all-files: Cache all files including binaries.<br>Typically, you cache temporary files created by your build command to debug issues in tracing the command. |

| Option | Argument | Description |
|---|---|---|
| `-cache-path` | Path | Location of folder where cache information is stored.<br>When tracing a Visual Studio build (`devenv.exe`), if you see the error:<br>`path is too long`<br>try using a shorter path for this option to work around the error.<br>**Example:** `-cache-path ../cache` |
| `-keep-cache`<br>`-no-keep-cache` (default) | None | Option to preserve or clean up cache information after `polyspace-configure (polyspaceConfigure)` completes execution.<br>If `polyspace-configure (polyspaceConfigure)` fails, you can provide this cache information to technical support for debugging purposes. |

# polyspaceJobsManager

Manage Polyspace jobs on a MATLAB Parallel Server cluster

## Syntax

```
polyspaceJobsManager('listjobs')
polyspaceJobsManager('cancel','-job',jobNumber)
polyspaceJobsManager('remove','-job',jobNumber)
polyspaceJobsManager('getlog','-job',jobNumber)
polyspaceJobsManager('wait','-job',jobNumber)
polyspaceJobsManager('promote','-job',jobNumber)
polyspaceJobsManager('demote','-job',jobNumber)
```

```
polyspaceJobsManager('download','-job',jobNumber)
polyspaceJobsManager('download','-job',jobNumber,'-results-folder',
resultsFolder)
```

```
polyspaceJobsManager( ___ ,'-scheduler',scheduler)
```

## Description

`polyspaceJobsManager('listjobs')` lists all Polyspace jobs in your cluster.

`polyspaceJobsManager('cancel','-job',jobNumber)` cancels the specified job. The job appears in your queue as cancelled.

`polyspaceJobsManager('remove','-job',jobNumber)` removes the specified job from your cluster.

`polyspaceJobsManager('getlog','-job',jobNumber)` displays the log for the specified job.

`polyspaceJobsManager('wait','-job',jobNumber)` pauses until the specified job is done.

`polyspaceJobsManager('promote','-job',jobNumber)` moves the specified job up in the MATLAB job scheduler queue.

`polyspaceJobsManager('demote','-job',jobNumber)` moves the specified job down in the MATLAB job scheduler queue.

`polyspaceJobsManager('download','-job',jobNumber)` downloads the results from the specified job. The results are downloaded to the folder you specified when starting analysis, using the `-results-dir` on page 3-63 option.

`polyspaceJobsManager('download','-job',jobNumber,'-results-folder', resultsFolder)` downloads the results from the specified job to `resultsFolder`.

`polyspaceJobsManager( ___ ,'-scheduler',scheduler)` performs the specified action on the job scheduler specified. If you do not specify a server with any of the previous syntaxes, Polyspace uses the server stored in your Polyspace preferences.

## Examples

### Manipulate Two Jobs in the Cluster

In this example, use a MATLAB Job Scheduler scheduler to run Polyspace remotely and monitor your jobs through the queue.

Before performing this example, set up a MATLAB Job Scheduler. This example uses the *myMJS@myCompany.com* scheduler. When you perform this example, replace this scheduler with your own cluster name.

Set up your source files.

```
tempDir = fullfile(tempdir, 'psdemo', 'src');
mkdir(tempDir);
demo = fullfile(polyspaceroot,'polyspace','examples','cxx',...
'Bug_Finder_Example','sources');
copyfile(demo,tempDir,'f');
```

Submit two jobs to your scheduler.

If your jobs have not started running, promote the second job to run before the first job.

```
polyspaceJobsManager('promote','-job','20','-scheduler',...
    'myMJS@myCompany.com')
```

Job 20 starts running before job 19.

Cancel job 19.

```
polyspaceJobsManager('cancel','-job','19','-scheduler',...
   'myMJS@myCompany.com')
polyspaceJobsManager('listjobs','-scheduler','myMJS@myCompany.com')
```

Remove job 19.

```
polyspaceJobsManager('remove','-job','19','-scheduler',...
   'myMJS@myCompany.com')
polyspaceJobsManager('listjobs','-scheduler','myMJS@myCompany.com')
```

Get the log for job 20.

```
polyspaceJobsManager('getlog','-job','20','-scheduler',...
   'myMJS@myCompany.com')
```

Download the information from job 20.

```
resFolder3 = fullfile(tempDir, 'res3');
polyspaceJobsManager('download','-job','20','-results-folder', ...
   resFolder3,'-scheduler','myCluster')
```

## Input Arguments

### `jobNumber` — Queued job number

character vector of job number

Number of the queued job that you want to manage, specified as a character vector in single quotes.

Example: `'-job','10'`

### `resultsFolder` — Path to results folder

character vector

Path to results folder specified as a character vector in single quotes. This folder stores the downloaded results files.

Example: `'-results-folder','C:\psdemo\myresults'`

### `scheduler` — job scheduler

head node of your cluster | job scheduler name | cluster profile

Job scheduler for remote verifications specified as one of the following:

- Name of the computer that hosts the head node of your MATLAB Parallel Server cluster (*`NodeHost`*).
- Name of the MATLAB Job Scheduler on the head node host (*`MJSName@NodeHost`*).
- Name of a MATLAB cluster profile (*`ClusterProfile`*).

Example: `'-scheduler','myscheduler@mycompany.com'`

# polyspaceroot

Get Polyspace installation folder

## Syntax

```
polyspaceroot
```

## Description

`polyspaceroot` returns the Polyspace installation folder.

Starting in R2019a, to run MATLAB scripts for Polyspace analysis, you install MATLAB and Polyspace in separate folders and link between them. After installation and linking, to access files in the Polyspace installation folder from MATLAB, use this function. See also “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Examples

### Get Polyspace Installation Folder

To determine the Polyspace installation folder, use the `polyspaceroot` function.

```
polyspaceroot
```

```
C:\Program Files\Polyspace\R2019a
```

With the products, Polyspace Bug Finder Server or Polyspace Code Prover Server, the default installation folder in Windows is:

```
C:\Program Files\Polyspace Server\R2019a
```

### Run Polyspace on Sample Files in Polyspace Installation Folder

To access sample files in the Polyspace installation folder, use the `polyspaceroot` function to get the root of the installation folder. Append subfolders to the root folder path with the `fullfile` function.

Run Bug Finder on the file `numerical.c` in the subfolder `polyspace\examples\cxx\Bug_Finder_Example\sources` of the Polyspace installation folder.

```
proj = polyspace.Project

% Specify sources and includes
sourceFile = fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c');
includeFolder = fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources');

% Configure analysis
proj.Configuration.Sources = {sourceFile};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.EnvironmentSettings.IncludeFolders = {includeFolder};
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = proj.run('bugFinder');
```

# polyspace_report

Generate reports from Polyspace analysis results

## Syntax

```
polyspace_report('-template', template, '-results-dir', resultsFolder,
options)
polyspace_report('-generate-results-list-file', '-results-dir',
resultsFolder, options)
polyspace_report('-generate-variable-access-file', '-results-dir',
resultsFolder, options)
```

## Description

`polyspace_report('-template', template, '-results-dir', resultsFolder, options)` generates a report using a predefined template specified by `template`. By default, the report is named after the results file in the folder `resultsFolder` and saved in the `Polyspace-Doc` subfolder. You can change the default behavior using additional options.

`polyspace_report('-generate-results-list-file', '-results-dir', resultsFolder, options)` exports the list of Polyspace results to a tab-delimited text file.

`polyspace_report('-generate-variable-access-file', '-results-dir', resultsFolder, options)` exports the list of global variables to a tab-delimited text file.

**Note**

- Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.
- You need MATLAB Report Generator™ to use this function.

## Examples

### Generate PDF Report from Results

Generate a PDF report from sample Polyspace Code Prover results.

```
template = fullfile(polyspaceroot,'toolbox','polyspace','psrptgen','templates',...
    'Developer.rpt');
resPath = fullfile(polyspaceroot,'polyspace','examples','cxx','Code_Prover_Example',...
    'Module_1','CP_Result');
polyspace_report('-template', template, '-results-dir', resPath, '-format', 'PDF');
```

## Input Arguments

### `template` — Path to report template file

character vector

Path to report template file, specified as a character vector. To generate multiple reports, specify a comma-separated list of report template paths in the character vector (do not put a space after the commas). The templates are available in `*polyspaceroot*\toolbox\polyspace\psrptgen\templates\` as `.rpt` files. Here, `*polyspaceroot*` is the Polyspace installation folder. For more information on the available templates, see `Bug Finder and Code Prover report (-report-template)`.

Example: `fullfile(polyspaceroot,'toolbox','polyspace','psrptgen','templates', 'Developer.rpt');`

### `resultsFolder` — Folder containing analysis results

character vector

Folder containing analysis results, specified as a character vector. The folder must contain a `.psbf` file containing Polyspace Bug Finder results or a `.pscp` file containing Polyspace Code Prover results.

To generate reports for multiple analyses, specify a comma-separated list of folder paths (do not put a space after the commas).

Example: `'C:\Polyspace_Workspace\My_project\Module_1\results'`

### `options` — Options for generating report

character vector

Options to control report generation, for instance, output format and output name.

Specify each option as a character vector, followed by the option value as a separate character vector. For instance, you can specify the PDF format by using the syntax `polyspace_report(..., '-format','PDF')`.

| Option | Value | Description |
|---|---|---|
| '-format' | 'PDF', 'HTML' or 'WORD' | File format of the report that you generate. By default, the command generates a Word document.<br>To generate reports in multiple formats, specify a comma-separated list of formats. (Do not put a space after the commas). For instance, polyspace_report(..., '-format', 'PDF,HTML').<br>This option is not compatible with -generate-variable-access-file and -generate-results-list-file. |
| '-set-language-english' | | Generate the report in English. Use this option if your display option is set to another language. |
| '-output-name' | Report name, for instance, PolyspaceReport. | Name of the generated report or folder name if you generate multiple reports.<br>The full path to the report is created by appending the name to the current working folder. To store the reports on a different path, specify the full path as value for this option. |

## Version History

**Introduced in R2013b**

# polyspace.Project

Run Polyspace analysis on C and C++ code and read results

## Description

Run a Polyspace analysis on C and C++ source files by using this MATLAB object. To specify source files and customize analysis options, use the `Configuration` property. To run the analysis, use the `run` method. To read results after analysis, use the `Results` property.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Creation

`proj = polyspace.Project` creates an object that you can use to configure and run a Polyspace analysis, and then read the analysis results.

### Properties

**`Configuration` — Analysis options**
`polyspace.Options` object

Options for running Polyspace analysis, implemented as a `polyspace.Options` object. The object has properties corresponding to the analysis options. For more information on those properties, see polyspace.Project.Configuration properties.

You can retain the default options or change them in one of these ways:

- Set the source code language to '`C`', '`CPP`', or '`C-CPP`' (default). Some analysis options might not be available depending on the language setting of the object.

  ```
  proj=polyspace.Project;
  proj.Configuration=polyspace.Options('C');
  ```
- Modify the properties directly.

  ```
  proj = polyspace.Project;
  proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
  ```
- Obtain the options from another `polyspace.Project` object.

  ```
  proj1 = polyspace.Project;
  proj1.Configuration.TargetCompiler.Compiler = 'gnu4.9';

  proj2 = proj1;
  ```

  To use common analysis options across multiple projects, follow this approach. For instance, you want to reuse all options and change only the source files.

- Obtain the options from a project created in the user interface of the Polyspace desktop products (`.psprj` file).

  ```
  proj = polyspace.Project;
  projectLocation = fullfile(polyspaceroot, 'polyspace', ...
      'examples', 'cxx', 'Bug_Finder_Example', 'Bug_Finder_Example.psprj')
  proj.Configuration = polyspace.loadProject(projectLocation);
  ```

  To determine the optimal set of options, set your options in the user interface and then import them to a `polyspace.Project` object. In the user interface, you can get tooltip help on options.
- Obtain the options from a Simulink model (applies only to Polyspace desktop products). Before obtaining the options, generate code from the model.

  ```
  modelName = 'rtwdemo_roll';
  load_system(modelName);

  % Set parameters for Embedded Coder target
  set_param(modelName, 'SystemTargetFile', 'ert.tlc');
  set_param(modelName,'Solver','FixedStepDiscrete');
  set_param(modelName,'SupportContinuousTime','on');
  set_param(modelName,'LaunchReport','off');
  set_param(modelName,'InitFltsAndDblsToZero','on');

  if exist(fullfile(pwd,'rtwdemo_roll_ert_rtw'), 'dir') == 0
      slbuild(modelName);
  end

  % Obtain configuration from model
  proj = polyspace.Project;
  proj.Configuration = polyspace.ModelLinkOptions(modelName);
  ```

  Use the options to analyze the code generated from the model.

### Results — Analysis results

`polyspace.BugFinderResults` or `polyspace.CodeProverResults` object

Results of Polyspace analysis. When you create a `polyspace.Project` object, this property is initially empty. The property is populated only after you execute the `run` method of the object. Depending on the argument to the `run` method, `'bugFinder'` or `'codeProver'`, the property is implemented as a `polyspace.BugFinderResults` object or `polyspace.CodeProverResults` object.

To read the results, use these methods of the `polyspace.BugFinderResults` or `polyspace.CodeProverResults` object:

- `getSummary`: Obtain a summarized format of the results into a MATLAB table.

  ```
  proj = polyspace.Project;
  proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
      'cxx', 'Code_Prover_Example', 'sources', 'single_file_analysis.c')};
  proj.Configuration.ResultsDir = fullfile(pwd,'results');

  run(proj, 'bugFinder');

  resObj = proj.Results;
  resTable = getSummary(resObj, 'defects');
  ```

For more information, see getSummary.

- getResults: Obtain the full results or a more readable format into a MATLAB table.

  ```
  proj = polyspace.Project;
  proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
      'cxx', 'Code_Prover_Example', 'sources', 'single_file_analysis.c')};
  proj.Configuration.ResultsDir = fullfile(pwd,'results');

  run(proj, 'bugFinder');

  resObj = proj.Results;
  resTable = getResults(resObj, 'readable');
  ```

  For more information, see getResults.

## Object Functions

run Run a Polyspace analysis

## Examples

### Check for Bugs

Run a Polyspace Bug Finder analysis on the example file numerical.c. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a results subfolder of the current working folder.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = run(proj, 'bugFinder');

% Read results
resObj = proj.Results;
bfSummary = getSummary(resObj, 'defects');
```

### Prove Absence of Run-Time Errors

Run a Polyspace Code Prover analysis on the example file single_file_analysis.c. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a results subfolder of the current working folder.
- Specify that a main function must be generated, if the function does not exist in the source code.

```
proj = polyspace.Project

% Configure analysis
```

```
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Code_Prover_Example', 'sources', 'single_file_analysis.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');
proj.Configuration.CodeProverVerification.MainGenerator = true;

% Run analysis
cpStatus = run(proj, 'codeProver');

% Read results
resObj = proj.Results;
cpSummary = getSummary(resObj, 'runtime');
```

### Check for Bugs and MISRA C:2012 Violations

Run a Polyspace Bug Finder analysis on the example file `single_file_analysis.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.
- Enable checking of MISRA C:2012 rules. Check for the mandatory rules only.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');
proj.Configuration.CodingRulesCodeMetrics.EnableMisraC3 = true;
proj.Configuration.CodingRulesCodeMetrics.MisraC3Subset = 'mandatory';

% Run analysis
bfStatus = run(proj, 'bugFinder');

% Read results
resObj = proj.Results;
defectsSummary = getSummary(resObj, 'defects');
misraSummary = getSummary(resObj, 'misraC2012');
```

## Version History

**Introduced in R2017b**

# polyspace.Options class

**Package:** polyspace

Create object for running Polyspace analysis on handwritten code

## Description

Create an object that specifies Polyspace options. When running a Polyspace analysis from MATLAB, specify the configuration by using this options object. To specify source files and customize analysis options, change the object properties.

polyspace.Options object apply to handwritten code. To analyze model-generated code (using the Polyspace desktop products), use polyspace.ModelLinkOptions instead.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Construction

opts = polyspace.Options creates an object whose properties correspond to options for running a Polyspace analysis.

proj = polyspace.Project creates a polyspace.Project object. The object has a property Configuration, which is a polyspace.Options object.

opts = polyspace.Options(lang) creates a Polyspace options object with options that are applicable to the language lang.

opts = polyspace.loadProject(projectFile) creates a Polyspace options object from an existing Polyspace project projectFile. You set the options in your project in the Polyspace user interface and create the options object from that project for programmatically running the analysis.

### Input Arguments

**lang — Language of analysis**
'C-CPP' (default) | 'C' | 'CPP'

The language of the analysis specified as 'C-CPP', 'C', or 'CPP'. This argument determines the object properties.

Data Types: char

**projectFile — Name of .psprj file**
character vector

Name of Polyspace project file with extension .psprj, specified as a character vector.

If the file is not in the current folder, projectFile must include a full or relative path. To identify the current folder, use pwd. To change the current folder, use cd.

**Note** You cannot use the `loadProject` method on a project file that is created from a build command by using `polyspace-configure`.

Example: `'C:\projects\myProject.psprj'`

## Properties

The object properties correspond to the analysis options for Polyspace projects. The properties are organized in the same categories as the Polyspace interface. The property names are a shortened version of the DOS/UNIX command-line name. For syntax details, see polyspace.Project.Configuration properties.

## Methods

| | |
|---|---|
| copyTo | Copy common settings between Polyspace options objects |
| generateProject | Generate psprj project from options object |
| toScript | Add Polyspace options object definition to a script |

## Examples

### Customize and Run Analysis

Create a Polyspace analysis options object and customize the properties. Then, run an analysis.

Create object and customize properties. In case you do not have write access to your current folder, a temporary folder is being used for storing analysis results.

```
sources = fullfile(polyspaceroot, 'polyspace','examples','cxx','Bug_Finder_Example',...
    'sources','numerical.c');
opts = polyspace.Options();
opts.Prog = 'MyProject';
opts.Sources = {sources};
opts.TargetCompiler.Compiler = 'gnu4.7';
opts.ResultsDir = tempname;
```

Run a Bug Finder analysis. To run a Code Prover analysis, use `polyspaceCodeProver` instead of `polyspaceBugFinder`.

```
results = polyspaceBugFinder(opts);
```

With the Polyspace Server products, you can use the functions `polyspaceBugFinderServer` or `polyspaceCodeProverServer`.

Open the results in the Polyspace user interface of the desktop products.

```
polyspaceBugFinder('-results-dir',opts.ResultsDir);
```

### Run Polyspace by Generating a Project File

Create a Polyspace analysis options object and customize the properties. Then, run a Bug Finder analysis.

Create object and customize properties.

```
sources=fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example',...
    'sources','numerical.c');
opts = polyspace.Options();
opts.Prog = 'MyProject';
opts.Sources = {sources};
opts.TargetCompiler.Compiler = 'gnu4.7';
opts.ResultsDir = tempname;
```

Generate a Polyspace project, name it using the `Prog` property, and open the project in the Polyspace interface.

```
psprj = opts.generateProject(opts.Prog);
polyspaceBugFinder(psprj);
```

You can also analyze the project from the command line. Run the analysis and open the results in the Polyspace interface.

```
results = polyspaceBugFinder(psprj, '-nodesktop');
polyspaceBugFinder('-results-dir',opts.ResultsDir);
```

## Alternatives

If you are analyzing code generated from a model, use `polyspace.ModelLinkOptions` instead.

# Version History

**Introduced in R2017a**

# polyspace.ModelLinkOptions class

**Package:** `polyspace`

Create a project configuration object for running Polyspace analysis on generated code

## Description

Run a Polyspace analysis from MATLAB by using a project configuration object. To specify source files and customize analysis options, change the object properties.

This class is intended for model-generated code. If you are analyzing handwritten code, use `polyspace.Options` instead.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Construction

`psprjConfig = polyspace.ModelLinkOptions` creates a project configuration object that is configured for running a Polyspace analysis on generated code.

`psprjConfig = polyspace.ModelLinkOptions(lang)` creates a project configuration object that is configured to run analysis on code generated in the language `lang`.

`psprjConfig = polyspace.ModelLinkOptions(model)` creates a project configuration object that is configured by using model specific information from the Simulink model `model`. Prior to extracting options from `model`, you must load the model and generate code from it.

`psprjConfig = polyspace.ModelLinkOptions(model, psOpt)` creates a model-specific project configuration object that is configured by using the Polyspace analysis options specified in `psOpt`.

`psprjConfig = polyspace.ModelLinkOptions(model, psOpt, asModelRef)` creates a project configuration object that uses `asModelRef` to specify which type of generated code to analyze—standalone code or model reference code.

### Input Arguments

#### `lang` — Language of analysis

`'C-CPP'` (default) | `'C'` | `'CPP'`

The language of the analysis specified as `'C-CPP'`, `'C'`, or `'CPP'`. This argument determines the object properties.

#### `model` — Model or subsystem name

character vector

Name or path to model or subsystem, specified as a character vector.

Prior to extracting options from the model, you must:

1. Load the model. Use `load_system` or `open_system`.
2. Generate code from the model. Use `slbuild` or `slbuild`.

Example: `'psdemo_model_link_sl'`

**`psOpt` — Polyspace analysis options object**
`pslinkoptions` object

An object containing the options that you use for the Polyspace analysis. You create this by calling the function `pslinkoptions`. You can customize the options object by changing the properties of the `psOpt` object.

Example: `psOpt = pslinkoptions(model)` where `model` is the name of a Simulink model.

**`asModelRef` — Indicator for model reference analysis**
`false` (default) | `true`

Indicator for model reference analysis, specified as true or false.

- To analyze generated code used or called elsewhere, set the flag `asModelRef` to `true`. This option is equivalent to choosing **Analyze Code from** > **Code Generated as Model Reference** on the Polyspace tab in the Simulink toolstrip.
- To analyze code that is generated to be used as stand-alone code, set the flag `asModelRef` to `false`. This option is equivalent to choosing **Analyze Code from** > **Code Generated as Top model** on the Polyspace tab in the Simulink toolstrip.

Data Types: `logical`

## Properties

The object properties correspond to the configuration options for Polyspace projects. The properties are organized in the same categories as the Polyspace interface. The property names are a shortened version of the DOS command-line name. For syntax details, see polyspace.ModelLinkOptions.

## Methods

| | |
|---|---|
| copyTo | Copy common settings between Polyspace options objects |
| generateProject | Generate psprj project from options object |
| toScript | Add Polyspace options object definition to a script |

## Examples

### Script Analysis of Model Generated Code

This example shows how to customize and run an analysis on code generated from a model.

Generate code from the model `rtwdemo_roll`. Before code generation, set a system target file appropriate for code analysis. See also “Recommended Model Configuration Parameters for Polyspace Analysis”.

```
modelName = 'rtwdemo_roll';
[TEMPDIR, CGDIR] = rtwdemodir();
```

```
load_system(modelName);

% Set parameters for Embedded Coder target
set_param(modelName, 'SystemTargetFile', 'ert.tlc');
set_param(modelName,'Solver','FixedStepDiscrete');
set_param(modelName,'SupportContinuousTime','on');
set_param(modelName,'LaunchReport','off');
set_param(modelName,'InitFltsAndDblsToZero','on');

slbuild(modelName);
```

Associate a `polyspace.ModelLinkOptions` object with the model. A subset of the object properties are set from the configuration parameters associated with the model. The other properties take their default values. For details on the configuration parameters, see “Bug Finder Analysis in Simulink”.

```
psprjCfg = polyspace.ModelLinkOptions(modelName);
```

Change the property values if needed. For instance, you can specify that the analysis must check for all MISRA C: 2012 violations and generate a PDF report of the results. You can also specify a folder for the analysis results.

```
psprjCfg.CodingRulesCodeMetrics.EnableMisraC3 = true;
psprjCfg.CodingRulesCodeMetrics.MisraC3Subset = 'all';
psprjCfg.MergedReporting.EnableReportGeneration = true;
psprjCfg.MergedReporting.ReportOutputFormat = 'PDF';
psprjCfg.ResultsDir = 'newResfolder';
```

Create a `polyspace.Project` object. Associate the `Configuration` property of this object to the options that you previously specified.

```
proj = polyspace.Project;
proj.Configuration = psprjCfg;
```

Optionally, you might want to submit the analysis to a remote server to run batches of analysis together. To setup analysis in batch mode, set the property `BatchBugFinder` or `BatchCodeProver` to `true`, depending on your analysis. Then, specify the head node that manages the Polyspace analysis jobs:

```
% Setup batch analysis
psprjCfg.MergedComputingSettings.BatchBugFinder = true;
psprjCfg.Advanced.Additional = '-scheduler NodeID';
```

Run analysis and open results.

```
cpStatus = proj.run('codeProver');
proj.Results.getResults('readable');
```

### Analyze Code Generated as Model Reference

This example shows how to analyze generated code used as a callable entity in another model or code.

Load the Simulink model `rtwdemo_roll` and configure it for a Polyspace analysis. For details, see “Recommended Model Configuration Parameters for Polyspace Analysis” for details.

```
% Make directory for code generation
[TEMPDIR, CGDIR] = rtwdemodir();
```

```
%  Specify model name
model = 'rtwdemo_roll';
% Load the model
load_system(model);
% Configure the model for generating code
set_param(model, 'SystemTargetFile', 'ert.tlc');
set_param(model,'MatFileLogging','off');
set_param(model,'GenerateComments','on');
set_param(model,'Solver','FixedStepDiscrete');
set_param(model,'LaunchReport','off');
```

To generate code as a model reference from the Simulink model, use `slbuild`. Set the `buildspec` parameter to `'ModelReferenceCoderTarget'`.

```
slbuild(model,'ModelReferenceCoderTarget');
```

To configure the Polyspace analysis of the generated code, create an options object `psOpt` by using the function `pslinkoptions`. Change the properties of the object as needed. For instance, to run a **Code Prover** analysis, set the `Verificationmode` to `'CodeProver'`.

```
psOpt = pslinkoptions(model);
psOpt.VerificationMode = 'CodeProver';
```

To run a Polyspace analysis, create and configure a Polyspace project configuration object.

- To create the Polyspace project configuration object, use the function `polyspace.ModelLinkOptions`.
- To associate the Polyspace analysis options with the project configuration, set the object `psOpt` as the second argument in `polyspace.ModelLinkOptions()`.
- To specify that the generated code must be analyzed as a model reference, specify the third argument as `'true'`.

For instance:

```
psprjCfg = polyspace.ModelLinkOptions(model, psOpt,true);
```

To configure the Polyspace project, change the properties of the `psprjCfg` object. For instance, to enable checkers for the mandatory MISRA C: 2012 rules and to generate a PDF report of the results, use:

```
psprjCfg.CodingRulesCodeMetrics.EnableMisraC3 = true;
psprjCfg.CodingRulesCodeMetrics.MisraC3Subset = 'mandatory-required';
psprjCfg.MergedReporting.EnableReportGeneration = true;
psprjCfg.MergedReporting.ReportOutputFormat = 'PDF';
```

For convenience, you can specify a separate result folder.

```
psprjCfg.ResultsDir = 'newResfolder';
```

Create a Polyspace project by using `polyspace.Project` and associate the project configuration with it.

```
proj = polyspace.Project;
proj.Configuration = psprjCfg;
```

Run the Polyspace analysis by using the `run` function of the object `proj`.

```
cpStatus = proj.run('codeProver');
```

Because you enabled PDF report generation, the result of the Polyspace analysis is reported in a PDF file, which can be found in *newResfolder/Polyspace-Doc*. To view the results in a MATLAB table, use:

```
result = proj.Results.getResults('readable');
```

## Alternatives

If you are analyzing handwritten code, use a `polyspace.Project` object directly. Alternatively, use a `polyspace.Options` object.

# Version History

**Introduced in R2017a**

# polyspace.BugFinderOptions class

**Package:** `polyspace`

(Removed) Create Polyspace Bug Finder object for handwritten code

**Note** This class is removed. Use `polyspace.Options` instead. See “Version History”.

## Description

Customize a Polyspace Bug Finder analysis from MATLAB by creating a Bug Finder options object. To specify source files and customize analysis options, change the object properties.

If you are analyzing model-generated code, use `polyspace.ModelLinkBugFinderOptions` instead.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink”.

## Construction

`opts = polyspace.BugFinderOptions` creates a Bug Finder options object with available options.

`opts = polyspace.BugFinderOptions(lang)` creates a Bug Finder options object with options that are applicable for the language `lang`.

### Input Arguments

**`lang` — Language of analysis**
`'C-CPP'` (default) | `'C'` | `'CPP'`

The language of the analysis specified as `'C-CPP'`, `'C'`, or `'CPP'`. This argument determines which properties the object has.

## Properties

The object properties are the analysis options for Polyspace Bug Finder projects. The properties are organized in the same categories as the Polyspace interface. The property names are a shortened version of the DOS/UNIX command-line name. For syntax details, see polyspace.Options.

## Methods

| | |
|---|---|
| copyTo | Copy common settings between Polyspace options objects |
| generateProject | Generate psprj project from options object |
| toScript | Add Polyspace options object definition to a script |

## Examples

### Customize and Run Analysis

Create a Bug Finder analysis options object and customize the properties. Then, run an analysis.

Create object and customize properties.

```
sources = fullfile(polyspaceroot, 'polyspace','examples','cxx','Bug_Finder_Example',...
    'sources','numerical.c');
optsBF = polyspace.BugFinderOptions();
optsBF.Prog = 'MyProject';
optsBF.Sources = {sources};
optsBF.TargetCompiler.Compiler = 'gnu4.7';
optsBF.ResultsDir = tempname;
```

Run the analysis and open the results in the Polyspace interface.

```
results = polyspaceBugFinder(optsBF);
polyspaceBugFinder('-results-dir',optsBF.ResultsDir);
```

### Run Polyspace by Generating a Project File

Create a Bug Finder analysis options object and customize the properties. Then, run an analysis.

Create object and customize properties.

```
sources = fullfile(polyspaceroot, 'polyspace','examples','cxx','Bug_Finder_Example',...
    'sources','numerical.c');
optsBF = polyspace.BugFinderOptions();
optsBF.Prog = 'MyProject';
optsBF.Sources = {sources};
optsBF.TargetCompiler.Compiler = 'gnu4.7';
optsBF.ResultsDir = tempname;
```

Generate a Polyspace project, name it using the `Prog` property, and open the project in the Polyspace interface.

```
psprj = generateProject(optsBF, optsBF.Prog);
polyspaceBugFinder(psprj);
```

Run the analysis and open the results in the Polyspace interface.

```
results = polyspaceBugFinder(psprj, '-nodesktop');
polyspaceBugFinder('-results-dir',optsBF.ResultsDir);
```

## Alternatives

If you are analyzing generated code, use `polyspace.ModelLinkOptions` instead.

# Version History

**Introduced in R2016b**

### R2022b: Class removed

*Errors starting in R2022b*

Using this class to set Polyspace analysis options results in an error. Use the class `polyspace.Options` instead. For instance, replace this code:

```
optsBF = polyspace.BugFinderOptions();
```

with this:

```
optsBF = polyspace.Options();
```

### R2017a: Class to be removed

*Warns starting in R2017a*

If you use this class to set Polyspace analysis options, MATLAB produces an warning.

## See Also

polyspace.Options | `polyspace.ModelLinkBugFinderOptions` | `polyspaceBugFinder`

### Topics

"Run Polyspace Analysis by Using MATLAB Scripts"

# polyspace.DefectsOptions class

**Package:** `polyspace`

Create custom list of defects to check

## Description

Create a custom list of defects to check in a Polyspace analysis.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Construction

`defectsList = polyspace.DefectsOptions` creates the defect options object `defectsList`. You can customize the list of active defects by changing the properties.

## Properties

An object is created with supported defects as properties. The defects are listed by their command-line name. See “Short Names of Bug Finder Defect Groups and Defect Checkers”.

By default, all defects are turned off. To turn on a defect, set the defect to true. For example:

```
defectsList = polyspace.DefectsOptions;
defectsList.FLOAT_ZERO_DIV = true;
```

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

## Examples

### Customize List of Defects to Check

Customize the list of defects checked during a Polyspace Bug Finder analysis.

Create two objects: a `polyspace.DefectsOptions` object for setting coding rules and a `polyspace.Project` object for running the Polyspace analysis.

```
defectsList = polyspace.DefectsOptions;
proj = polyspace.Project;
```

Enable the numerical defects.

```
defectsList.FLOAT_ZERO_DIV = true;
defectsList.INT_ZERO_DIV = true;
defectsList.FLOAT_ABSORPTION = true;
defectsList.BITWISE_NEG = true;
defectsList.FLOAT_CONV_OVFL = true;
defectsList.FLOAT_OVFL = true;
defectsList.INT_CONV_OVFL = true;
defectsList.INT_OVFL = true;
defectsList.FLOAT_STD_LIB = true;
defectsList.INT_STD_LIB = true;
defectsList.SHIFT_NEG = true;
defectsList.SHIFT_OVFL = true;
defectsList.SIGN_CHANGE = true;
defectsList.UINT_CONV_OVFL = true;
defectsList.UINT_OVFL = true;
defectsList.BAD_PLAIN_CHAR_USE = true;
```

Add the customized list of defects to the `Configuration` property of the `polyspace.Project` object.

```
proj.Configuration.BugFinderAnalysis.CheckersList = defectsList;
proj.Configuration.BugFinderAnalysis.CheckersPreset = 'custom';
```

You can now use the `polyspace.Project` object to run the analysis.

### Script Analysis of Model Generated Code

This example shows how to customize and run an analysis on model generated code with MATLAB functions and objects.

Create a custom configuration that checks MISRA C 2012 rules and generates a PDF report.

```
opts = polyspace.ModelLinkBugFinderOptions();
opts.CodingRulesCodeMetrics.EnableMisraC3 = true;
opts.CodingRulesCodeMetrics.MisraC3Subset = 'all';
opts.MergedReporting.ReportOutputFormat = 'PDF';
opts.MergedReporting.EnableReportGeneration = true;
```

Generate code from `psdemo_model_link_sl`.

```
[TEMPDIR, CGDIR] = rtwdemodir();
model = 'psdemo_model_link_sl';
load_system(model);
slbuild(model);
```

Add the configuration to `pslinkoptions` object.

```
prjfile = opts.generateProject('model_link_opts');
mlopts = pslinkoptions(model);
mlopts.EnablePrjConfigFile = true;
mlopts.PrjConfigFile = prjfile;
mlopts.VerificationMode = 'BugFinder';
```

Run analysis.

```
[polyspaceFolder, resultsFolder] = pslinkrun(model);
```

## Alternatives

If you are analyzing handwritten code, use `polyspace.Options` instead.

# Version History

**Topics**

"Run Polyspace Analysis by Using MATLAB Scripts"

# polyspace.GenericTargetOptions class

**Package:** `polyspace`

Create a generic target configuration

## Description

Create a custom target for a Polyspace analysis if your target processor does not match one of the predefined targets,.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Construction

`genericTarget = polyspace.GenericTargetOptions` creates a generic target that you can customize. To specify the sizes and alignment of data types, change the properties of the object. For instance:

```
target = polyspace.GenericTargetOptions;
target.CharNumBits = 16;
```

## Properties

For more details about any of the properties below, see `Generic target options`.

### `Alignment` — Largest alignment of struct or array objects

32 (default) | 16 | 8

Largest alignment of struct or array objects, specified as `32`, `16`, or `8`. Comparable with the DOS/UNIX command-line option `-align`.

Example: `target.Alignment = 8`

### `CharNumBits` — Define the number of bits for a `char`

8 (default) | 16

Define the number of bits for a `char`, specified as `8` or `16`. Comparable with the DOS/UNIX command-line option `-char-is-16bits`.

Example: `target.CharNumBits = 16`

### `DoubleNumBits` — Define the number of bits for a `double`

32 (default) | 64

Define the number of bits for a `double`, specified as `32` or `64`. Comparable with the DOS/UNIX command-line option `-double-is-64bits`.

Example: `target.DoubleNumBits = 64`

### `Endianness` — Endianness of target architecture

`little` (default) | `big`

Endianness of target architecture, specified as `little` or `big`. Comparable with the DOS/UNIX command-line options `-little-endian` or `-big-endian`.

Example: `target.Endianess = 'big'`

### `IntNumBits` — Define the number of bits for an `int`

16 (default) | 32

Define the number of bits for an `int`, specified as `16` or `32`. Comparable with the DOS/UNIX command-line option `-int-is-32bits`.

Example: `target.IntNumBits = 32`

### `LongLongNumBits` — Define the number of bits for a `long long`

32 (default) | 64

Define the number of bits for a `long long`, specified as `32` or `64`. Comparable with the DOS/UNIX command-line option `-long-long-is-64bits`.

Example: `target.LongNumBits = 64`

### `LongNumBits` — Define the number of bits for a `long`

32 (default)

Define the number of bits for a `long`, specified as `32`. Comparable with the DOS/UNIX command-line option `-long-is-32bits`.

Example: `target.LongNumBits = 32`

### `PointerNumBits` — Define the number of bits for a pointer

16 (default) | 24 | 32

Define the number of bits for a pointer, specified as `16`, `24`, or `32`. Comparable with the DOS/UNIX command-line options `-pointer-is-24bits` and `-pointer-is-32bits`.

Example: `target.PointerNumBits = 32`

### `ShortNumBits` — Define the number of bits for a `short`

16 (default) | 8

Define the number of bits for an `int`, specified as `16` or `8`. Comparable with the DOS/UNIX command-line option `-short-is-8bits`.

Example: `target.ShortNumBits = 8`

### `SignOfChar` — Default sign of plain `char`

`signed` (default) | `unsigned`

Default sign of plain `char`, specified as `signed` or `unsigned`. Comparable with the DOS/UNIX command-line option `-default-sign-of-char`.

Example: `target.SignOfChar = 'unsigned'`

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

## Examples

### Customize Generic Target Settings

Use a custom target for the Polyspace analysis.

Create two objects: a `polyspace.GenericTargetOptions` object for creating a custom target and a `polyspace.Project` object for running the Polyspace analysis.

```
target = polyspace.GenericTargetOptions;
proj = polyspace.Project;
```

Customize the generic target.

```
target.Endianess = 'big';
target.LongLongNumBits = 64;
target.ShortNumBits = 8;
```

Add the custom target to the `Configuration` property of the `polyspace.Project` object.

```
proj.Configuration.TargetCompiler.Target = target;
```

You can now use the `polyspace.Project` object to run the analysis.

`polyspace.Project` | `polyspace.Options` | `polyspace.ModelLinkOptions` | `polyspace.CodingRulesOptions` | `Generic target options`

# Version History

**Introduced in R2016b**

# polyspace.CodingRulesOptions class

**Package:** polyspace

Create custom list of coding rules to check

## Description

Create a custom list of coding rules to check in a Polyspace analysis.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Construction

ruleList = polyspace.CodingRulesOptions(RuleSet) creates the coding rules object ruleList for the RuleSet coding rule set. Set the active rules in the coding rules object.

### Input Arguments

**RuleSet — Standard coding rule set**
misraC (default) | misraC2012 | misraAcAgc | misraCpp | jsf | certC | certCpp | iso17961 | autosarCpp14 | guidelines | cwe

Standard coding rule set specified as one of the coding rule acronyms.

Example: 'misraCpp'

Data Types: char

## Properties

For each coding rule set, an object is created with all supported rules divided into sections. By default, all rules are on. To turn off a rule, set the rule to false. For example:

```
misraRules = polyspace.CodingRulesOptions('misraC');
misraRules.Section_20_Standard_libraries.rule_20_1 = false;
```

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

## Examples

### Customize List of Coding Rules to Check

Customize the coding rules that are checked in a Polyspace analysis. Since all rules are enabled by default, you can create a custom subset by disabling some rules.

Create two objects: a `polyspace.CodingRulesOptions` object for setting coding rules and a `polyspace.Project` object for running the Polyspace analysis.

```
misraRules = polyspace.CodingRulesOptions('misraC2012');
proj = polyspace.Project;
```

Customize the coding rule list by turning off rules 2.1-2.7.

```
misraRules.Section_2_Unused_code.rule_2_1 = false;
misraRules.Section_2_Unused_code.rule_2_2 = false;
misraRules.Section_2_Unused_code.rule_2_3 = false;
misraRules.Section_2_Unused_code.rule_2_4 = false;
misraRules.Section_2_Unused_code.rule_2_5 = false;
misraRules.Section_2_Unused_code.rule_2_6 = false;
misraRules.Section_2_Unused_code.rule_2_7 = false;
```

Add the customized list of coding rules to the `Configuration` property of the `polyspace.Project` object.

```
proj.Configuration.CodingRulesCodeMetrics.MisraC3Subset = misraRules;
proj.Configuration.CodingRulesCodeMetrics.EnableMisraC3 = true;
proj.Configuration.CodingRulesCodeMetrics.EnableCheckersSelectionByFile = true;
```

You have to enable checkers selection by file because the Polyspace run uses an XML file underneath to enable the coding rule checkers. The XML file is saved in a `.settings` subfolder of the results folder.

You can now use the `polyspace.Project` object to run the analysis. For instance, you can enter:

```
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
run(proj, 'bugfinder');
```

### Create Coding Rules Object Using Rule Numbers to Enable

Suppose that you want to specify a subset of MISRA C: 2012 rules for the analysis. Instead of enumerating rules that you want disabled, you can specify the rules that you want to keep enabled. You can also specify the rule numbers only without the MISRA C: 2012 sections containing the rules.

Specify the rule numbers in a cell array to the `createRulesObject` function defined as follows.

```
function rulesObject = createRulesObject(rulesToEnable)

%% This function takes a cell array of MISRA C:2012 rules and returns
%% a polyspace.CodingRulesOptions object with the rules enabled.
%% Example input argument: {'2.7', '3.1'}

    rulesObject = polyspace.CodingRulesOptions('misraC2012');

    % Coding Standards documents have many sections. Loop over all
    % sections.
    ruleSections = properties(rulesObject);
    for i=1:length(ruleSections)
         sectionName = ruleSections{i};
         rulesInSection = properties(rulesObject.(sectionName));
```

```
        % Loop over all rules in a section, enable or disable rule based
        % on input
        for j=1:length(rulesInSection)
            ruleNumberAsProperty = rulesInSection{j};
            ruleNumber = strrep(strrep(ruleNumberAsProperty,'rule_',''),'_','.');
            if(any(strcmp(rulesToEnable,ruleNumber)))
                rulesObject.(sectionName).(ruleNumberAsProperty)=1;
            else
                rulesObject.(sectionName).(ruleNumberAsProperty)=0;
            end
        end
    end
end
```

For instance, to enable rules 1.1 and 2.2, enter:

```
createRulesObject({'1.1','2.2'})
```

## Version History

**Introduced in R2016b**

polyspace.Project | polyspace.Options | polyspace.ModelLinkOptions

# polyspace.BugFinderResults

Read Polyspace Bug Finder results from MATLAB

## Description

Read Polyspace Bug Finder analysis results to MATLAB tables by using this object. You can obtain a high-level overview of results or details such as each instance of a defect.

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” or “Integrate Polyspace Server Products with MATLAB”.

## Creation

### Syntax

```
resObj = polyspace.BugFinderResults(resultsFolder)
proj = polyspace.Project; resObj = proj.Results;
```

#### Description

`resObj = polyspace.BugFinderResults(resultsFolder)` creates an object for reading a specific set of Bug Finder results into MATLAB tables. Use the object methods to read the results.

`proj = polyspace.Project; resObj = proj.Results;` creates a `polyspace.Project` object with a `Results` property. If you run a Bug Finder analysis, this property is a `polyspace.BugFinderResults` object.

#### Input Arguments

**`resultsFolder` — Name of result folder**
character vector

Name of result folder, specified as a character vector. The folder must directly contain the results file with extension `.psbf`. Even if the results file resides in a *subfolder* of the specified folder, it cannot be accessed.

If the folder is not in the current folder, `resultsFolder` must include a full or relative path.

Example: `'C:\Polyspace\Results\'`

### Object Functions

| | |
|---|---|
| getSummary | View number of Polyspace results organized by results type (Bug Finder) or color and file (Code Prover) |
| getResults | View all instances of Bug Finder or Code Prover results |

## Examples

### Read Existing Results to MATLAB Tables

This example shows how to read Bug Finder analysis results from MATLAB.

Copy a demo result set to a temporary folder.

```
resPath=fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example',...
'Module_1','BF_Result');
userResPath = tempname;
copyfile(resPath,userResPath);
```

Create the results object.

```
resObj = polyspace.BugFinderResults(userResPath);
```

Read results to MATLAB tables using the object.

```
resSummary = getSummary (resObj);
resTable = getResults (resObj);
```

### Run Analysis and Read Results to MATLAB Tables

Run a Polyspace Bug Finder analysis on the demo file `numerical.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.

```
proj = polyspace.Project;

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace',...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = run(proj, 'bugFinder');

% Read results
resObj = proj.Results;
bfSummary = getResults(resObj, 'readable');
```

# Version History

**Introduced in R2017a**

# pslinkoptions Properties

Properties for the `pslinkoptions` object

## Description

You can create a `pslinkoptions` object to customize your analysis at the command-line. Use these properties to specify configuration options, where and how to store results, additional files to include, and data range modes.

### Properties

**Configuration Options**

**`VerificationSettings` — Coding rule and configuration settings for C code**
`'PrjConfig'` (default) | `'PrjConfigAndMisraAGC'` | `'PrjConfigAndMisra'` | `'PrjConfigAndMisraC2012'` | `'MisraAGC'` | `'Misra'` | `'MisraC2012'`

Coding rule and configuration settings for C code specified as:

- `'PrjConfig'` – Inherit options from the project configuration.
- `'PrjConfigAndMisraAGC'` – Inherit options from the project configuration and enable MISRA AC AGC rule checking.
- `'PrjConfigAndMisra'` – Inherit options from the project configuration and enable MISRA C:2004 rule checking.
- `'PrjConfigAndMisraC2012'` – Inherit options from the project configuration and enable MISRA C:2012 guideline checking.
- `'MisraAGC'` – Enable MISRA AC AGC rule checking. This option runs only compilation and rule checking.
- `'Misra'` – Enable MISRA C:2004 rule checking. This option runs only compilation and rule checking.
- `'MisraC2012'` – Enable MISRA C:2012 rule checking. This option runs only compilation and guideline checking.

Example: `opt.VerificationSettings = 'PrjConfigAndMisraC2012'`

**`VerificationMode` — Polyspace mode**
`'BugFinder'` (default) | `'CodeProver'`

Polyspace mode specified as `'BugFinder'`, for a Bug Finder analysis, or `'CodeProver'`, for a Code Prover verification.

Example: `opt.VerificationMode = 'BugFinder';`

**`EnablePrjConfigFile` — Allow a custom configuration file**
`false` (default) | `true`

Allows a custom configuration file instead of the default configuration specified as true or false. Use the `PrjConfigFile` option to specify the configuration file.

Example: `opt.EnablePrjConfigFile = true;`

### `PrjConfigFile` — Custom configuration file

`''` (default) | full path to a `.psprj` file

Custom configuration file to use instead of the default configuration specified by the full path to a `.psprj` file. Use the `EnablePrjConfigFile` option to use this configuration file during your analysis.

Example: `opt.PrjConfigFile = 'C:\Polyspace\config.psprj';`

### `CheckConfigBeforeAnalysis` — Configuration check before analysis

`'OnWarn'` (default) | `'OnHalt'` | `'Off'`

This property sets the level of configuration checking done before the analysis starts. The configuration check before analysis is specified as:

- **`'Off'`** — Checks only for errors. Stops if errors are found.
- **`'OnWarn'`** — Stops for errors. Displays a message for warnings.
- **`'OnHalt'`** — Stops for errors and warnings.

Example: `opt.CheckConfigBeforeAnalysis = 'OnHalt';`

#### Results

### `ResultDir` — Results folder name and location

`'C:\Polyspace_Results\results_$ModelName$'` (default) | folder name | folder path

Results folder name and location specified as the local folder name or the folder path. This folder is where Polyspace writes the analysis results. This folder name can be either an absolute path or a path relative to the current folder. The text `$ModelName$` is replaced with the name of the original model.

Example: `opt.ResultDir = '\results_v1_$ModelName$';`

### `AddSuffixToResultDir` — Add unique number to the results folder name

`false` (default) | `true`

Add unique number to the results folder name specified as true or false. If true, a unique number is added to the end of every new result. Using this option helps you avoid overwriting the previous results folders.

Example: `opt.AddSuffixToResultDir = true;`

### `OpenProjectManager` — Open the Polyspace environment

`false` (default) | `true`

Open the Polyspace environment to monitor the progress of the analysis, specified as true or false. Afterward, you can review the results.

Example: `opt.OpenProjectManager = true;`

### `AddToSimulinkProject` — Add results to the open Simulink project

`false` (default) | `true`

Add your results to the currently open Simulink project, if any, specified as true or false. This option allows you to keep your Polyspace results organized with the rest of your project files. If a Simulink project is not open, the results are not added to a Simulink project.

Example: `opt.AddToSimulinkProject = true;`

#### Additional Files

### `EnableAdditionalFileList` — Allow an additional file list

`false` (default) | `true`

Allow an additional file list to be analyzed, specified as true or false. Use with the `AdditionalFileList` option.

Example: `opt.EnableAdditionalFileList = true;`

### `AdditionalFileList` — List of additional files to be analyzed

`{0x1 cell}` (default) | cell array of files

List of additional files to be analyzed specified as a cell array of files. Use with the `EnableAdditionalFileList` option to add these files to the analysis.

Example: `opt.AdditionalFileList = {'sources\file1.c', 'sources\file2.c'};`

Data Types: `cell`

#### Data Ranges

### `InputRangeMode` — Enable design range information

`'DesignMinMax'` (default) | `'FullRange'`

Enable design range information specified as `'DesignMinMax'`, to use data ranges defined in blocks and workspaces, or `'FullRange'`, to treat inputs as full-range values.

Example: `opt.InputRangeMode = 'FullRange';`

### `ParamRangeMode` — Enable constant parameter values

`'None'` (default) | `'DesignMinMax'`

Enable constant parameter values, specified as `'None'`, to use constant parameters values specified in the code, or `'DesignMinMax'` to use a range defined in blocks and workspaces.

Example: `opt.ParamRangeMode = 'DesignMinMax';`

### `OutputRangeMode` — Enable output assertions

`'None'` (default) | `'DesignMinMax'`

Enable output assertions specified by `'None'`, to not apply assertions, or `'DesignMinMax'` to apply assertions to outputs using a range defined in blocks and workspace.

Example: `opt.ParamRangeMode = 'DesignMinMax';`

#### Embedded Coder Only

### `ModelRefVerifDepth` — Depth of verification

`'Current model only'` (default) | `'1'` | `'2'` | `'3'` | `'All'`

Specify the depth for analyzing the models that are referenced by the current model.

- `'Current Model Only'`: Analyze only the top model without analyzing the referenced models. For instance, you might use this option when the referenced models are library models.
- `'1'`, `'2'`, or `'3'`: Analyze referenced models up to the specified depth in the reference hierarchy. For instance, to analyze the models that are referenced by the top model, specify the property

ModelRefVerifDepth as '1'. To analyze models that are referenced by the first level of references, specify this property as '2'.

- 'All': Analyze all referenced models with the current model.

*For Embedded Coder only*

Example: opt.ModelRefVerifDepth = '3';

### ModelRefByModelRefVerif — Model reference analysis mode

false (default) | true

Specify whether you want to analyze all referenced models together, or analyze the models individually.

- false: Analyze the top model and the referenced models together. For instance, you might want to use this option to check for integration or scaling issues.
- true: Analyze the top model and the referenced models individually.

*For Embedded Coder only*

Example: opt.ModelRefByModelRefVerif = true;

### CxxVerificationSettings — Coding rule and configuration settings for C++ code

'PrjConfig' (default) | 'PrjConfigAndMisraCxx' | 'PrjConfigAndJSF' | 'MisraCxx' | 'JSF'

Coding rule and configuration settings for C++ code specified as:

- 'PrjConfig' – Inherit options from project configuration and run complete analysis.
- 'PrjConfigAndMisraCxx' – Inherit options from project configuration, enable MISRA C++ rule checking, and run complete analysis.
- 'PrjConfigAndJSF' – Inherit options from project configuration, enable JSF rule checking, and run complete analysis.
- 'MisraCxx' – Enable MISRA C++ rule checking, and run compilation phase only.
- 'JSF' – Enable JSF rule checking, and run compilation phase only.

*Only for Embedded Coder*

Example: opt.CxxVerificationSettings = 'MisraCxx';

#### TargetLink Only

### AutoStubLUT — Lookup Table code usage

false (default) | true

Lookup Table code usage, specified as true or false.

- true — use Lookup Table code during the analysis.
- false — stub Lookup Table code.

*Only for TargetLink*

Example: opts.AutoStubLUT = true;

# polyspace.Project.Configuration Properties

Customize Polyspace analysis of handwritten code with options object properties

## Description

To customize your Polyspace analysis, use these `polyspace.Options` or `polyspace.Project.Configuration` properties. Each property corresponds to an analysis option on the **Configuration** pane in the Polyspace user interface.

The properties are grouped using the same categories as the **Configuration** pane. This page only shows what values each property can take. For details about:

- The different options, see the analysis option reference pages.
- How to create and use the object, see `polyspace.Options` or `polyspace.Project`.

  Avoid using the classes `polyspace.BugFinderOptions` and `polyspace.CodeProverOptions` to set these properties. These classes will be removed in a future release.

Each property description below also highlights if the option affects only one of Bug Finder or Code Prover.

**Note** Some options might not be available depending on the language setting of the object. You can set the source code language (`Language`) to `'C'`, `'CPP'` or `'C-CPP'` during object creation, but cannot change it later.

### Properties

**Advanced**

**`Additional` — Additional flags for analysis**
character vector

Additional flags for analysis specified as a character vector.

For more information, see `Other`.

Example: `opts.Advanced.Additional = '-extra-flags -option -extra-flags value'`

**`PostAnalysisCommand` — Command or script software should execute after analysis finishes**
character vector

Command or script software should execute after analysis finishes, specified as a character vector.

For more information, see `Command/script to apply after the end of the code verification (-post-analysis-command)`.

Example: `opts.Advanced.PostAnalysisCommand = '"C:\Program Files\perl\win32\bin\perl.exe" "C:\My_Scripts\send_email"'`

#### BugFinderAnalysis (Affects Bug Finder Only)

**`CheckersList` — List of custom checkers to activate**
`polyspace.DefectsOptions` object | cell array of defect acronyms

*This property affects Bug Finder analysis only.*

List of custom checkers to activate specified by using the name of a `polyspace.DefectsOptions` object or a cell array of defect acronyms. To use this custom list in your analysis, set `CheckersPreset` to `custom`.

For more information, see `polyspace.DefectsOptionspolyspace.DefectsOptions`.

Example: `defects = polyspace.DefectsOptions; opts.BugFinderAnalysis.CheckersList = defects`

Example: `opts.BugFinderAnalysis.CheckersList = {'INT_ZERO_DIV','FLOAT_ZERO_DIV'}`

**`CheckersPreset` — Subset of Bug Finder defects**
`'default'` (default) | `'all'` | `'custom'`

*This property affects Bug Finder analysis only.*

Preset checker list, specified as a character vector of one of the preset options: `'default'`, `'all'`,or `'custom'`. To use `'custom'`, specify a value for the property `BugFinderAnalysis.CheckersList`.

For more information, see `Find defects (-checkers)`.

Example: `opts.BugFinderAnalysis.CheckersPreset = 'all'`

**`ChecksUsingSystemInputValues` — Activate stricter checks for system inputs**
false (default) | true

*This property affects Bug Finder analysis only.*

Activate stricter checks that consider all possible value for:

- Global variables.
- Reads of volatile variables.
- Returns of stubbed functions.
- Inputs to functions specified with **SystemInputsFrom**.

The analysis considers all possible values for a subset of **Numerical** and **Static memory** defects.

This property is equivalent to the **Run stricter checks considering all values of system inputs** check box in the Polyspace interface.

For more information, see `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

Example: `opts.BugFinderAnalysis.ChecksUsingSystemInputValues = true`

**`EnableCheckers` — Activate defect checking**
true (default) | false

*This property affects Bug Finder analysis only.*

Activate defect checking, specified as true or false. Setting this property to false disables all defects. If you want to disable defect checking but still get results, turn on coding rules checking or code metric checking.

This property is equivalent to the **Find defects** check box in the Polyspace interface.

Example: `opts.BugFinderAnalysis.EnableCheckers = false`

### `SystemInputsFrom` — List of functions for which you run stricter checks

`'auto'` (default) | `'uncalled'` | `'all'` | `'custom'`

*This property affects Bug Finder analysis only.*

Functions for which you want to run stricter checks that consider all possible values of the function inputs. Specify the list of functions as `'auto'`, `'uncalled'`, `'all'`, or as a character array beginning with `custom=` followed by a comma-separated list of function names.

To enable this option, set `BugFinderAnalysis.ChecksUsingSystemInputValues = true`.

For more information, see `Consider inputs to these functions (-system-inputs-from)`.

Example: `opts.BugFinderAnalysis.SystemInputsFrom = 'custom=foo,bar'`

#### ChecksAssumption (Affects Code Prover Only)

### `AllowNegativeOperandInShift` — Allow left shift operations on a negative number

false (default) | true

*This property affects Code Prover analysis only.*

Allow left shift operations on a negative number, specified as true or false.

For more information, see `Allow negative operand for left shifts (-allow-negative-operand-in-shift)`.

Example: `opts.ChecksAssumption.AllowNegativeOperandInShift = true`

### `AllowNonFiniteFloats` — Incorporate infinities and/or NaNs

false (default) | true

*This property affects Code Prover analysis only.*

Incorporate infinities and/or NaNs, specified as true or false.

For more information, see `Consider non finite floats (-allow-non-finite-floats)`.

Example: `opts.ChecksAssumption.AllowNonFiniteFloats = true`

### `AllowPtrArithOnStruct` — Allow arithmetic on pointer to a structure field so that it points to another field

false (default) | true

*This property affects Code Prover analysis only.*

Allow arithmetic on pointer to a structure field so that it points to another field, specified as true or false.

For more information, see `Enable pointer arithmetic across fields (-allow-ptr-arith-on-struct)`.

Example: `opts.ChecksAssumption.AllowPtrArithOnStruct = true`

### `CheckInfinite` — Detect floating-point operations that result in infinities

`'allow'` (default) | `'warn-first'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect floating-point operations that result in infinities.

To activate this option, specify `ChecksAssumption.AllowNonFiniteFloats`.

For more information, see `Infinities (-check-infinite)`.

Example: `opts.ChecksAssumption.CheckInfinite = 'forbid'`

### `CheckNan` — Detect floating-point operations that result in NaN-s

`'allow'` (default) | `'warn-first'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect floating-point operations that result in NaN-s.

To activate this option, specify `ChecksAssumption.AllowNonFiniteFloats`.

For more information, see `NaNs (-check-nan)`.

Example: `opts.ChecksAssumption.CheckNan = 'forbid'`

### `CheckSubnormal` — Detect operations that result in subnormal floating point values

`'allow'` (default) | `'warn-first'` | `'warn-all'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect operations that result in subnormal floating point values.

For more information, see `Subnormal detection mode (-check-subnormal)`.

Example: `opts.ChecksAssumption.CheckSubnormal = 'forbid'`

### `DetectPointerEscape` — Find cases where a function returns a pointer to one of its local variables

false (default) | true

*This property affects Code Prover analysis only.*

Find cases where a function returns a pointer to one of its local variables, specified as true or false.

For more information, see `Detect stack pointer dereference outside scope (-detect-pointer-escape)`.

Example: `opts.ChecksAssumption.DetectPointerEscape = true`

### `DisableInitializationChecks` — Disable checks for noninitialized variables and pointers

false (default) | true

*This property affects Code Prover analysis only.*

Disable checks for noninitialized variables and pointers, specified as true or false.

For more information, see `Disable checks for non-initialization (-disable-initialization-checks)`.

Example: `opts.ChecksAssumption.DisableInitializationChecks = true`

**`PermissiveFunctionPointer` — Allow type mismatch between function pointers and the functions they point to**
false (default) | true

*This property affects Code Prover analysis only.*

Allow type mismatch between function pointers and the functions they point to, specified as true or false.

For more information, see `Permissive function pointer calls (-permissive-function-pointer)`.

Example: `opts.ChecksAssumption.PermissiveFunctionPointer = true`

**`SignedIntegerOverflows` — Behavior of signed integer overflows**
`'forbid'` (default) | `'allow'` | `'warn-with-wrap-around'`

*This property affects Code Prover analysis only.*

Enable the check for signed integer overflows and the assumptions to make following an overflow specified as `'forbid'`, `'allow'`, or `'warn-with-wrap-around'`.

For more information, see `Overflow mode for signed integer (-signed-integer-overflows)`.

Example: `opts.ChecksAssumption.SignedIntegerOverflows = 'warn-with-wrap-around'`

**`SizeInBytes` — Allow a pointer with insufficient memory buffer to point to a structure**
false (default) | true

*This property affects Code Prover analysis only.*

Allow a pointer with insufficient memory buffer to point to a structure, specified as true or false.

For more information, see `Allow incomplete or partial allocation of structures (-size-in-bytes)`.

Example: `opts.ChecksAssumption.SizeInBytes = true`

**`StackUsage` — Calculate the estimated stack usage of your code**
false (default) | true

*This property affects Code Prover analysis only.*

Calculate stack usage metrics such as maximum or minimum stack usage and estimates of local variable size.

For more information, see `Calculate stack usage (-stack-usage)`.

Example: `opts.ChecksAssumption.StackUsage = true`

### `UncalledFunctionCheck` — Detect functions that are not called directly or indirectly from main or another entry-point function

`'none'` (default) | `'never-called'` | `'called-from-unreachable'` | `'all'`

*This property affects Code Prover analysis only.*

Detect functions that are not called directly or indirectly from main or another entry-point function, specified as `none`, `never-called`, `called-from-unreachable`, or `all`.

For more information, see `Detect uncalled functions (-uncalled-function-checks)`.

Example: `opts.ChecksAssumption.UncalledFunctionCheck = 'all'`

### `UnsignedIntegerOverflows` — Behavior of unsigned integer overflows

`'allow'` (default) | `'forbid'` | `'warn-with-wrap-around'`

*This property affects Code Prover analysis only.*

Enable the check for unsigned integer overflows and the assumptions to make following an overflow, specified as `'forbid'`, `'allow'`, or `'warn-with-wrap-around'`.

For more information, see `Overflow mode for unsigned integer (-unsigned-integer-overflows)`.

Example: `opts.ChecksAssumption.UnsignedIntegerOverflows = 'allow'`

#### CodeProverVerification (Affects Code Prover only)

### `ClassAnalyzer` — Classes that you want to verify

`'all'` (default) | `'none'` | `'custom=`*`class1[,class2,...]`*`'`

*This property affects Code Prover analysis only.*

Classes that you want to verify, specified as `'all'`, `'none'`, or as a character array beginning with `custom=` followed by a comma-separated list of class names.

For more information, see `Class (-class-analyzer)`.

Example: `opts.CodeProverVerification.ClassAnalyzer = 'custom=myClass1,myClass2'`

### `ClassAnalyzerCalls` — Class methods that you want to verify

`'unused'` (default) | `'all'` | `'all-public'` | `'inherited-all'` | `'inherited-all-public'` | `'unused-public'` | `'inherited-unused'` | `'inherited-unused-public'` | `'custom=`*`method1[,method2,...]`*`'`

*This property affects Code Prover analysis only.*

Class methods that you want to verify, specified as one of the predefined sets or as a character array beginning with `custom=` followed by a comma-separated list of method names.

For more information, see `Functions to call within the specified classes (-class-analyzer-calls)`.

Example: `opts.CodeProverVerification.ClassAnalyzerCalls = 'unused-public'`

### `ClassOnly` — Analyze only class methods

false (default) | true

*This property affects Code Prover analysis only.*

Analyze only class methods, specified as true or false.

For more information, see `Analyze class contents only (-class-only)`.

Example: `opts.CodeProverVerification.ClassOnly = true`

### `EnableMain` — Use `main` function provided in application

false (default) | true

*This property affects Code Prover analysis only.*

Use `main` function provided in application, specified as true or false. If you set this property to false, the analysis generates a `main` function, if it is not present in the source files.

For more information, see `Verify whole application`.

Example: `opts.CodeProverVerification.EnableMain = true`

### `FunctionsCalledBeforeMain` — Functions that you want the generated main to call ahead of other functions

cell array of function names

*This property affects Code Prover analysis only.*

Functions that you want the generated main to call ahead of other functions, specified as a cell array of function names.

For more information, see `Initialization functions (-functions-called-before-main)`.

Example: `opts.CodeProverVerification.FunctionsCalledBeforeMain = {'func1','func2'}`

### `Main` — Use a Microsoft Visual C++ extensions of main

`'_tmain'` (default) | `'wmain'` | `'_tWinMain'` | `'wWinMain'` | `'WinMain'` | `'DllMain'`

*This property applies to a Code Prover analysis only .*

Use a Microsoft Visual C++ extension of main, specified as one of the predefined main extensions.

For more information, see `Main entry point (-main)`.

Example: `opts.CodeProverVerification.Main = 'wmain'`

### `MainGenerator` — Generate a main function if it is not present in source files

true (default) | false

*This property applies to a Code Prover analysis only .*

Generate a main function if it is not present in source files, specified as true or false.

For more information, see `Verify module or library (-main-generator)`.

Example: `opts.CodeProverVerification.MainGenerator = false`

### `MainGeneratorCalls` — Functions that you want the generated main to call after the initialization functions

`'unused'` (default) | `'none'` | `'all'` | `'custom=`*`function1[,function2,...]`*`'`

*This property applies to a Code Prover analysis only .*

Functions that you want the generated main to call after the initialization functions, specified as `'unused'`, `'all'`, `'none'`, or as a character array beginning with `custom=` followed by a comma-separated list of function names.

For more information, see `Functions to call (-main-generator-calls)`.

Example: `opts.CodeProverVerification.MainGeneratorCalls = 'all'`

### `MainGeneratorWriteVariables` — Global variables that you want the generated main to initialize

`'uninit'` (C++ default) | `'public'` (C default) | `'none'` | `'all'` |
`'custom=`*`variable1[,variable2,...]`*`'`

*This property applies to a Code Prover analysis only .*

Global variables that you want the generated main to initialize, specified as one of the predefined sets, or as a character array beginning with `custom=` followed by a comma-separated list of variable names.

For more information, see `Variables to initialize (-main-generator-writes-variables)`.

Example: `opts.CodeProverVerification.MainGeneratorWriteVariables = 'all'`

### `NoConstructorsInitCheck` — Do not check if class constructor initializes class members

false (default) | true

*This property applies to a Code Prover analysis only .*

Do not check if class constructor initializes class members, specified as true or false.

For more information, see `Skip member initialization check (-no-constructors-init-check)`.

Example: `opts.CodeProverVerification.NoConstructorsInitCheck = true`

### `UnitByUnit` — Verify each source file independently of other source files

false (default) | true

*This property affects Code Prover analysis only.*

Verify each source file independently of other source files, specified as true or false.

For more information, see `Verify files independently (-unit-by-unit)`.

Example: `opts.CodeProverVerification.UnitByUnit = true`

### `UnitByUnitCommonSource` — Files that you want to include with each source file during a file-by-file verification

cell array of file paths

*This property affects Code Prover analysis only.*

Files that you want to include with each source file during a file-by-file verification, specified as a cell array of file paths.

For more information, see `Common source files (-unit-by-unit-common-source)`.

Example: `opts.CodeProverVerification.UnitByUnitCommonSource = {'/inc/file1.h','/inc/file2.h'}`

**CodingRulesCodeMetrics**

### `AcAgcSubset` — Subset of MISRA AC AGC rules to check

`'OBL-rules'` (default) | `'OBL-REC-rules'` | `'single-unit-rules'` | `'system-decidable-rules'` | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA AC AGC rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA AC AGC (-misra-ac-agc)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA AC AGC rules, also set `EnableAcAgc` to true.

Example: `opts.CodingRulesCodeMetrics.AcAgcSubset = 'all-rules'`

Data Types: `char`

### `AllowedPragmas` — Pragma directives for which MISRA C:2004 rule 3.4 or MISRA C++ 16-6-1 must not be applied

cell array of character vectors

Pragma directives for which MISRA C:2004 rule 3.4 or MISRA C++ 16-6-1 must not be applied, specified as a cell array of character vectors. This property affects only MISRA C:2004 or MISRA AC AGC rule checking.

For more information, see `Allowed pragmas (-allowed-pragmas)`.

Example: `opts.CodingRulesCodeMetrics.AllowedPragmas = {'pragma_01','pragma_02'}`

Data Types: `cell`

### `AutosarCpp14` — Set of AUTOSAR C++ 14 rules to check

`'all'` (default) | `'required'` | `'automated'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of AUTOSAR C++ 14 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check AUTOSAR C++ 14 security checks (-autosar-cpp14)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check AUTOSAR C++ 14 rules, also set `EnableAutosarCpp14` to true.

Example: `opts.CodingRulesCodeMetrics.AutosarCpp14 = 'all'`

Data Types: `char`

**`BooleanTypes` — Data types the coding rule checker must treat as effectively Boolean**
cell array of character vectors

Data types that the coding rule checker must treat as effectively Boolean, specified as a cell array of character vectors.

For more information, see `Effective boolean types (-boolean-types)`.

Example: `opts.CodingRulesCodeMetrics.BooleanTypes = {'boolean1_t','boolean2_t'}`

Data Types: `cell`

**`CertC` — Set of CERT C rules and recommendations to check**
`'all'` (default) | `'publish-2016'` | `'all-rules'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of CERT C rules and recommendations to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CERT-C security checks (-cert-c)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `from-file` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C rules and recommendations, also set `EnableCertC` to true.

Example: `opts.CodingRulesCodeMetrics.CertC = 'all'`

Data Types: `char`

### `CertCpp` — Set of CERT C++ rules to check

`'all'` (default) | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of CERT C++ rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CERT-C++ security checks (-cert-cpp)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C++ rules, also set `EnableCertCpp` to true.

Example: `opts.CodingRulesCodeMetrics.CertCpp = 'all'`

Data Types: `char`

### `CheckersSelectionByFile` — File that defines custom set of coding standard checkers

full file path of `.xml` file

File where you define a custom set of coding standards checkers to check, specified as a `.xml` file. You can, in the same file, define a custom set of checkers for each of the coding standards that Polyspace supports. To create a file that defines a custom selection of coding standard checkers, in the Polyspace interface, select a coding standard on the **Coding Standards & Code Metrics** node of the **Configuration** pane and click **Edit**.

For more information, see `Set checkers by file (-checkers-selection-file)`.

Example: `opts.CodingRulesCodeMetrics.CheckersSelectionByFile = 'C:\ps_settings \coding_rules\custom_rules.xml'`

Data Types: `char`

### `CodeMetrics` — Activate code metric calculations

false (default) | true

Activate code metric calculations, specified as true or false. If this property is turned off, Polyspace does not calculate code metrics even if you upload your results to Polyspace Metrics.

For more information about the code metrics, see `Calculate code metrics (-code-metrics)`.

If you assign a coding rules options object to this property, an XML file gets created automatically with the rules specified.

Example: `opts.CodingRulesCodeMetrics.CodeMetrics = true`

### `Cwe` — Set of CWE rules to check

`'all'` (default) | `'cwe-658-659'` | `'from-file'` | `polyspace.CodingRulesOptions` object

*This property affects Bug Finder only.*

Set of CWE rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CWE (-cwe)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C++ rules, also set `EnableCwe` to true.

Example: `opts.CodingRulesCodeMetrics.Cwe = 'cwe-658-659'`

Data Types: `char`

### `EnableAcAgc` — Check MISRA AC AGC rules

false (default) | true

Check MISRA AC AGC rules, specified as true or false. To customize which rules are checked, use `AcAgcSubset`.

For more information about the MISRA AC AGC checker, see `Check MISRA AC AGC (-misra-ac-agc)`.

Example: `opts.CodingRulesCodeMetrics.EnableAcAgc = true;`

### `EnableAutosarCpp14` — Check AUTOSAR C++ 14 rules

false (default) | true

*This property affects Bug Finder only.*

Check AUTOSAR C++ 14 rules, specified as true or false. To customize which rules are checked, use `AutosarCpp14`.

For more information about the AUTOSAR C++ 14 checker, see `Check AUTOSAR C++ 14 checks (-autosar-cpp14)`.

Example: `opts.CodingRulesCodeMetrics.EnableAutosarCpp14 = true;`

### `EnableCertC` — check CERT C rules and recommendations

false (default) | true

*This property affects Bug Finder only.*

Check CERT C rules and recommendations, specified as true or false. To customize which rules are checked, use `CertC`.

For more information about the CERT C checker, see `Check SEI CERT-C checks (-cert-c)`.

Example: `opts.CodingRulesCodeMetrics.EnableCertC = true;`

### `EnableCertCpp` — check CERT C++ rules

false (default) | true

*This property affects Bug Finder only.*

Check CERT C++ rules, specified as true or false. To customize which rules are checked, use `CertCpp`.

For more information about the CERT C++ checker, see `Check SEI-CERT-C++ (-cert-cpp)`.

Example: `opts.CodingRulesCodeMetrics.EnableCertCpp = true;`

### `EnableCheckersSelectionByFile` — Check custom set of coding standard checkers

false (default) | true

Check custom set of coding standard checkers, specified as true or false. If you set this property to true, specify the path of checkers selection XML file for the property `CheckersSelectionByFile` and set one of these properties to 'from-file' to enable the corresponding coding standard custom set:

- `opts.CodingRulesCodeMetrics.AcAgcSubset='from-file'`
- `opts.CodingRulesCodeMetrics.AutosarCpp14='from-file'`
- `opts.CodingRulesCodeMetrics.CertC='from-file'`
- `opts.CodingRulesCodeMetrics.CertCpp='from-file'`
- `opts.CodingRulesCodeMetrics.Cwe='from-file'`
- `opts.CodingRulesCodeMetrics.Guidelines='from-file'`
- `opts.CodingRulesCodeMetrics.Iso17961='from-file'`
- `opts.CodingRulesCodeMetrics.JsfSubset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraC3Subset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraCSubset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraCppSubset='from-file'`

For more information, see `Check custom rules (-custom-rules)`.

Example: `opts.CodingRulesCodeMetrics.EnableCheckersSelectionByFile = true;`

### `EnableCustomRules` — Check custom coding rules

false (default) | true

Check custom coding rules, specified as true or false. The file you specify with `CheckersSelectionByFile` defines the custom coding rules.

Use with `EnableCheckersSelectionByFile`.

For more information, see `Check custom rules (-custom-rules)`.

Example: `opts.CodingRulesCodeMetrics.EnableCustomRules = true;`

**EnableCwe — check CWE rules**
false (default) | true

*This property affects Bug Finder only.*

Check CWE rules, specified as true or false. To customize which rules are checked, use Cwe.

For more information about the CWE checker, see Check CWE (-cwe).

Example: `opts.CodingRulesCodeMetrics.Cwe = true;`

**EnableGuidelines — Check for violations of coding guidelines**
false (default) | true

*This property affects Bug Finder only.*

Specify whether to check for violations of Guidelines. To customize which rules are checked, use Guidelines.

For more information about the Guidelines checker, see Check guidelines (-guidelines).

Example: `opts.CodingRulesCodeMetrics.EnableGuidelines = true;`

**EnableIso17961 — check ISO-17961 rules**
false (default) | true

*This property affects Bug Finder only.*

Check ISO/IEC TS 17961 rules, specified as true or false. To customize which rules are checked, use Iso17961.

For more information about the ISO-17961 checker, see Check ISO-17961 security checks (-iso-17961).

Example: `opts.CodingRulesCodeMetrics.EnableIso17961 = true;`

**EnableJsf — Check JSF C++ rules**
false (default) | true

Check JSF C++ rules, specified as true or false. To customize which rules are checked, use JsfSubset.

For more information, see Check JSF C++ rules (-jsf-coding-rules).

Example: `opts.CodingRulesCodeMetrics.EnableJsf = true;`

**EnableMisraC — Check MISRA C:2004 rules**
false (default) | true

Check MISRA C:2004 rules, specified as true or false. To customize which rules are checked, use MisraCSubset.

For more information, see Check MISRA C:2004 (-misra2).

Example: `opts.CodingRulesCodeMetrics.EnableMisraC = true;`

**EnableMisraC3 — Check MISRA C:2012 rules**
false (default) | true

Check MISRA C:2012 rules, specified as true or false. To customize which rules are checked, use `MisraC3Subset`.

For more information about the MISRA C:2012 checker, see `Check MISRA C:2012 (-misra3)`.

Example: `opts.CodingRulesCodeMetrics.EnableMisraC3 = true;`

#### `EnableMisraCpp` — Check MISRA C++:2008 rules

false (default) | true

Check MISRA C++:2008 rules, specified as true or false. To customize which rules are checked, use `MisraCppSubset`.

For more information about the MISRA C++:2008 checker, see `Check MISRA C++ rules (-misra-cpp)`.

Example: `opts.CodingRulesCodeMetrics.EnableMisraCpp = true;`

#### `Guidelines` — Set of Guidelines to check

`'all'` (default) | `'his'` | `'from-file'`

*This property affects Bug Finder only.*

Sets of Guideline rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check guidelines (-guidelines)`.
- An XML file specifying Guidelines checkers and their thresholds. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”.

Example: `opts.CodingRulesCodeMetrics.Guidelines = 'his';`

#### `Iso17961` — Set of ISO-17961 rules to check

`'all'` (default) | `'decidable'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of ISO/IEC TS 17961 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check ISO-17961 (-iso-17961)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check ISO/IEC TS 17961 rules, also set `EnableIso17961` to true.

Example: `opts.CodingRulesCodeMetrics.Iso17961 = 'all'`

Data Types: `char`

### `JsfSubset` — Subset of JSF C++ rules to check

`'shall-rules'` (default) | `'shall-will-rules'` | `'all-rules'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of JSF C++ rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check JSF C++ rules (-jsf-coding-rules)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check JSF C++ rules, set `EnableJsf` to true.

Example: `opts.CodingRulesCodeMetrics.JsfSubset = 'all-rules'`

Data Types: `char`

### `Misra3AgcMode` — Use the MISRA C:2012 categories for automatically generated code

false (default) | true

Use the MISRA C:2012 categories for automatically generated code, specified as true or false.

For more information, see `Use generated code requirements (-misra3-agc-mode)`.

Example: `opts.CodingRulesCodeMetrics.Misra3AgcMode = true;`

### `MisraC3Subset` — Subset of MISRA C:2012 rules to check

`'mandatory-required'` (default) | `'mandatory'` | `'single-unit-rules'` | `'system-decidable-rules'` | `'all'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C:2012 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C:2012 (-misra3)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.

- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C:2012 rules, also set `EnableMisraC3` to true.

Example: `opts.CodingRulesCodeMetrics.MisraC3Subset = 'all'`

Data Types: `char`

### `MisraCSubset` — Subset of MISRA C:2004 rules to check

`'required-rules'` (default) | `'single-unit-rules'` | `'system-decidable-rules'` | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C:2004 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C:2004 (-misra2)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C:2004 rules, also set `EnableMisraC` to true.

Example: `opts.CodingRulesCodeMetrics.MisraCSubset = 'all-rules'`

Data Types: `char`

### `MisraCppSubset` — Subset of MISRA C++ rules

`'required-rules'` (default) | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C++:2008 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C++ rules (-misra-cpp)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C++ rules, set `EnableMisraCpp` to true.

Example: `opts.CodingRulesCodeMetrics.MisraCppSubset = 'all-rules'`

Data Types: `char`

#### EnvironmentSettings

### `Dos` — Consider that file paths are in MS-DOS style

true (default) | false

Consider that file paths are in MS-DOS style, specified as true or false.

For more information, see `Code from DOS or Windows file system (-dos)`.

Example: `opts.EnvironmentSettings.Dos = true;`

### `IncludeFolders` — Include folders needed for compilation

cell array of include folder paths

Include folders needed for compilation, specified as a cell array of the include folder paths.

To specify all subfolders of a folder, use folder path followed by `**`, for instance, `'C:\includes\**'`. The notation follows the syntax of the `dir` function. See also “Specify Multiple Source Files”.

For more information, see `-I`.

Example: `opts.EnvironmentSettings.IncludeFolders = {'/includes','/com1/inc'};`

Example: `opts.EnvironmentSettings.IncludeFolders = {'C:\project1\common\includes'};`

Data Types: `cell`

### `Includes` — Files to be #include-ed by each C file

cell array of files

Files to be `#include`-ed by each C source file in the analysis, specified by a cell array of files.

For more information, see `Include (-include)`.

Example: `opts.EnvironmentSettings.Includes = {'/inc/inc_file.h','/inc/inc_math.h'}`

### `NoExternC` — Ignore linking errors inside extern blocks

false (default) | true

Ignore linking errors inside extern blocks, specified as true or false.

For more information, see `Ignore link errors (-no-extern-c)`.

Example: `opts.EnvironmentSettings.NoExternC = false;`

### `PostPreProcessingCommand` — Command or script to run on source files after preprocessing

character vector

Command or script to run on source files after preprocessing, specified as a character vector of the command to run.

For more information, see `Command/script to apply to preprocessed files (-post-preprocessing-command)`.

Example: Linux — `opts.EnvironmentSettings.PostPreProcessingCommand = [pwd,'/replace_keyword.pl']`

Example: Windows — `opts.EnvironmentSettings.PostPreProcessingCommand = '"C:\Program Files\MATLAB\R2015b\sys\perl\win32\bin\perl.exe" "C:\My_Scripts\replace_keyword.pl"'`

### `StopWithCompileError` — Stop analysis if a file does not compile

false (default) | true

Stop analysis if a file does not compile, specified as true or false.

For more information, see `Stop analysis if a file does not compile (-stop-if-compile-error)`.

Example: `opts.EnvironmentSettings.StopWithCompileError = true;`

#### InputsStubbing

### `DataRangeSpecifications` — Constrain global variables, function inputs, and return values of stubbed functions

file path

Constrain global variables, function inputs, and return values of stubbed functions specified by the path to an XML constraint file. For more information about the constraint file, see “Specify External Constraints for Polyspace Analysis”.

For more information about this option, see `Constraint setup (-data-range-specifications)`.

Example: `opts.InputsStubbing.DataRangeSpecifications = 'C:\project\constraint_file.xml'`

### `DoNotGenerateResultsFor` — Files on which you do not want analysis results

`'include-folders'` (default) | `'all-headers'` | `'custom=`*`folder1[,folder2,...]`*`'`

Files on which you do not want analysis results, specified by `'include-folders'`, `'all-headers'`, or a character array beginning with `custom=` followed by a comma-separated list of file or folder names.

Use this option with `InputsStubbing.GenerateResultsFor`. For more information, see `Do not generate results for (-do-not-generate-results-for)`.

Example: `opts.InputsStubbing.DoNotGenerateResultsFor = 'custom=C:\project\file1.c,C:\project\file2.c'`

### `GenerateResultsFor` — Files on which you want analysis results

`'source-headers'` (default) | `'all-headers'` | `'custom=`*`folder1[,folder2,...]`*`'`

Files on which you want analysis results, specified by `'source-headers'`, `'all-headers'`, or a character array beginning with `custom=` followed by a comma-separated list of file or folder names.

Use this option with `InputsStubbing.DoNotGenerateResultsFor`. For more information, see `Generate results for sources and (-generate-results-for)`.

Example: `opts.InputsStubbing.GenerateResultsFor = 'custom=C:\project\includes_common_1,C:\project\includes_common_2'`

**`FunctionsToStub` — Functions to stub during analysis**
cell array of function names

*This property affects Code Prover analysis only.*

Functions to stub during analysis, specified as a cell array of function names.

For more information, see `Functions to stub (-functions-to-stub)`.

Example: `opts.InputsStubbing.FunctionsToStub = {'func1', 'func2'}`

**`NoDefInitGlob` — Consider global variables as uninitialized**
false (default) | true

*This property affects Code Prover analysis only.*

Consider global variables as uninitialized, specified as true or false.

For more information, see `Ignore default initialization of global variables (-no-def-init-glob)`.

Example: `opts.InputsStubbing.NoDefInitGlob = true`

**`StubECoderLookupTables` — Specify that the analysis must stub functions in the generated code that use lookup tables**
true (default) | false

*This property applies only to a Code Prover analysis of code generated from models.*

Specify that the analysis must stub functions in the generated code that use lookup tables. By replacing the functions with stubs, the analysis assumes more precise return values for the functions.

For more information, see `Generate stubs for Embedded Coder lookup tables (-stub-embedded-coder-lookup-table-functions)`.

Example: `opts.InputsStubbing.StubECoderLookupTables = true`

#### Macros

**`DefinedMacros` — Macros to be replaced**
cell array of macros

In preprocessed code, macros are replaced by the definition, specified in a cell array of macros and definitions. Specify the macro as `Macro=Value`. If you want Polyspace to ignore the macro, leave the `Value` blank. A macro with no equal sign replaces all instances of that macro by 1.

For more information, see `Preprocessor definitions (-D)`.

Example: `opts.Macros.DefinedMacros = {'uint32=int','name3=','var'}`

### `UndefinedMacros` — Macros to undefine

cell array of macros

In preprocessed code, macros are undefined, specified by a cell array of macros to undefine.

For more information, see `Disabled preprocessor definitions (-U)`.

Example: `opts.Macros.DefinedMacros = {'name1','name2'}`

#### MergedComputingSettings

### `BatchBugFinder` — Send Bug Finder analysis to remote server

false (default) | true

*This property affects Bug Finder analysis only.*

Send Bug Finder analysis to remote server, specified as true or false. To use this option, in your Polyspace preferences, you must specify a metrics server.

For more information, see:

- `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`
- “Run Analysis on Server”

Example: `opts.MergedComputingSettings.BatchBugFinder = true;`

### `BatchCodeProver` — Send Code Prover analysis to remote server

false (default) | true

*This property affects Code Prover analysis only.*

Send Code Prover analysis to remote server, specified as true or false. To use this option, in your Polyspace preferences, you must specify a metrics server.

For more information, see:

- `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`
- “Run Analysis on Server”

Example: `opts.MergedComputingSettings.BatchCodeProver = true;`

### `FastAnalysis` — Run Bug Finder analysis using faster local mode

false (default) | true

*This property affects Bug Finder analysis only.*

Use fast analysis mode for Bug Finder analysis, specified as true or false.

For more information, see `Use fast analysis mode for Bug Finder (-fast-analysis)`.

Example: `opts.MergedComputingSettings.FastAnalysis = true;`

#### MergedReporting

### `EnableReportGeneration` — Generate a report after the analysis

false (default) | true

After the analysis, generate a report, specified as true or false.

For more information, see `Generate report`.

Example: `opts.MergedReporting.EnableReportGeneration = true`

**`ReportOutputFormat` — Output format of generated report**
`'Word'` (default) | `'HTML'` | `'PDF'`

Output format of generated report, specified as one of the report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Output format (-report-output-format)`.

Example: `opts.MergedReporting.ReportOutputFormat = 'PDF'`

**`BugFinderReportTemplate` — Template for generating Bug Finder analysis report**
`'BugFinderSummary'` (default) | `'BugFinder'` | `'SecurityCWE'` | `'CodeMetrics'` | `'CodingStandards'`

*This property affects a Bug Finder analysis only.*

Template for generating analysis report, specified as one of the report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Bug Finder and Code Prover report (-report-template)`.

Example: `opts.MergedReporting.BugFinderReportTemplate = 'CodeMetrics'`

**`CodeProverReportTemplate` — Template for generating Code Prover analysis report**
`'Developer'` (default) | `'CallHierarchy'` | `'CodeMetrics'` | `'CodingStandards'` | `'DeveloperReview'` | `'Developer_withGreenChecks'` | `'Quality'` | `'VariableAccess'`

*This property affects a Code Prover analysis only.*

Template for generating analysis report, specified as one of the predefined report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Bug Finder and Code Prover report (-report-template)`.

Example: `opts.MergedReporting.CodeProverReportTemplate = 'CodeMetrics'`

#### Multitasking

**`ArxmlMultitasking` — Specify path of ARXML files to parse for multitasking configuration**
cell array of file paths

Specify the path to the ARXML files the software parses to set up your multitasking configuration.

To activate this option, specify `Multitasking.EnableExternalMultitasking` and set `Multitasking.ExternalMultitaskingType` to `autosar`.

For more information, see `ARXML files selection (-autosar-multitasking)`

Example: `opts.Multitasking.ArxmlMultitasking={'C:\Polyspace_Workspace\AUTOSAR\myFile.arxml'}`

### `CriticalSectionBegin` — Functions that begin critical sections

cell array of critical section function names

Functions that begin critical sections specified as a cell array of critical section function names. To activate this option, specify `Multitasking.EnableMultitasking` and `Multitasking.CriticalSectionEnd`.

For more information, see `Critical section details (-critical-section-begin -critical-section-end)`.

Example: `opts.Multitasking.CriticalSectionBegin = {'function1:cs1','function2:cs2'}`

### `CriticalSectionEnd` — Functions that end critical sections

cell array of critical section function names

Functions that end critical sections specified as a cell array of critical section function names. To activate this option, specify `Multitasking.EnableMultitasking` and `Multitasking.CriticalSectionBegin`.

For more information, see `Critical section details (-critical-section-begin -critical-section-end)`.

Example: `opts.Multitasking.CriticalSectionEnd = {'function1:cs1','function2:cs2'}`

### `CyclicTasks` — Specify functions that represent cyclic tasks

cell array of function names

Specify functions that represent cyclic tasks.

To activate this option, also specify `Multitasking.EnableMultitasking`.

For more information, see `Cyclic tasks (-cyclic-tasks)`.

Example: `opts.Multitasking.CyclicTasks = {'function1','function2'}`

### `EnableConcurrencyDetection` — Enable automatic detection of certain families of threading functions

false (default) | true

*This property affects Code Prover analysis only.*

Enable automatic detection of certain families of threading functions, specified as true or false.

For more information, see `Enable automatic concurrency detection for Code Prover (-enable-concurrency-detection)`.

Example: `opts.Multitasking.EnableConcurrencyDetection = true`

### `EnableExternalMultitasking` — Enable automatic multitasking configuration from external file definitions

false (default) | true

Enable multitasking configuration of your projects from external files you provide. Configure multitasking from ARXML files for an AUTOSAR project, or from OIL files for an OSEK project.

Activate this option to enable `Multitasking.ArxmlMultitasking` or `Multitasking.OsekMultitasking`.

For more information, see `OIL files selection (-osek-multitasking)` and `ARXML files selection (-autosar-multitasking)`.

Example: `opts.Multitasking.EnableExternalMultitasking = 1`

**`EnableMultitasking` — Configure multitasking manually**
false (default) | true

Configure multitasking manually by specifying `true`. This property activates the other manual, multitasking properties.

For more information, see `Configure multitasking manually`.

Example: `opts.Multitasking.EnableMultitasking = 1`

**`EntryPoints` — Functions that serve as entry-points to your multitasking application**
cell array of entry-point function names

Functions that serve as entry-points to your multitasking application specified as a cell array of entry-point function names. To activate this option, also specify `Multitasking.EnableMultitasking`.

For more information, see `Tasks (-entry-points)`.

Example: `opts.Multitasking.EntryPoints = {'function1','function2'}`

**`ExternalMultitaskingType` — Specify type of file to parse for multitasking configuration**
`'osek'` (default) | `'autosar'`

Specify the type of file the software parses to set up your multitasking configuration:

- For `osek` type, the analysis looks for OIL files in the file or folder paths that you specify.
- For `autosar` type, the analysis looks for ARXML files in the file paths that you specify.

To activate this option, specify `Multitasking.EnableExternalMultitasking`.

For more information, see `OIL files selection (-osek-multitasking)` and `ARXML files selection (-autosar-multitasking)`.

Example: `opts.Multitasking.ExternalMultitaskingType = 'autosar'`

**`Interrupts` — Specify functions that represent nonpreemptable interrupts**
cell array of function names

Specify functions that represent nonpreemptable interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Interrupts (-interrupts)`.

Example: `opts.Multitasking.Interrupts = {'function1','function2'}`

**`InterruptsDisableAll` — Specify routine that disable interrupts**
cell array with one function name

*This property affects Bug Finder analysis only.*

Specify function that disables all interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Example: `opts.Multitasking.InterruptsDisableAll = {'function'}`

### `InterruptsEnableAll` — Specify routine that reenable interrupts

cell array with one function name

*This property affects Bug Finder analysis only.*

Specify function that reenables all interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Example: `opts.Multitasking.InterruptsEnableAll = {'function'}`

### `OsekMultitasking` — Specify path of OIL files to parse for multitasking configuration

`'auto'` (default) | `'custom=`*`folder1[,folder2,...]`*`'`

Specify the path to the OIL files the software parses to set up your multitasking configuration:

- In the mode specified with `'auto'`, the analysis uses OIL files in your project source and include folders, but not their subfolders.
- In the mode specified with `'custom=`*`folder1[,folder2,...]`*`'`, the analysis uses the OIL files at the specified path, and the path subfolders.

To activate this option, specify `Multitasking.EnableExternalMultitasking` and set `Multitasking.ExternalMultitaskingType` to `osek`.

For more information, see `OIL files selection (-osek-multitasking)`

Example: `opts.Multitasking.OsekMultitasking = 'custom=file_path, dir_path'`

### `TemporalExclusion` — Entry-point functions that cannot execute concurrently

cell array of entry-point function names

Entry-point functions that cannot execute concurrently specified as a cell array of entry-point function names. Each set of exclusive tasks is one cell array entry with functions separated by spaces. To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Temporally exclusive tasks (-temporal-exclusions-file)`.

Example: `opts.Multitasking.TemporalExclusion = {'function1 function2', 'function3 function4 function5'}` where function1 and function2 are temporally exclusive, and function3, function4, and function 5 are temporally exclusive.

**Precision (Affects Code Prover Only)**

**`ContextSensitivity` — Store call context information to identify function call that caused errors**
`'none'` (default) | `'auto'` | `'custom=`*`function1[,function2,...]`*`'`

*This property affects Code Prover analysis only.*

Store call context information to identify a function call that caused errors, specified as `none`, `auto`, or as a character array beginning with `custom=` followed by a list of comma-separated function names.

For more information, see `Sensitivity context (-context-sensitivity)`.

Example: `opts.Precision.ContextSensitivity = 'auto'`

Example: `opts.Precision.ContextSensitivity = 'custom=func1'`

**`ModulesPrecision` — Source files you want to verify at higher precision**
cell array of file names and precision levels

*This property affects Code Prover analysis only.*

Source files that you want to verify at higher precision, specified as a cell array of file names without the extension and precision levels using this syntax: *`filename`*`:O`*`level`*

For more information, see `Specific precision (-modules-precision)`.

Example: `opts.Precision.ModulesPrecision = {'file1:O0', 'file2:O3'}`

**`OLevel` — Precision level for the verification**
2 (default) | 0 | 1 | 3

*This property affects Code Prover analysis only.*

Precision level for the verification, specified as 0, 1, 2, or 3.

For more information, see `Precision level (-O)`.

Example: `opts.Precision.OLevel = 3`

**`PathSensitivityDelta` — Avoid certain verification approximations for code with fewer lines**
positive integer

*This property affects Code Prover analysis only.*

Avoid certain verification approximations for code with fewer lines, specified as a positive integer representing how sensitive the analysis is. Higher values can increase verification time exponentially.

For more information, see `Improve precision of interprocedural analysis (-path-sensitivity-delta)`.

Example: `opts.Precision.PathSensitivityDelta = 2`

**`Timeout` — Time limit on your verification**
character vector

*This property affects Code Prover analysis only.*

Time limit on your verification, specified as a character vector of time in hours.

For more information, see `Verification time limit (-timeout)`.

Example: `opts.Precision.Timeout = '5.75'`

### `To` — Number of times the verification process runs

`'Software Safety Analysis level 2'` (default) | `'Software Safety Analysis level 0'` | `'Software Safety Analysis level 1'` | `'Software Safety Analysis level 3'` | `'Software Safety Analysis level 4'` | `'Source Compliance Checking'` | `'other'`

*This property affects Code Prover analysis only.*

Number of times the verification process runs, specified as one of the preset analysis levels.

For more information, see `Verification level (-to)`.

Example: `opts.Precision.To = 'Software Safety Analysis level 3'`

#### Scaling (Affects Code Prover Only)

### `Inline` — Functions on which separate results must be generated for each function call

cell array of function names

*This property affects Code Prover analysis only.*

Functions on which separate results must be generated for each function call, specified as a cell array of function names.

For more information, see `Inline (-inline)`.

Example: `opts.Scaling.Inline = {'func1','func2'}`

### `KLimiting` — Limit depth of analysis for nested structures

positive integer

*This property affects Code Prover analysis only.*

Limit depth of analysis for nested structures, specified as a positive integer indicating how many levels into a nested structure to verify.

For more information, see `Depth of verification inside structures (-k-limiting)`.

Example: `opts.Scaling.KLimiting = 3`

#### TargetCompiler

### `Compiler` — Compiler that builds your source code

`'generic'` (default) | `'gnu3.4'` | `'gnu4.6'` | `'gnu4.7'` | `'gnu4.8'` | `'gnu4.9'` | `'gnu5.x'` | `'gnu6.x'` | `'gnu7.x'` | `'clang3.x'` | `'clang4.x'` | `'clang5.x'` | `'visual9.0'` | `'visual10'` | `'visual11.0'` | `'visual12.0'` | `'visual14.0'` | `'visual15.x'` | `'keil'` | `'iar'` | `'armcc'` | `'armclang'` | `'codewarrior'` | `'diab'` | `'greenhills'` | `'iar-ew'` | `'renesas'` | `'tasking'` | `'ti'`

Compiler that builds your source code.

For more information, see `Compiler (-compiler)`.

Example: `opts.TargetCompiler.Compiler = 'Visual11.0'`

### `CppVersion` — Specify C++ standard version followed in code

`'defined-by-compiler'` (default) | `'cpp03'` | `'cpp11'` | `'cpp14'` | `'cpp17'`

Specify C++ standard version followed in code, specified as a character vector.

For more information, see `C++ standard version (-cpp-version)`.

Example: `opts.TargetCompiler.CppVersion = 'cpp11';`

### `CVersion` — Specify C standard version followed in code

`'defined-by-compiler'` (default) | `'c90'` | `'c99'` | `'c11'`

Specify C standard version followed in code, specified as a character vector.

For more information, see `C standard version (-c-version)`.

Example: `opts.TargetCompiler.CVersion = 'c90';`

### `DivRoundDown` — Round down quotients from division or modulus of negative numbers

false (default) | true

Round down quotients from division or modulus of negative numbers, specified as true or false.

For more information, see `Division round down (-div-round-down)`.

Example: `opts.TargetCompiler.DivRoundDown = true`

### `EnumTypeDefinition` — Base type representation of enum

`'defined-by-compiler'` (default) | `'auto-signed-first'` | `'auto-unsigned-first'`

Base type representation of enum, specified by an allowed base-type set. For more information about the different values, see `Enum type definition (-enum-type-definition)`.

Example: `opts.TargetCompiler.EnumTypeDefinition = 'auto-unsigned-first'`

### `IgnorePragmaPack` — Ignore #pragma pack directives

false (default) | true

Ignore #pragma pack directives, specified as true or false.

For more information, see `Ignore pragma pack directives (-ignore-pragma-pack)`.

Example: `opts.TargetCompiler.IgnorePragmaPack = true`

### `Language` — Language of analysis

`'C-CPP'` (default) | `'C'` | `'CPP'`

This property is read-only.

Language of the analysis, specified during the object construction. This value changes which properties appear.

For more information, see `Source code language (-lang)`.

**LogicalSignedRightShift — Treatment of signed bit on signed variables**
'Arithmetical' (default) | 'Logical'

Treatment of signed bit on signed variables, specified as Arithmetical or Logical. For more information, see Signed right shift (-logical-signed-right-shift).

Example: opts.TargetCompiler.LogicalSignedRightShift = 'Logical'

**NoUliterals — Do not use predefined typedefs for char16_t or char32_t**
false (default) | true

Do not use predefined typedefs for char16_t or char32_t, specified as true or false. For more information, see Block char16/32_t types (-no-uliterals).

Example: opts.TargetCompiler.NoUliterals = true

**PackAlignmentValue — Default structure packing alignment**
'defined-by-compiler' (default) | '1' | '2' | '4' | '8' | '16'

Default structure packing alignment, specified as 'defined-by-compiler', '1', '2', '4', '8', or '16'. This property is available only for Visual C++ code.

For more information, see Pack alignment value (-pack-alignment-value).

Example: opts.TargetCompiler.PackAlignmentValue = '4'

**SfrTypes — sfr types**
cell array of sfr keywords

sfr types, specified as a cell array of sfr keywords using the syntax *sfr_name=size_in_bits*. For more information, see Sfr type support (-sfr-types).

This option only applies when you set TargetCompiler.Compiler to keil or iar.

Example: opts.TargetCompiler.SfrTypes = {'sfr32=32'}

**SizeTTypeIs — Underlying type of size_t**
'defined-by-compiler' (default) | 'unsigned-int' | 'unsigned-long' | 'unsigned-long-long'

Underlying type of size_t, specified as 'defined-by-compiler', 'unsigned-int', 'unsigned-long', or 'unsigned-long-long'. See Management of size_t (-size-t-type-is).

Example: opts.TargetCompiler.SizeTTypeIs = 'unsigned-long'

**Target — Target processor**
'i386' (default) | 'arm' | 'arm64' | 'avr' | 'c-167' | 'c166' | 'c18' | 'c28x' | 'c6000' | 'coldfire' | 'hc08' | 'hc12' | 'm68k' | 'mcore' | 'mips' | 'mpc5xx' | 'msp430' | 'necv850' | 'powerpc' | 'powerpc64' | 'rh850' | 'rl78' | 'rx' | 's12z' | 'sharc21x61' | 'sparc' | 'superh' | 'tms320c3x' | 'tricore' | 'x86_64' | generic target object

Set size of data types and endianness of processor, specified as one of the predefined target processors or a generic target object.

For more information about the predefined processors, see Target processor type (-target).

For more information about creating a generic target, see polyspace.GenericTargetOptions.

Example: `opts.TargetCompiler.Target = 'hc12'`

**`WcharTTypeIs` — Underlying type of `wchar_t`**
`'defined-by-compiler'` (default) | `'signed-short'` | `'unsigned-short'` | `'signed-int'` | `'unsigned-int'` | `'signed-long'` | `'unsigned-long'`

Underlying type of `wchar_t`, specified as `'defined-by-compiler'`, `'signed-short'`, `'unsigned-short'`, `'signed-int'`, `'unsigned-int'`, `'signed-long'`, or `'unsigned-long'`. See `Management of wchar_t (-wchar-t-type-is)`.

Example: `opts.TargetCompiler.WcharTTypeIs = 'unsigned-int'`

**VerificationAssumption (Affects Code Prover Only)**

**`ConsiderVolatileQualifierOnFields` — Assume that volatile qualified structure fields can have all possible values at any point in code**
false (default) | true

*This property affects Code Prover analysis only.*

Assume that volatile qualified structure fields can have all possible values at any point in code.

For more information, see `Consider volatile qualifier on fields (-consider-volatile-qualifier-on-fields)`.

Example: `opts.VerificationAssumption.ConsiderVolatileQualifierOnFields = true`

**`ConstraintPointersMayBeNull` — Specify that environment pointers can be NULL unless constrained otherwise**
false (default) | true

*This property affects Code Prover analysis only.*

Specify that environment pointers can be NULL unless constrained otherwise.

For more information, see `Consider environment pointers as unsafe (-stubbed-pointers-are-unsafe)`.

Example: `opts.VerificationAssumption.ConstraintPointersMayBeNull = true`

**`FloatRoundingMode` — Rounding modes to consider when determining the results of floating-point arithmetic**
`to-nearest` (default) | `all`

*This property affects Code Prover analysis only.*

Rounding modes to consider when determining the results of floating-point arithmetic, specified as `to-nearest` or `all`.

For more information, see `Float rounding mode (-float-rounding-mode)`.

Example: `opts.VerificationAssumption.FloatRoundingMode = 'all'`

**Other Properties**

**`Author` — Project author**
username of current user (default) | character vector

Name of project author, specified as a character vector.

For more information, see `-author`.

Example: `opts.Author = 'JaneDoe'`

### `ImportComments` — Import comments and justifications from previous analysis

character vector

To import comments and justifications from a previous analysis, specify the path to the results folder of the previous analysis.

You can also point to a previous results folder to see only new results compared to the previous run. See “Compare Results from Different Polyspace Runs by Using MATLAB Scripts”.

For more information, see `-import-comments`

Example: `opts.ImportComments = fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example','Module_1','BF_Result')`

### `Prog` — Project name

`PolyspaceProject` (default) | character vector

Project name, specified as a character vector.

For more information, see `-prog`.

Example: `opts.Prog = 'myProject'`

### `ResultsDir` — Location to store results

folder path

Location to store results, specified as a folder path. By default, the results are stored in the current folder.

For more information, see `-results-dir`.

You can also create a separate results folder for each new run. See “Compare Results from Different Polyspace Runs by Using MATLAB Scripts”.

Example: `opts.ResultsDir = 'C:\project\myproject\results\'`

### `Sources` — Source files

cell array of files

Source files to analyze, specified as a cell array of files.

To specify all files in a folder, use folder path followed by `*`, for instance, `'C:\src\*'`. To specify all files in a folder and its subfolders, use folder path followed by `**`, for instance, `'C:\src\**'`. The notation follows the syntax of the `dir` function. See also “Specify Multiple Source Files”.

For more information, see `-sources`.

Example: `opts.Sources = {'file1.c', 'file2.c', 'file3.c'}`

Example: `opts.Sources = {'project/src1/file1.c', 'project/src2/file2.c', 'project/src3/file3.c'}`

### `Version` — Project version number

`'1.0'` (default) | character array of a number

Version number of project, specified as a character array of a number. This option is useful if you upload your results to Polyspace Metrics. If you increment version numbers each time that you reanalyze your object, you can compare the results from two versions in Polyspace Metrics.

For more information, see `-v[ersion]`.

Example: `opts.Version = '2.3'`

## Version History

**Introduced in R2017a**

### R2023a: `CheckersPreset` option value `CWE` is removed

*Not recommended starting in R2023a*

The option to select the CWE subset of Polyspace Bug Finder defect checkers is removed. To check your code for compliance with the CWE standard, use these properties instead:

```
opts=polyspace.Options;
opts.CodingRulesCodeMetrics.EnableCwe=1
opts.CodingRulesCodeMetrics.Cwe='all';
```

See also `Check CWE (-cwe)`.

### R2021b: Automatic Orange Tester is removed

*Not recommended starting in R2021b*

The Automatic Orange Tester is removed. If you use these properties in your scripts, remove them (`opts=polyspace.Options('C')`):

- `opts.Advanced.AutomaticOrangeTester`
- `opts.Advanced.AutomaticOrangeTesterLoopMaxIteration`
- `opts.Advanced.AutomaticOrangeTesterTestsNumber`
- `opts.Advanced.AutomaticOrangeTesterTimeout`

"Complete List of Polyspace Bug Finder Analysis Engine Options"

# polyspace.ModelLinkOptions Properties

Customize Polyspace analysis of generated code with options object properties

## Description

To customize your Polyspace analysis of generated code, modify the `polyspace.ModelLinkOptions` object properties. Each property corresponds to an analysis option on the **Configuration** pane in the Polyspace user interface.

The properties are grouped using the same categories as the **Configuration** pane. This page only shows what values each property can take. For details about:

- The different options, see the analysis options reference pages.
- How to create and use the object, see `polyspace.ModelLinkOptions`.

  The same properties are also available with the deprecated classes `polyspace.ModelLinkBugFinderOptions` and `polyspace.ModelLinkCodeProverOptions`.

Each property description below also highlights if the option affects only one of Bug Finder or Code Prover.

**Note** Some options might not be available depending on the language setting of the object. You can set the source code language (`Language`) to `'C'`, `'CPP'` or `'C-CPP'` during object creation, but cannot change it later.

### Properties

**Advanced**

**`Additional` — Additional flags for analysis**
character vector

Additional flags for analysis specified as a character vector.

For more information, see `Other`.

Example: `opts.Advanced.Additional = '-extra-flags -option -extra-flags value'`

**`PostAnalysisCommand` — Command or script software should execute after analysis finishes**
character vector

Command or script software should execute after analysis finishes, specified as a character vector.

For more information, see `Command/script to apply after the end of the code verification (-post-analysis-command)`.

Example: `opts.Advanced.PostAnalysisCommand = '"C:\Program Files\perl\win32\bin\perl.exe" "C:\My_Scripts\send_email"'`

#### BugFinderAnalysis (Affects Bug Finder Only)

### `CheckersList` — List of custom checkers to activate

`polyspace.DefectsOptions` object | cell array of defect acronyms

*This property affects Bug Finder analysis only.*

List of custom checkers to activate specified by using the name of a `polyspace.DefectsOptions` object or a cell array of defect acronyms. To use this custom list in your analysis, set `CheckersPreset` to `custom`.

For more information, see `polyspace.DefectsOptionspolyspace.DefectsOptions`.

Example: `defects = polyspace.DefectsOptions; opts.BugFinderAnalysis.CheckersList = defects`

Example: `opts.BugFinderAnalysis.CheckersList = {'INT_ZERO_DIV','FLOAT_ZERO_DIV'}`

### `CheckersPreset` — Subset of Bug Finder defects

`'default'` (default) | `'all'` | `'custom'`

*This property affects Bug Finder analysis only.*

Preset checker list, specified as a character vector of one of the preset options: `'default'`, `'all'`,or `'custom'`. To use `'custom'`, specify a value for the property `BugFinderAnalysis.CheckersList`.

For more information, see `Find defects (-checkers)`.

Example: `opts.BugFinderAnalysis.CheckersPreset = 'all'`

### `ChecksUsingSystemInputValues` — Activate stricter checks for system inputs

false (default) | true

*This property affects Bug Finder analysis only.*

Activate stricter checks that consider all possible value for:

- Global variables.
- Reads of volatile variables.
- Returns of stubbed functions.
- Inputs to functions specified with **SystemInputsFrom**.

The analysis considers all possible values for a subset of **Numerical** and **Static memory** defects.

This property is equivalent to the **Run stricter checks considering all values of system inputs** check box in the Polyspace interface.

For more information, see `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

Example: `opts.BugFinderAnalysis.ChecksUsingSystemInputValues = true`

### `EnableCheckers` — Activate defect checking

true (default) | false

*This property affects Bug Finder analysis only.*

Activate defect checking, specified as true or false. Setting this property to false disables all defects. If you want to disable defect checking but still get results, turn on coding rules checking or code metric checking.

This property is equivalent to the **Find defects** check box in the Polyspace interface.

Example: `opts.BugFinderAnalysis.EnableCheckers = false`

### `SystemInputsFrom` — List of functions for which you run stricter checks

`'auto'` (default) | `'uncalled'` | `'all'` | `'custom'`

*This property affects Bug Finder analysis only.*

Functions for which you want to run stricter checks that consider all possible values of the function inputs. Specify the list of functions as `'auto'`, `'uncalled'`, `'all'`, or as a character array beginning with `custom=` followed by a comma-separated list of function names.

To enable this option, set `BugFinderAnalysis.ChecksUsingSystemInputValues = true`.

For more information, see `Consider inputs to these functions (-system-inputs-from)`.

Example: `opts.BugFinderAnalysis.SystemInputsFrom = 'custom=foo,bar'`

#### ChecksAssumption (Affects Code Prover Only)

### `AllowNegativeOperandInShift` — Allow left shift operations on a negative number

true (default) | false

*This property affects Code Prover analysis only.*

Allow left shift operations on a negative number, specified as true or false.

For more information, see `Allow negative operand for left shifts (-allow-negative-operand-in-shift)`.

Example: `opts.ChecksAssumption.AllowNegativeOperandInShift = true`

### `AllowNonFiniteFloats` — Incorporate infinities and/or NaNs

false (default) | true

*This property affects Code Prover analysis only.*

Incorporate infinities and/or NaNs, specified as true or false.

For more information, see `Consider non finite floats (-allow-non-finite-floats)`.

Example: `opts.ChecksAssumption.AllowNonFiniteFloats = true`

### `AllowPtrArithOnStruct` — Allow arithmetic on pointer to a structure field so that it points to another field

false (default) | true

*This property affects Code Prover analysis only.*

Allow arithmetic on pointer to a structure field so that it points to another field, specified as true or false.

For more information, see `Enable pointer arithmetic across fields (-allow-ptr-arith-on-struct)`.

Example: `opts.ChecksAssumption.AllowPtrArithOnStruct = true`

**`CheckInfinite` — Detect floating-point operations that result in infinities**
`'allow'` (default) | `'warn-first'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect floating-point operations that result in infinities.

To activate this option, specify `ChecksAssumption.AllowNonFiniteFloats`.

For more information, see `Infinities (-check-infinite)`.

Example: `opts.ChecksAssumption.CheckInfinite = 'forbid'`

**`CheckNan` — Detect floating-point operations that result in NaN-s**
`'allow'` (default) | `'warn-first'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect floating-point operations that result in NaN-s.

To activate this option, specify `ChecksAssumption.AllowNonFiniteFloats`.

For more information, see `NaNs (-check-nan)`.

Example: `opts.ChecksAssumption.CheckNan = 'forbid'`

**`CheckSubnormal` — Detect operations that result in subnormal floating point values**
`'allow'` (default) | `'warn-first'` | `'warn-all'` | `'forbid'`

*This property affects Code Prover analysis only.*

Detect operations that result in subnormal floating point values.

For more information, see `Subnormal detection mode (-check-subnormal)`.

Example: `opts.ChecksAssumption.CheckSubnormal = 'forbid'`

**`DetectPointerEscape` — Find cases where a function returns a pointer to one of its local variables**
false (default) | true

*This property affects Code Prover analysis only.*

Find cases where a function returns a pointer to one of its local variables, specified as true or false.

For more information, see `Detect stack pointer dereference outside scope (-detect-pointer-escape)`.

Example: `opts.ChecksAssumption.DetectPointerEscape = true`

**`DisableInitializationChecks` — Disable checks for noninitialized variables and pointers**
false (default) | true

*This property affects Code Prover analysis only.*

Disable checks for noninitialized variables and pointers, specified as true or false.

For more information, see `Disable checks for non-initialization (-disable-initialization-checks)`.

Example: `opts.ChecksAssumption.DisableInitializationChecks = true`

### `PermissiveFunctionPointer` — Allow type mismatch between function pointers and the functions they point to

false (default) | true

*This property affects Code Prover analysis only.*

Allow type mismatch between function pointers and the functions they point to, specified as true or false.

For more information, see `Permissive function pointer calls (-permissive-function-pointer)`.

Example: `opts.ChecksAssumption.PermissiveFunctionPointer = true`

### `SignedIntegerOverflows` — Behavior of signed integer overflows

`'warn-with-wrap-around'` (default) | `'forbid'` | `'allow'`

*This property affects Code Prover analysis only.*

Enable the check for signed integer overflows and the assumptions to make following an overflow specified as `'forbid'`, `'allow'`, or `'warn-with-wrap-around'`.

For more information, see `Overflow mode for signed integer (-signed-integer-overflows)`.

Example: `opts.ChecksAssumption.SignedIntegerOverflows = 'warn-with-wrap-around'`

### `SizeInBytes` — Allow a pointer with insufficient memory buffer to point to a structure

false (default) | true

*This property affects Code Prover analysis only.*

Allow a pointer with insufficient memory buffer to point to a structure, specified as true or false.

For more information, see `Allow incomplete or partial allocation of structures (-size-in-bytes)`.

Example: `opts.ChecksAssumption.SizeInBytes = true`

### `UncalledFunctionCheck` — Detect functions that are not called directly or indirectly from main or another entry-point function

`'none'` (default) | `'never-called'` | `'called-from-unreachable'` | `'all'`

*This property affects Code Prover analysis only.*

Detect functions that are not called directly or indirectly from main or another entry-point function, specified as `'none'`, `'never-called'`, `'called-from-unreachable'`, or `'all'`.

For more information, see `Detect uncalled functions (-uncalled-function-checks)`.

Example: `opts.ChecksAssumption.UncalledFunctionCheck = 'all'`

### `UnsignedIntegerOverflows` — Behavior of unsigned integer overflows

`'allow'` (default) | `'forbid'` | `'warn-with-wrap-around'`

*This property affects Code Prover analysis only.*

Enable the check for unsigned integer overflows and the assumptions to make following an overflow, specified as `'forbid'`, `'allow'`, or `'warn-with-wrap-around'`.

For more information, see `Overflow mode for unsigned integer (-unsigned-integer-overflows)`.

Example: `opts.ChecksAssumption.UnsignedIntegerOverflows = 'allow'`

#### CodeProverVerification (Affects Code Prover only)

### `ClassAnalyzer` — Classes that you want to verify

`'none'` (default) | `'all'` | `'custom=`*`class1[,class2,...]`*`'`

*This property affects Code Prover analysis only.*

Classes that you want to verify, specified as `'all'`, `'none'`, or as a character array beginning with `custom=` followed by a comma-separated list of class names.

For more information, see `Class (-class-analyzer)`.

Example: `opts.CodeProverVerification.ClassAnalyzer = 'none'`

### `FunctionsCalledAfterLoop` — Functions that the generated main must call after the cyclic code loop

cell array of function names

*This property affects Code Prover analysis only.*

Functions that the generated main must call after the cyclic code loop, specified as a cell array of function names.

For more information, see `Termination functions (-functions-called-after-loop)`.

Example: `opts.CodeProverVerification.FunctionsCalledAfterLoop = {'func1','func2'}`

### `FunctionsCalledBeforeLoop` — Functions that the generated main must call before the cyclic code loop

cell array of function names

*This property affects Code Prover analysis only.*

Model Link only. Functions that the generated main must call before the cyclic code loop, specified as a cell array of function names.

For more information, see `Initialization functions (-functions-called-before-loop))`.

Example: `opts.CodeProverVerification.FunctionsCalledBeforeLoop = {'func1','func2'}`

### `FunctionsCalledInLoop` — Functions that the generated main must call in the cyclic code loop

`'none'` (default) | `'all'` | `'custom=`*`function1[,function2,...]`*`'`

*This property affects Code Prover analysis only.*

Functions that the generated main must call in the cyclic code loop, specified as `'none'`, `'all'`, or as a character array beginning with `custom=` followed by a comma-separated list of function names..

For more information, see `Step functions (-functions-called-in-loop)`.

Example: `opts.CodeProverVerification.FunctionsCalledInLoop = 'all'`

### `MainGenerator` — Generate a main function if it is not present in source files

true (default) | false

*This property affects Code Prover analysis only.*

Generate a main function if it is not present in source files, specified as true or false.

For more information, see `Verify module or library (-main-generator)`.

Example: `opts.CodeProverVerification.MainGenerator = false`

### `VariablesWrittenBeforeLoop` — Variables that the generated main must initialize before the cyclic code loop

`'none'` (default) | `'all'` | `'custom=`*`variable1[,variable2,...]`*`'`

*This property affects Code Prover analysis only.*

Variables that the generated main must initialize before the cyclic code loop, specified as `'none'`, `'all'`, or as a character array beginning with `custom=` followed by a comma-separated list of variable names.

For more information, see `Parameters (-variables-written-before-loop)`.

Example: `opts.CodeProverVerification.VariablesWrittenBeforeLoop = 'all'`

### `VariablesWrittenInLoop` — Variables that the generated main must initialize in the cyclic code loop

`'none'` (default) | `'all'` | `'custom=`*`variable1[,variable2,...]`*`'`

*This property affects Code Prover analysis only.*

Variables that the generated main must initialize in the cyclic code loop, specified as `'none'`, `'all'`, or as a character array beginning with `custom=` followed by a comma-separated list of variable names.

For more information, see `Inputs (-variables-written-in-loop)`.

Example: `opts.CodeProverVerification.VariablesWrittenInLoop = 'all'`

#### CodingRulesCodeMetrics

### `AcAgcSubset` — Subset of MISRA AC AGC rules to check

`'OBL-rules'` (default) | `'OBL-REC-rules'` | `'single-unit-rules'` | `'system-decidable-rules'` | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA AC AGC rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA AC AGC (-misra-ac-agc)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA AC AGC rules, also set `EnableAcAgc` to true.

Example: `opts.CodingRulesCodeMetrics.AcAgcSubset = 'all-rules'`

Data Types: `char`

### `AllowedPragmas` — Pragma directives for which MISRA C:2004 rule 3.4 or MISRA C++ 16-6-1 must not be applied

cell array of character vectors

Pragma directives for which MISRA C:2004 rule 3.4 or MISRA C++ 16-6-1 must not be applied, specified as a cell array of character vectors. This property affects only MISRA C:2004 or MISRA AC AGC rule checking.

For more information, see `Allowed pragmas (-allowed-pragmas)`.

Example: `opts.CodingRulesCodeMetrics.AllowedPragmas = {'pragma_01','pragma_02'}`

Data Types: `cell`

### `AutosarCpp14` — Set of AUTOSAR C++ 14 rules to check

`'all'` (default) | `'required'` | `'automated'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of AUTOSAR C++ 14 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check AUTOSAR C++ 14 security checks (-autosar-cpp14)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check AUTOSAR C++ 14 rules, also set `EnableAutosarCpp14` to true.

Example: `opts.CodingRulesCodeMetrics.AutosarCpp14 = 'all'`

Data Types: `char`

**`BooleanTypes` — Data types the coding rule checker must treat as effectively Boolean**
cell array of character vectors

Data types that the coding rule checker must treat as effectively Boolean, specified as a cell array of character vectors.

For more information, see `Effective boolean types (-boolean-types)`.

Example: `opts.CodingRulesCodeMetrics.BooleanTypes = {'boolean1_t','boolean2_t'}`

Data Types: `cell`

**`CertC` — Set of CERT C rules and recommendations to check**
`'all'` (default) | `'publish-2016'` | `'all-rules'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of CERT C rules and recommendations to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CERT-C security checks (-cert-c)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `from-file` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See "Check for and Review Coding Standard Violations". If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C rules and recommendations, also set `EnableCertC` to true.

Example: `opts.CodingRulesCodeMetrics.CertC = 'all'`

Data Types: `char`

**`CertCpp` — Set of CERT C++ rules to check**
`'all'` (default) | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of CERT C++ rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CERT-C++ security checks (-cert-cpp)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.

- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C++ rules, also set `EnableCertCpp` to true.

Example: `opts.CodingRulesCodeMetrics.CertCpp = 'all'`

Data Types: `char`

### `CheckersSelectionByFile` — File that defines custom set of coding standard checkers

full file path of `.xml` file

File where you define a custom set of coding standards checkers to check, specified as a `.xml` file. You can, in the same file, define a custom set of checkers for each of the coding standards that Polyspace supports. To create a file that defines a custom selection of coding standard checkers, in the Polyspace interface, select a coding standard on the **Coding Standards & Code Metrics** node of the **Configuration** pane and click **Edit**.

For more information, see `Set checkers by file (-checkers-selection-file)`.

Example: `opts.CodingRulesCodeMetrics.CheckersSelectionByFile = 'C:\ps_settings\coding_rules\custom_rules.xml'`

Data Types: `char`

### `CodeMetrics` — Activate code metric calculations

false (default) | true

Activate code metric calculations, specified as true or false. If this property is turned off, Polyspace does not calculate code metrics even if you upload your results to Polyspace Metrics.

For more information about the code metrics, see `Calculate code metrics (-code-metrics)`.

If you assign a coding rules options object to this property, an XML file gets created automatically with the rules specified.

Example: `opts.CodingRulesCodeMetrics.CodeMetrics = true`

### `Cwe` — Set of CWE rules to check

`'all'` (default) | `'cwe-658-659'` | `'from-file'` | `polyspace.CodingRulesOptions` object

*This property affects Bug Finder only.*

Set of CWE rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check CWE (-cwe)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.

- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check CERT C++ rules, also set `EnableCwe` to true.

Example: `opts.CodingRulesCodeMetrics.Cwe = 'cwe-658-659'`

Data Types: `char`

### `EnableAcAgc` — Check MISRA AC AGC rules

false (default) | true

Check MISRA AC AGC rules, specified as true or false. To customize which rules are checked, use `AcAgcSubset`.

For more information about the MISRA AC AGC checker, see `Check MISRA AC AGC (-misra-ac-agc)`.

Example: `opts.CodingRulesCodeMetrics.EnableAcAgc = true;`

### `EnableAutosarCpp14` — Check AUTOSAR C++ 14 rules

false (default) | true

*This property affects Bug Finder only.*

Check AUTOSAR C++ 14 rules, specified as true or false. To customize which rules are checked, use `AutosarCpp14`.

For more information about the AUTOSAR C++ 14 checker, see `Check AUTOSAR C++ 14 checks (-autosar-cpp14)`.

Example: `opts.CodingRulesCodeMetrics.EnableAutosarCpp14 = true;`

### `EnableCertC` — check CERT C rules and recommendations

false (default) | true

*This property affects Bug Finder only.*

Check CERT C rules and recommendations, specified as true or false. To customize which rules are checked, use `CertC`.

For more information about the CERT C checker, see `Check SEI CERT-C checks (-cert-c)`.

Example: `opts.CodingRulesCodeMetrics.EnableCertC = true;`

### `EnableCertCpp` — check CERT C++ rules

false (default) | true

*This property affects Bug Finder only.*

Check CERT C++ rules, specified as true or false. To customize which rules are checked, use `CertCpp`.

For more information about the CERT C++ checker, see `Check SEI-CERT-C++ (-cert-cpp)`.

Example: `opts.CodingRulesCodeMetrics.EnableCertCpp = true;`

**`EnableCheckersSelectionByFile` — Check custom set of coding standard checkers**
false (default) | true

Check custom set of coding standard checkers, specified as true or false. If you set this property to true, specify the path of checkers selection XML file for the property `CheckersSelectionByFile` and set one of these properties to 'from-file' to enable the corresponding coding standard custom set:

- `opts.CodingRulesCodeMetrics.AcAgcSubset='from-file'`
- `opts.CodingRulesCodeMetrics.AutosarCpp14='from-file'`
- `opts.CodingRulesCodeMetrics.CertC='from-file'`
- `opts.CodingRulesCodeMetrics.CertCpp='from-file'`
- `opts.CodingRulesCodeMetrics.Cwe='from-file'`
- `opts.CodingRulesCodeMetrics.Guidelines='from-file'`
- `opts.CodingRulesCodeMetrics.Iso17961='from-file'`
- `opts.CodingRulesCodeMetrics.JsfSubset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraC3Subset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraCSubset='from-file'`
- `opts.CodingRulesCodeMetrics.MisraCppSubset='from-file'`

For more information, see `Check custom rules (-custom-rules)`.

Example: `opts.CodingRulesCodeMetrics.EnableCheckersSelectionByFile = true;`

**`EnableCustomRules` — Check custom coding rules**
false (default) | true

Check custom coding rules, specified as true or false. The file you specify with `CheckersSelectionByFile` defines the custom coding rules.

Use with `EnableCheckersSelectionByFile`.

For more information, see `Check custom rules (-custom-rules)`.

Example: `opts.CodingRulesCodeMetrics.EnableCustomRules = true;`

**`EnableCwe` — check CWE rules**
false (default) | true

*This property affects Bug Finder only.*

Check CWE rules, specified as true or false. To customize which rules are checked, use `Cwe`.

For more information about the CWE checker, see `Check CWE (-cwe)`.

Example: `opts.CodingRulesCodeMetrics.Cwe = true;`

**`EnableGuidelines` — Check for violations of coding guidelines**
false (default) | true

*This property affects Bug Finder only.*

Specify whether to check for violations of Guidelines. To customize which rules are checked, use `Guidelines`.

For more information about the Guidelines checker, see `Check guidelines (-guidelines)`.

Example: `opts.CodingRulesCodeMetrics.EnableGuidelines = true;`

### `EnableIso17961` — check ISO-17961 rules

false (default) | true

*This property affects Bug Finder only.*

Check ISO/IEC TS 17961 rules, specified as true or false. To customize which rules are checked, use `Iso17961`.

For more information about the ISO-17961 checker, see `Check ISO-17961 security checks (-iso-17961)`.

Example: `opts.CodingRulesCodeMetrics.EnableIso17961 = true;`

### `EnableJsf` — Check JSF C++ rules

false (default) | true

Check JSF C++ rules, specified as true or false. To customize which rules are checked, use `JsfSubset`.

For more information, see `Check JSF C++ rules (-jsf-coding-rules)`.

Example: `opts.CodingRulesCodeMetrics.EnableJsf = true;`

### `EnableMisraC` — Check MISRA C:2004 rules

false (default) | true

Check MISRA C:2004 rules, specified as true or false. To customize which rules are checked, use `MisraCSubset`.

For more information, see `Check MISRA C:2004 (-misra2)`.

Example: `opts.CodingRulesCodeMetrics.EnableMisraC = true;`

### `EnableMisraC3` — Check MISRA C:2012 rules

false (default) | true

Check MISRA C:2012 rules, specified as true or false. To customize which rules are checked, use `MisraC3Subset`.

For more information about the MISRA C:2012 checker, see `Check MISRA C:2012 (-misra3)`.

Example: `opts.CodingRulesCodeMetrics.EnableMisraC3 = true;`

### `EnableMisraCpp` — Check MISRA C++:2008 rules

false (default) | true

Check MISRA C++:2008 rules, specified as true or false. To customize which rules are checked, use `MisraCppSubset`.

For more information about the MISRA C++:2008 checker, see `Check MISRA C++ rules (-misra-cpp)`.

Example: `opts.CodingRulesCodeMetrics.EnableMisraCpp = true;`

### `Guidelines` — Set of Guidelines to check

`'all'` (default) | `'his'` | `'from-file'`

*This property affects Bug Finder only.*

Sets of Guideline rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check guidelines (-guidelines)`.
- An XML file specifying Guidelines checkers and their thresholds. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”.

Example: `opts.CodingRulesCodeMetrics.Guidelines = 'his';`

### `Iso17961` — Set of ISO-17961 rules to check

`'all'` (default) | `'decidable'` | `polyspace.CodingRulesOptions` object | `'from-file'`

*This property affects Bug Finder only.*

Set of ISO/IEC TS 17961 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check ISO-17961 (-iso-17961)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check ISO/IEC TS 17961 rules, also set `EnableIso17961` to true.

Example: `opts.CodingRulesCodeMetrics.Iso17961 = 'all'`

Data Types: `char`

### `JsfSubset` — Subset of JSF C++ rules to check

`'shall-rules'` (default) | `'shall-will-rules'` | `'all-rules'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of JSF C++ rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check JSF C++ rules (-jsf-coding-rules)`.

- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check JSF C++ rules, set `EnableJsf` to true.

Example: `opts.CodingRulesCodeMetrics.JsfSubset = 'all-rules'`

Data Types: `char`

### `Misra3AgcMode` — Use the MISRA C:2012 categories for automatically generated code

false (default) | true

Use the MISRA C:2012 categories for automatically generated code, specified as true or false.

For more information, see `Use generated code requirements (-misra3-agc-mode)`.

Example: `opts.CodingRulesCodeMetrics.Misra3AgcMode = true;`

### `MisraC3Subset` — Subset of MISRA C:2012 rules to check

`'mandatory-required'` (default) | `'mandatory'` | `'single-unit-rules'` | `'system-decidable-rules'` | `'all'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C:2012 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C:2012 (-misra3)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C:2012 rules, also set `EnableMisraC3` to true.

Example: `opts.CodingRulesCodeMetrics.MisraC3Subset = 'all'`

Data Types: `char`

### `MisraCSubset` — Subset of MISRA C:2004 rules to check

`'required-rules'` (default) | `'single-unit-rules'` | `'system-decidable-rules'` | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C:2004 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C:2004 (-misra2)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C:2004 rules, also set `EnableMisraC` to true.

Example: `opts.CodingRulesCodeMetrics.MisraCSubset = 'all-rules'`

Data Types: `char`

### `MisraCppSubset` — Subset of MISRA C++ rules

`'required-rules'` (default) | `'all-rules'` | `'SQO-subset1'` | `'SQO-subset2'` | `polyspace.CodingRulesOptions` object | `'from-file'`

Subset of MISRA C++:2008 rules to check, specified by:

- Character vector of one of the subset names. For more information about the different subsets, see `Check MISRA C++ rules (-misra-cpp)`.
- A coding rules options object. To create a coding rules options object, see `polyspace.CodingRulesOptions`.
- An XML file specifying coding standard checkers. Use `'from-file'` for this property and then use the `EnableCheckersSelectionByFile` and `CheckersSelectionByFile` property to specify the full path to the file where you define a custom subset of checkers.

  You can create this file manually or in the Polyspace interface. See “Check for and Review Coding Standard Violations”. If you assign a coding rules options object to this property, an XML file is created automatically and assigned to the `CheckersSelectionByFile` property. The XML file enables rules extracted from the coding rules options object.

To check MISRA C++ rules, set `EnableMisraCpp` to true.

Example: `opts.CodingRulesCodeMetrics.MisraCppSubset = 'all-rules'`

Data Types: `char`

#### EnvironmentSettings

### Dos — Consider that file paths are in MS-DOS style

true (default) | false

Consider that file paths are in MS-DOS style, specified as true or false.

For more information, see `Code from DOS or Windows file system (-dos)`.

Example: `opts.EnvironmentSettings.Dos = true;`

### `IncludeFolders` — Include folders needed for compilation

cell array of include folder paths

Include folders needed for compilation, specified as a cell array of the include folder paths.

To specify all subfolders of a folder, use folder path followed by `**`, for instance, `'C:\includes\**'`. The notation follows the syntax of the `dir` function. See also “Specify Multiple Source Files”.

For more information, see `-I`.

Example: `opts.EnvironmentSettings.IncludeFolders = {'/includes','/com1/inc'};`

Example: `opts.EnvironmentSettings.IncludeFolders = {'C:\project1\common\includes'};`

Data Types: `cell`

### `Includes` — Files to be `#include`-ed by each C file

cell array of files

Files to be `#include`-ed by each C source file in the analysis, specified by a cell array of files.

For more information, see `Include (-include)`.

Example: `opts.EnvironmentSettings.Includes = {'/inc/inc_file.h','/inc/inc_math.h'}`

### `NoExternC` — Ignore linking errors inside extern blocks

false (default) | true

Ignore linking errors inside extern blocks, specified as true or false.

For more information, see `Ignore link errors (-no-extern-c)`.

Example: `opts.EnvironmentSettings.NoExternC = false;`

### `PostPreProcessingCommand` — Command or script to run on source files after preprocessing

character vector

Command or script to run on source files after preprocessing, specified as a character vector of the command to run.

For more information, see `Command/script to apply to preprocessed files (-post-preprocessing-command)`.

Example: Linux — `opts.EnvironmentSettings.PostPreProcessingCommand = [pwd,'/replace_keyword.pl']`

Example: Windows — `opts.EnvironmentSettings.PostPreProcessingCommand = '"C:\Program Files\MATLAB\R2015b\sys\perl\win32\bin\perl.exe" "C:\My_Scripts\replace_keyword.pl"'`

### `StopWithCompileError` — Stop analysis if a file does not compile

false (default) | true

Stop analysis if a file does not compile, specified as true or false.

For more information, see `Stop analysis if a file does not compile (-stop-if-compile-error)`.

Example: `opts.EnvironmentSettings.StopWithCompileError = true;`

**InputsStubbing**

### `DataRangeSpecifications` — Constrain global variables, function inputs, and return values of stubbed functions

file path

Constrain global variables, function inputs, and return values of stubbed functions specified by the path to an XML constraint file. For more information about the constraint file, see “Specify External Constraints for Polyspace Analysis”.

For more information about this option, see `Constraint setup (-data-range-specifications)`.

Example: `opts.InputsStubbing.DataRangeSpecifications = 'C:\project\constraint_file.xml'`

### `DoNotGenerateResultsFor` — Files on which you do not want analysis results

`'include-folders'` (default) | `'all-headers'` | `'custom=`*`folder1[,folder2,...]`*`'`

Files on which you do not want analysis results, specified by `'include-folders'`, `'all-headers'`, or a character array beginning with `custom=` followed by a comma-separated list of file or folder names.

Use this option with `InputsStubbing.GenerateResultsFor`. For more information, see `Do not generate results for (-do-not-generate-results-for)`.

Example: `opts.InputsStubbing.DoNotGenerateResultsFor = 'custom=C:\project\file1.c,C:\project\file2.c'`

### `GenerateResultsFor` — Files on which you want analysis results

`'source-headers'` (default) | `'all-headers'` | `'custom=`*`folder1[,folder2,...]`*`'`

Files on which you want analysis results, specified by `'source-headers'`, `'all-headers'`, or a character array beginning with `custom=` followed by a comma-separated list of file or folder names.

Use this option with `InputsStubbing.DoNotGenerateResultsFor`. For more information, see `Generate results for sources and (-generate-results-for)`.

Example: `opts.InputsStubbing.GenerateResultsFor = 'custom=C:\project\includes_common_1,C:\project\includes_common_2'`

### `FunctionsToStub` — Functions to stub during analysis

cell array of function names

*This property affects Code Prover analysis only.*

Functions to stub during analysis, specified as a cell array of function names.

For more information, see `Functions to stub (-functions-to-stub)`.

Example: `opts.InputsStubbing.FunctionsToStub = {'func1', 'func2'}`

### `NoDefInitGlob` — Consider global variables as uninitialized

false (default) | true

*This property affects Code Prover analysis only.*

Consider global variables as uninitialized, specified as true or false.

For more information, see `Ignore default initialization of global variables (-no-def-init-glob)`.

Example: `opts.InputsStubbing.NoDefInitGlob = true`

### `StubECoderLookupTables` — Specify that the analysis must stub functions in the generated code that use lookup tables

true (default) | false

*This property applies only to a Code Prover analysis of code generated from models.*

Specify that the analysis must stub functions in the generated code that use lookup tables. By replacing the functions with stubs, the analysis assumes more precise return values for the functions.

For more information, see `Generate stubs for Embedded Coder lookup tables (-stub-embedded-coder-lookup-table-functions)`.

Example: `opts.InputsStubbing.StubECoderLookupTables = true`

#### Macros

### `DefinedMacros` — Macros to be replaced

cell array of macros

In preprocessed code, macros are replaced by the definition, specified in a cell array of macros and definitions. Specify the macro as `Macro=Value`. If you want Polyspace to ignore the macro, leave the `Value` blank. A macro with no equal sign replaces all instances of that macro by 1.

For more information, see `Preprocessor definitions (-D)`.

Example: `opts.Macros.DefinedMacros = {'uint32=int','name3=','var'}`

### `UndefinedMacros` — Macros to undefine

cell array of macros

In preprocessed code, macros are undefined, specified by a cell array of macros to undefine.

For more information, see `Disabled preprocessor definitions (-U)`.

Example: `opts.Macros.DefinedMacros = {'name1','name2'}`

#### MergedComputingSettings

### `BatchBugFinder` — Send Bug Finder analysis to remote server

false (default) | true

*This property affects Bug Finder analysis only.*

Send Bug Finder analysis to remote server, specified as true or false. To use this option, in your Polyspace preferences, you must specify a metrics server.

For more information, see:

- `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`
- “Run Analysis on Server”

Example: `opts.MergedComputingSettings.BatchBugFinder = true;`

**`BatchCodeProver` — Send Code Prover analysis to remote server**
false (default) | true

*This property affects Code Prover analysis only.*

Send Code Prover analysis to remote server, specified as true or false. To use this option, in your Polyspace preferences, you must specify a metrics server.

For more information, see:

- `Run Bug Finder or Code Prover analysis on a remote cluster (-batch)`
- “Run Analysis on Server”

Example: `opts.MergedComputingSettings.BatchCodeProver = true;`

**`FastAnalysis` — Run Bug Finder analysis using faster local mode**
false (default) | true

*This property affects Bug Finder analysis only.*

Use fast analysis mode for Bug Finder analysis, specified as true or false.

For more information, see `Use fast analysis mode for Bug Finder (-fast-analysis)`.

Example: `opts.MergedComputingSettings.FastAnalysis = true;`

**MergedReporting**

**`EnableReportGeneration` — Generate a report after the analysis**
false (default) | true

After the analysis, generate a report, specified as true or false.

For more information, see `Generate report`.

Example: `opts.MergedReporting.EnableReportGeneration = true`

**`ReportOutputFormat` — Output format of generated report**
`'Word'` (default) | `'HTML'` | `'PDF'`

Output format of generated report, specified as one of the report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Output format (-report-output-format)`.

Example: `opts.MergedReporting.ReportOutputFormat = 'PDF'`

**`BugFinderReportTemplate` — Template for generating Bug Finder analysis report**
`'BugFinderSummary'` (default) | `'BugFinder'` | `'SecurityCWE'` | `'CodeMetrics'` | `'CodingStandards'`

*This property affects a Bug Finder analysis only.*

Template for generating analysis report, specified as one of the report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Bug Finder and Code Prover report (-report-template)`.

Example: `opts.MergedReporting.BugFinderReportTemplate = 'CodeMetrics'`

### `CodeProverReportTemplate` — Template for generating Code Prover analysis report

`'Developer'` (default) | `'CallHierarchy'` | `'CodeMetrics'` | `'CodingStandards'` | `'DeveloperReview'` | `'Developer_withGreenChecks'` | `'Quality'` | `'VariableAccess'`

*This property affects a Code Prover analysis only.*

Template for generating analysis report, specified as one of the predefined report formats. To activate this option, specify `Reporting.EnableReportGeneration`.

For more information about the different values, see `Bug Finder and Code Prover report (-report-template)`.

Example: `opts.MergedReporting.CodeProverReportTemplate = 'CodeMetrics'`

#### Multitasking

### `ArxmlMultitasking` — Specify path of ARXML files to parse for multitasking configuration

cell array of file paths

Specify the path to the ARXML files the software parses to set up your multitasking configuration.

To activate this option, specify `Multitasking.EnableExternalMultitasking` and set `Multitasking.ExternalMultitaskingType` to `autosar`.

For more information, see `ARXML files selection (-autosar-multitasking)`

Example: `opts.Multitasking.ArxmlMultitasking={'C:\Polyspace_Workspace\AUTOSAR\myFile.arxml'}`

### `CriticalSectionBegin` — Functions that begin critical sections

cell array of critical section function names

Functions that begin critical sections specified as a cell array of critical section function names. To activate this option, specify `Multitasking.EnableMultitasking` and `Multitasking.CriticalSectionEnd`.

For more information, see `Critical section details (-critical-section-begin -critical-section-end)`.

Example: `opts.Multitasking.CriticalSectionBegin = {'function1:cs1','function2:cs2'}`

### `CriticalSectionEnd` — Functions that end critical sections

cell array of critical section function names

Functions that end critical sections specified as a cell array of critical section function names. To activate this option, specify `Multitasking.EnableMultitasking` and `Multitasking.CriticalSectionBegin`.

For more information, see `Critical section details (-critical-section-begin -critical-section-end)`.

Example: `opts.Multitasking.CriticalSectionEnd = {'function1:cs1','function2:cs2'}`

**`CyclicTasks` — Specify functions that represent cyclic tasks**
cell array of function names

Specify functions that represent cyclic tasks.

To activate this option, also specify `Multitasking.EnableMultitasking`.

For more information, see `Cyclic tasks (-cyclic-tasks)`.

Example: `opts.Multitasking.CyclicTasks = {'function1','function2'}`

**`EnableConcurrencyDetection` — Enable automatic detection of certain families of threading functions**
false (default) | true

*This property affects Code Prover analysis only.*

Enable automatic detection of certain families of threading functions, specified as true or false.

For more information, see `Enable automatic concurrency detection for Code Prover (-enable-concurrency-detection)`.

Example: `opts.Multitasking.EnableConcurrencyDetection = true`

**`EnableExternalMultitasking` — Enable automatic multitasking configuration from external file definitions**
false (default) | true

Enable multitasking configuration of your projects from external files you provide. Configure multitasking from ARXML files for an AUTOSAR project, or from OIL files for an OSEK project.

Activate this option to enable `Multitasking.ArxmlMultitasking` or `Multitasking.OsekMultitasking`.

For more information, see `OIL files selection (-osek-multitasking)` and `ARXML files selection (-autosar-multitasking)`.

Example: `opts.Multitasking.EnableExternalMultitasking = 1`

**`EnableMultitasking` — Configure multitasking manually**
false (default) | true

Configure multitasking manually by specifying `true`. This property activates the other manual, multitasking properties.

For more information, see `Configure multitasking manually`.

Example: `opts.Multitasking.EnableMultitasking = 1`

**`EntryPoints` — Functions that serve as entry-points to your multitasking application**
cell array of entry-point function names

Functions that serve as entry-points to your multitasking application specified as a cell array of entry-point function names. To activate this option, also specify `Multitasking.EnableMultitasking`.

For more information, see `Tasks (-entry-points)`.

Example: `opts.Multitasking.EntryPoints = {'function1','function2'}`

**`ExternalMultitaskingType` — Specify type of file to parse for multitasking configuration**
`'osek'` (default) | `'autosar'`

Specify the type of file the software parses to set up your multitasking configuration:

- For `osek` type, the analysis looks for OIL files in the file or folder paths that you specify.
- For `autosar` type, the analysis looks for ARXML files in the file paths that you specify.

To activate this option, specify `Multitasking.EnableExternalMultitasking`.

For more information, see `OIL files selection (-osek-multitasking)` and `ARXML files selection (-autosar-multitasking)`.

Example: `opts.Multitasking.ExternalMultitaskingType = 'autosar'`

**`Interrupts` — Specify functions that represent nonpreemptable interrupts**
cell array of function names

Specify functions that represent nonpreemptable interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Interrupts (-interrupts)`.

Example: `opts.Multitasking.Interrupts = {'function1','function2'}`

**`InterruptsDisableAll` — Specify routine that disable interrupts**
cell array with one function name

*This property affects Bug Finder analysis only.*

Specify function that disables all interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Example: `opts.Multitasking.InterruptsDisableAll = {'function'}`

**`InterruptsEnableAll` — Specify routine that reenable interrupts**
cell array with one function name

*This property affects Bug Finder analysis only.*

Specify function that reenables all interrupts.

To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Example: `opts.Multitasking.InterruptsEnableAll = {'function'}`

### `OsekMultitasking` — Specify path of OIL files to parse for multitasking configuration

`'auto'` (default) | `'custom=`*`folder1[,folder2,...]`*`'`

Specify the path to the OIL files the software parses to set up your multitasking configuration:

- In the mode specified with `'auto'`, the analysis uses OIL files in your project source and include folders, but not their subfolders.
- In the mode specified with `'custom=`*`folder1[,folder2,...]`*`'`, the analysis uses the OIL files at the specified path, and the path subfolders.

To activate this option, specify `Multitasking.EnableExternalMultitasking` and set `Multitasking.ExternalMultitaskingType` to `osek`.

For more information, see `OIL files selection (-osek-multitasking)`

Example: `opts.Multitasking.OsekMultitasking = 'custom=file_path, dir_path'`

### `TemporalExclusion` — Entry-point functions that cannot execute concurrently

cell array of entry-point function names

Entry-point functions that cannot execute concurrently specified as a cell array of entry-point function names. Each set of exclusive tasks is one cell array entry with functions separated by spaces. To activate this option, specify `Multitasking.EnableMultitasking`.

For more information, see `Temporally exclusive tasks (-temporal-exclusions-file)`.

Example: `opts.Multitasking.TemporalExclusion = {'function1 function2', 'function3 function4 function5'}` where function1 and function2 are temporally exclusive, and function3, function4, and function 5 are temporally exclusive.

#### Precision (Affects Code Prover Only)

### `ContextSensitivity` — Store call context information to identify function call that caused errors

`'none'` (default) | `'auto'` | `'custom=`*`function1[,function2,...]`*`'`

*This property affects Code Prover analysis only.*

Store call context information to identify a function call that caused errors, specified as `none`, `auto`, or as a character array beginning with `custom=` followed by a list of comma-separated function names.

For more information, see `Sensitivity context (-context-sensitivity)`.

Example: `opts.Precision.ContextSensitivity = 'auto'`

Example: `opts.Precision.ContextSensitivity = 'custom=func1'`

### `ModulesPrecision` — Source files you want to verify at higher precision

cell array of file names and precision levels

*This property affects Code Prover analysis only.*

Source files that you want to verify at higher precision, specified as a cell array of file names without the extension and precision levels using this syntax: `filename:Olevel`

For more information, see `Specific precision (-modules-precision)`.

Example: `opts.Precision.ModulesPrecision = {'file1:O0', 'file2:O3'}`

### `OLevel` — Precision level for the verification

2 (default) | 0 | 1 | 3

*This property affects Code Prover analysis only.*

Precision level for the verification, specified as 0, 1, 2, or 3.

For more information, see `Precision level (-O)`.

Example: `opts.Precision.OLevel = 3`

### `PathSensitivityDelta` — Avoid certain verification approximations for code with fewer lines

positive integer

*This property affects Code Prover analysis only.*

Avoid certain verification approximations for code with fewer lines, specified as a positive integer representing how sensitive the analysis is. Higher values can increase verification time exponentially.

For more information, see `Improve precision of interprocedural analysis (-path-sensitivity-delta)`.

Example: `opts.Precision.PathSensitivityDelta = 2`

### `Timeout` — Time limit on your verification

character vector

*This property affects Code Prover analysis only.*

Time limit on your verification, specified as a character vector of time in hours.

For more information, see `Verification time limit (-timeout)`.

Example: `opts.Precision.Timeout = '5.75'`

### `To` — Number of times the verification process runs

`'Software Safety Analysis level 2'` (default) | `'Software Safety Analysis level 0'` | `'Software Safety Analysis level 1'` | `'Software Safety Analysis level 3'` | `'Software Safety Analysis level 4'` | `'Source Compliance Checking'` | `'other'`

*This property affects Code Prover analysis only.*

Number of times the verification process runs, specified as one of the preset analysis levels.

For more information, see `Verification level (-to)`.

Example: `opts.Precision.To = 'Software Safety Analysis level 3'`

#### Scaling (Affects Code Prover Only)

### `Inline` — Functions on which separate results must be generated for each function call

cell array of function names

*This property affects Code Prover analysis only.*

Functions on which separate results must be generated for each function call, specified as a cell array of function names.

For more information, see `Inline (-inline)`.

Example: `opts.Scaling.Inline = {'func1','func2'}`

### `KLimiting` — Limit depth of analysis for nested structures

positive integer

*This property affects Code Prover analysis only.*

Limit depth of analysis for nested structures, specified as a positive integer indicating how many levels into a nested structure to verify.

For more information, see `Depth of verification inside structures (-k-limiting)`.

Example: `opts.Scaling.KLimiting = 3`

#### TargetCompiler

### `Compiler` — Compiler that builds your source code

`'generic'` (default) | `'gnu3.4'` | `'gnu4.6'` | `'gnu4.7'` | `'gnu4.8'` | `'gnu4.9'` | `'gnu5.x'` | `'gnu6.x'` | `'gnu7.x'` | `'clang3.x'` | `'clang4.x'` | `'clang5.x'` | `'visual9.0'` | `'visual10'` | `'visual11.0'` | `'visual12.0'` | `'visual14.0'` | `'visual15.x'` | `'keil'` | `'iar'` | `'armcc'` | `'armclang'` | `'codewarrior'` | `'diab'` | `'greenhills'` | `'iar-ew'` | `'renesas'` | `'tasking'` | `'ti'`

Compiler that builds your source code.

For more information, see `Compiler (-compiler)`.

Example: `opts.TargetCompiler.Compiler = 'Visual11.0'`

### `CppVersion` — Specify C++ standard version followed in code

`'defined-by-compiler'` (default) | `'cpp03'` | `'cpp11'` | `'cpp14'` | `'cpp17'`

Specify C++ standard version followed in code, specified as a character vector.

For more information, see `C++ standard version (-cpp-version)`.

Example: `opts.TargetCompiler.CppVersion = 'cpp11';`

### `CVersion` — Specify C standard version followed in code

`'defined-by-compiler'` (default) | `'c90'` | `'c99'` | `'c11'`

Specify C standard version followed in code, specified as a character vector.

For more information, see `C standard version (-c-version)`.

Example: `opts.TargetCompiler.CVersion = 'c90';`

**`DivRoundDown` — Round down quotients from division or modulus of negative numbers**
false (default) | true

Round down quotients from division or modulus of negative numbers, specified as true or false.

For more information, see `Division round down (-div-round-down)`.

Example: `opts.TargetCompiler.DivRoundDown = true`

**`EnumTypeDefinition` — Base type representation of enum**
`'defined-by-compiler'` (default) | `'auto-signed-first'` | `'auto-unsigned-first'`

Base type representation of enum, specified by an allowed base-type set. For more information about the different values, see `Enum type definition (-enum-type-definition)`.

Example: `opts.TargetCompiler.EnumTypeDefinition = 'auto-unsigned-first'`

**`IgnorePragmaPack` — Ignore #pragma pack directives**
false (default) | true

Ignore #pragma pack directives, specified as true or false.

For more information, see `Ignore pragma pack directives (-ignore-pragma-pack)`.

Example: `opts.TargetCompiler.IgnorePragmaPack = true`

**`Language` — Language of analysis**
`'C-CPP'` (default) | `'C'` | `'CPP'`

This property is read-only.

Language of the analysis, specified during the object construction. This value changes which properties appear.

For more information, see `Source code language (-lang)`.

**`LogicalSignedRightShift` — Treatment of signed bit on signed variables**
`'Arithmetical'` (default) | `'Logical'`

Treatment of signed bit on signed variables, specified as `Arithmetical` or `Logical`. For more information, see `Signed right shift (-logical-signed-right-shift)`.

Example: `opts.TargetCompiler.LogicalSignedRightShift = 'Logical'`

**`NoUliterals` — Do not use predefined typedefs for char16_t or char32_t**
false (default) | true

Do not use predefined typedefs for char16_t or char32_t, specified as true or false. For more information, see `Block char16/32_t types (-no-uliterals)`.

Example: `opts.TargetCompiler.NoUliterals = true`

**`PackAlignmentValue` — Default structure packing alignment**
`'defined-by-compiler'` (default) | `'1'` | `'2'` | `'4'` | `'8'` | `'16'`

Default structure packing alignment, specified as `'defined-by-compiler'`, `'1'`, `'2'`, `'4'`, `'8'`, or `'16'`. This property is available only for Visual C++ code.

For more information, see Pack alignment value (-pack-alignment-value).

Example: opts.TargetCompiler.PackAlignmentValue = '4'

### SfrTypes — sfr types

cell array of sfr keywords

sfr types, specified as a cell array of sfr keywords using the syntax *sfr_name=size_in_bits*. For more information, see Sfr type support (-sfr-types).

This option only applies when you set TargetCompiler.Compiler to keil or iar.

Example: opts.TargetCompiler.SfrTypes = {'sfr32=32'}

### SizeTTypeIs — Underlying type of size_t

'defined-by-compiler' (default) | 'unsigned-int' | 'unsigned-long' | 'unsigned-long-long'

Underlying type of size_t, specified as 'defined-by-compiler', 'unsigned-int', 'unsigned-long', or 'unsigned-long-long'. See Management of size_t (-size-t-type-is).

Example: opts.TargetCompiler.SizeTTypeIs = 'unsigned-long'

### Target — Target processor

'i386' (default) | 'arm' | 'arm64' | 'avr' | 'c-167' | 'c166' | 'c18' | 'c28x' | 'c6000' | 'coldfire' | 'hc08' | 'hc12' | 'm68k' | 'mcore' | 'mips' | 'mpc5xx' | 'msp430' | 'necv850' | 'powerpc' | 'powerpc64' | 'rh850' | 'rl78' | 'rx' | 's12z' | 'sharc21x61' | 'sparc' | 'superh' | 'tms320c3x' | 'tricore' | 'x86_64' | generic target object

Set size of data types and endianness of processor, specified as one of the predefined target processors or a generic target object.

For more information about the predefined processors, see Target processor type (-target).

For more information about creating a generic target, see polyspace.GenericTargetOptions.

Example: opts.TargetCompiler.Target = 'hc12'

### WcharTTypeIs — Underlying type of wchar_t

'defined-by-compiler' (default) | 'signed-short' | 'unsigned-short' | 'signed-int' | 'unsigned-int' | 'signed-long' | 'unsigned-long'

Underlying type of wchar_t, specified as 'defined-by-compiler', 'signed-short', 'unsigned-short', 'signed-int', 'unsigned-int', 'signed-long', or 'unsigned-long'. See Management of wchar_t (-wchar-t-type-is).

Example: opts.TargetCompiler.WcharTTypeIs = 'unsigned-int'

#### VerificationAssumption (Affects Code Prover Only)

### ConsiderVolatileQualifierOnFields — Assume that volatile qualified structure fields can have all possible values at any point in code

false (default) | true

*This property affects Code Prover analysis only.*

Assume that volatile qualified structure fields can have all possible values at any point in code.

For more information, see `Consider volatile qualifier on fields (-consider-volatile-qualifier-on-fields)`.

Example: `opts.VerificationAssumption.ConsiderVolatileQualifierOnFields = true`

### `ConstraintPointersMayBeNull` — Specify that environment pointers can be NULL unless constrained otherwise

false (default) | true

*This property affects Code Prover analysis only.*

Specify that environment pointers can be NULL unless constrained otherwise.

For more information, see `Consider environment pointers as unsafe (-stubbed-pointers-are-unsafe)`.

Example: `opts.VerificationAssumption.ConstraintPointersMayBeNull = true`

### `FloatRoundingMode` — Rounding modes to consider when determining the results of floating-point arithmetic

`to-nearest` (default) | `all`

*This property affects Code Prover analysis only.*

Rounding modes to consider when determining the results of floating-point arithmetic, specified as `to-nearest` or `all`.

For more information, see `Float rounding mode (-float-rounding-mode)`.

Example: `opts.VerificationAssumption.FloatRoundingMode = 'all'`

#### Other Properties

### `Author` — Project author

username of current user (default) | character vector

Name of project author, specified as a character vector.

For more information, see `-author`.

Example: `opts.Author = 'JaneDoe'`

### `ImportComments` — Import comments and justifications from previous analysis

character vector

To import comments and justifications from a previous analysis, specify the path to the results folder of the previous analysis.

You can also point to a previous results folder to see only new results compared to the previous run. See “Compare Results from Different Polyspace Runs by Using MATLAB Scripts”.

For more information, see `-import-comments`

Example:
```
opts.ImportComments =
fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example','Module_1','BF_Result')
```

### `Prog` — Project name

`PolyspaceProject` (default) | character vector

Project name, specified as a character vector.

For more information, see `-prog`.

Example: `opts.Prog = 'myProject'`

### `ResultsDir` — Location to store results

folder path

Location to store results, specified as a folder path. By default, the results are stored in the current folder.

For more information, see `-results-dir`.

You can also create a separate results folder for each new run. See “Compare Results from Different Polyspace Runs by Using MATLAB Scripts”.

Example: `opts.ResultsDir = 'C:\project\myproject\results\'`

### `Sources` — Source files

cell array of files

Source files to analyze, specified as a cell array of files.

To specify all files in a folder, use folder path followed by *, for instance, `'C:\src\*'`. To specify all files in a folder and its subfolders, use folder path followed by **, for instance, `'C:\src\**'`. The notation follows the syntax of the `dir` function. See also “Specify Multiple Source Files”.

For more information, see `-sources`.

Example: `opts.Sources = {'file1.c', 'file2.c', 'file3.c'}`

Example: `opts.Sources = {'project/src1/file1.c', 'project/src2/file2.c', 'project/src3/file3.c'}`

### `Version` — Project version number

`'1.0'` (default) | character array of a number

Version number of project, specified as a character array of a number. This option is useful if you upload your results to Polyspace Metrics. If you increment version numbers each time that you reanalyze your object, you can compare the results from two versions in Polyspace Metrics.

For more information, see `-v[ersion]`.

Example: `opts.Version = '2.3'`

## Version History

**Introduced in R2017a**

## See Also

### Topics

“Complete List of Polyspace Bug Finder Analysis Engine Options”

# copyTo

**Class:** `polyspace.Options`
**Package:** `polyspace`

Copy common settings between Polyspace options objects

## Syntax

`optsFrom.copyTo(optsTo)`

## Description

`optsFrom.copyTo(optsTo)` copies the common options from `optsFrom` to `optsTo`. The options objects do not need to be the same type of options object. This method copies only properties that are common between the two objects.

## Input Arguments

**`optsFrom` — Options object you want to copy properties from**
`polyspace.Options` or `polyspace.ModelLinkOptions` object

Option object that you want to copy properties from, specified as a `polyspace.Options` or `polyspace.ModelLinkOptions` object.

Example: `opts = polyspace.Options;`

**`optsTo` — Options object you want to copy properties to**
`polyspace.Options` object

Option object that you want to copy properties to, specified as a `polyspace.Options` or `polyspace.ModelLinkOptions` object.

Example: `opts = polyspace.Options;`

## Examples

### Copy Polyspace Options Object

This example shows how to set the properties of one options object and then copy that object to another one.

Create a Polyspace options object and set properties.

```
opts1 = polyspace.Options();
opts1.Prog = 'DataRaceProject';
opts1.Sources = {'datarace.c'};
opts1.TargetCompiler.Compiler = 'gnu4.9';
```

Create another object and use copyTo to copy over options from the previous object.

```
opts2 = polyspace.Options();
opts1.copyTo(opts2);
```

## Version History

**Introduced in R2016b**

### See Also

`polyspace.Options` | `generateProject` | `polyspace.ModelLinkOptions`

# generateProject

**Class:** polyspace.Options
**Package:** polyspace

Generate psprj project from options object

## Syntax

opts.generateProject(projectName)

## Description

opts.generateProject(projectName) creates a .psprj project called projectName from the options specified in the polyspace.Options object opts. You can open a .psprj project in the user interface of the Polyspace desktop products.

## Input Arguments

**opts — Options object to convert into a psprj file**
polyspace.Options or polyspace.ModelLinkOptions object

Option object convert into a psprj file, specified as a polyspace.Options or polyspace.ModelLinkOptions object.

Example: opts = polyspace.Options;

**projectName — Project file name**
character vector

Project file name specified as a character vector. This argument is used as the name of the psprj file.

Example: 'myProject'

## Examples

### Generate Project from a Bug Finder Options Object

This example shows how to create and use a Polyspace project that was generated from an options object.

Create a Bug Finder object and set properties.

```
sources = fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example',...
   'sources','numerical.c');
opts = polyspace.Options();
opts.Prog = 'MyProject';
opts.Sources = {sources};
opts.TargetCompiler.Compiler = 'gnu4.7';
```

Generate a Polyspace project. Name the project using the Prog property.

```
psprj = opts.generateProject(opts.Prog);
```

Run a Bug Finder analysis using one of these commands. Both commands produce identical analysis results. The only difference is that the psprj project can be rerun in the Polyspace interface.

```
polyspaceBugFinder(psprj, '-nodesktop');
polyspaceBugFinder(opts);
```

To run a Code Prover analysis, use polyspaceCodeProver instead of polyspaceBugFinder.

## Tips

If you want to include an options object in a pslinkoptions object:

1. Use this method to convert your object to a project.
2. Add the project to the pslinkoptions property PrjConfig.
3. Turn on the property EnablePrjConfig.

# Version History

**Introduced in R2016b**

## See Also

polyspace.Options | copyTo | polyspace.ModelLinkOptions

# toScript

**Class:** `polyspace.Options`
**Package:** `polyspace`

Add Polyspace options object definition to a script

## Syntax

```
filePath = opts.toScript(fileName,positionInScript)
```

## Description

`filePath = opts.toScript(fileName,positionInScript)` adds the properties of a `polyspace.Options` object to a MATLAB script. The script shows the values assigned to all the properties of the object. You can run the script later to define the object in the MATLAB workspace and use it.

## Input Arguments

### `opts` — Options object with Polyspace analysis options

`polyspace.Options` or `polyspace.ModelLinkOptions` object

Option object to store in MATLAB script, specified as a `polyspace.Options` or `polyspace.ModelLinkOptions` object.

Example: `opts = polyspace.Options;`

### `fileName` — Script name

character vector

Name or path to script, specified as a character vector. If you specify a relative path, the script is created in subfolder of the current working folder.

Example: `'runPolyspace.m'`

### `positionInScript` — Where to add object definition

`'create'` (default) | `'append'`

Position in script where the object properties are added, specified as `'create'` or `'append'`. If you specify `'append'`, the object properties are added to the end of an existing script. Otherwise, a new script is created.

## Output Arguments

### `filePath` — Full path to script

character vector

Full path to script, specified as a character vector.

Example: `'C:\myScripts\runPolyspace.m'`

## Version History

**Introduced in R2017b**

`polyspace.Options` | `generateProject` | `polyspace.ModelLinkOptions` | `copyTo`

# run

Run a Polyspace analysis

## Syntax

`run(proj, product)`

## Description

`status` = `run(proj, product)` runs a Polyspace Bug Finder or Polyspace Code Prover analysis using the configuration specified in the `polyspace.Project` object `proj`. The analysis results are also stored in `proj`.

## Input Arguments

**`proj` — Polyspace project**
`polyspace.Project` object

Polyspace project with configuration and results, specified as a `polyspace.Project` object.

**`product` — Type of analysis**
`'bugFinder'` | `'codeProver'`

Type of analysis to run.

## Output Arguments

**`status` — Results of a Code Prover analysis**
`true` | `false`

Status of analysis. If the analysis succeeds, the status is `false`. Otherwise, it is `true`.

The analysis can fail for multiple reasons:

- You provide source files that do not exist.
- None of your files compile. Even if one file compiles, unless you set the property `StopWithCompileError` to `true`, the analysis succeeds and returns a `false` status.

There can be many other reasons why the analysis fails. If the analysis fails, in your results folder, check the log file. You can see the results folder using the `Configuration` property of the `polyspace.Project` object:

```
proj = polyspace.Project;
proj.Configuration.ResultsDir
```

The log file is named `Polyspace_R20##`*`n_ProjectName_date-time`*`.log`.

## Examples

### Read Results to MATLAB Tables

Run a Polyspace Bug Finder analysis on the demo file `numerical.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = run(proj, 'bugFinder');

% Read results
bfSummary = proj.Results.getSummary('defects');
```

# Version History

**Introduced in R2017b**

# getSummary

View number of Polyspace results organized by results type (Bug Finder) or color and file (Code Prover)

## Syntax

```
resSummary = getSummary(resObj, resultsType)
```

## Description

`resSummary = getSummary(resObj, resultsType)` returns the distribution of results of type `resultsType` in a Polyspace results set, `resObj`. The results set `resObj` can be a Bug Finder results set denoted by a `polyspace.BugFinderResults` object or a Code Prover results set denoted by a `polyspace.CodeProverResults` object.

For instance:

- If you choose to see Bug Finder defects, you can see how many defects of each type are present in the result set, for instance, how many non-initialized variables or declaration mismatches.
- If you choose to see Code Prover run-time checks, you see how many red, orange, gray and green checks are present in each file.

## Examples

### Read Existing Bug Finder Results to MATLAB Tables

This example shows how to read Bug Finder analysis results from MATLAB.

Copy a demo result set to a temporary folder.

```
resPath=fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example', ...
'Module_1','BF_Result');
userResPath = tempname;
copyfile(resPath,userResPath);
```

Create the results object.

```
resObj = polyspace.BugFinderResults(userResPath);
```

Read results to MATLAB tables using the object.

```
resSummary = getSummary(resObj, 'defects');
resTable = getResults(resObj);
```

### Run Bug Finder Analysis and Read Results to MATLAB Tables

Run a Polyspace Bug Finder analysis on the demo file `numerical.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = run(proj, 'bugFinder');

% Read results
resObj = proj.Results;
bfSummary = getSummary(resObj, 'defects');
```

#### Read Existing Code Prover Results to MATLAB Tables

This example shows how to read Code Prover analysis results from MATLAB.

Copy a demo result set to a temporary folder.

```
resPath = fullfile(polyspaceroot,'polyspace','examples','cxx','Code_Prover_Example', ...
'Module_1','CP_Result');
userResPath = tempname;
copyfile(resPath,userResPath);
```

Create the results object.

```
resObj = polyspace.CodeProverResults(userResPath);
```

Read results to MATLAB tables using the object.

```
resSummary = getSummary(resObj, 'runtime');
resTable = getResults(resObj);
```

#### Run Code Prover Analysis and Read Results to MATLAB Tables

Run a Polyspace Code Prover analysis on the demo file `single_file_analysis.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.
- Specify that a `main` function must be generated, if it does not exist in the source code.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Code_Prover_Example', 'sources', 'single_file_analysis.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');
proj.Configuration.CodeProverVerification.MainGenerator = true;

% Run analysis
cpStatus = run(proj, 'codeProver');

% Read results
resObj = proj.Results;
cpSummary = getResults(resObj, 'readable');
```

## Input Arguments

### resObj — Bug Finder or Code Prover results

polyspace.BugFinderResults or polyspace.CodeProverResults object

Bug Finder or Code Prover results set, specified as a polyspace.BugFinderResults or polyspace.CodeProverResults object respectively.

### resultsType — Type of Bug Finder or Code Prover analysis result

'defects' | 'runtime' | 'misraC' | 'misraCAGC' | 'misraCPP' | 'misraC2012' | 'jsf' | 'certC' | 'certCpp' | 'iso17961' | 'autosarCPP14' | 'metrics' | 'customRules'

Type of result, specified as a character vector. The default for a Bug Finder results set is 'defects' and the default for a Code Prover results set is 'runtime'.

| Entry | Meaning |
|---|---|
| 'defects' | Bug Finder defects. |
| 'runtime' | Code Prover checks for run-time errors. |
| 'misraC' | MISRA C:2004 rules. |
| 'misraCAGC' | MISRA C:2004 rules for generated code. |
| 'misraCPP' | MISRA C++ rules. |
| 'misraC2012' | MISRA C:2012 rules. |
| 'jsf' | JSF C++ rules. |
| 'certC' | CERT C rules. |
| 'certCpp' | CERT C++ rules. |
| 'iso17961' | ISO/IEC TS 17961 rules. |
| 'autosarCPP14' | AUTOSAR C++ 14 rules. |
| 'metrics' | Code complexity metrics. |
| 'customRules' | Custom rules enforcing naming conventions for identifiers. |

## Output Arguments

### resSummary — Distribution of Bug Finder results by result type or Code Prover run-time checks by check color and file

table

Distribution of results, specified as a table. For instance:

- If you choose to see a summary of Bug Finder defects, an extract of the table looks like this:

  | Category | Defect | Impact | Total |
  |---|---|---|---|
  | Concurrency | Data race | High | 2 |
  | Concurrency | Deadlock | High | 1 |
  | Data flow | Non-initialized variable | High | 2 |

  The table above shows that the result set contains two data races, one deadlock and two non-initialized variables.
- If you choose to see a summary of Code Prover run-time checks, an extract of the table looks like this:

  | File | Proven | Green | Red | Gray | Orange |
  |---|---|---|---|---|---|
  | `file1.c` | 92.0% | 87 | 3 | 2 | 8 |
  | `file2.c` | 97.7% | 41 | 0 | 1 | 1 |

  The table above shows that `file1.c` has:

  - 3 red, 2 gray and 8 orange checks.
  - 92% of operations proven.

    In other words, of every 100 operations that the verification checked, 92 operations were proven green, red or gray. See “Code Prover Result and Source Code Colors” (Polyspace Code Prover).

For more information on MATLAB tables, see “Tables”.

# Version History

**Introduced in R2017a**

## See Also

`polyspace.BugFinderResults` | `polyspace.CodeProverResults`

# getResults

View all instances of Bug Finder or Code Prover results

## Syntax

```
resTable = getResults(resObj, content)
```

## Description

`resTable = getResults(resObj, content)` returns a table showing all results in a Polyspace result set, `resObj`. The results set `resObj` can be a Bug Finder results set denoted by a `polyspace.BugFinderResults` object or a Code Prover results set denoted by a `polyspace.CodeProverResults` object. You can manipulate the table to produce graphs and statistics about your results that you cannot obtain readily from the user interface.

## Examples

### Read Existing Bug Finder Results to MATLAB Tables

This example shows how to read Bug Finder analysis results from MATLAB.

Copy a demo result set to a temporary folder.

```
resPath = fullfile(polyspaceroot,'polyspace','examples','cxx','Bug_Finder_Example', ...
'Module_1','BF_Result');
userResPath = tempname;
copyfile(resPath,userResPath);
```

Create the results object.

```
resObj = polyspace.BugFinderResults(userResPath);
```

Read results to MATLAB tables using the object.

```
resSummary = getSummary(resObj, 'defects');
resTable = getResults(resObj);
```

### Run Bug Finder Analysis and Read Results to MATLAB Tables

Run a Polyspace Bug Finder analysis on the demo file `numerical.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', ...
    'examples', 'cxx', 'Bug_Finder_Example', 'sources', 'numerical.c')};
```

```
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');

% Run analysis
bfStatus = proj.run('bugFinder');

% Read results
resObj = proj.Results;
bfSummary = getResults(resObj, 'readable');
```

### Read Existing Code Prover Results to MATLAB Tables

This example shows how to read Code Prover analysis results from MATLAB.

Copy a demo result set to a temporary folder.

```
resPath=fullfile(polyspaceroot,'polyspace','examples','cxx','Code_Prover_Example', ...
'Module_1','CP_Result');
userResPath = tempname;
copyfile(resPath,userResPath);
```

Create the results object.

```
resObj = polyspace.CodeProverResults(userResPath);
```

Read results to MATLAB tables using the object.

```
resSummary = getSummary (resObj);
resTable = getResults (resObj);
```

### Run Code Prover Analysis and Read Results to MATLAB Tables

Run a Polyspace Code Prover analysis on the demo file `single_file_analysis.c`. Configure these options:

- Specify GCC 4.9 as your compiler.
- Save the results in a `results` subfolder of the current working folder.
- Specify that a `main` function must be generated, if it does not exist in the source code.

```
proj = polyspace.Project

% Configure analysis
proj.Configuration.Sources = {fullfile(polyspaceroot, 'polyspace', 'examples',...
    'cxx', 'Code_Prover_Example', 'sources', 'single_file_analysis.c')};
proj.Configuration.TargetCompiler.Compiler = 'gnu4.9';
proj.Configuration.ResultsDir = fullfile(pwd,'results');
proj.Configuration.CodeProverVerification.MainGenerator = true;

% Run analysis
cpStatus = proj.run('codeProver');

% Read results
```

```
resObj = proj.Results;
cpSummary = getResults(resObj, 'readable');
```

## Input Arguments

### `resObj` — Bug Finder or Code Prover results

`polyspace.BugFinderResults` or `polyspace.CodeProverResults` object

Bug Finder or Code Prover results set, specified as a `polyspace.BugFinderResults` or `polyspace.CodeProverResults` object respectively.

### `content` — Result information to include

`''` (default) | `'readable'`

Amount of information to be included for each result. If you specify `''`, all information is included. If you specify `'readable'`, the following information is not included:

- ID: Unique number for a result for the current analysis.
- Group: Defect groups, Check groups (Polyspace Code Prover), MISRA C:2012 groups, etc.
- Status, Severity, Comment: Information that *you* enter about a result.

If you do not specify this argument, the full table is included.

See “Export Polyspace Analysis Results”.

## Output Arguments

### `resTable` — Results of a Bug Finder or Code Prover analysis

table

Table showing all results from a single Bug Finder or Code Prover analysis. For each result, the table has information such as file, family, and so on. If a particular information is not available for a result, the entry in the table states `<undefined>`.

For more information on:

- The columns of the table, see “Export Polyspace Analysis Results”.
- MATLAB tables, see “Tables”.

# Version History

**Introduced in R2017a**

## See Also

`polyspace.BugFinderResults` | `polyspace.CodeProverResults`

# Configuration Parameters

# Settings from (C)

Select settings for the analysis configuration. You can quickly activate coding rules checking for generated C code

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `Project configuration`

`Project configuration`

Run Polyspace with the options specified in the “Project configuration” on page 6-7 or “Use custom project file” on page 6-6.

You do not check coding rules unless you select a rule set in the configuration.

`Project configuration and MISRA AC AGC checking`

Run Polyspace with the options specified in the **Project configuration** plus MISRA AC-AGC obligatory and recommended rules.

`Project configuration and MISRA C 2004 checking`

Run Polyspace with the options specified in the **Project configuration** plus all MISRA C 2004 rules.

`Project configuration and MISRA C 2012 checking`

Run Polyspace with the options specified in the **Project configuration** plus all MISRA C 2012 rules. This option automatically applies the rule categories for generated code. See `Use generated code requirements (-misra3-agc-mode)`.

`MISRA AC AGC checking`

Check compliance with the MISRA AC-AGC obligatory and recommended rules. After rules checking, Polyspace stops.

`MISRA C 2004 checking`

Check compliance with all MISRA C 2004 rules. After rules checking, Polyspace stops.

`MISRA C 2012 checking`

Check compliance with all MISRA C 2012 rules. This option automatically applies the rule categories for generated code. See `Use generated code requirements (-misra3-agc-mode)`. After rules checking, Polyspace stops.

## Dependency

This setting overrides custom configuration settings in “Project configuration” on page 6-7 and “Use custom project file” on page 6-6. If you want to use your custom coding rule settings, select the `Project configuration` option.

## Command-Line Information

Use the `pslinkoptions` property `VerificationSettings`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSVerificationSettings` with the same value as for the `pslinkoptions` property `VerificationSettings`. See pslinkoptions.

## See Also

pslinkoptions | `pslinkoptions`

## Related Examples

- “Run Polyspace Analysis on Code Generated with Embedded Coder”

# Settings from (C++)

Select settings for the analysis configuration. This option allows you to quickly activate coding rules checking for generated C++ code.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `Project configuration`

`Project configuration`

Run Polyspace with the options specified in the “Project configuration” on page 6-7 or “Use custom project file” on page 6-6.

You do not check coding rules unless you select a rule set in the configuration.

`Project configuration and MISRA C++ checking`

Run Polyspace with the options specified in the **Project configuration** plus MISRA C++ required rules.

`Project configuration and JSF C++ checking`

Run Polyspace with the options specified in the **Project configuration** plus JSF C++ shall rules.

`MISRA C++ checking`

Check compliance with the MISRA C++: 2008 required rules. After rules checking, Polyspace stops.

`JSF C++ checking`

Check compliance with the JSF C++ shall rules. After rules checking, Polyspace stops.

## Dependency

This setting overrides custom configuration settings in “Project configuration” on page 6-7 and “Use custom project file” on page 6-6. If you want to use your custom coding rule settings, select the `Project configuration` option.

## Command-Line Information

Use the `pslinkoptions` property `CxxVerificationSettings`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSCxxVerificationSettings` with the same value as for the `pslinkoptions` property `CxxVerificationSettings`. See pslinkoptions.

## Related Examples

- "Run Polyspace Analysis on Code Generated with Embedded Coder"

# Use custom project file

Set Polyspace configuration options with a custom `.psprj` file

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** Off □

Off □

Analysis uses configuration options from **Project configuration** on page 6-7 parameters.

On ☑

Analysis uses configuration options from the specified `.psprj` project file.

## Dependency

The **Settings from** parameter overrides custom configuration settings for coding rules. If you want to use your custom coding rule settings, set **Settings from** > **Project configuration**.

## Command-Line Information

Use the `pslinkoptions` properties `EnablePrjConfigFile` and `PrjConfigFile`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameters `PSEnablePrjConfigFile` and `PSPrjConfigFile` with the same values as for the `pslinkoptions` properties `EnablePrjConfigFile` and `PrjConfigFile`. See pslinkoptions.

# Project configuration

Set advanced configuration options to customize the analysis.

## Settings

Open the Polyspace Configuration window by using the **Configure** button. Customize additional settings in this window and save your project configuration. If you added a custom project file in the parameter "Use custom project file" on page 6-6, that project file configuration is shown. Otherwise, the default project template is used.

For details about the advanced options, see "Complete List of Polyspace Bug Finder Analysis Engine Options".

## Dependency

The **Settings from** parameter overrides custom configuration settings for coding rules. If you want to use your custom coding rule settings, set **Settings from > Project configuration**.

## Command-Line Information

Use a Polyspace project (`.psprj` file) with the `pslinkoptions` properties `EnablePrjConfigFile` and `PrjConfigFile`.

`polyspace.ModelLinkOptions` | `pslinkoptions` | pslinkoptions

## More About

- "Run Polyspace Analysis on Code Generated with Embedded Coder"

# Enable additional file list

Add additional supporting code files to the analysis.

For instance, suppose you use C files for testing results from the generated code or providing inputs to the generated code. The analysis of generated code only considers files generated from the Simulink model. If you want the analysis to consider the C files that you use for testing or inputs, provide them as additional files.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** Off □

Off □

The analysis includes no additional files.

On ☑

Polyspace analyzes the specified C/C++ files with the generated code. Use the **Select files** button to specify these additional files.

## Command-Line Information

Use the `pslinkoptions` properties `EnableAdditionalFileList` and `AdditionalFileList`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameters `PSEnableAdditionalFileList` and `PSAdditionalFileList` with the same values as for the `pslinkoptions` properties `EnableAdditionalFileList` and `AdditionalFileList`. See pslinkoptions.

## More About

- "Run Polyspace Analysis on Code Generated with Embedded Coder"

# Stub lookup tables

Specify that the verification must stub auto-generated functions that use certain kinds of lookup tables in their body. The lookup tables in these functions use linear interpolation and do not allow extrapolation. That is, the result of using the lookup table always lies between the lower and upper bounds of the table.

If you use this option, the verification is more precise and has fewer orange checks. The verification of lookup table functions is usually imprecise. The software has to make certain assumptions about these functions. To avoid missing a run-time error, the verification assumes that the result of using the lookup table is within the full range allowed by the result data type. This assumption can cause many unproven results (orange checks) when a lookup table function is called. By using this option, you narrow down the assumption. For functions using lookup tables with linear interpolation and no extrapolation, the result is at least within the bounds of the table.

The option is relevant only if your model uses Lookup Table blocks.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** On ☑

On ☑

For autogenerated functions that use lookup tables with linear interpolation and no extrapolation, the verification:

- Does not check for run-time errors in the function body.
- Calls a function stub instead of the actual function at the function call sites. The stub ensures that the result of using the lookup table is within the bounds of the table.

To identify if the lookup table in the function uses linear interpolation and no extrapolation, the verification uses information provided by the code generation product. For instance, if you use Embedded Coder to generate code, the lookup table functions with linear interpolation and no extrapolation follow specific naming conventions.

Off □

The verification does not stub autogenerated functions that use lookup tables.

## Tips

- The option applies only to autogenerated functions. If you integrate your own C/C++ S-Function using lookup tables with the model, the option does not cause them to be stubbed.
- The option is on by default. For certification purposes, if you want your verification tool to be independent of the code generation tool, turn off the option.

## Command-Line Information

Use the `pslinkoptions` property `AutoStubLUT`.

The pslinkoptions function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the set_param function to associate this property with the model. Use the parameter PSAutoStubLUT with the same value as for the pslinkoptions property AutoStubLUT. See pslinkoptions.

# Input

Choose whether to constrain Inport block variables.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `Use specified minimum and maximum values`

`Use specified minimum and maximum values`

Analysis assumes minimum and maximum values for input variables. These values are specified in the Inport block dialog box. Use this value to reduce the number of false positive results.

`Unbounded inputs`

Analysis assumes full range for input variables. Use this value to run a robust analysis that includes values outside the expected range.

## Command-Line Information

Use the `pslinkoptions` property `InputRangeMode`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSInputRangeMode` with the same value as for the `pslinkoptions` property `InputRangeMode`. See pslinkoptions.

# Tunable parameters

Choose how to treat tunable parameter values during the analysis. Treat values as either constants or a range of values.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `Use calibration data`

`Use calibration data`

  Analysis assumes constant values for tunable parameters. Use this value to run a contextual analysis. This option can reduce the number of false positive results.

`Use specified minimum and maximum values`

  Analysis assumes a range of values for the tunable parameter variables. Specify maximum and minimum values in the model. Use this option to run a robust analysis that includes values outside the expected parameter value.

## Command-Line Information

Use the `pslinkoptions` property `ParamRangeMode`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSParamRangeMode` with the same value as for the `pslinkoptions` property `ParamRangeMode`. See pslinkoptions.

# Output

Choose whether to verify output values.

Code Prover option only. Bug Finder cannot check output values.

This options is available only for Embedded Coder.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `No verification`

`No verification`

Polyspace does not verify output values.

`Verify outputs are within minimum and maximum values`

Polyspace checks to see if the output variable values are within the expected minimum and maximum values. Specify the minimum and maximum values in the output block dialog boxes.

## Command-Line Information

Use the `pslinkoptions` property `OutputRangeMode`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSOutputRangeMode` with the same value as for the `pslinkoptions` property `OutputRangeMode`. See pslinkoptions.

# Model reference verification depth

Only for models that use Embedded Coder generated code. Indicate how deep into the model hierarchy to analyze.

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** `Current model only`

`Current model only`

Polyspace analyzes only the current model

`1`

Polyspace analyzes the current model and the referenced models that are one level below the current model.

`2`

Polyspace analyzes the current model and the referenced models that are up to two levels below the current model.

`3`

Polyspace analyzes the current model and the referenced models that are up to three levels below the current model.

`All`

Polyspace analyzes the current model and all referenced models.

## Command-Line Information

Use the `pslinkoptions` property `ModelRefVerifDepth`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSModelRefVerifDepth` with the same value as for the `pslinkoptions` property `ModelRefVerifDepth`. See pslinkoptions.

## More About

- “Run Polyspace Analysis on Code Generated with Embedded Coder”

# Model by model verification

Only for models that use Embedded Coder generated code. Analyze each model or referenced model individually. If you have a large project, this option can help modularize your analysis .

**Model Configuration Parameters Category**: Polyspace

## Settings

**Default:** Off □

Off □

Polyspace analyzes your models together. Model interactions are analyzed.

On ☑

Polyspace analyzes your model and each of its referenced models in isolation. This option does not analyze model interactions.

## Command-Line Information

Use the `pslinkoptions` property `ModelRefByModelRefVerif`.

The `pslinkoptions` function allows you to create a Polyspace options object that you can reuse for multiple models. You can also use the `set_param` function to associate this property with the model. Use the parameter `PSModelRefByModelRefVerif` with the same value as for the `pslinkoptions` property `ModelRefByModelRefVerif`. See pslinkoptions.

# Polyspace Results: Defect Checkers

7

# Numerical Defects

# Absorption of float operand

One addition or subtraction operand is absorbed by the other operand

## Description

This defect occurs when one operand of an addition or subtraction operation is *always* negligibly small compared to the other operand. Therefore, the result of the operation is always equal to the value of the larger operand, making the operation redundant.

### Risk

Redundant operations waste execution cycles of your processor.

The absorption of a float operand can indicate design issues elsewhere in the code. It is possible that the developer expected a different range for one of the operands and did not expect the redundancy of the operation. However, the operand range is different from what the developer expects because of issues elsewhere in the code.

### Fix

See if the operand ranges are what you expect. To see the ranges, place your cursor on the operation.

- If the ranges are what you expect, justify why you have the redundant operation in place. For instance, the code is only partially written and you anticipate other values for one or both of the operands from future unwritten code.

  If you cannot justify the redundant operation, remove it.
- If the ranges are not what you expect, in your code, trace back to see where the ranges come from. To begin your traceback, search for instances of the operand in your code. Browse through previous instances of the operand and determine where the unexpected range originates.

To determine when one operand is negligible compared to the other operand, the defect uses rules based on IEEE 754 standards. To fix the defect, instead of using the actual rules, you can use this heuristic: the ratio of the larger to the smaller operand must be less than $2^{p-1}$ at least for some values. Here, `p` is equal to 24 for 32-bit precision and 53 for 64-bit precision. To determine the precision, the defect uses your specification for `Target processor type (-target)`.

This defect appears only if one operand is *always* negligibly smaller than the other operand. To see instances of subnormal operands or results, use the check **Subnormal Float** in Polyspace Code Prover.

## Examples

### One Addition Operand Negligibly Smaller Than The Other Operand

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);
```

```
float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-30)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

float input_signal2(void) {
    float temp = get_signal();
    if(temp > 1.)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    float signal2 = input_signal2();
    float super_signal = signal1 + signal2;
    do_operation(super_signal);
}
```

In this example, the defect appears on the addition because the operand `signal1` is in the range `(0,1e-30)` but `signal2` is greater than `1`.

**Correction — Remove Redundant Operation**

One possible correction is to remove the redundant addition operation. In the following corrected code, the operand `signal2` and its associated code is also removed from consideration.

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);

float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-30)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    do_operation(signal1);
}
```

**Correction — Verify Operand Range**

Another possible correction is to see if the operand ranges are what you expect. For instance, if one of the operand range is not supposed to be negligibly small, fix the issue causing the small range. In the following corrected code, the range `(0,1e-2)` is imposed on `signal2` so that it is not *always* negligibly small as compared to `signal1`.

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);

float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-2)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

float input_signal2(void) {
    float temp = get_signal();
    if(temp > 1.)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    float signal2 = input_signal2();
    float super_signal = signal1 + signal2;
    do_operation(super_signal);
}
```

## Result Information

# Bitwise operation on negative value

Undefined behavior for bitwise operations on negative values

## Description

This defect occurs when bitwise operators (>>, ^, |, ~, but, not, &) are used on signed integer variables with negative values.

### Risk

If the value of the signed integer is negative, bitwise operation results can be unexpected because:

- Bitwise operations on negative values can produce compiler-specific results.
- Unexpected calculations can lead to additional vulnerabilities, such as buffer overflow.

### Fix

When performing bitwise operations, use unsigned integers to avoid unexpected results.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Right-Shift of Negative Integer

```
#include <stdio.h>
#include <stdarg.h>

static void demo_sprintf(const char *format, ...)
{
    int rc;
    va_list ap;
    char buf[sizeof("256")];

    va_start(ap, format);
    rc = vsprintf(buf, format, ap);
    if (rc == -1 || rc >= sizeof(buf)) {
        /* Handle error */
    }
    va_end(ap);
}

void bug_bitwiseneg()
{
    int stringify = 0x80000000;
    demo_sprintf("%u", stringify >> 24);
}
```

In this example, the statement `demo_sprintf("%u", stringify >> 24)` stops the program unexpectedly. You expect the result of `stringify >> 24` to be `0x80`. However, the actual result is `0xffffff80` because `stringify` is signed and negative. The sign bit is also shifted.

#### Correction — Add `unsigned` Keyword

By adding the `unsigned` keyword, `stringify` is not negative and the right-shift operation gives the expected result of `0x80`.

```
#include <stdio.h>
#include <stdarg.h>

static void demo_sprintf(const char *format, ...)
{
    int rc;
    va_list ap;
    char buf[sizeof("256")];

    va_start(ap, format);
    rc = vsprintf(buf, format, ap);
    if (rc == -1 || rc >= sizeof(buf)) {
        /* Handle error */
    }
    va_end(ap);
}

void corrected_bitwiseneg()
{
    unsigned int stringify = 0x80000000;
    demo_sprintf("%u", stringify >> 24);
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `BITWISE_NEG`
**Impact:** Medium

# Float conversion overflow

Overflow when converting between floating point data types

## Description

This defect occurs when converting a floating point number to a smaller floating point data type. If the variable does not have enough memory to represent the original number, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing conversion in subsequent computations and do not account for the overflow, you can see unexpected results.

### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being converted acquires its current value You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller floating point types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats).`

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Converting from `double` to `float`

```
float convert(void) {

    double diam = 1e100;
    return (float)diam;
}
```

In the return statement, the variable `diam` of type double (64 bits) is converted to a variable of type float (32 bits). However, the value 1^100 requires more than 32 bits to be precisely represented.

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `FLOAT_CONV_OVFL`
**Impact:** High

# Version History

**Introduced in R2013b**

# Float division by zero

Dividing floating point number by zero

## Description

This defect occurs when the denominator of a division operation can be a zero-valued floating point number.

### Risk

A division by zero can result in a program crash.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats).`

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Dividing a Floating Point Number by Zero

```
float fraction(float num)
{
    float denom = 0.0;
    float result = 0.0;

    result = num/denom;

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
float fraction(float num)
{
    float denom = 0.0;
    float result = 0.0;

    if( ((int)denom) != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
float fraction(float num)
{
    float denom = 2.0;
    float result = 0.0;

    result = num/denom;

    return result;
}
```

## Result Information

**Group:** Numerical

# Float overflow

Overflow from operation between floating points

## Description

This defect occurs when an operation on floating point variables results in values that cannot be represented by the data type that the operation uses. This data type depends on the operand types and determines the number of bytes allocated for storing the result, thus constraining the range of allowed values.

Note that:

- The data type used to determine an overflow is based on the operand data types. If you then assign the result of an operation to another variable, a different checker, `Float conversion overflow`, determines if the value assigned also overflows the variable assigned to. For instance, in an operation such as:

  ```
  res = x + y;
  ```

  This checker checks for an overflow based on the types of `x` and `y`, and not on the type of `res`. The checker for float conversion overflows then checks for an overflow based on the type of `res`.
- The two operands in a binary operation might undergo promotion before the operation occurs. See also “Code Prover Assumptions About Implicit Data Type Conversions” (Polyspace Code Prover).

The exact storage allocation for different types depends on your processor. See `Target processor type (-target)`.

### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing computation in subsequent computations and do not account for the overflow, you can see unexpected results.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.

- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and NaNs. Operations that results in infinities and NaNs might be flagged as defects. To handle infinities and NaN values in your code, use the option Consider non finite floats (-allow-non-finite-floats)..

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Multiplication of Floats

```
#include <float.h>

float square(void) {

   float val = FLT_MAX;
   return val * val;
}
```

In the return statement, the variable val is multiplied by itself. The square of the maximum float value cannot be represented by a float (the return type for this function) because the value of val is the maximum float value.

#### Correction — Different Storage Type

One possible correction is to store the result of the operation in a larger data type. In this example, by returning a double instead of a float, the overflow defect is fixed.

```
#include <float.h>

double square(void) {
    float val = FLT_MAX;

    return (double)val * (double)val;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** FLOAT_OVFL
**Impact:** Low

# Integer constant overflow

Constant value falls outside range of integer data type

## Description

This defect occurs in the following cases:

- You assign a compile-time integer constant to a signed integer variable whose data type cannot accommodate the value.

  See "Constant Overflows from Assignments" on page 7-17.
- You use an `enum` value that cannot be accommodated by the underlying type of the `enum` (and the underlying type is signed). For most C compilers, the default underlying type is `signed int` (based on the C standard).

  See "Constant Overflows from enum Values" on page 7-17.
- You perform a binary operation involving two integer constants that results in an overflow, that is, a value outside the range allowed by the data type that the operation uses. A binary operation with integer constants uses the `signed int` data type (unless you use modifiers such as `u` or `L`).

  See "Constant Overflows from Binary Operations" on page 7-18.

An `n`-bit signed integer holds values in the range [-$2^{n-1}$, $2^{n-1}$-1]. For instance, `c` is an 8-bit signed `char` variable that cannot hold the value 255.

```
signed char c = 255;
```

This defect checker depends on the following options:

- `Target processor type (-target)`: Determines the sizes of fundamental types.
- `Enum type definition (-enum-type-definition)`: Determines the underlying types of enumerations.
- `Compiler (-compiler)`: Impacts the interpretation of code.

You do not see the defect in these situations:

- Creation of new constants from `const` variables (for specific compilers only).

  Different compilers might define compile-time constants differently. In the following code, `c+1` is considered a compile-time constant by GCC compilers, but not by the standard C compiler:

  ```
  const int16_t c = 32767;
  int16_t y = c + 1;
  ```

  Whether you see a violation of this check on `y` might depend on your compiler.
- Bitwise `NOT` operation.

  Polyspace does not raise this violation when you perform a bitwise `NOT` operation.

### Risk

The default behavior for constant overflows can vary between compilers and platforms. Retaining constant overflows can reduce the portability of your code.

Even if your compilers wraps around overflowing constants with a warning, the wrap-around behavior can be unintended and cause unexpected results.

### Fix

Check if the constant value is what you intended. If the value is correct, use a different, possibly wider, data type for the variable.

## Examples

### Constant Overflows from Assignments

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127

void main() {
    char c1 = MAX_UNSIGNED_CHAR;
    char c2 = MAX_SIGNED_CHAR+1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow. To reproduce these defects, use a `Target processor type (-target)` where `char` is signed by default.

#### Correction — Use Different Data Type

One possible correction is to use a different data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR;
    unsigned char c2 = MAX_SIGNED_CHAR+1;
}
```

### Constant Overflows from `enum` Values

```
enum {
  a=0x7fffffff,
  b,
  c=0xffffffff
} MyEnumA;
```

In this example, the `enum` has an underlying type `int`. The `int` type can accommodate values in the range [-$2^{31}$, $2^{31}$-1]. However, the value of the enumerator `b` is 0x80000000 or $2^{31}$ (one more than the previous value `a`). This value falls outside the allowed range of `int`.

The value of `c`, that is 0xffffffff or $2^{32}$-1, is even larger and also causes an overflow.

To see this defect:

- Specify `Compiler (-compiler)` as `generic`.
- Specify `Source code language (-lang)` as `c`.

**Constant Overflows from Binary Operations**

```
const unsigned int K_ATM_Label_Ram_init_value [] = {
     0x06 | ( 3 << 29) ,
     0x80 | ( 9 << 29) ,
     ( 2 << 31 )        ,
};
```

In this example, two of the shift operations result in values that cannot be accommodated by the `signed int` data type. The `signed int` data type can accommodate values in the range [-$2^{31}$, $2^{31}$-1]. The operation:

- `9 << 29` results in the value $2^{32}$+536870912.
- `2 << 31` results in the value $2^{32}$.

Note that even though the result is assigned to an `unsigned int` variable, the overflow detection uses the underlying type of the binary operation, that is, `signed int`.

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INT_CONSTANT_OVFL`
**Impact:** Medium

# Version History

# Integer conversion overflow

Overflow when converting between integer types

## Description

This defect occurs when converting an integer to a smaller integer type. If the variable does not have enough bytes to represent the original value, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

### Risk

Integer conversion overflows result in undefined behavior.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Converting from int to char

```
char convert(void) {

    int num = 1000000;

    return (char)num;
}
```

In the return statement, the integer variable num is converted to a char. However, an 8-bit or 16-bit character cannot represent 1000000 because it requires at least 20 bits. So the conversion operation overflows.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number.

```
long convert(void) {

    int num = 1000000;

    return (long)num;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** INT_CONV_OVFL
**Impact:** High

# Version History

**Introduced in R2013b**

# Integer division by zero

Dividing integer number by zero

## Description

This defect occurs when the denominator of a division or modulo operation can be a zero-valued integer.

### Risk

A division by zero can result in a program crash.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Dividing an Integer by Zero

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    result = num/denom;

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    if (denom != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
int fraction(int num)
{
    int denom = 2;
    int result = 0;

    result = num/denom;

    return result;
}
```

### Modulo Operation with Zero

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        arr[i] = input % i;
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

In this example, Polyspace flags the modulo operation as a division by zero. Because modulo is inherently a division operation, the divisor (right hand argument) cannot be zero. The modulo operation uses the `for` loop index as the divisor. However, the `for` loop starts at zero, which cannot be an iterator.

#### Correction — Check Divisor Before Operation

One possible correction is checking the divisor before the modulo operation. In this example, see if the index `i` is zero before the modulo operation.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        if(i != 0)
        {
             arr[i] = input % i;
        }
        else
        {
             arr[i] = input;
        }
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

#### Correction — Change Divisor

Another possible correction is changing the divisor to a nonzero integer. In this example, add one to the index before the `%` operation to avoid dividing by zero.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
         arr[i] = input % (i+1);
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `INT_ZERO_DIV`
**Impact:** High

# Version History

# Integer overflow

Overflow from operation between integers

## Description

This defect occurs when an operation on integer variables results in values that cannot be represented by the data type that the operation uses. This data type depends on the operand types and determines the number of bytes allocated for storing the result, thus constraining the range of allowed values.

Note that:

- The data type used to determine an overflow is based on the operand data types. If you then assign the result of an operation to another variable, a different checker, `Integer conversion overflow`, determines if the value assigned also overflows the variable assigned to. For instance, in an operation such as:

  ```
  res = x + y;
  ```

  This checker checks for an overflow based on the types of `x` and `y`, and not on the type of `res`. The checker for integer conversion overflows then checks for an overflow based on the type of `res`.
- The two operands in a binary operation might undergo promotion before the operation occurs. See also “Code Prover Assumptions About Implicit Data Type Conversions” (Polyspace Code Prover).

The exact storage allocation for different data types depends on your processor. See `Target processor type (-target)`.

### Risk

Integer overflows on signed integers result in undefined behavior.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.

- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++;
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

## Result Information

# Integer precision exceeded

Operation using integer size instead of precision can cause undefined behavior

## Description

This defect occurs when an integer expression uses the integer size in an operation that exceeds the integer precision. On some architectures, the size of an integer in memory can include sign and padding bits. On these architectures, the integer size is larger than the precision which is just the number of bits that represent the value of the integer.

### Risk

Using the size of an integer in an operation on the integer precision can result in integer overflow, wrap around, or unexpected results. For instance, an unsigned integer can be stored in memory in 64 bits, but uses only 48 bits to represent its value. A 56 bits left-shift operation on this integer is undefined behavior.

Assuming that the size of an integer is equal to its precision can also result in program portability issues between different architectures.

### Fix

Do not use the size of an integer instead of its precision. To determine the integer precision, implement a precision computation routine or use a builtin function such as `__builtin_popcount()`.

## Examples

### Using Size of `unsigned int` for Left Shift Operation

```
#include <limits.h>

unsigned int func(unsigned int exp)
{
    if (exp >= sizeof(unsigned int) * CHAR_BIT) {
        /* Handle error */
    }
    return 1U << exp;
}
```

In this example, the function uses a left shift operation to return the value of 2 raised to the power of `exp`. The operation shifts the bits of `1U` by `exp` positions to the left. The `if` statement ensures that the operation does not shift the bits by a number of positions `exp` greater than the size of an `unsigned int`. However, if `unsigned int` contains padding bits, the value returned by `sizeof()` is larger than the precision of `unsigned int`. As a result, some values of `exp` might be too large, and the shift operation might be undefined behavior.

#### Correction — Implement Function to Compute Precision of `unsigned int`

One possible correction is to implement a function `popcount()` that computes the precision of `unsigned int` by counting the number of set bits.

```
#include <stddef.h>
#include <stdint.h>
#include <limits.h>

size_t popcount(uintmax_t);
#define PRECISION(umax_value) popcount(umax_value)

unsigned int func(unsigned int exp)
{
    if (exp >= PRECISION(UINT_MAX)) {
        /* Handle error */
    }
    return 1 << exp;
}

size_t popcount(uintmax_t num)
{
    size_t precision = 0;
    while (num != 0) {
        if (num % 2 == 1) {
            precision++;
        }
        num >>= 1;
    }
    return precision;
}
```

### Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INT_PRECISION_EXCEEDED`
**Impact:** Low

## Version History

# Invalid use of standard library floating point routine

Wrong arguments to standard library function

## Description

This defect occurs when you use invalid arguments with a floating point function from the standard library and the standard name space. This defect picks up:

- Rounding and absolute value routines

  `ceil, fabs, floor, fmod`
- Fractions and division routines

  `fmod, modf`
- Exponents and log routines

  `frexp, ldexp, sqrt, pow, exp, log, log10`
- Trigonometry function routines

  `cos, sin, tan, acos, asin, atan, atan2, cosh, sinh, tanh, acosh, asinh, atanh`

### Risk

Domain errors on standard library floating point functions result in implementation-defined values. If you use the function return value in subsequent computations, you can see unexpected results.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

It is a good practice to handle for domain errors before using a standard library floating point function. For instance, before calling the `acos` function, check if the argument is in [-1.0, 1.0] and handle the error.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats).`

**Extend Checker**

Extend this checker to check for defects caused by specific values and invalid use of functions from a custom library. For instance:

- You might be using a custom library of mathematical floating point functions. If a custom library function have the same domain and range as another function from the standard library, you can extend this checker to check the custom library function. See “Extend Bug Finder Checkers for Standard Library Functions to Custom Libraries”.
- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Arc Cosine Operation

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    return acos(degree);
}
```

The input value to `acos` must be in the interval `[-1,1]`. This input argument, `degree`, is outside this range.

**Correction — Change Input Argument**

One possible correction is to change the input value to fit the specified range. In this example, change the input value from degrees to radians to fix this defect.

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    double radian = degree * 3.14159 / 180.;
    return acos(radian);
}
```

### Invalid Use of Functions in Standard Namespace

```
#include <cmath>

void InvalidUse(double& val1, double& val2){
  int in = -5;
  int ratio = 0;
  //...
  val1 = std::sqrt(in);
  val2 = std::log(ratio);
}
```

The input value to `std::sqrt()` must be nonnegative. Polyspace flags the use of negative input argument `in`. The input value to `std::log` must be greater than zero. Polyspace flags calling `std::log` by using `ratio`.

#### Correction — Refactor Code

One possible correction is to check the logic and refactor your code. For instance, instead of taking the square root of `-5`, perhaps `val1` is indented to be the negative square root of `5`. The function might be defining `ratio` incorrectly as well.

```
#include <cmath>
int getRatio(void);
void ValidUse(double& val1, double& val2){
  int in = 5;
  int ratio = getRatio();
  //...
  val1 = -1* std::sqrt(in);
  val2 = std::log(ratio);
}
```

### Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `FLOAT_STD_LIB`
**Impact:** High

## Version History

**Introduced in R2013b**

# Invalid use of standard library integer routine

Wrong arguments to standard library function

## Description

This defect occurs when you use invalid arguments with an integer function from the standard library. This defect picks up:

- Character Conversion

  `toupper, tolower`
- Character Checks

  `isalnum, isalpha, iscntrl, isdigit, isgraph, islower, isprint, ispunct, isspace, isupper, isxdigit`
- Integer Division

  `div, ldiv`
- Absolute Values

  `abs, labs`

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

Extend this checker to check for defects caused by specific values and invalid use of functions from a custom library. For instance:

- You might be using a custom library of mathematical functions. If a custom library function have the same domain and range as another function from the standard library, you can extend this checker to check the custom library function. See “Extend Bug Finder Checkers for Standard Library Functions to Custom Libraries”.

- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Absolute Value of Large Negative

```
#include <limits.h>
#include <stdlib.h>

int absoluteValue(void) {

    int neg = INT_MIN;
    return abs(neg);
}
```

The input value to `abs` is `INT_MIN`. The absolute value of `INT_MIN` is `INT_MAX+1`. This number cannot be represented by the type `int`.

#### Correction — Change Input Argument

One possible correction is to change the input value to fit returned data type. In this example, change the input value to `INT_MIN+1`.

```
#include <limits.h>
#include <stdlib.h>

int absoluteValue(void) {

    int neg = INT_MIN+1;
    return abs(neg);
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `INT_STD_LIB`
**Impact:** High

# Possible invalid operation on boolean operand

Operation can exceed precision of Boolean operand or result in arbitrary value

## Description

This defect occurs when you use a Boolean operand in an arithmetic, relational, or bitwise operation and:

- The Boolean operand has a trap representation. The size of a Boolean type in memory is at least one addressable unit (size of `char`). A Boolean type requires only one bit to represent the value `true (1)` or `false (0)`. The representation of a Boolean operand in memory contains padding bits. The memory representation can result in values that are not `true` or `false`, a trap representation.
- The result of the operation can exceed the precision of the Boolean operand.

For example, in this code snippet:

```
bool_v >> 2
```

- If the value of `bool_v` is `true (1)` or `false (0)`, the bitwise shift exceeds the one-bit precision of `bool_v` and always results in `0`.
- If `bool_v` has a trap representation, the result of the operation is an arbitrary value.

**Possible invalid operation on boolean operand** raises no defect when:

- The operation does not result in a precision overflow. For instance, bitwise & or `|` operations with `0x01` or `0x00`.
- The Boolean operand cannot have a trap representation. For instance, a constant expression that results in `0` or `1`, or a comparison evaluated to `true` or `false`.

### Risk

Arithmetic, relational, or bitwise operations on a Boolean operand can exceed the operand precision and cause unexpected results when used as a Boolean value. Operations on Boolean operands with trap representations can return arbitrary values.

### Fix

Avoid performing operations on Boolean operands other than these operations:

- Assignment operation (=).
- Equality operations (== or `!=`).
- Logical operations (&&, `||`, or `!`).

## Examples

### Possible Trap Representation of Boolean Operand

```
#include <stdio.h>
#include <stdbool.h>
```

```
#define BOOL _Bool

int arr[2] = {1, 2};

int func(BOOL b)
{
    return arr[b];
}

int main(void)
{
    BOOL b;
    char* ptr = (char*)&b;
    *ptr = 64;
    return func(b);
}
```

In this example, Boolean operand `b` is used as an array index in `func` for an array with two elements. Depending on the compiler and optimization flags you use, the value `b` might not be `0` or `1`. For instance, in Linux Debian 8, if you use `gcc` version 4.9 with optimization flag `-O0`, the value of `b` is 64, which causes a buffer overflow.

**Correction — Use Only Last Significant Bit Value of Boolean Operand**

One possible correction is to use a variable `b0` of type `unsigned int` to get only the value of the last significant bit of the Boolean operand. The value of this bit is in the range `[0..1]`, even if the Boolean operand has a trap representation.

```
#include <stdio.h>
#include <stdbool.h>

#define BOOL _Bool

int arr[2] = {1, 2};

int func(BOOL b)
{
    unsigned int b0 = (unsigned int)b;
    b0 &= 0x1;
    return arr[b0];
}

int main(void)
{
    BOOL b;
    char* ptr = (char*)&b;
    *ptr = 64;
    return func(b);
}
```

Note that a trap representation is often the result of an earlier issue in the code, such as:

- A non-initialized variable of bool type.
- A side effect that modifies any part of a bool type object using a lvalue expression.
- A read of a bool member from a union type with the last stored value of another type.

As such, it is best practice to respect boolean semantics even in C++ code.

### <= Operation Uses Boolean Operands

```
#include <iostream>

template <typename T>
bool less_or_equal(const T& x, const T& y)
{
    std::cout << "INTEGER VERSION" << '\n';
    return x <= y;
}
bool b1 = true, b2 = false;
int i1 = 2, i2 = 3;

int main()
{
    std::cout << std::boolalpha;
    std::cout << "less_or_equal(" << b1 << ',' << b2 << ") = " << less_or_equal<bool>(b1, b2) << '\n';
    std::cout << "less_or_equal(" << i1 << ',' << i2 << ") = " << less_or_equal<int>(11, 12) << '\n';
    return 0;
}
```

In this example, function template `less_or_equal` evaluates whether variable x is less than or equal to y. When you pass boolean types to this function, the <= operation might result in an arbitrary value if the memory representation of the operands, including their padding bits, is neither 1 nor 0.

#### Correction — Specialize Function Template for Boolean Types

One possible correction is to specialize the function template for boolean types. The specialized function template uses a logical (`||`) operation to compare the boolean operands.

```
#include <iostream>

template <typename T>
bool less_or_equal(const T& x, const T& y)
{
    std::cout << "INTEGER VERSION" << '\n';
    return x <= y;
}

template<>
bool less_or_equal<bool>(const bool& x, const bool& y)
{
    std::cout << "BOOLEAN VERSION" << '\n';
    return !x || y;
}

bool b1 = true, b2 = false;
int i1 = 2, i2 = 3;

int main()
{
    std::cout << std::boolalpha;
    std::cout << "less_or_equal(" << b1 << ',' << b2 << ") = " << less_or_equal<bool>(b1, b2) << '\n';
    std::cout << "less_or_equal(" << i1 << ',' << i2 << ") = " << less_or_equal<int>(11, 12) << '\n';
    return 0;
}
```

## Result Information

# Precision loss in integer to float conversion

Least significant bits of integer lost during conversion to floating-point type

## Description

This defect occurs when you cast an integer value to a floating-point type that cannot represent the original integer value.

For instance, the `long int` value `1234567890L` is too large for a variable of type `float` .

### Risk

If the floating-point type cannot represent the integer value, the behavior is undefined (see C11 standard, 6.3.1.4, paragraph 2). For instance, least significant bits of the variable value can be dropped leading to unexpected results.

### Fix

Convert to a floating-point type that can represent the integer value.

For instance, if the `float` data type cannot represent the integer value, use the `double` data type instead.

When writing a function that converts an integer to floating point type, before the conversion, check if the integer value can be represented in the floating-point type. For instance, `DBL_MANT_DIG * log2(FLT_RADIX)` represents the number of base-2 digits in the type `double`. Before conversion to the type `double`, check if this number is greater than or equal to the precision of the integer that you are converting. To determine the precision of an integer `num`, use this code:

```
size_t precision = 0;
while (num != 0) {
   if (num % 2 == 1) {
     precision++;
   }
   num >>= 1;
}
```

Some implementations provide a builtin function to determine the precision of an integer. For instance, GCC provides the function `__builtin_popcount`.

## Examples

### Conversion of Large Integer to Floating-Point Type

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  float approx = big;
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

In this C code, the `long int` variable `big` is converted to `float`.

#### Correction — Use a Wider Floating-Point Type

One possible correction is to convert to the `double` data type instead of `float`.

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  double approx = big;
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INT_TO_FLOAT_PRECISION_LOSS`
**Impact:** Low

# Shift of a negative value

Shift operator on negative value

## Description

This defect occurs when a bit-wise shift is used on a variable that can have negative values.

### Risk

Shifts on negative values overwrite the sign bit that identifies a number as negative. The shift operation can result in unexpected values.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

To fix the defect, check for negative values before the bit-wise shift operation and perform appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Shifting a negative variable

```
int shifting(int val)
{
    int res = -1;
    return res << val;
}
```

In the return statement, the variable `res` is shifted a certain number of bits to the left. However, because `res` is negative, the shift might overwrite the sign bit.

#### Correction — Change the Data Type

One possible correction is to change the data type of the shifted variable to unsigned. This correction eliminates the sign bit, so left shifting does not change the sign of the variable.

```
int shifting(int val)
{
    unsigned int res = -1;
    return res << val;
}
```

### Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `SHIFT_NEG`
**Impact:** Low

## Version History

**Introduced in R2013b**

# Right operand of shift operation outside allowed bounds

Overflow from shifting operation

## Description

This defect occurs when a shift operation can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different data types depends on your processor. See `Target processor type (-target)`.

### Risk

Shift operation overflows can result in undefined behavior.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface" or "Interpret Bug Finder Results in Polyspace Access Web Interface".

You can fix the defect by:

- Using a bigger data type for the result of the shift operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Left Shift of Integer

```
int left_shift(void) {

    int foo = 33;
    return 1 << foo;
}
```

In the return statement of this function, bit-wise shift operation is performed shifting 1 `foo` bits to the left. However, an `int` has only 32 bits, so the range of the shift must be between 0 and 31. Therefore, this shift operation causes an overflow.

#### Correction — Different storage type

One possible correction is to store the shift operation result in a larger data type. In this example, by returning a `long long` instead of an `int`, the overflow defect is fixed.

```
long long left_shift(void) {

    int foo = 33;
    return 1LL << foo;
}
```

## Result Information

# Sign change integer conversion overflow

Overflow when converting between signed and unsigned integers

## Description

This defect occurs when converting an unsigned integer to a signed integer. If the variable does not have enough bytes to represent both the original constant and the sign bit, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Convert from `unsigned char` to `char`

```
char sign_change(void) {
    unsigned char count = 255;

    return (char)count;
}
```

In the return statement, the unsigned character variable `count` is converted to a signed character. However, `char` has 8 bits, 1 for the sign of the constant and 7 to represent the number. The conversion operation overflows because 255 uses 8 bits.

#### Correction — Change conversion types

One possible correction is using a larger integer type. By using an `int`, there are enough bits to represent the sign and the number value.

```
int sign_change(void) {
    unsigned char count = 255;

    return (int)count;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `SIGN_CHANGE`
**Impact:** Medium

# Version History

**Introduced in R2013b**

# Unsigned integer constant overflow

Constant value falls outside range of unsigned integer data type

## Description

This defect occurs in the following cases:

- You assign a compile-time constant to an unsigned integer variable whose data type cannot accommodate the value.
- You use an enum value that cannot be accommodated by the underlying type of the enum (and the underlying type is unsigned).

An n-bit unsigned integer holds values in the range [0, $2^n$-1]. For instance, c is an 8-bit unsigned char variable that cannot hold the value 256.

```
unsigned char c = 256;
```

This defect checker depends on the following options:

- To determine the sizes of fundamental types, Bug Finder uses your specification for Target processor type (-target).
- To determine the underlying types of enumerations, Bug Finder uses your specification for Enum type definition (-enum-type-definition).

You do not see the defect in these situations:

- Creation of new constants from const variables (for specific compilers only).

  Different compilers might define compile-time constants differently. In the following code, c+1u is considered a compile time-constant by GCC compilers, but not by the standard C compiler:

  ```
  const uint16_t c = 0xffffu;
  uint16_t y = c + 1u;
  ```

  Whether you see a violation of this check on y might depend on your compiler.
- Bitwise NOT operation.

  Polyspace does not raise this violation when you perform a bitwise NOT operation.

### Risk

The C standard states that overflowing unsigned integers must be wrapped around (see, for instance, the C11 standard, section 6.2.5). However, the wrap-around behavior can be unintended and cause unexpected results.

### Fix

Check if the constant value is what you intended. If the value is correct, use a wider data type for the variable.

## Examples

### Overflows from Assignments

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_UNSIGNED_SHORT 65535

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned short c2 = MAX_UNSIGNED_SHORT + 1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow.

#### Correction — Use Wider Data Type

One possible correction is to use a wider data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_UNSIGNED_SHORT 65535

void main() {
    unsigned short c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned int c2 = MAX_UNSIGNED_SHORT + 1;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `UINT_CONSTANT_OVFL`
**Impact:** Low

# Unsigned integer conversion overflow

Overflow when converting between unsigned integer types

## Description

This defect occurs when converting an unsigned integer to a smaller unsigned integer type. If the variable does not have enough bytes to represent the original constant, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

### Risk

Integer conversion overflows result in undefined behavior.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Converting from int to char

```
unsigned char convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned char)unum;
}
```

In the return statement, the unsigned integer variable `unum` is converted to an unsigned character type. However, the conversion overflows because 1000000 requires at least 20 bits. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `unum` is reduced by modulo `2^8` because a character data type can only represent `2^8-1`.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number. For example, `long`.

```
unsigned long convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned long)unum;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `UINT_CONV_OVFL`
**Impact:** Low

# Version History

**Introduced in R2013b**

# Unsigned integer overflow

Overflow from operation between unsigned integers

## Description

This defect occurs when an operation on unsigned integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

### Risk

The C11 standard states that unsigned integer overflows result in wrap-around behavior. However, a wrap around behavior might not always be desirable. For instance, if the result of a computation is used as an array size and the computation overflows, the array size is much smaller than expected.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling. In the error handling code, you can override the default wrap-around behavior for overflows and implement saturation behavior, for instance.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Add One to Maximum Unsigned Integer

```
#include <limits.h>

unsigned int plusplus(void) {

    unsigned uvar = UINT_MAX;
    uvar++;
    return uvar;
}
```

In the third statement of this function, the variable `uvar` is increased by 1. However, the value of `uvar` is the maximum unsigned integer value, so 1 plus the maximum integer value cannot be represented by an `unsigned int`. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `uvar` is reduced by modulo `UINT_MAX`. The result is `uvar = 1`.

#### Correction — Different Storage Type

One possible correction is to store the operation result in a larger data type. In this example, by returning an `unsigned long long` instead of an `unsigned int`, the overflow error is fixed.

```
#include <limits.h>

unsigned long long plusplus(void) {

    unsigned long long ullvar = UINT_MAX;
    ullvar++;
    return ullvar;
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `UINT_OVFL`
**Impact:** Low

# Version History

**Introduced in R2013b**

# Use of plain char type for numeric value

Plain `char` variable in arithmetic operation without explicit signedness

## Description

This defect occurs when `char` variables without explicit signedness are used in these ways:

- To store non-`char` constants.
- In an arithmetic operation when the `char` is:
  - A negative value.
  - The result of a sign changing overflow.
- As a buffer offset.

`char` variables without a `signed` or `unsigned` qualifier can be signed or unsigned depending on your compiler.

### Risk

Operations on a plain char can result in unexpected numerical values. If the char is used as an offset, the char can cause buffer overflow or underflow.

### Fix

When initializing a char variable, to avoid implementation-defined confusion, explicitly state whether the char is signed or unsigned.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Divide by `char` Variable

```
#include <stdio.h>

void badplaincharuse(void)
{
    char c = 200;
    int i = 1000;
    (void)printf("i/c = %d\n", i/c);
}
```

In this example, the char variable `c` can be signed or unsigned depending on your compiler. Assuming 8-bit, two's complement character types, the result is either `i/c = 5` (unsigned char) or `i/c = -17` (signed char). The correct result is unknown without knowing the signedness of `char`.

#### Correction — Add signed Qualifier

One possible correction is to add a signed qualifier to char. This clarification makes the operation defined.

```
#include <stdio.h>

void badplaincharuse(void)
{
    signed char c = -56;
    int i = 1000;
    (void)printf("i/c = %d\n", i/c);
}
```

## Result Information

**Group:** Numerical
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** BAD_PLAIN_CHAR_USE
**Impact:** Medium

# Version History

**Introduced in R2016b**

# Static Memory Defects

# Arithmetic operation with NULL pointer

Arithmetic operation performed on NULL pointer

## Description

This defect occurs when an arithmetic operation involves a pointer whose value is NULL.

### Risk

Performing pointer arithmetic on a null pointer and dereferencing the resulting pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

### Fix

Check a pointer for NULL before arithmetic operations on the pointer.

If the issue occurs despite an earlier check for NULL, look for intermediate events between the check and the subsequent dereference. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

## Examples

### Arithmetic Operation with NULL Pointer Error

```
#include<stdlib.h>

int Check_Next_Value(int *loc, int val)
 {
  int *ptr = loc, found = 0;

  if (ptr==NULL)
   {
     ptr++;
     /* Defect: NULL pointer shifted */

     if (*ptr==val) found=1;
   }

  return(found);
 }
```

When ptr is a NULL pointer, the code enters the if statement body. Therefore, a NULL pointer is shifted in the statement ptr++.

#### Correction — Avoid NULL Pointer Arithmetic

One possible correction is to perform the arithmetic operation when `ptr` is not `NULL`.

```
#include<stdlib.h>

int Check_Next_Value(int *loc, int val)
 {
  int *ptr = loc, found = 0;

  /* Fix: Perform operation when ptr is not NULL */
  if (ptr!=NULL)
   {
     ptr++;

     if (*ptr==val) found=1;
   }

  return(found);
 }
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `NULL_PTR_ARITH`
**Impact:** Low

# Version History

**Introduced in R2013b**

# Array access out of bounds

Array index outside bounds during array access

## Description

This defect occurs when an array index falls outside the range `[0...array_size-1]` during array access.

### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Array Access Out of Bounds Error

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);
    /* Defect: Value of i is greater than allowed value of 9 */
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

#### Correction — Keep Array Index Within Array Bounds

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];

   for (i = 0; i < 10; i++)
    {
        if (i < 2)
            fib[i] = 1;
        else
            fib[i] = fib[i-1] + fib[i-2];
    }

    /* Fix: Print fib[9] instead of fib[10] */
    printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `OUT_BOUND_ARRAY`
**Impact:** High

# Buffer overflow from incorrect string format specifier

String format specifier causes buffer argument of standard library functions to overflow

## Description

This defect occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

### Fix

Use a format specifier that is compatible with the memory buffer size.

## Examples

### Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf);
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

**Correction — Use Smaller Precision in Format Specifier**

One possible correction is to read a smaller number of elements into the buffer.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `STR_FORMAT_BUFFER_OVERFLOW`
**Impact:** High

## Version History

# Destination buffer overflow in string manipulation

Function writes to buffer at offset greater than buffer size

## Description

This defect occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

## Examples

### Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string);
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

**Correction — Use `snprintf` Instead of `sprintf`**

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `STRLIB_BUFFER_OVERFLOW`
**Impact:** High

# Version History

**Introduced in R2015b**

# Destination buffer underflow in string manipulation

Function writes to buffer at a negative offset from beginning of buffer

## Description

This defect occurs when certain string manipulation functions write to their destination buffer argument at a negative offset from the beginning of the buffer.

For instance, for the function `sprintf(char* buffer, const char* format)`, you obtain the `buffer` from an operation `buffer = (char*)arr; ... buffer += offset;`. `arr` is an array and `offset` is a negative value.

### Risk

Buffer underflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer underflow also introduces the risk of code injection.

### Fix

If the destination buffer argument results from pointer arithmetic, see if you are decrementing a pointer. Fix the pointer decrement by modifying either the original value before decrement or the decrement value.

## Examples

### Buffer Underflow in `sprintf` Use

```
#include <stdio.h>
#define offset -2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";

    sprintf(&buffer[offset], fmt_string);
}
```

In this example, `&buffer[offset]` is at a negative offset from the memory allocated to `buffer`.

#### Correction — Change Pointer Decrementer

One possible correction is to change the value of `offset`.

```
#include <stdio.h>
#define offset 2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";
    sprintf(&buffer[offset], fmt_string);
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `STRLIB_BUFFER_UNDERFLOW`
**Impact:** High

# Version History

**Introduced in R2015b**

# Invalid use of standard library memory routine

Standard library memory function called with invalid arguments

## Description

This defect occurs when a memory library function is called with invalid arguments. For instance, the `memcpy` function copies to an array that cannot accommodate the number of bytes copied.

### Risk

Use of a memory library function with invalid arguments can result in issues such as buffer overflow.

### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Invalid Use of Standard Library Memory Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  char str1[10],str2[5];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  /* Defect: Arguments of memcpy invalid: str2 has size < 6 */

  return str2;
 }
```

The size of string `str2` is 5, but six characters of string `str1` are copied into `str2` using the `memcpy` function.

#### Correction — Call Function with Valid Arguments

One possible correction is to adjust the size of `str2` so that it accommodates the characters copied with the `memcpy` function.

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  /* Fix: Declare str2 with size 6 */
  char str1[10],str2[6];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  return str2;
 }
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `MEM_STD_LIB`
**Impact:** High

# Version History

# Invalid use of standard library string routine

Standard library string function called with invalid arguments

## Description

This defect occurs when a string library function is called with invalid arguments.

### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source)
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Invalid Use of Standard Library String Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_String(void)
{
 char *res;
 char gbuffer[5],text[20]="ABCDEFGHIJKL";

 res=strcpy(gbuffer,text);
 /* Error: Size of text is less than gbuffer */

 return(res);
}
```

The string text is larger in size than gbuffer. Therefore, the function strcpy cannot copy text into gbuffer.

**Correction — Use Valid Arguments**

One possible correction is to declare the destination string gbuffer with equal or larger size than the source string text.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

## Result Information

# Move operation on const object

`std::move` function is called with object declared `const` or `const&`

## Description

This defect occurs when the `std::move` function is called with an object declared `const` or `const&`.

### Risk

For objects declared `const` or `const&`, unlike what you might expect, the copy constructor is called instead of the move constructor.

### Fix

Avoid calling the `std::move` function on `const` objects. If you want to perform a move operation, cast the `const` object to a non-`const` one and then move the non-`const` object.

Note that this issue might also trigger the checker `Const std::move input may cause a more expensive object copy`. If you decide to justify the issue, you can use the same justification for both results.

## Result Information

**Group:** Programming
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `MOVE_CONST_OBJECT`
**Impact:** High

# Dereference of a null pointer

NULL pointer dereferenced

## Description

This defect occurs when you use a pointer with a value of NULL as if it points to a valid memory location. If you dereference the zero address, such as 0x00, Polyspace considers the null address as equivalent to NULL and raises this defect.

### Risk

Dereferencing a null pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

### Fix

Check a pointer for NULL before dereference.

If the issue occurs despite an earlier check for NULL, look for intermediate events between the check and the subsequent dereference. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Null pointer error

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 int* p=NULL;

 *p=arr[0];
 /* Defect: Null pointer dereference */

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

The pointer p is initialized with value of NULL. However, when the value arr[0] is written to *p, p is assumed to point to a valid memory location.

**Correction — Assign Address to Null Pointer Before Dereference**

One possible correction is to initialize p with a valid memory address before dereference.

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 /* Fix: Assign address to null pointer */
 int* p=&arr[0];

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** NULL_PTR
**Impact:** High

# Version History

**Introduced in R2013b**

# Pointer access out of bounds

Pointer dereferenced outside its bounds

## Description

This defect occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i;
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

## Result Information

# Pointer or reference to stack variable leaving scope

Pointer to local variable leaves the variable scope

## Description

This defect occurs when a pointer or reference to a local variable leaves the scope of the variable. For instance:

- A function returns a pointer to a local variable.
- A function performs the assignment `globPtr = &locVar`. `globPtr` is a global pointer variable and `locVar` is a local variable.
- A function performs the assignment `*paramPtr = &locVar`. `paramPtr` is a function parameter that is, for instance, an `int**` pointer and `locVar` is a local `int` variable.
- A C++ method performs the assignment `memPtr = &locVar`. `memPtr` is a pointer data member of the class the method belongs to. `locVar` is a variable local to the method.
- (C++11 and later) A function returns a lambda expression object that captures local variables of the function by reference.

The defect also applies to memory allocated using the `alloca` function. The defect does not apply to static, local variables. Polyspace assumes that the local objects within a function definition are in the same scope.

### Risk

Local variables are allocated an address on the stack. Once the scope of a local variable ends, this address is available for reuse. Using this address to access the local variable value outside the variable scope can cause unexpected behavior.

If a pointer to a local variable leaves the scope of the variable, Polyspace Bug Finder highlights the defect. The defect appears even if you do not use the address stored in the pointer. For maintainable code, it is a good practice to not allow the pointer to leave the variable scope. Even if you do not use the address in the pointer now, someone else using your function can use the address, causing undefined behavior.

### Fix

Do not allow a pointer or reference to a local variable to leave the variable scope.

## Examples

### Pointer to Local Variable Returned from Function

```
void func2(int *ptr) {
    *ptr = 0;
}
```

```
int* func1(void) {
    int ret = 0;
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

In this example, `func1` returns a pointer to local variable `ret`.

In `main`, `ptr` points to the address of the local variable. When `ptr` is accessed in `func2`, the access is illegal because the scope of `ret` is limited to `func1`,

#### Pointer to Local Variable Escapes Through Lambda Expression

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;
  auto adder = [&] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

In this example, the `createAdder` function defines a lambda expression `adder` that captures the local variable `addThis` by reference. The scope of `addThis` is limited to the `createAdder` function. When the object returned by `createAdder` is called, a reference to the variable `addThis` is accessed outside its scope. When accessed in this way, the value of `addThis` is undefined.

##### Correction – Capture Local Variables by Copy in Lambda Expression Instead of Reference

If a function returns a lambda expression object, avoid capturing local variables by reference in the lambda object. Capture the variables by copy instead.

Variables captured by copy have the same lifetime as the lambda object, but variables captured by reference often have a smaller lifetime than the lambda object itself. When the lambda object is used, these variables accessed outside scope have undefined values.

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;
  auto adder = [=] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `LOCAL_ADDR_ESCAPE`
**Impact:** High

# Subtraction or comparison between pointers to different arrays

Subtraction or comparison between pointers causes undefined behavior

## Description

This defect occurs when you subtract or compare pointers that are null or that point to elements in different arrays. The relational operators for the comparison are >, <, >=, and <=.

### Risk

When you subtract two pointers to elements in the same array, the result is the difference between the subscripts of the two array elements. Similarly, when you compare two pointers to array elements, the result is the positions of the pointers relative to each other. If the pointers are null or point to different arrays, a subtraction or comparison operation is undefined. If you use the subtraction result as a buffer index, it can cause a buffer overflow.

### Fix

Before you subtract or use relational operators to compare pointers to array elements, check that they are non-null and that they point to the same array.

## Examples

### Subtraction Between Pointers to Elements in Different Arrays

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int end;
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation is undefined unless array nums
    is adjacent to variable end in memory. */
    free_elements = &end - next_num_ptr;
    return free_elements;
}
```

In this example, the array `nums` is incrementally filled. Pointer subtraction is then used to determine how many free elements remain. Unless `end` points to a memory location one past the last element of `nums`, the subtraction operation is undefined.

#### Correction — Subtract Pointers to the Same Array

Subtract the pointer to the last element that was filled from the pointer to the last element in the array.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation involves pointers to the same array. */
    free_elements = &(nums[SIZE20 - 1]) - next_num_ptr;

    return free_elements + 1;
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `PTR_TO_DIFF_ARRAY`
**Impact:** High

# Unreliable cast of function pointer

Function pointer cast to another function pointer with different argument or return type

## Description

This defect occurs when a function pointer is cast to another function pointer that has different argument or return type.

### Risk

If you cast a function pointer to another function pointer with different argument or return type and then use the latter function pointer to call a function, the behavior is undefined.

### Fix

Avoid a cast between two function pointers with mismatch in argument or return types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Unreliable cast of function pointer error

```
#include <stdio.h>
#include <math.h>
#define PI 3.142

double Calculate_Sum(int (*fptr)(double))
{
    double  sum = 0.0;
    double  y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);
    /* Defect: fp implicitly cast to int(*) (double) */

    printf("sum(sin): %f\n", sum);
    return 0;
}
```

The function pointer `fp` is declared as `double (*)(double)`. However in passing it to function `Calculate_Sum`, `fp` is implicitly cast to `int (*)(double)`.

**Correction — Avoid Function Pointer Cast**

One possible correction is to check that the function pointer in the definition of `Calculate_Sum` has the same argument and return type as `fp`. This step makes sure that `fp` is not implicitly cast to a different argument or return type.

```
#include <stdio.h>
#include <math.h>
# define PI 3.142

/*Fix: fptr has same argument and return type everywhere*/
double Calculate_Sum(double (*fptr)(double))
{
    double  sum = 0.0;
    double y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);
    printf("sum(sin): %f\n", sum);

    return 0;
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `FUNC_CAST`

**Impact:** Medium

## Version History

**Introduced in R2013b**

# Unreliable cast of pointer

Pointer implicitly cast to different data type

## Description

This defect occurs when a pointer is implicitly cast to a data type different from its declaration type. Such an implicit casting can take place, for instance, when a pointer to data type `char` is assigned the address of an integer.

This defect applies only if the code language for the project is C.

### Risk

Casting a pointer to data type different from its declaration type can result in issues such as buffer overflow. If the cast is implicit, it can indicate a coding error.

### Fix

Avoid *implicit* cast of a pointer to a data type different from its declaration type.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Unreliable cast of pointer error

```
#include <string.h>

void Copy_Integer_To_String()
{
 int src[]={1,2,3,4,5,6,7,8,9,10};
 char buffer[]="Buffer_Text";
 strcpy(buffer,src);
 /* Defect: Implicit cast of (int*) to (char*) */
}
```

`src` is declared as an `int*` pointer. The `strcpy` statement, while copying to `buffer`, implicitly casts `src` to `char*`.

#### Correction — Avoid Pointer Cast

One possible correction is to declare the pointer `src` with the same data type as `buffer`.

```
#include <string.h>
 void Copy_Integer_To_String()
{
 /* Fix: Declare src with same type as buffer */
 char *src[10]={"1","2","3","4","5","6","7","8","9","10"};
 char *buffer[10];

 for(int i=0;i<10;i++)
   buffer[i]="Buffer_Text";

 for(int i=0;i<10;i++)
   buffer[i]= src[i];
 }
```

### Result Information

**Group:** Static memory
**Language:** C
**Default:** On
**Command-Line Syntax:** PTR_CAST
**Impact:** Medium

## Version History

**Introduced in R2013b**

# Use of automatic variable as putenv-family function argument

putenv-family function argument not accessible outside its scope

## Description

This defect occurs when the argument of a `putenv`-family function is a local variable with automatic duration.

### Risk

The function `putenv(char *string)` inserts a pointer to its supplied argument into the environment array, instead of making a copy of the argument. If the argument is an automatic variable, its memory can be overwritten after the function containing the `putenv()` call returns. A subsequent call to `getenv()` from another function returns the address of an out-of-scope variable that cannot be dereferenced legally. This out-of-scope variable can cause environment variables to take on unexpected values, cause the program to stop responding, or allow arbitrary code execution vulnerabilities.

### Fix

Use `setenv()`/`unsetenv()` to set and unset environment variables. Alternatively, use `putenv`-family function arguments with dynamically allocated memory, or, if your application has no reentrancy requirements, arguments with static duration. For example, a single thread execution with no recursion or interrupts does not require reentrancy. It cannot be called (reentered) during its execution.

## Examples

### Automatic Variable as Argument of `putenv()`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
{
    char env[SIZE1024];
    int retval = sprintf(env, "TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }
    /* Environment variable TEST is set using putenv().
    The argument passed to putenv is an automatic variable. */
    retval = putenv(env);
    if (retval != 0) {
        /* Handle error */
    }
}
```

In this example, sprintf() stores the character string TEST=var in env. The value of the environment variable TEST is then set to var by using putenv(). Because env is an automatic variable, the value of TEST can change once func() returns.

#### Correction — Use static Variable for Argument of putenv()

Declare env as a static-duration variable. The memory location of env is not overwritten for the duration of the program, even after func() returns.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024
void func(int var)
{
    /* static duration variable */
    static char env[SIZE1024];
    int retval = sprintf(env,"TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }

    /* Environment variable TEST is set using putenv() */
    retval=putenv(env);
    if (retval != 0) {
        /* Handle error */
    }
}
```

#### Correction — Use setenv() to Set Environment Variable Value

To set the value of TEST to var, use setenv().

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
{
    /* Environment variable TEST is set using setenv() */
    int retval = setenv("TEST", var ? "1" : "0", 1);

    if (retval != 0) {
        /* Handle error */
    }
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** On for handwritten code, off for generated code

**Command-Line Syntax:** `PUTENV_AUTO_VAR`
**Impact:** High

## Version History

**Introduced in R2017b**

# Use of path manipulation function without maximum-sized buffer checking

Destination buffer of getwd or realpath is smaller than PATH_MAX bytes

## Description

This defect occurs when the destination argument of a path manipulation function such as realpath or getwd has a buffer size less than PATH_MAX bytes.

### Risk

A buffer smaller than PATH_MAX bytes can overflow but you cannot test the function return value to determine if an overflow occurred. If an overflow occurs, following the function call, the content of the buffer is undefined.

For instance, char *getwd(char *buf) copies an absolute path name of the current folder to its argument. If the length of the absolute path name is greater than PATH_MAX bytes, getwd returns NULL and the content of *buf is undefined. You can test the return value of getwd for NULL to see if the function call succeeded.

However, if the allowed buffer for buf is less than PATH_MAX bytes, a failure can occur for a smaller absolute path name. In this case, getwd does not return NULL even though a failure occurred. Therefore, the allowed buffer for buf must be PATH_MAX bytes long.

### Fix

Possible fixes are:

- Use a buffer size of PATH_MAX bytes. If you obtain the buffer from an unknown source, before using the buffer as argument of getwd or realpath function, make sure that the size is less than PATH_MAX bytes.
- Use a path manipulation function that allows you to specify a buffer size.

  For instance, if you are using getwd to get the absolute path name of the current folder, use char *getcwd(char *buf, size_t size); instead. The additional argument size allows you to specify a size greater than or equal to PATH_MAX.
- Allow the function to allocate additional memory dynamically, if possible.

  For instance, char *realpath(const char *path, char *resolved_path); dynamically allocates memory if resolved_path is NULL. However, you have to deallocate this memory later using the free function.

## Examples

### Possible Buffer Overflow in Use of getwd Function

```
#include <unistd.h>
#include <linux/limits.h>
```

```
#include <stdio.h>

void func(void) {
    char buf[PATH_MAX];
    if (getwd(buf+1)!= NULL)         {
        printf("cwd is %s\n", buf);
    }
}
```

In this example, although the array `buf` has `PATH_MAX` bytes, the argument of `getwd` is `buf + 1`, whose allowed buffer is less than `PATH_MAX` bytes.

#### Correction — Use Array of Size PATH_MAX Bytes

One possible correction is to use an array argument with size equal to `PATH_MAX` bytes.

```
#include <unistd.h>
#include <linux/limits.h>
#include <stdio.h>

void func(void) {
    char buf[PATH_MAX];
    if (getwd(buf)!= NULL)         {
        printf("cwd is %s\n", buf);
    }
}
```

## Result Information

**Group:** Static memory
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `PATH_BUFFER_OVERFLOW`
**Impact:** High

# Version History

**Introduced in R2015b**

# Wrong allocated object size for cast

Allocated memory does not match destination pointer

## Description

This defect occurs during pointer conversion when the pointer's address is misaligned. If a pointer is converted to a different pointer type, the size of the allocated memory must be a multiple of the size of the destination pointer.

### Risk

Dereferencing a misaligned pointer has undefined behavior and can cause your program to crash.

### Fix

Suppose you convert a pointer `ptr1` to `ptr2`. If `ptr1` points to a buffer of `N` bytes and `ptr2` is a *`type`* `*` pointer where `sizeof(`*`type`*`)` is `n` bytes, make sure that `N` is an integer multiple of `n`.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Dynamic Allocation of Pointers

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(13);
    long *dest;

    dest = (long*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to a `long*`. The dynamically allocated memory of `ptr`, 13 bytes, is not a multiple of the size of `dest`, 4 bytes. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the allocated memory to 12 instead of 13.

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(12);
    long *dest;

    dest = (long*)ptr;
}
```

### Static Allocation of Pointers

```
void static_non_align(void){
    char arr[13], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to an `int*` in line 6. `ptr` has a memory size of 13 bytes because the array `arr` has a size of 13 bytes. The size of `dest` is 4 bytes, which is not a multiple of 13. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the size of the array `arr` to a multiple of 4.

```
void static_non_align(void){
    char arr[12], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr;
}
```

### Allocation with a Function

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(13);  //defect
    dest2 = (char*)my_alloc(13); //not a defect
}
```

In this example, the software raises a defect on the conversion of the pointer returned by `my_alloc(13)` to an `int*` in line 11. `my_alloc(13)` returns a pointer with a dynamically allocated size of 13 bytes. The size of `dest1` is 4 bytes, which is not a divisor of 13. This misalignment causes the **Wrong allocated object size for cast** defect. In line 12, the same function call, `my_alloc(13)`, does not call a defect for the conversion to `dest2` because the size of `char*`, 1 byte, a divisor of 13.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the argument for `my_alloc` to a multiple of 4.

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(12);
    dest2 = (char*)my_alloc(13);
}
```

# Dynamic Memory Defects

# Alignment changed after memory reallocation

Memory reallocation changes the originally stricter alignment of an object

## Description

This defect occurs when you use `realloc()` to modify the size of objects with strict memory alignment requirements.

### Risk

The pointer returned by `realloc()` can be suitably assigned to objects with less strict alignment requirements. A misaligned memory allocation can lead to buffer underflow or overflow, an illegally dereferenced pointer, or access to arbitrary memory locations. In processors that support misaligned memory, the allocation impacts the performance of the system.

### Fix

To reallocate memory:

1. Resize the memory block.
   - In Windows, use `_aligned_realloc()` with the alignment argument used in `_aligned_malloc()` to allocate the original memory block.
   - In UNIX/Linux, use the same function with the same alignment argument used to allocate the original memory block.
2. Copy the original content to the new memory block.
3. Free the original memory block.

**Note** This fix has implementation-defined behavior. The implementation might not support the requested memory alignment and can have additional constraints for the size of the new memory.

## Examples

### Memory Reallocated Without Preserving the Original Alignment

```
#include <stdio.h>
#include <stdlib.h>

#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;
    int *ptr1;

    /* Allocate memory with 4096 bytes alignment */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
      }

    /*Reallocate memory without using the original alignment.
    ptr1 may not be 4096 bytes aligned. */

    ptr1 = (int *)realloc(ptr, sizeof(int) * resize);

    if (ptr1 == NULL)
    {
        /* Handle error */
    }

    /* Processing using ptr1 */

    /* Free before exit */
    free(ptr1);
}
```

In this example, the allocated memory is 4096-bytes aligned. `realloc()` then resizes the allocated memory. The new pointer `ptr1` might not be 4096-bytes aligned.

**Correction — Specify the Alignment for the Reallocated Memory**

When you reallocate the memory, use `posix_memalign()` and pass the alignment argument that you used to allocate the original memory.

```
#include <stdio.h>
#include <stdlib.h>

#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;

    /* Allocate memory with 4096 bytes alignment */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
    }

    /* Reallocate memory using the original alignment. */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int) * resize) != 0)
    {
        /* Handle error */
        free(ptr);
        ptr = NULL;
    }
    /* Processing using ptr */

    /* Free before exit */
    free(ptr);
}
```

## Result Information

# Deallocation of previously deallocated pointer

Memory freed more than once without allocation

## Description

This defect occurs when a block of memory is freed more than once using the `free` function without an intermediate allocation.

### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to free this block of memory can result in a segmentation fault.

### Fix

The fix depends on the root cause of the defect. See if you intended to allocate a memory block to the pointer between the first deallocation and the second. Otherwise, remove the second `free` statement.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before freeing pointers, check them for NULL values and handle the error. In this way, you are protected against freeing an already freed block.

## Examples

### Deallocation of Previously Deallocated Pointer Error

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    free (pi);
    /* Defect: pi has already been freed */
}
```

The first `free` statement releases the block of memory that `pi` refers to. The second `free` statement on `pi` releases a block of memory that has been freed already.

#### Correction — Remove Duplicate Deallocation

One possible correction is to remove the second `free` statement.

```
#include <stdlib.h>
```

```
void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    /* Fix: remove second deallocation */
 }
```

#### Freeing Pointer Previously Reallocated With Possibly Zero Size

```
#include <stdlib.h>

void reshape(char *buf, size_t size) {
  char *reshaped_buf = (char *)realloc(buf, size);
  if (reshaped_buf == NULL) {
    free(buf);
  }
}
```

In this example, the argument `size` of the `reshape()` function can be zero and result in a zero-size reallocation with `realloc()`. In some implementations such as the GNU library, zero-size reallocations free the memory leading to a double free defect.

##### Correction – Guard Against Zero-Size Reallocations

One possible correction is to check size argument of `realloc()` for zero values before use. If the size argument is zero, you can simply free the memory instead of reallocating it.

```
#include <stdlib.h>

void reshape(char *buf, size_t size) {
  if (size != 0) {
    char *reshaped_buf = (char *)realloc(buf, size);
    if (reshaped_buf == NULL) {
      free(buf);
    }
  }
  else {
    free(buf);
  }

}
```

## Result Information

# Invalid deletion of pointer

Pointer deallocation using `delete` without corresponding allocation using `new`

## Description

This defect occurs when:

- You release a block of memory with the `delete` operator but the memory was previously not allocated with the `new` operator.
- You release a block of memory with the `delete` operator using the single-object notation but the memory was previously allocated as an array with the `new` operator.

This defect applies only to C++ source files.

### Risk

The risk depends on the cause of the issue:

- The `delete` operator releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.
- If you use the single-object notation for `delete` on a pointer that is previously allocated with the array notation for `new`, the behavior is undefined.

The issue can also highlight other coding errors. For instance, you perhaps wanted to use the `delete` operator or a previous `new` operator on a different pointer.

### Fix

The fix depends on the cause of the issue:

- In most cases, you can fix the issue by removing the `delete` statement. If the pointer is not allocated memory from the heap with the `new` operator, you do not need to release the pointer with `delete`. You can simply reuse the pointer as required or let the object be destroyed at the end of its scope.
- In case of mismatched notation for `new` and `delete`, correct the mismatch. For instance, to allocate and deallocate a single object, use this notation:

  ```
  classType* ptr = new classType;
  delete ptr;
  ```

  To allocate and deallocate an array objects, use this notation:

  ```
  classType* p2 = new classType[10];
  delete[] p2;
  ```

If the issue highlights a coding error such as use of `delete` or `new` on the wrong pointer, correct the error.

## Examples

### Deleting Static Memory

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;

    delete[] ptr;
}
```

The pointer `ptr` is released using the `delete` operator. However, `ptr` points to a memory location that was not dynamically allocated.

#### Correction: Remove Pointer Deallocation

If the number of elements of the array `ptr` is known at compile time, one possible correction is to remove the deallocation of the pointer `ptr`.

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;
}
```

#### Correction — Add Pointer Allocation

If the number of array elements is not known at compile time, one possible correction is to dynamically allocate memory to the array `ptr` using the `new` operator.

```
void assign_ones(int num)
{
    int *ptr = new int[num];

    for(int i=0; i < num; i++)
        *(ptr+i) = 1;

    delete[] ptr;
   }
```

### Mismatched new and delete

```
int main (void)
{
    int *p_scale = new int[5];

    //more code using scal

    delete p_scale;
}
```

In this example, `p_scale` is initialized to an array of size 5 using `new int[5]`. However, `p_scale` is deleted with `delete` instead of `delete[]`. The `new`-`delete` pair does not match. Do not use `delete` without the brackets when deleting arrays.

### Correction — Match delete to new

One possible correction is to add brackets so the `delete` matches the `new []` declaration.

```
int main (void)
{
    int *p_scale = new int[5];

    //more code using p_scale

    delete[] p_scale;
}
```

### Correction — Match new to delete

Another possible correction is to change the declaration of `p_scale`. If you meant to initialize `p_scale` as 5 itself instead of an array of size 5, you must use different syntax. For this correction, change the square brackets in the initialization to parentheses. Leave the `delete` statement as it is.

```
int main (void)
{
    int *p_scale = new int(5);

    //more code using p_scale

    delete p_scale;
}
```

## Result Information

**Group:** Dynamic memory
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `BAD_DELETE`
**Impact:** High

# Invalid free of pointer

Pointer deallocation without a corresponding dynamic allocation

## Description

This defect occurs when a block of memory released using the free function was not previously allocated using malloc, calloc, or realloc.

### Risk

The free function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the free function or a previous malloc function on a different pointer.

### Fix

In most cases, you can fix the issue by removing the free statement. If the pointer is not allocated memory from the heap with malloc or calloc, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of free or malloc on the wrong pointer, correct the error.

If the issue occurs because you use the free function to free memory allocated with the new operator, replace the free function with the delete operator.

## Examples

### Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;

  free(p);
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer p is deallocated using the free function. However, p points to a memory location that was not dynamically allocated.

#### Correction — Remove Pointer Deallocation

If the number of elements of the array p is known at compile time, one possible correction is to remove the deallocation of the pointer p.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

**Correction — Introduce Pointer Allocation**

If the number of elements of the array `p` is not known at compile time, one possible correction is to dynamically allocate memory to the array `p`.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

## Result Information

# Memory leak

Memory allocated dynamically not freed

## Description

This defect occurs when you do not free a block of memory allocated through `malloc`, `calloc`, `realloc`, or `new`. If the memory is allocated in a function, the defect does not occur if:

- Within the function, you free the memory using `free` or `delete`.
- The function returns the pointer assigned by `malloc`, `calloc`, `realloc`, or `new`.
- The function stores the pointer in a global variable or in a parameter.

### Risk

Dynamic memory allocation functions such as `malloc` allocate memory on the heap. If you do not release the memory after use, you reduce the amount of memory available for another allocation. On embedded systems with limited memory, you might end up exhausting available heap memory even during program execution.

### Fix

Determine the scope where the dynamically allocated memory is accessed. Free the memory block at the end of this scope.

To free a block of memory, use the `free` function on the pointer that was used during memory allocation. For instance:

```
ptr = (int*)malloc(sizeof(int));
...
free(ptr);
```

It is a good practice to allocate and free memory in the same module at the same level of abstraction. For instance, in this example, `func` allocates and frees memory at the same level but `func2` does not.

```
void func() {
  ptr = (int*)malloc(sizeof(int));
  {
    ...
  }
  free(ptr);
}

void func2() {
  {
   ptr = (int*)malloc(sizeof(int));
   ...
  }
  free(ptr);
}
```

See CERT-C Rule MEM00-C.

## Examples

### Dynamic Memory Not Released Before End of Function

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }

    *pi = 42;
    /* Defect: pi is not freed */
}
```

In this example, `pi` is dynamically allocated by `malloc`. The function `assign_memory` does not free the memory, nor does it return `pi`.

#### Correction — Free Memory

One possible correction is to free the memory referenced by `pi` using the `free` function. The `free` function must be called before the function `assign_memory` terminates

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }
    *pi = 42;

    /* Fix: Free the pointer pi*/
    free(pi);
}
```

#### Correction — Return Pointer from Dynamic Allocation

Another possible correction is to return the pointer `pi`. Returning `pi` allows the function calling `assign_memory` to free the memory block using `pi`.

```
#include<stdlib.h>
#include<stdio.h>

int* assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
```

```
        {
            printf("Memory allocation failed");
            return(pi);
        }
    *pi = 42;

    /* Fix: Return the pointer pi*/
    return(pi);
}
```

#### Memory Leak with New/Delete

```
#define NULL '\0'

void initialize_arr1(void)
{
    int *p_scalar = new int(5);
}

void initialize_arr2(void)
{
    int *p_array = new int[5];
}
```

In this example, the functions create two variables, `p_scalar` and `p_array`, using the `new` keyword. However, the functions end without cleaning up the memory for these pointers. Because the functions used `new` to create these variables, you must clean up their memory by calling `delete` at the end of each function.

##### Correction — Add Delete

To correct this error, add a `delete` statement for every `new` initialization. If you used brackets `[]` to instantiate a variable, you must call delete with brackets as well.

```
#define NULL '\0'

void initialize_arrs(void)
{
    int *p_scalar = new int(5);
    int *p_array = new int[5];

    delete p_scalar;
    p_scalar = NULL;

    delete[] p_array;
    p_scalar = NULL;
}
```

## Result Information

# Mismatched alloc/dealloc functions on Windows

Improper deallocation function causes memory corruption issues

## Description

This defect occurs when you use a Windows deallocation function that is not properly paired to its corresponding allocation function.

### Risk

Deallocating memory with a function that does not match the allocation function can cause memory corruption or undefined behavior. If you are using an older version of Windows, the improper function can also cause compatibility issues with newer versions.

### Fix

Properly pair your allocation and deallocation functions according to the functions listed in this table.

| Allocation Function | Deallocation Function |
|---|---|
| malloc() | free() |
| realloc() | free() |
| calloc() | free() |
| _aligned_malloc() | _aligned_free() |
| _aligned_offset_malloc() | _aligned_free() |
| _aligned_realloc() | _aligned_free() |
| _aligned_offset_realloc() | _aligned_free() |
| _aligned_recalloc() | _aligned_free() |
| _aligned_offset_recalloc() | _aligned_free() |
| _malloca() | _freea() |
| LocalAlloc() | LocalFree() |
| LocalReAlloc() | LocalFree() |
| GlobalAlloc() | GlobalFree() |
| GlobalReAlloc() | GlobalFree() |
| VirtualAlloc() | VirtualFree() |
| VirtualAllocEx() | VirtualFreeEx() |
| VirtualAllocExNuma() | VirtualFreeEx() |
| HeapAlloc() | HeapFree() |
| HeapReAlloc() | HeapFree() |

## Examples

### Memory Deallocated with Incorrect Function

```
#ifdef _WIN32_
#include <windows.h>
#else
#define _WIN32_
typedef void *HANDLE;
typedef HANDLE HGLOBAL;
typedef HANDLE HLOCAL;
typedef unsigned int UINT;
extern HLOCAL LocalAlloc(UINT uFlags, UINT uBytes);
extern HLOCAL LocalFree(HLOCAL hMem);
extern HGLOBAL GlobalFree(HGLOBAL hMem);
#endif

#define SIZE9 9

void func(void)
{
    /* Memory allocation */
    HLOCAL p = LocalAlloc(0x0000, SIZE9);

    if (p) {
        /* Memory deallocation. */
        GlobalFree(p);

    }
}
```

In this example, memory is allocated with `LocallAlloc()`. The program then erroneously uses `GlobalFree()` to deallocate the memory.

#### Correction — Properly Pair Windows Allocation and Deallocation Functions

When you allocate memory with `LocalAllocate()`, use `LocalFree()` to deallocate the memory.

```
#ifdef _WIN32_
#include <windows.h>
#else
#define _WIN32_
typedef void *HANDLE;
typedef HANDLE HGLOBAL;
typedef HANDLE HLOCAL;
typedef unsigned int UINT;
extern HLOCAL LocalAlloc(UINT uFlags, UINT uBytes);
extern HLOCAL LocalFree(HLOCAL hMem);
extern HGLOBAL GlobalFree(HGLOBAL hMem);
#endif

#define SIZE9 9
void func(void)
{
    /* Memory allocation */
    HLOCAL p = LocalAlloc(0x0000, SIZE9);
    if (p) {
        /* Memory deallocation. */
        LocalFree(p);
    }
}
```

### Result Information

**Group:** Dynamic memory
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `WIN_MISMATCH_DEALLOC`
**Impact:** Low

## Version History

**Introduced in R2017b**

# Unprotected dynamic memory allocation

Pointer returned from dynamic allocation not checked for NULL or nullptr value

## Description

This defect occurs when you access dynamically allocated memory without first checking if the prior memory allocation succeeded.

### Risk

When memory is dynamically allocated using malloc, calloc, or realloc, it returns a value NULL if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this NULL value, this access is not protected from failures.

### Fix

Check the return value of malloc, calloc, or realloc for NULL before accessing the allocated memory location.

```
int *ptr = malloc(size * sizeof(int));

if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

## Examples

### Unprotected dynamic memory allocation error

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));

  *p = 2;
  /* Defect: p is not checked for NULL value */

  free(p);
}
```

If the memory allocation fails, the function calloc returns NULL to p. Before accessing the memory through p, the code does not check whether p is NULL

#### Correction — Check for NULL Value

One possible correction is to check whether p has value NULL before dereference.

```
#include <stdlib.h>

void Assign_Value(void)
```

```
 {
   int* p = (int*)calloc(5, sizeof(int));

   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;

   free(p);
 }
```

**Unprotected dynamic memory allocation error only on dereference**

```
#include <stdlib.h>
#include<string.h>
typedef struct recordType {
    const char* id;
    const char* data;
} RECORD;

RECORD* MakerecordType(const char *id,unsigned int size){
    RECORD *rec = (RECORD *)calloc(1, sizeof(RECORD));
    rec->id = strdup(id);

    const char *newData = (char *)calloc(1, size);
    rec->data = newData;
    return rec;
}
```

In this example, the checker raises a defect when you dereference the pointer `rec` without checking for a `NULL` value from the prior dynamic memory allocation.

A similar issue happens with the pointer `newData`. However, a defect is not raised because the pointer is not dereferenced but simply copied over to `rec->data`. Simply copying over a possibly null pointer is not an issue by itself. For instance, callers of the `recordType_new` function might check for `NULL` value of `rec->data` before dereferencing, thereby avoiding a null pointer dereference.

## Result Information

# Use of previously freed pointer

Memory accessed after deallocation

## Description

This defect occurs when you access a block of memory after freeing the block using the `free` function.

### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to access this block of memory can result in unpredictable behavior or even a segmentation fault.

### Fix

The fix depends on the root cause of the defect. See if you intended to free the memory later or allocate another memory block to the pointer before access.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

## Examples

### Use of Previously Freed Pointer Error

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   {
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);

    j = *pi + shift;
    /* Defect: Reading a freed pointer */

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing`pi` after the `free` statement is not valid.

#### Correction — Free Pointer After Use

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

## Result Information

**Group:** Dynamic memory
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `FREED_PTR`
**Impact:** High

# C++ Exception Defects

# Exception caught by value

catch statement accepts an object by value

## Description

This defect occurs when a catch statement accepts an object by value.

### Risk

If a throw statement passes an object and the corresponding catch statement accepts the exception by value, the object is copied to the catch statement parameter. This copy can lead to unexpected behavior such as:

- Object slicing, if the throw statement passes a derived class object.
- Undefined behavior of the exception, if the copy fails.

### Fix

Catch the exception by reference or by pointer. Catching an exception by reference is recommended.

## Examples

### Standard Exception Caught by Value

```
#include <exception>

extern void print_str(const char* p);
extern void throw_exception();

void func() {
    try {
        throw_exception();
    }

    catch(std::exception exc) {
        print_str(exc.what());
    }
}
```

In this example, the catch statement takes a std::exception object by value. Catching an exception by value causes copying of the object. It can cause undefined behavior of the exception if the copy fails.

#### Correction: Catch Exception by Reference

One possible solution is to catch the exception by reference.

```
#include <exception>

extern void print_str(const char* p);
extern void throw_exception();
```

```
void corrected_excpcaughtbyvalue() {
    try {
        throw_exception();
    }
    catch(std::exception& exc) {
        print_str(exc.what());
    }
}
```

### Derived Class Exception Caught by Value

```
#include <exception>
#include <string>
#include <typeinfo>
#include <iostream>

// Class declarations
class BaseExc {
public:
    explicit BaseExc();
    virtual ~BaseExc() {};
protected:
    BaseExc(const std::string& type);
private:
    std::string _id;
};

class IOExc: public BaseExc {
public:
    explicit IOExc();
};

//Class method declarations
BaseExc::BaseExc():_id(typeid(this).name()) {
}
BaseExc::BaseExc(const std::string& type): _id(type) {
}
IOExc::IOExc(): BaseExc(typeid(this).name()) {
}

int input(void);

int main(void) {
    int rnd = input();
    try {
        if (rnd==0) {
            throw IOExc();
        } else {
            throw BaseExc();
        }
    }

    catch(BaseExc exc) {
        std::cout << "Intercept BaseExc" << std::endl;
    }
    return 0;
}
```

In this example, the `catch` statement takes a `BaseExc` object by value. Catching exceptions by value causes copying of the object. The copying can cause:

- Undefined behavior of the exception if it fails.
- Object slicing if an exception of the derived class `IOExc` is caught.

**Correction — Catch Exceptions by Reference**

One possible correction is to catch exceptions by reference.

```
#include <exception>
#include <string>
#include <typeinfo>
#include <iostream>

// Class declarations
class BaseExc {
public:
    explicit BaseExc();
    virtual ~BaseExc() {};
protected:
    BaseExc(const std::string& type);
private:
    std::string _id;
};

class IOExc: public BaseExc {
public:
    explicit IOExc();
};

//Class method declarations
BaseExc::BaseExc():_id(typeid(this).name()) {
}
BaseExc::BaseExc(const std::string& type): _id(type) {
}
IOExc::IOExc(): BaseExc(typeid(this).name()) {
}

int input(void);

int main(void) {
    int rnd = input();
    try {
        if (rnd==0) {
            throw IOExc();
        } else {
            throw BaseExc();
        }
    }

    catch(BaseExc& exc) {
        std::cout << "Intercept BaseExc" << std::endl;
    }
    return 0;
}
```

## Result Information

**Group:** C++ Exception
**Language:** C++

# Exception handler hidden by previous handler

catch statement is not reached because of an earlier catch statement for the same exception

## Description

This defect occurs when a catch statement is not reached because a previous catch statement handles the exception.

For instance, a catch statement accepts an object of a class my_exception and a later catch statement accepts one of the following:

- An object of the my_exception class.
- An object of a class derived from the my_exception class.

### Risk

Because the catch statement is not reached, it is effectively dead code.

### Fix

One possible fix is to remove the redundant catch statement.

Another possible fix is to reverse the order of catch statements. Place the catch statement that accepts the derived class exception before the catch statement that accepts the base class exception.

## Examples

### catch Statement Hidden by Previous Statement

```
#include <new>

extern void print_str(const char* p);
extern void throw_exception();

void func() {
    try {
        throw_exception();
    }
    catch(std::exception& exc) {
        print_str(exc.what());
    }

    catch(std::bad_alloc& exc) {
        print_str(exc.what());
    }
}
```

In this example, the second catch statement accepts a std::bad_alloc object. Because the std::bad_alloc class is derived from a std::exception class, the second catch statement is hidden by the previous catch statement that accepts a std::exception object.

The defect appears on the parameter type of the `catch` statement. To find which `catch` statement hides the current `catch` statement:

1. On the **Source** pane, right-click the keyword `catch` and select **Search For** `"catch"`**in Current Source File**.
2. On the **Search** pane, click each search result, proceeding backwards from the current `catch` statement. Continue until you find the `catch` statement that hides the `catch` statement with the defect.

#### Correction — Reorder `catch` Statement

One possible correction is to place the `catch` statement with the derived class parameter first.

```
#include <new>

extern void print_str(const char* p);
extern void throw_exception();

void corrected_excphandlerhidden() {
    try {
        throw_exception();
    }

    catch(std::bad_alloc& exc) {
        print_str(exc.what());
    }
    catch(std::exception& exc) {
        print_str(exc.what());
    }
}
```

## Result Information

**Group:** C++ Exception

# Argument expression of throw statement might raise unexpected exception

The argument expression in a `throw` statement raises unexpected exceptions, leading to resource leaks and security vulnerabilities

## Description

This defect occurs when the argument expression of a throw statement might raise an exception. Expressions that can raise exceptions include:

- Functions that are specified as `noexcept(false)`
- Functions that contain one or more explicit `throw` statements
- Constructors that perform memory allocation operations
- Expressions that involve dynamic casting

### Risk

When raising an exception explicitly by using `throw` statements, the compiler first creates the expected exception by evaluating the argument of the throw statement, and then raises the expected exception. If an unexpected exception is raised when the compiler is creating the expected exception in a `throw` statement, the unexpected exception is propagated instead of the expected one. This unexpected exception might become an unhandled exception. Depending on your environment, the compiler might call `std::abort` to abnormally terminate the program execution without unwinding the stack when exceptions become unhandled, leading to resource leak and security vulnerabilities. Consider this code where a `throw` statement raises an explicit exception of class `myException`.

```
class myException{
    myException(){
        msg = new char[10];
        //...
    }
    //...
};

foo(){
    try{
        //..
        throw myException();
    }
    catch(myException& e){
        //...
    }
}
```

During construction of the temporary `myException` object, the `new` operator can raise a `bad_alloc` exception. In such a case, the `throw` statement raises a `bad_alloc` exception, instead of `myException`. Because `myException` was the expected exception, the catch block is incompatible with `bad_alloc`. The `bad_alloc` exception becomes an unhandled exception. It might cause the program to abort abnormally without unwinding the stack, leading to resource leak and security vulnerabilities.

#### Fix

Avoid using expressions that might raise exceptions as argument in a `throw` statement.

## Examples

### Use of Functions Specified as `noexcept(false)` in `throw` Statements

```
int f_throw() noexcept(false);
int foo(){
    try{
        //...
        throw f_throw();
    }
    catch(...){
        //...
    }
}
```

In this example, the function `f_throw()` is specified as `noexcept(false)`. If an exception is raised in `f_throw()`, it can cause the program to terminate without unwinding the stack, resulting in resource leak and security vulnerabilities.

#### Correction – Use Functions Specified As `noexcept(true)` as Argument Expression of `throw` Statements

One possible correction is to use functions that do not raise exceptions in argument expression of a `throw` statement. These functions are specified as `noexcept(true)`.

```
int f_throw() noexcept(true);
int foo(){
    try{
        //...
        throw f_throw();
    }
    catch(...){
        //...
    }
}
```

### Use of Constructors with Dynamic Memory Allocation in `throw` Statements

```
class WithDynamicAlloc {
public:
    WithDynamicAlloc(int n) {
        m_data = new int[n];
    }
    ~WithDynamicAlloc() {
        delete[] m_data;
    }
private:
    int* m_data;
};
int foo(){
    try{
        //...
        throw WithDynamicAlloc(10);
    }
    catch(WithDynamicAlloc& e){
        //...
    }
}
```

In this example, the constructor of the object `WithDynamicAlloc` performs a dynamic memory allocation operation. This constructor might raise an exception such as `bad_alloc` that might cause the program to terminate without unwinding the stack, resulting in resource leak and security vulnerabilities.

#### Correction – Use Constructors that Does Not Allocate Memory as Argument Expression of `throw` Statements

One possible correction is to use objects that do not require dynamic memory allocation as exception objects.

```
class WithoutDynamicAlloc {
public:
    WithoutDynamicAlloc(int n) : m_data(n){
    }
    ~WithoutDynamicAlloc() {
    }
private:
    int m_data;
};
int foo(){
    try{
        //...
        throw WithoutDynamicAlloc(10);
    }
    catch(WithoutDynamicAlloc& e){
        //...
    }
}
```

### Use of Functions That Might Raise Exceptions in `throw` Statements

```
int MightThrow(bool b) {
    if (b) {
        throw 2.1;
    }
    return 42;
}
int foo(){
    try{
        //...
        throw MightThrow(false);
        throw MightThrow(true);
    }
    catch(int e){
        //...
    }
}
```

In this example, the function `MightThrow()` raises an exception depending on the input `b`. Because Polyspace analyzes functions statically, it assumes that `MightThrow()` raises exceptions regardless of input, and raises a violation of this checker on both `throw MightThrow(true)` and `throw MightThrow(false)`.

**Correction – Use Comments To Justify Result**

Because `MightThrow(false)` does not raise an exception, a possible correction is to use comments to justify the statement `throw MightThrow(false)`.See“Address Results in Polyspace User Interface Through Bug Fixes or Justifications”

```
int MightThrow(bool b) {
    if (b) {
        throw 2.1;
    }
    return 42;
}
int foo(){
    try{
        //...
        throw MightThrow(false);// polyspace DEFECT:THROW_THROWS [Justified:Low] "Does not Throw"
        throw MightThrow(true);
    }
    catch(int e){
        //...
    }
}
```

## Result Information

**Group:** C++ Exception
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `THROW_ARGUMENT_EXPRESSION_THROWS`
**Impact:** High

# Noexcept function might exit with an exception

Functions specified as noexcept, noexcept(true) or noexcept(<true condition>) exits with an exception, which causes abnormal termination of program execution, leading to resource leak and security vulnerability

## Description

This defect occurs when a callable entity that is specified by using noexcept, noexcept(true), or noexcept(<true condition>) might exit with an exception.

When a callable entity invokes other callable entities, Polyspace makes certain assumptions to calculate whether there might be unhandled exceptions.

- Functions: When a noexcept function calls another function, Polyspace checks whether the called function might raise an exception only if it is specified as noexcept(<false>).If the called function is specified as noexcept, Polyspace assumes that it does not raise an exception. Some standard library functions, such as the constructor of std::string, use pointers to functions to perform memory allocation, which might raise exceptions. Because these functions are not specified as noexcept(<false>), Polyspace does not flag a function that calls these standard library functions.
- External function: When a noexcept function calls an external function, Polyspace flags the function declaration if the external function is specified as noexcept(<false>).
- Virtual function: When a function calls a virtual function, Polyspace flags the function declaration if the virtual function is specified as noexcept(<false>) in a derived class. For instance, if a noexcept function calls a virtual function that is declared as noexcept(<true>) in the base class, and noexcept(<false>) in a subsequent derived class, Polyspace flags the declaration of the noexcept function.
- Pointers to function: When a noexcept function invokes a pointer to a function, Polyspace assumes that the pointer to function does not raise exceptions.

When analyzing whether a function raises unhandled exceptions, Polyspace ignores:

- Exceptions raised in destructors
- Exceptions raised in atexit() operations
- Compiler generated functions

Polyspace also ignores the dynamic context when checking for exceptions. For instance, a function might raise unhandled exceptions that arise only in certain dynamic contexts. Polyspace flags such a function even if the exception might not be raised.

### Risk

You can specify that a callable entity does not exit with an exception by specifying it as noexcept, noexcept(true), or noexcept(<true condition>). The compiler omits the exception handing process for noexcept entities. When such an entity exits with an exception,the compiler implicitly invokes std::terminate().

Depending on the hardware and software you use, the function std::terminate() might invoke std::abort() to abnormally abort the execution without unwinding the stack. If the stack is not unwound before program termination, then the destructors of the variables in the stack are not invoked, leading to resource leak and security vulnerabilities.

### Fix

Specify functions as `noexcept` or `noexcept(true)` only when you know the functions raise no exceptions. If you cannot determine the exception specification of a function, specify it by using `noexcept(false)`

## Examples

### Use of `noexcept` Functions That Might Raise Exceptions

```
#include <stdexcept>
#include <typeinfo>
void LibraryFunc();
void LibraryFunc_noexcept_false() noexcept(false);
void LibraryFunc_noexcept_true() noexcept(true);

void SpecFalseCT() noexcept
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}

class A {
public:
    virtual void f() {}
};

class B : A {
public:
    virtual void f() noexcept {}
};

class C : B {
public:
    virtual void f() noexcept {}
};

class D : A {
public:
    virtual void f() noexcept(false) { throw(2);}
};

void A1(A &a) noexcept {
    a.f();
}
```

```
void D2(D &d) noexcept {
    try {
        d.f();
    } catch (int i) {
    } catch (...) {
    }
}

void B2(B *b) noexcept {
    b->f();
}
template <class T>
T f_tp(T a) noexcept(sizeof(T)<=4)
{
    if (sizeof(T) >4 ) {
        throw std::runtime_error("invalid case");
    }
    return a;
}
void instantiate(void)
{
    f_tp<char>(1);
}
void f() noexcept {
    throw std::runtime_error("dead code");
}

void g() noexcept {
    f();
}
```

In this example, there are several `noexcept` functions. These functions invoke other callable entities like functions, external functions, and virtual functions.

- Polyspace flags the declaration of the function template `f_tp` even though the `throw` statement is not reached because Polyspace ignores dynamic context. Polyspace also analyzes only the instantiated templates in your code. For instance, if `f_tp` is not instantiated in the function `instantiate()`, Polyspace does not analyze the template.
- Polyspace flags the `noexcept` function `SpecFaleCT()` because this function calls the `noexcept(false)`external function `LibraryFunc_noexcept_false()` without encapsulating it in a `try-catch` block. Any exceptions raised by this call to the external function might raise an unhandled exception.
- Polyspace flags the declaration of the `noexcept` function `A1()` because this function might call the `noexcept(false)` function `D.f()` when the input parameter `a` is of class `D`. Depending on the class of the input parameter, the `noexcept` polymorphic function `A1()` might raise an unhandled exception.
- Polyspace flags the function `f()` because it is a `noexcept` function that uses `throw` to raise an unhandled exception. Polyspace does not flag the `noexcept` function `g()` even though it calls `f()` because `f()` is specified as `noexcept`.
- Polyspace doe not flag the `noexcept` function `D2()` even though it calls the `noexcept(false)` function `D.f()` because `D2()` handles the exceptions that might arise by using a `catch(...)` block.

#### Correction – Specify Functions as noexcept(false)

You can modify your code so that the functions that might exit with an exception are specified as `noexcept(false)`. Such functions can exit with an exceptions without abnormally terminating the program and this defect is not raised.

```
#include <stdexcept>
#include <typeinfo>
void LibraryFunc_noexcept_false() noexcept(false);
void SpecFalseCT() noexcept(false)
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}
```

The function `SpecFalseCT()` uses an external function that is specified as `noexcept(false)`. The function `SpecFalseCT()` is specified as `noexcept(false)` because it might exit with an exception. This function does not raise the defect.

#### Correction – Handle Exceptions in noexcept Functions

You can modify your code so that exceptions are handled within a `noexcept` function. If raised exceptions and handled within the function, then the `noexcept` function does not exit with an exception and this defect is not raised.

```
#include <stdexcept>
#include <typeinfo>

void f() noexcept(false) {
throw(2);
}
void CallerFunc() noexcept {
    try {
        f();
    } catch (int i) {
    } catch (...) {
    }
}
```

The `noexcept` function `CallerFunc()` calls `f()` which can raise exceptions. `CallerFunc()` has handlers to handle exceptions that might be raised and does not exit with an exception. This functions does not raise the defect.

#### Correction – Justify Defects Using Comments

You can justify raised defects using comments: Because Polyspace analyzes functions statically, it might raise this defect to flag exceptions that are in dead code. Use comments to justify defects if you think the exception might not be raised.

```
#include <stdexcept>
```

```
#include <typeinfo>
void MightThrow(unsigned int input) noexcept{// polyspace DEFECT:NOEXCEPT_FUNCTION_THROWS
    if(input<0)
        throw 1;
    //..

}
```

The `noexcept` function `MightThrow()` exits with an exception in a dynamic context that might not arise. For instance, the `unsigned int` input is nonnegative and the `throw` statement does not execute. Because Polyspace analyzes functions statically, it raises the defect on the `throw` statement. Justify the defect using a comment. See“Address Results in Polyspace User Interface Through Bug Fixes or Justifications”

### Result Information

**Group:** C++ Exception
**Language:** C++

# Uncaught exception

An exception is raised from a function but it is not caught and handled

## Description

This defect occurs when a function that is called in `main()` raises an exception and the exception is not handled. Polyspace highlights the location in the function body where the unhandled exception is raised and flags the call to the function in `main()`. For instance:

```
void foo(){
    throw std::exception(); //Uncaught exception
}
int main(){
    foo(); //Defect
    return 1;
}
```

Polyspace does not raise this defect when an `std::bad_alloc` raised by a `new` operator remains unhandled.

### Risk

When an exception remains unhandled, the compiler might invoke the function `std::terminate()`, which terminates the program abruptly. The abrupt termination does not invoke any exit handlers, does not call the destructors of the constructed objects, and does not unwind the stack.

Exceptions that are unhandled might result in issues such as memory leaks, security vulnerability, and other unintended behaviors. Poorly designed exception handling process might make your program vulnerable to denial-of-service attacks.

### Fix

To fix this defect, design the exception handling in your code to handle expected and unexpected exceptions. Call functions that are not `noexcept` in `try` blocks. Handle the exceptions that these functions might raise by using matching `catch()` blocks. Include a `catch-all` block to handle unexpected exceptions.

## Examples

### Avoid Unhandled Exceptions

```
#include <exception>
#include <stdexcept>

int flag();

void foo() {
    if (flag()==0) {
        //....
        throw std::exception();
    }
}

void bar() {
    if (flag()!=0 & flag()!=1) {
        throw std::logic_error("Error");
    }
}

void fubar() {
    foo();
}

int main() {
    foo(); // Defect
    bar(); // Defect
    fubar(); // Defect

}
```

In this exception, the functions `foo()` and `bar()` raise exceptions that are not handled. The function `fubar()` raises an unhandled exception by calling `foo()`. These functions are invoked in `main()`. Because these functions raise exceptions that are unhandled and are called from the `main()` function, Polyspace flags the calls to these functions in `main`.

**Correction — Handle the exceptions**

To resolve this defect, handle the exceptions in your code. For instance, in the `main()` function, call the exception raising function in a `try` block and handle the exception by using a series of `catch()` blocks, including a `catch(...)` block.

```
#include <exception>
#include <stdexcept>

int flag();

void foo() {
    if (flag()==0) {
        //....
        throw std::exception();
    }
}

void bar() {
    if (flag()!=0 & flag()!=1) {
        throw std::logic_error("bla");
    }
}

void fubar() {
    foo();
}

int main() {
    try{
```

```
    foo(); // Defect
    bar(); // Defect
    fubar(); // Defect
    }catch(std::logic_error& e){
        //...
    }catch(std::exception& e){
        //...
    }catch(...){
        //..
    }

}
```

# Programming Defects

# Partially duplicated code

A section of code is duplicated in other places with very minor changes

## Description

This defect occurs when a block of code is duplicated in multiple places with only slight changes.

The defect checker does not flag certain blocks as duplicates. For instance, the blocks of code considered almost duplicates have to typically consist of more than a certain number of lines. See also “Duplicate Code Detection in Polyspace Bug Finder” on page 32-6.

Sometimes, two blocks might appear as exact duplicates, but might be reported as partial duplicates because some of the variables in the duplicate sections have different data types. The event list below the result points to the lines containing such variables.

### Risk

Sections of code that do almost the same operations might require unnecessary additional maintenance. Duplicated code also increases the chances you will update the code in one place but forget to update the other. See also `Duplicated code` and `Possible copy-paste error`.

### Fix

Try to refactor the sections of code to reduce the duplication. For instance, identify parts of the code blocks that are duplicates of each other and refactor them into a dedicated function. You can then replace the duplicated code with calls to the dedicated function.

## Examples

### Partially Duplicate Blocks of Code

In this example, the two code blocks in the functions `updatePinOne()` and `updatePinTwo()` are partial duplicates of each other. The duplicate section of each block copies one structure `currentBoard` to another structure `backupBoard` field by field. The only difference is that a different member of the structure `currentBoard` is updated in each function.

The code duplication can make maintenance difficult. For instance, if the structure type `board` is updated with more fields, it can be easy to forget copying the new fields in one of the duplicate sections. This omission can lead to a partial structure copy.

```
typedef struct {
    int pin1;
    int pin2;
    int pin3;
    int pin4;
    int pin5;
    int pin6;
    int pin7;
    int pin8;
} board;
```

```
board currentBoard;
board backupBoard;

void updatePinOne(int newVal1) {
     backupBoard.pin1 = currentBoard.pin1; //Beginning of duplicate section #1
     currentBoard.pin1 = newVal1;
     backupBoard.pin2 = currentBoard.pin2;
     backupBoard.pin3 = currentBoard.pin3;
     backupBoard.pin4 = currentBoard.pin4;
     backupBoard.pin5 = currentBoard.pin5;
     backupBoard.pin6 = currentBoard.pin6;
     backupBoard.pin7 = currentBoard.pin7;
     backupBoard.pin8 = currentBoard.pin8; //End of duplicate section #1
}

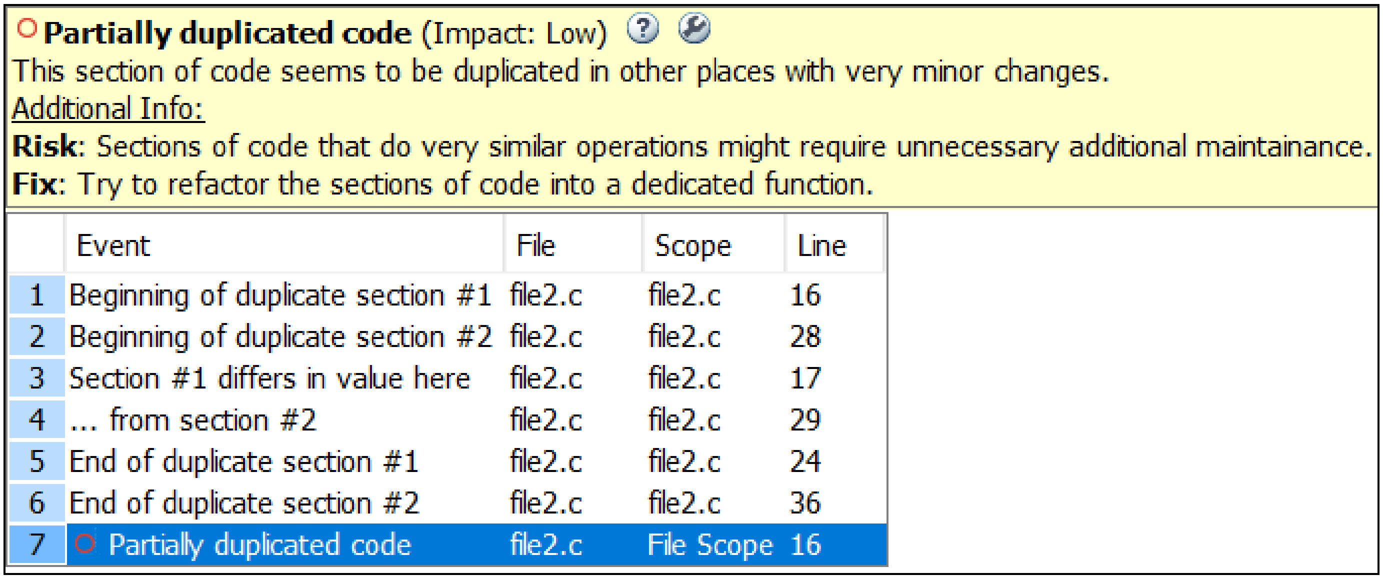
void updatePinTwo(int newVal2) {
     backupBoard.pin1 = currentBoard.pin1; //Beginning of duplicate section #2
     currentBoard.pin2 = newVal2;
     backupBoard.pin2 = currentBoard.pin2;
     backupBoard.pin3 = currentBoard.pin3;
     backupBoard.pin4 = currentBoard.pin4;
     backupBoard.pin5 = currentBoard.pin5;
     backupBoard.pin6 = currentBoard.pin6;
     backupBoard.pin7 = currentBoard.pin7;
     backupBoard.pin8 = currentBoard.pin8; //End of duplicate section #2
}
```

The event list on the **Result Details** pane shows:

- The beginning and end of each duplicate block of code.
- The line where each block differs from the other.

  If two blocks are exactly identical except for the name of one variable and if the variable is used in multiple places, the event list shows only the first usage of the variable.

Click on an event to navigate to the corresponding location in the source code.



○ **Partially duplicated code** (Impact: Low)

This section of code seems to be duplicated in other places with very minor changes.

Additional Info:

**Risk**: Sections of code that do very similar operations might require unnecessary additional maintainance.

**Fix**: Try to refactor the sections of code into a dedicated function.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Beginning of duplicate section #1 | file2.c | file2.c | 16 |
| 2 | Beginning of duplicate section #2 | file2.c | file2.c | 28 |
| 3 | Section #1 differs in value here | file2.c | file2.c | 17 |
| 4 | ... from section #2 | file2.c | file2.c | 29 |
| 5 | End of duplicate section #1 | file2.c | file2.c | 24 |
| 6 | End of duplicate section #2 | file2.c | file2.c | 36 |
| 7 | ○ Partially duplicated code | file2.c | File Scope | 16 |

In the Polyspace user interface, you can see the duplicated code blocks side by side on the **Source** pane. See “Navigate in Separate Window”.

#### Correction – Refactor Code to Avoid Duplication

You can refactor the duplicate sections of code into a common function and replace the sections with calls to this function. In this example, the duplicate sections of the two blocks have been refactored into the `backupCurrentBoard()` function.

```
typedef struct {
    int pin1;
    int pin2;
    int pin3;
    int pin4;
    int pin5;
    int pin6;
    int pin7;
    int pin8;
} board;

board currentBoard;
board backupBoard;

void backupCurrentBoard(void) {
     backupBoard.pin1 = currentBoard.pin1;
     backupBoard.pin2 = currentBoard.pin2;
     backupBoard.pin3 = currentBoard.pin3;
     backupBoard.pin4 = currentBoard.pin4;
     backupBoard.pin5 = currentBoard.pin5;
     backupBoard.pin6 = currentBoard.pin6;
     backupBoard.pin7 = currentBoard.pin7;
     backupBoard.pin8 = currentBoard.pin8;
}

void updatePinOne(int newVal1) {
    backupCurrentBoard();
    currentBoard.pin1 = newVal1;
}

void updatePinTwo(int newVal2) {
    backupCurrentBoard();
    currentBoard.pin2 = newVal2;
}
```

## Result Information

# Abnormal termination of exit handler

Exit handler function interrupts the normal execution of a program

## Description

This defect occurs when an exit handler itself calls another function that interrupts the program’s expected termination sequence and causes an abnormal exit.

- Exit handlers are functions designated for execution when a program terminates. These functions are first registered with specific functions such as `atexit`, (WinAPI) `_onexit`, or `at_quick_exit()`.
- Some functions that can cause abnormal exits are `exit`, `abort`, `longjmp`, or (WinAPI) `_onexit`.

### Risk

If your exit handler terminates your program, you can have undefined behavior. Abnormal program termination means other exit handlers are not invoked. These additional exit handlers may do additional clean up or other required termination steps.

### Fix

In inside exit handlers, remove calls to functions that prevent the exit handler from terminating normally.

## Examples

### Exit Handler With Call to exit

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        exit(0);
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() performs additional cleanup */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

In this example, demo_install_exitabnormalhandler registers two exit handlers, demo_exit1 and exitabnormalhandler. Exit handlers are invoked in the reverse order of which they are registered. When the program ends, exitabnormalhandler runs, then demo_exit1. However, exitabnormalhandler calls exit interrupting the program exit process. Having this exit inside an exit handler causes undefined behavior because the program is not finished cleaning up safely.

#### Correction — Remove exit from Exit Handler

One possible correction is to let your exit handlers terminate normally. For this example, exit is removed from exitabnormalhandler, allowing the exit termination process to complete as expected.

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        /* Return normally */
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() continues clean up */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

## Result Information

# Accessing object with temporary lifetime

Read or write operations on the object are undefined behavior

## Description

This defect occurs when you attempt to read from or write to an object with temporary lifetime that is returned by a function call. In a structure or union returned by a function, and containing an array, the array members are temporary objects. The lifetime of temporary objects ends:

- When the full expression or full declarator containing the call ends, as defined in the C11 Standard.
- After the next sequence point, as defined in the C90 and C99 Standards. A sequence point is a point in the execution of a program where all previous evaluations are complete and no subsequent evaluation has started yet.

For C++ code, **Accessing object with temporary lifetime** raises a defect only when you write to an object with a temporary lifetime.

If the temporary lifetime object is returned by address, no defect is raised.

### Risk

Modifying objects with temporary lifetime is undefined behavior and can cause abnormal program termination and portability issues.

### Fix

Assign the object returned from the function call to a local variable. The content of the temporary lifetime object is copied to the variable. You can now modify it safely.

## Examples

### Modifying Temporary Lifetime Object Returned by Function Call

```
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

/* func_temp() returns a struct value containing
* an array with a temporary lifetime.
```

```
*/
int func(void) {

/*Writing to temporary lifetime object is
 undefined behavior
 */
    return ++(func_temp().a[0]);
}

void main(void) {
    (void)func();
}
```

In this example, `func_temp()` returns by value a structure with an array member `a`. This member has temporary lifetime. Incrementing it is undefined behavior.

**Correction — Assign Returned Value to Local Variable Before Writing**

One possible correction is to assign the return of the call to `func_temp()` to a local variable. The content of the temporary object `a` is copied to the variable, which you can safely increment.

```
 #include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

int func(void) {

/* Assign object returned by function call to
 *local variable
 */
    struct S_Array s = func_temp();

/* Local variable can safely be
 *incremented
 */
    ++(s.a[0]);
    return s.a[0];
}

void main(void) {
    (void)func();
}
```

## Result Information

# Alternating input and output from a stream without flush or positioning call

Undefined behavior for input or output stream operations

## Description

This defect occurs when:

- You do not perform a flush or function positioning call between an output operation and a following input operation on a file stream in update mode.
- You do not perform a function positioning call between an input operation and a following output operation on a file stream in update mode.

### Risk

Alternating input and output operations on a stream without an intervening flush or positioning call is undefined behavior.

### Fix

Call `fflush()` or a file positioning function such as `fseek()` or `fsetpos()` between output and input operations on an update stream.

Call a file positioning function between input and output operations on an update stream.

## Examples

### Read After Write Without Intervening Flush

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
```

```
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Read operation after write without
    intervening flush. */
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
          (void)fclose(file);
          /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

In this example, the file `demo.txt` is opened for reading and appending. After the call to `fwrite()`, a call to `fread()` without an intervening flush operation is undefined behavior.

**Correction — Call `fflush()` Before the Read Operation**

After writing data to the file, before calling `fread()`, perform a flush call.

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Buffer flush after write and before read */
    if (fflush(file) != 0)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

# Assertion

Failed assertion statement

## Description

This defect occurs when you use an `assert`, and the asserted expression is or could be false.

**Note** Polyspace does not flag `assert(0)` as an assertion defect because these statements are commonly used to disable certain sections of code.

### Risk

Typically you use `assert` statements for functional testing in debug mode. An assertion failure found using static analysis indicates that the corresponding functional test would fail at run time.

### Fix

The fix depends on the root cause of the defect. For instance, the root cause can be unconstrained input from an external source that eventually led to the assertion failure.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

A default Bug Finder analysis might not raise this defect when the input values are unknown and only a subset of inputs cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Check Assertion on Unsigned Integer

```
#include <assert.h>

void asserting_x(unsigned int theta) {
    theta =+ 5;
    assert(theta < 0);
}
```

In this example, the `assert` function checks if the input variable, `theta`, is less than or equal to zero. The assertion fails because `theta` is an unsigned integer, so the value at the beginning of the function is at least zero. The += statement increases this positive value by five. Therefore, the range of `theta` is `[5..MAX_INT]`. `theta` is always greater than zero.

#### Correction — Change Assert Expression

One possible correction is to change the assertion expression. By changing the *less-than-or-equal-to* sign to a *greater-than-or-equal-to* sign, the assertion does not fail.

```
#include <assert.h>

void asserting_x(unsigned int theta) {
    theta =+ 5;
    assert(theta > 0);
}
```

#### Correction — Fix Code

One possible correction is to fix the code related to the assertion expression. If the assertion expression is true, fix your code so the assertion passes.

```
#include <assert.h>
#include <stdlib.h>

void asserting_x(int theta) {
    theta = -abs(theta);
    assert(theta < 0);
}
```

### Asserting Zero

```
#include <assert.h>

#define FLAG 0

int main(void){
    int i_test_z = 0;
    float f_test_z = (float)i_test_z;

    assert(i_test_z);
    assert(f_test_z);
    assert(FLAG);

    return 0;
}
```

In this example, Polyspace does not flag `assert(FLAG)` as a violation because a macro defines `FLAG` as `0`. The Polyspace Bug Finder assertion checker does not flag assertions with a constant zero parameter, `assert(0)`. These types of assertions are commonly used as dynamic checks during runtime. By inserting `assert(0)`, you indicate that the program must not reach this statement during run time, otherwise the program crashes.

However, the assertion checker does flag failed assertions caused by a variable value equal to zero, as seen in the example with `assert(i_test_z)` and `assert(f_test_z)`.

### Result Information

# Bad file access mode or status

Access mode argument of function in `fopen` or `open` group is invalid

## Description

This defect occurs when you use functions in the `fopen` or `open` group with invalid or incompatible file access modes, file creation flags, or file status flags as arguments. For instance, for the `open` function, examples of valid:

- Access modes include `O_RDONLY`, `O_WRONLY`, and `O_RDWR`
- File creation flags include `O_CREAT`, `O_EXCL`, `O_NOCTTY`, and `O_TRUNC`.
- File status flags include `O_APPEND`, `O_ASYNC`, `O_CLOEXEC`, `O_DIRECT`, `O_DIRECTORY`, `O_LARGEFILE`, `O_NOATIME`, `O_NOFOLLOW`, `O_NONBLOCK`, `O_NDELAY`, `O_SHLOCK`, `O_EXLOCK`, `O_FSYNC`, `O_SYNC` and so on.

The defect can occur in the following situations.

| Situation | Risk | Fix |
|---|---|---|
| You pass an empty or invalid access mode to the `fopen` function.<br>According to the ANSI C standard, the valid access modes for `fopen` are:<br>• `r`,`r+`<br>• `w`,`w+`<br>• `a`,`a+`<br>• `rb`, `wb`, `ab`<br>• `r+b`, `w+b`, `a+b`<br>• `rb+`, `wb+`, `ab+` | `fopen` has undefined behavior for invalid access modes.<br>Some implementations allow extension of the access mode such as:<br>• GNU: `rb+cmxe,ccs=utf`<br>• Visual C++: `a+t`, where `t` specifies a text mode.<br>However, your access mode string must begin with one of the valid sequences. | Pass a valid access mode to `fopen`. |
| You pass the status flag `O_APPEND` to the `open` function without combining it with either `O_WRONLY` or `O_RDWR`. | `O_APPEND` indicates that you intend to add new content at the end of a file. However, without `O_WRONLY` or `O_RDWR`, you cannot write to the file.<br>The `open` function does not return -1 for this logical error. | Pass either `O_APPEND\|O_WRONLY` or `O_APPEND\|O_RDWR` as access mode. |

| Situation | Risk | Fix |
|---|---|---|
| You pass the status flags O_APPEND and O_TRUNC together to the open function. | O_APPEND indicates that you intend to add new content at the end of a file. However, O_TRUNC indicates that you intend to truncate the file to zero. Therefore, the two modes cannot operate together.<br>The open function does not return -1 for this logical error. | Depending on what you intend to do, pass one of the two modes. |
| You pass the status flag O_ASYNC to the open function. | On certain implementations, the mode O_ASYNC does not enable signal-driven I/O operations. | Use the fcntl(pathname, F_SETFL, O_ASYNC); instead. |

### Fix

The fix depends on the function and the flags used. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Invalid Access Mode with fopen

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "rw");
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

In this example, the access mode rw is invalid. Because r indicates that you open the file for reading and w indicates that you create a new file for writing, the two access modes are incompatible.

#### Correction — Use Either r or w as Access Mode

One possible correction is to use the access mode corresponding to what you intend to do.

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "w");
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

# Call through non-prototyped function pointer

Function pointer declared without its type or number of parameters causes unexpected behavior

## Description

This defect occurs when a function without a complete prototype is called using a function pointer.

A function prototype specifies the type and number of parameters.

### Risk

Arguments passed to a function without a prototype might not match the number and type of parameters of the function definition, which can cause undefined behavior. If the parameters are restricted to a subset of their type domain, arguments from untrusted sources can trigger vulnerabilities in the called function.

### Fix

Before calling the function through a pointer, provide a function prototype.

## Examples

### Argument Does Not Match Parameter Restriction

```
#include <stdio.h>
#include <limits.h>
#define SIZE2 2

typedef void (*func_ptr)();
extern int getchar_wrapper(void);
extern void restricted_int_sink(int i);
/* Integer value restricted to
range [-1, 255] */
extern void restricted_float_sink(double i);
/* Double value restricted to > 0.0 */

func_ptr generic_callback[SIZE2] =
{
    (func_ptr)restricted_int_sink,
    (func_ptr)restricted_float_sink
};

void func(void)
{
    int ic;
    ic = getchar_wrapper();
    /* Wrong index used for generic_callback.
    Negative 'int' passed to restricted_float_sink. */
    (*generic_callback[1])(ic);
}
```

In this example, a call through `func_ptr` passes `ic` as an argument to function `generic_callback[1]`. The type of `ic` can have negative values, while the parameter of `generic_callback[1]` is restricted to float values greater than `0.0`. Typically, compilers and static analysis tools cannot perform type checking when you do not provide a pointer prototype.

**Correction — Provide Prototype of Pointer to Function**

Pass the argument `ic` to a function with a parameter of type `int`, by using a properly prototyped pointer.

```
#include <stdio.h>
#include <limits.h>
#define SIZE2 2

typedef void (*func_ptr_proto)(int);
extern int getchar_wrapper(void);
extern void restricted_int_sink(int i);
/* Integer value restricted to
range [-1, 255] */
extern void restricted_float_sink(double i);
/* Double value restricted to > 0.0 */

func_ptr_proto generic_callback[SIZE2] =
{
    (func_ptr_proto)restricted_int_sink,
    (func_ptr_proto)restricted_float_sink
};

void func(void)
{
    int ic;
    ic = getchar_wrapper();
    /* ic passed to function through
properly prototyped pointer. */
    (*generic_callback[0])(ic);
}
```

## Result Information

**Group:** Programming
**Language:** C

# Call to memset family with unintended value

memset or wmemset used with possibly incorrect arguments

## Description

This defect occurs when Polyspace Bug Finder detects a use of the memset or wmemset function with possibly incorrect arguments.

void *memset (void *ptr, int value, size_t num) fills the first num bytes of the memory block that ptr points to with the specified value. If the argument value is incorrect, the memory block is initialized with an unintended value.

The unintended initialization can occur in the following cases.

| Issue | Risk | Possible Fix |
|---|---|---|
| The second argument is '0' instead of 0 or '\0'. | The ASCII value of character '0' is 48 (decimal), 0x30 (hexadecimal), 069 (octal) but not 0 (or '\0') . | If you want to initialize with '0', use one of the ASCII values. Otherwise, use 0 or '\0'. |
| The second and third arguments are probably reversed. For instance, the third argument is a literal and the second argument is not a literal. | If the order is reversed, a memory block of unintended size is initialized with incorrect arguments. | Reverse the order of the arguments. |
| The second argument cannot be represented in a byte. | If the second argument cannot be represented in a byte, and you expect each byte of a memory block to be filled with that argument, the initialization does not occur as intended. | Apply a bit mask to the argument to produce a wrapped or truncated result that can be represented in a byte. When you apply a bit mask, make sure that it produces an expected result.<br>For instance, replace memset(a, -13, sizeof(a)) with memset(a, (-13) & 0xFF, sizeof(a)). |

### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.

- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Value Cannot Be Represented in a Byte

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE];
    int c = -2;
    memset(buf, (char)c, sizeof(buf));
}
```

In this example, `(char)c` cannot be represented in a byte.

#### Correction — Apply Cast

One possible correction is to apply a cast so that the result can be represented in a byte. Check that the result of the cast is an acceptable initialization value. In this correction, Polyspace does not raise this defect. The cast from signed `int` to `unsigned char` is contrary to best practices and Polyspace raises the defect `Sign change integer conversion overflow`.

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE   ];
    int c = -2;
    memset(buf, (unsigned char)c, sizeof(buf));// Might Overflow
}
```

#### Correction — Avoid Using memset

One possible correction is to reserve the use of `memset` only for setting or clearing all bits in a buffer. For instance, in this code, `memset` is called to clear the bits of the character array `buf`.

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE   ];
    int c = -2;
    memset(buf, 0, sizeof(buf));//Compliant
    /* After clearing buf, use it in operations*/
}
```

## Result Information

# Character value absorbed into EOF

Data type conversion makes a valid character value same as End-of-File (EOF)

## Description

This defect occurs when you perform a data type conversion that makes a valid character value indistinguishable from `EOF` (End-of-File). Bug Finder flags the defect in one of the following situations:

- *End-of-File*: You perform a data type conversion such as from `int` to `char` that converts a non-EOF character value into `EOF`.

  ```
  char ch = (char)getchar()
  ```

  You then compare the result with EOF.

  ```
  if((int)ch == EOF)
  ```

  The conversion can be explicit or implicit.
- *Wide End-of-File*: You perform a data type conversion that can convert a non-WEOF wide character value into WEOF, and then compare the result with WEOF.

### Risk

The data type `char` cannot hold the value `EOF` that indicates the end of a file. Functions such as `getchar` have return type `int` to accommodate `EOF`. If you convert from `int` to `char`, the values `UCHAR_MAX` (a valid character value) and `EOF` get converted to the same value -1 and become indistinguishable from each other. When you compare the result of this conversion with `EOF`, the comparison can lead to false detection of `EOF`. This rationale also applies to wide character values and `WEOF`.

### Fix

Perform the comparison with `EOF` or `WEOF` before conversion.

## Examples

### Return Value of `getchar` Converted to `char`

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

char func(void)
{
    char ch;
    ch = getchar();
    if (EOF == (int)ch) {
        fatal_error();
    }
```

```
    return ch;
}
```

In this example, the return value of `getchar` is implicitly converted to `char`. If `getchar` returns `UCHAR_MAX`, it is converted to -1, which is indistinguishable from EOF. When you compare with EOF later, it can lead to a false positive.

**Correction — Perform Comparison with EOF Before Conversion**

One possible correction is to first perform the comparison with EOF, and then convert from `int` to `char`.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

char func(void)
{
    int i;
    i = getchar();
    if (EOF == i) {
        fatal_error();
    }
    else {
        return (char)i;
    }
}
```

## Result Information

# Copy of overlapping memory

Source and destination arguments of a copy function have overlapping memory

## Description

This defect occurs when there is a memory overlap between the source and destination argument of a copy function such as `memcpy` or `strcpy`. For instance, the source and destination arguments of `strcpy` are pointers to different elements in the same string.

### Risk

If there is memory overlap between the source and destination arguments of copy functions, according to C standards, the behavior is undefined.

### Fix

Determine if the memory overlap is what you want. If so, find an alternative function. For instance:

- If you are using `memcpy` to copy values from one memory location to another, use `memmove` instead of `memcpy`.
- If you are using `strcpy` to copy one string to another, use `memmove` instead of `strcpy`, as follows:

  ```
  s = strlen(source);
  memmove(destination, source, s + 1);
  ```

  `strlen` determines the string length without the null terminator. Therefore, you must move `s+1` bytes instead of `s` bytes.

## Examples

### Overlapping Copy

```
#include <string.h>

char str[] = {"ABCDEFGH"};

void my_copy() {
    strcpy(&str[0],(const char*)&str[2]);
}
```

In this example, because the source and destination argument are pointers to the same string `str`, there is memory overlap between their allowed buffers.

## Result Information

# Possible copy-paste error

A section of code is duplicated in other places with exactly one minor change

## Description

This defect occurs when a block of code is duplicated in multiple places with exactly one minor change.

The defect checker does not flag certain blocks as duplicates. For instance, the blocks of code considered almost duplicates have to typically consist of more than a certain number of lines. See also “Duplicate Code Detection in Polyspace Bug Finder” on page 32-6.

### Risk

Sections of code that are exact duplicates apart from one minor change might indicate a programming error. You might have duplicated a section of code and later updated one of the duplicates but forgot to update the other.

Duplicated code also require unnecessary additional maintenance. See also `Almost duplicated code` and `Duplicated code`.

### Fix

See if the one minor change between the two duplicated blocks is the result of a programming error. Fix the error.

In the long run, try to refactor the sections of code to reduce the duplication. For instance, identify parts of the code blocks that are duplicates of each other and refactor them into a dedicated function. You can then replace the duplicated code with calls to the dedicated function.

## Examples

### Duplicate Blocks of Code With One Minor Change

In this example, the functions `getReadings()` and `isAllOk()` contain a duplicate block of code with only one minor change. This one difference strongly indicates the possibility of a copy-paste error. It is possible that the logic for calculating the variables `currentReading1` to `currentReading8` is intended to be the same in the both functions. The logic was initially the same, but possibly updated later in one function but not in the other.

```
int pin1;
int pin2;
int pin3;
int pin4;
int pin5;
int pin6;
int pin7;
int pin8;
int currentReading1;
int currentReading2;
int currentReading3;
int currentReading4;
int currentReading5;
int currentReading6;
int currentReading7;
int currentReading8;

int allOk;

void getReadings() {
    currentReading1 = pin1; //Beginning of duplicate section #1
    currentReading2 = pin2 - pin1;
    currentReading3 = pin2 + pin3;
    currentReading4 = pin4;
    currentReading5 = pin5;
    currentReading6 = pin6 - pin5 + pin2; //Minor change here
    currentReading7 = pin7;
    currentReading8 = pin8; //End of duplicate section #1

}

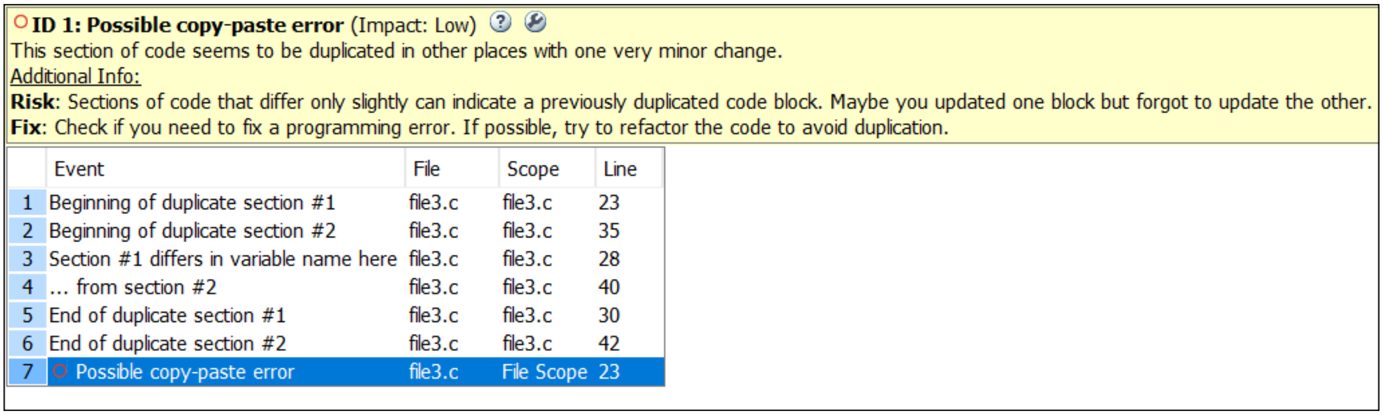
void isAllOk() {
    currentReading1 = pin1; //Beginning of duplicate section #2
    currentReading2 = pin2 - pin1;
    currentReading3 = pin2 + pin3;
    currentReading4 = pin4;
    currentReading5 = pin5;
    currentReading6 = pin6 - pin5 + pin1; //Minor change here
    currentReading7 = pin7;
    currentReading8 = pin8; //End of duplicate section #2

    if(currentReading1 > currentReading2
       && currentReading3 > currentReading4
       && currentReading5 > currentReading6
       && currentReading7 > currentReading8)
       allOk = 1;
}
```

The event list on the **Result Details** pane shows:

- The beginning and end of each duplicate block of code.
- The line where each block differs from the others.

Click on an event to navigate to the corresponding location in the source code.



○ **ID 1: Possible copy-paste error** (Impact: Low)
This section of code seems to be duplicated in other places with one very minor change.
Additional Info:
**Risk**: Sections of code that differ only slightly can indicate a previously duplicated code block. Maybe you updated one block but forgot to update the other.
**Fix**: Check if you need to fix a programming error. If possible, try to refactor the code to avoid duplication.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Beginning of duplicate section #1 | file3.c | file3.c | 23 |
| 2 | Beginning of duplicate section #2 | file3.c | file3.c | 35 |
| 3 | Section #1 differs in variable name here | file3.c | file3.c | 28 |
| 4 | ... from section #2 | file3.c | file3.c | 40 |
| 5 | End of duplicate section #1 | file3.c | file3.c | 30 |
| 6 | End of duplicate section #2 | file3.c | file3.c | 42 |
| 7 | ○ Possible copy-paste error | file3.c | File Scope | 23 |

In the Polyspace user interface, you can see the duplicated code blocks side by side on the **Source** pane. See “Navigate in Separate Window”.

**Correction – Fix Errors and Refactor Code to Avoid Duplication**

If the issue flagged indicates a possible copy-paste error such as a forgotten update, fix the programming error. If possible, refactor your code to avoid the code duplication.

In this example, the function `isAllOk()` has been refactored so that it calls the function `getReadings()` to calculate variables `currentReading1` to `currentReading8`. This refactoring eliminates chances of a copy-paste error.

```
int pin1;
int pin2;
int pin3;
int pin4;
int pin5;
int pin6;
int pin7;
int pin8;

int currentReading1;
int currentReading2;
int currentReading3;
int currentReading4;
int currentReading5;
int currentReading6;
int currentReading7;
int currentReading8;

int allOk;

void getReadings() {
    currentReading1 = pin1;
    currentReading2 = pin2 - pin1;
    currentReading3 = pin2 + pin3;
    currentReading4 = pin4;
    currentReading5 = pin5;
    currentReading6 = pin6 - pin5 + pin2;
    currentReading7 = pin7;
    currentReading8 = pin8;
}

void isAllOk() {
    getReadings();

    if(currentReading1 > currentReading2
       && currentReading3 > currentReading4
       && currentReading5 > currentReading6
       && currentReading7 > currentReading8)
       allOk = 1;
}
```

## Result Information

**Group:** Programming

# Declaration mismatch

Mismatch between function or variable declarations

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when a function or variable declaration does not match other instances of the function or variable.

### Risk

When a mismatch occurs between two variable declarations in different compilation units, a typical linker follows an algorithm to pick one declaration for the variable. If you expect a variable declaration that is different from the one chosen by the linker, you can see unexpected results when the variable is used.

A similar issue can occur with mismatch in function declarations.

### Fix

The fix depends on the type of declaration mismatch. If both declarations indeed refer to the same object, use the same declaration. If the declarations refer to different objects, change the names of the one of the variables. If you change a variable name, remember to make the change in all places that use the variable.

Sometimes, declaration mismatches can occur because the declarations are affected by previous preprocessing directives. For instance, a declaration occurs in a macro, and the macro is defined on one inclusion path but undefined in another. These declaration mismatches can be tricky to debug. Identify the divergence between the two inclusion paths and fix the conflicting macro definitions.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Inconsistent Declarations in Two Files

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
double foo(void);

int bar(void) {
    return (int)foo();
}
```

In this example, *file1.c* declares `foo()` as returning an integer. In *file2.c*, `foo()` is declared as returning a double. This difference might cause a compile failure. Polyspace raises a defect on the second instance of `foo` in *file2*.

#### Correction — Align the Function Return Values

One possible correction is to change the function declarations so that they match. In this example, by changing the declaration of `foo` in *file2.c* to match *file1.c*, the defect is fixed.

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
int foo(void);

int bar(void) {
    return foo();
}
```

### Inconsistent Structure Alignment

*test1.c*

```
#include<stdio.h>
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

void func2();

int main(){
    square.side=1;
    circle.radius=1;

    func2();
    return 0;
}
```

*test2.c*

```
#include<stdio.h>
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

void func2(){
    printf("%d\n", square.side);
    printf("%d\n", circle.radius);
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

In this example, a declaration mismatch defect is raised on `square` in *test2.c* because Polyspace infers that `square` in *square.h* does not have the same alignment as `square` in *test2.c*. This error occurs because the `#pragma pack(1)` statement in *circle.h* declares specific alignment. In *test2.c*, *circle.h* is included before *square.h*. Therefore, the `#pragma pack(1)` statement from *circle.h* is not reset to the default alignment after the `aCircle` structure. Because of this omission, *test2.c* infers that the `aSquare square` structure also has an alignment of `1` byte. This defect might cause a compilation failure.

### Correction — Close Packing Statements

One possible correction is to reset the structure alignment after the `aCircle` struct declaration. For the GNU or Microsoft Visual compilers, fix the defect by adding a `#pragma pack()` statement at the end of *circle.h*.

*test1.c*

```
#include<stdio.h>
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

void func2();

int main(){
    square.side=1;
    circle.radius=1;

    func2();
    return 0;
}
```

*test2.c*

```
#include<stdio.h>
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

void func2(){
    printf("%d\n", square.side);
    printf("%d\n", circle.radius);
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;

#pragma pack()
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

Other compilers require different `#pragma pack` syntax. For your syntax, see the documentation for your compiler.

### Correction — Use the `Ignore pragma pack directives` Option

One possible correction is to add the `Ignore pragma pack directives` option to your Bug Finder analysis. If you want the structure alignment to change for each structure, and you do not want to see this **Declaration mismatch** defect, use this correction.

1. On the Configuration pane, select the **Advanced Settings** pane.
2. In the **Other** box, enter `-ignore-pragma-pack`.
3. Rerun your analysis.

   The **Declaration mismatch** defect is resolved.

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `DECL_MISMATCH`
**Impact:** High

# Version History

**Introduced in R2013b**

# Duplicated code

A section of code is duplicated in other places

## Description

This defect occurs when a block of code is duplicated in multiple places.

The defect checker does not flag certain blocks as duplicates. For instance, the blocks of code considered almost duplicates have to typically consist of more than a certain number of lines. See also “Duplicate Code Detection in Polyspace Bug Finder” on page 32-6.

### Risk

Sections of code that do the same operations require unnecessary additional maintenance. Duplicated code also increases the chances you will update the code in one place but forget to update the other. See also `Almost duplicated code` and `Possible copy-paste error`.

### Fix

Refactor the sections of code into a dedicated function. In other words, if two blocks of code are duplicates of each other, write a new function containing this code block and replace the existing blocks with calls to the new function.

## Examples

### Duplicate Blocks of Code

This example contains two blocks of code that are exact duplicates of each other.

```
typedef struct {
    int pin1;
    int pin2;
    int pin3;
    int pin4;
    int pin5;
    int pin6;
    int pin7;
    int pin8;
} board;

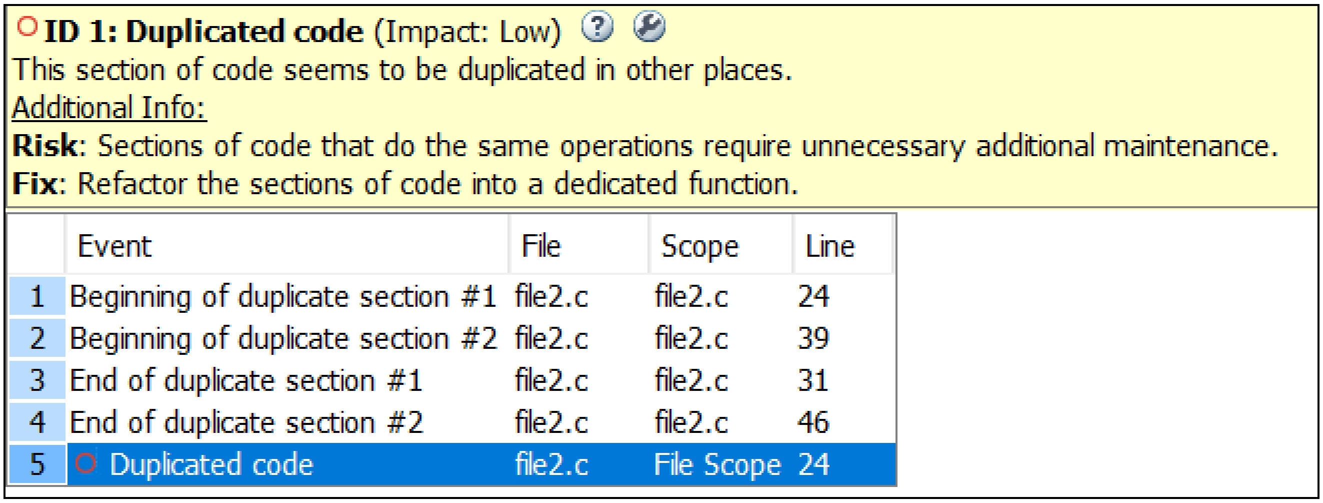
board Aboard;
extern int getPinVal();

void setAllPins() {
     int val1 = getPinVal();
     int val2 = getPinVal();
     int val3 = getPinVal();
     int val4 = getPinVal();
     int val5 = getPinVal();
     int val6 = getPinVal();
     int val7 = getPinVal();
     int val8 = getPinVal();
     Aboard.pin1 = val1; //Beginning of duplicate section #1
     Aboard.pin2 = val2;
     Aboard.pin3 = val3;
     Aboard.pin4 = val4;
     Aboard.pin5 = val5;
     Aboard.pin6 = val6;
     Aboard.pin7 = val7;
     Aboard.pin8 = val8; //End of duplicate section #1

}

void resetAllPins() {
     int val1 = 0, val2 = 1, val3 = 0,
         val4 = 0, val5 = 1, val6 = 0,
         val7 = 0, val8 = 1;
     Aboard.pin1 = val1; //Beginning of duplicate section #2
     Aboard.pin2 = val2;
     Aboard.pin3 = val3;
     Aboard.pin4 = val4;
     Aboard.pin5 = val5;
     Aboard.pin6 = val6;
     Aboard.pin7 = val7;
     Aboard.pin8 = val8; //End of duplicate section #2
}
```

The event list on the **Result Details** pane shows the beginning and end of each block of code. Click on an event to navigate to the corresponding location in the source code.



○ **ID 1: Duplicated code** (Impact: Low)

This section of code seems to be duplicated in other places.

Additional Info:

**Risk**: Sections of code that do the same operations require unnecessary additional maintenance.

**Fix**: Refactor the sections of code into a dedicated function.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Beginning of duplicate section #1 | file2.c | file2.c | 24 |
| 2 | Beginning of duplicate section #2 | file2.c | file2.c | 39 |
| 3 | End of duplicate section #1 | file2.c | file2.c | 31 |
| 4 | End of duplicate section #2 | file2.c | file2.c | 46 |
| 5 | ○ Duplicated code | file2.c | File Scope | 24 |

In the Polyspace user interface, you can see the duplicated code blocks side by side on the **Source** pane. See “Navigate in Separate Window”.

**Correction – Refactor Duplicate Sections Into Common Function**

You can refactor the duplicate sections of code into a common function and replace the sections with calls to this function. In this example, the duplicate block has been refactored into the `init()` function.

```
typedef struct {
    int pin1;
    int pin2;
    int pin3;
    int pin4;
    int pin5;
    int pin6;
    int pin7;
    int pin8;
} board;

board Aboard;
extern int getPinVal();

void init(int val1, int val2, int val3, int val4,
          int val5, int val6, int val7, int val8) {
     Aboard.pin1 = val1;
     Aboard.pin2 = val2;
     Aboard.pin3 = val3;
     Aboard.pin4 = val4;
     Aboard.pin5 = val5;
     Aboard.pin6 = val6;
     Aboard.pin7 = val7;
     Aboard.pin8 = val8;
}

void setAllPins() {
     int val1 = getPinVal();
     int val2 = getPinVal();
     int val3 = getPinVal();
     int val4 = getPinVal();
     int val5 = getPinVal();
     int val6 = getPinVal();
     int val7 = getPinVal();
     int val8 = getPinVal();
     init(val1, val2, val3, val4, val5, val6, val7, val8);
}

void resetAllPins() {
     int val1 = 0, val2 = 1, val3 = 0,
         val4 = 0, val5 = 1, val6 = 0,
         val7 = 0, val8 = 1;
     init(val1, val2, val3, val4, val5, val6, val7, val8);
}
```

# Environment pointer invalidated by previous operation

Call to setenv or putenv family function modifies environment pointed to by pointer

## Description

This defect occurs when you use the third argument of *main()* in a hosted environment to access the environment after an operation modifies the environment. In a hosted environment, many C implementations support the nonstandard syntax:

```
main (int argc, char *argv[], char *envp[])
```

A call to a setenv or putenv family function modifies the environment pointed to by *envp.

### Risk

When you modify the environment through a call to a setenv or putenv family function, the environment memory can potentially be reallocated. The hosted environment pointer is not updated and might point to an incorrect location. A call to this pointer can return unexpected results or cause an abnormal program termination.

### Fix

Do not use the hosted environment pointer. Instead, use global external variable environ in Linux, _environ or _wenviron in Windows, or their equivalent. When you modify the environment, these variables are updated.

## Examples

### Access Environment Through Pointer envp

```
#include <stdio.h>
#include <stdlib.h>

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

/* envp is from main function */
int func(char **envp)
{
    /* Call to setenv may cause environment
     *memory to be reallocated
     */
    if (setenv(("MY_NEW_VAR"),("new_value"),1) != 0)
    {
        /* Handle error */
        return -1;
    }
    /* envp not updated after call to setenv, and may
     *point to incorrect location.
     **/
    if (envp != ((void *)0)) {
        use_envp(envp);
/* No defect on second access to
*envp because defect already raised */
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func(envp);
    }
}
```

In this example, `envp` is accessed inside `func()` after a call to `setenv` that can reallocate the environment memory. `envp` can point to an incorrect location because it is not updated after `setenv` modifies the environment. No defect is raised when `use_envp()` is called because the defect is already raised on the previous line of code.

#### Correction — Use Global External Variable `environ`

One possible correction is to access the environment by using a variable that is always updated after a call to `setenv`. For instance, in the following code, the pointer `envp` is still available from `main()`, but the environment is accessed in `func()` through the global external variable `environ`.

```
#include <stdio.h>
#include <stdlib.h>
extern char **environ;

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

int func(void)
{
    if (setenv(("MY_NEW_VAR"), ("new_value"),1) != 0) {
        /* Handle error */
        return -1;
    }
  /* Use global external variable environ
   *which is always updated after a call to setenv */

    if (environ != NULL) {
        use_envp(environ);
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func();
    }
}
```

## Result Information

**Group:** Programming
**Language:** C | C++

# Errno not reset

`errno` not reset before calling a function that sets `errno`

## Description

This defect occurs when you do not reset `errno` before calling a function that sets `errno` to indicate error conditions. However, you check `errno` for those error conditions after the function call.

### Risk

The `errno` is not clean and can contain values from a previous call. Checking `errno` for errors can give the false impression that an error occurred.

`errno` is set to zero at program startup but subsequently, `errno` is not reset by a C standard library function. You must explicitly set `errno` to zero when required.

### Fix

Before calling a function that sets `errno` to indicate error conditions, reset `errno` to zero explicitly.

## Examples

### `errno` Not Reset Before Call to `strtod`

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
                  {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

In this example, `errno` is not reset to 0 before the first call to `strtod`. Checking `errno` for 0 later can lead to a false positive.

#### Correction — Reset `errno` Before Call

One possible correction is to reset `errno` to 0 before calling `strtod`.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    errno = 0;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
              {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

## Result Information

# Floating point comparison with equality operators

Imprecise comparison of floating-point variables

## Description

This defect occurs when you use an equality (==) or inequality (!=) operation with floating-point numbers.

Polyspace does not raise a defect for an equality or inequality operation with floating-point numbers when:

- The comparison is between two float constants.

  ```
      float flt = 1.0;
      if (flt == 1.1)
  ```
- The comparison is between a constant and a variable that can take a finite, reasonably small number of values.

  ```
  float x;

  int rand = random();
  switch(rand) {
  case 1: x = 0.0; break;
  case 2: x = 1.3; break;
  case 3: x = 1.7; break;
  case 4: x = 2.0; break;
  default: x = 3.5; break; }
  …
  if (x==1.3)
  ```
- The comparison is between floating-point expressions that contain only integer values.

  ```
  float x = 0.0;
  for (x=0.0;x!=100.0;x+=1.0) {
  …
  if (random) break;
  }

  if (3*x+4==2*x-1)
  …
  if (3*x+4 == 1.3)
  ```
- One of the operands is `0.0`, unless you use the option flag `-detect-bad-float-op-on-zero`.

  ```
  /* Defect detected when
  you use the option flag */

  if (x==0.0f)
  ```

  If you are running an analysis through the user interface, you can enter this option in the **Other** field, under the **Advanced Settings** node on the **Configuration** pane. See `Other`.

  At the command line, add the flag to your analysis command.

```
polyspace-bug-finder -sources filename ^
-checkers BAD_FLOAT_OP -detect-bad-float-op-on-zero
```

### Risk

Checking for equality or inequality of two floating-point values might return unexpected results because floating-point representations are inexact and involve rounding errors.

### Fix

Instead of checking for equality of floating-point values:

```
if (val1 == val2)
```

check if their difference is less than a predefined tolerance value (for instance, the value `FLT_EPSILON` defined in `float.h`):

```
#include <float.h>
if(fabs(val1-val2) < FLT_EPSILON)
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Floats Inequality in `for`-loop

```
#include <stdio.h>
#include <math.h>
#include <float.h>

void func(void)
{
    float f;
    for (f = 1.0; f != 2.0; f = f + 0.1)
        (void)printf("Value: %f\n", f);
}
```

In this function, the `for`-loop tests the inequality of `f` and the number 2.0 as a stopping mechanism. The number of iterations is difficult to determine, or might be infinite, because of the imprecision in floating-point representation.

#### Correction — Change the Operator

One possible correction is to use a different operator that is not as strict. For example, an inequality like >= or <=.

```
#include <stdio.h>
#include <math.h>
```

```
#include <float.h>

void func(void)
{
    float f;
    for (f = 1.0; f <= 2.0; f = f + 0.1)
        (void)printf("Value: %f\n", f);
}
```

### Result Information

# Format string specifiers and arguments mismatch

Format specifiers in `printf`-like functions do not match corresponding arguments

## Description

This defect occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
const char *message = "License not available";
int err_number = -4;
printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

In cases where integer promotion modifies the perceived data type of an argument, the analysis result shows both the original type and the type after promotion. The format specifier has to match the type after integer promotion.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Printing a Float

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", fst);
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

### Result Information

# Function called from signal handler not asynchronous-safe

Call to interrupted function causes undefined program behavior

## Description

This defect occurs when a signal handler calls a function that is not asynchronous-safe according to the POSIX standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

### Risk

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

### Fix

The POSIX standard defines these functions as asynchronous-safe. You can call these functions from a signal handler.

Functions not in the previous table are not asynchronous-safe, and should not be called from a signal hander.

## Examples

### Call to `printf()` Inside Signal Handler

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler(int signum)
{
    /* Call function printf() that is not
    asynchronous-safe */
    printf("signal %d received.", signum);
    e_flag = 1;
}

int main(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, sizeof(char));
    if (info == NULL)
    {
        /* Handle Error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

In this example, sig_handler calls printf() when catching a signal. If the handler catches another signal while printf() is executing, the behavior of the program is undefined.

**Correction — Set Flag Only in Signal Handler**

Use your signal handler to set only the value of a flag. e_flag is of type volatile sig_atomic_t. sig_handler can safely access it asynchronously.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler1(int signum)
{
    int s0 = signum;
    e_flag = 1;
}

int func(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler1) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, 1);
    if (info == NULL)
    {
        /* Handle error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** Off

# Function called from signal handler not asynchronous-safe (strict ISO C)

Call to interrupted function causes undefined program behavior

## Description

This defect occurs when a signal handler calls a function that is not asynchronous-safe according to the C standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

The C standard defines a stricter subset of functions as asynchronous-safe compared to the set of functions that are asynchronous-safe according to the POSIX standard. **Function called from signal handler not asynchronous-safe (strict ISO C)** reports a defect when a signal handler calls any function that is not part of that subset, even if the function is asynchronous-safe according to the POSIX standard.

To check for calls to functions that are not asynchronous-safe according to the POSIX standard, enable checker **Function called from signal handler not asynchronous-safe**.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

### Risk

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

### Fix

The C standard defines the following functions as asynchronous-safe. You can call these functions from a signal handler:

- `abort()`
- `_Exit()`
- `quick_exit()`
- `signal()`

## Examples

### Call to `raise()` Inside Signal Handler

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
```

```
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
{
    int s0 = signum;
    /* SIGTERM specific handling */
}

void sig_handler(int signum)
{
    int s0 = signum;
    /* Call raise() */
    if (raise(SIGTERM) != 0) {
        /* Handle error */
    }
}

int finc(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` calls `raise()` when catching a signal. If the handler catches another signal while `raise()` is executing, the behavior of the program is undefined.

**Correction — Remove Call to `raise()` in Signal Handler**

According to the C standard, the only functions that you can safely call from a signal handler are `abort()`, `_Exit()`, `quick_exit()`, and `signal()`.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
```

```
{
    int s0 = signum;
    /* SIGTERM specific handling */
}
void sig_handler(int signum)
{
    int s0 = signum;

}

int func(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

# Improper array initialization

Incorrect array initialization when using initializers

## Description

This defect occurs when Polyspace Bug Finder considers that an array initialization using initializers is incorrect.

This defect applies to normal and designated initializers. In C99, with designated initializers, you can place the elements of an array initializer in any order and implicitly initialize some array elements. The designated initializers use the array index to establish correspondence between an array element and an array initializer element. For instance, the statement `int arr[6] = { [4] = 29, [2] = 15 }` is equivalent to `int arr[6] = { 0, 0, 15, 0, 29, 0 }`.

You can use initializers incorrectly in one of the following ways.

| Issue | Risk | Possible Fix |
|---|---|---|
| In your initializer for a one-dimensional array, you have more elements than the array size. | Unused array initializer elements indicate a possible coding error. | Increase the array size or remove excess elements. |
| You place the braces enclosing initializer values incorrectly. | Because of the incorrect placement of braces, some array initializer elements are not used.<br>Unused array initializer elements indicate a possible coding error. | Place braces correctly. |
| In your designated initializer, you do not initialize the first element of the array explicitly. | The implicit initialization of the first array element indicates a possible coding error. You possibly overlooked the fact that array indexing starts from 0. | Initialize all elements explicitly. |
| In your designated initializer, you initialize an element twice. | The first initialization is overridden.<br>The redundant first initialization indicates a possible coding error. | Remove the redundant initialization. |
| You use designated and nondesignated initializers in the same initialization. | You or another reviewer of your code cannot determine the size of the array by inspection. | Use either designated or nondesignated initializers. |

#### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Incorrectly Placed Braces (C Only)

```
int arr[2][3]
= {{1, 2},
    {3, 4},
    {5, 6}
};
```

In this example, the array `arr` is initialized as `{1,2,0,3,4,0}`. Because the initializer contains `{5,6}`, you might expect the array to be initialized `{1,2,3,4,5,6}`.

#### Correction — Place Braces Correctly

One possible correction is to place the braces correctly so that all elements are explicitly initialized.

```
int a1[2][3]
= {{1, 2, 3},
    {4, 5, 6}
};
```

### First Element Not Explicitly Initialized

```
int arr[5]
= {
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};
```

In this example, `arr[0]` is not explicitly initialized. It is possible that the programmer did not consider that the array indexing starts from 0.

#### Correction — Explicitly Initialize All Elements

One possible correction is to initialize all elements explicitly.

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};
```

### Element Initialized Twice

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [2] = 4,
    [4] = 5
};
```

In this example, arr[2] is initialized twice. The first initialization is overridden. In this case, because arr[3] was not explicitly initialized, it is possible that the programmer intended to initialize arr[3] when arr[2] was initialized a second time.

#### Correction — Fix Redundant Initialization

One possible correction is to eliminate the redundant initialization.

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};
```

### Mix of Designated and Nondesignated Initializers

```
int arr[]
= {
    [0] = 1,
    [3] = 3,
    4,
    [5] = 5,
    6
    };
```

In this example, because a mix of designated and nondesignated initializers are used, it is difficult to determine the size of arr by inspection.

#### Correction — Use Only Designated Initializers

One possible correction is to use only designated initializers for array initialization.

```
int arr[]
= {
    [0] = 1,
    [3] = 3,
    [4] = 4,
    [5] = 5,
    [6] = 6
};
```

### Result Information

**Group:** Programming

# Incorrect data type passed to va_arg

Data type of variadic function argument does not match type in va_arg call

## Description

This defect occurs when the data type in a va_arg call does not match the data type of the variadic function argument that va_arg reads.

For instance, you pass an unsigned char argument to a variadic function func. Because of default argument promotion, the argument is promoted to int. When you use a va_arg call that reads an unsigned char argument, a type mismatch occurs.

```
void func (int n, ...) {
   ...
   va_list args;
   va_arg(args, unsigned char);
   ...
}

void main(void) {
   unsigned char c;
   func(1,c);
}
```

### Risk

In a variadic function (function with variable number of arguments), you use va_arg to read each argument from the variable argument list (va_list). The va_arg use does not guarantee that there actually exists an argument to read or that the argument data type matches the data type in the va_arg call. You have to make sure that both conditions are true.

Reading an incorrect type with a va_arg call can result in undefined behavior. Because function arguments reside on the stack, you might access an unwanted area of the stack.

### Fix

Make sure that the data type of the argument passed to the variadic function matches the data type in the va_arg call.

Arguments of a variadic function undergo default argument promotions. The argument data types of a variadic function cannot be determined from a prototype. The arguments of such functions undergo default argument promotions (see Sec. 6.5.2.2 and 7.15.1.1 in the C99 Standard). Integer arguments undergo integer promotion and arguments of type float are promoted to double. For integer arguments, if a data type can be represented by an int, for instance, char or short, it is promoted to an int. Otherwise, it is promoted to an unsigned int. All other arguments do not undergo promotion.

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for MISRA C:2012 Rule 17.1 or MISRA C++:2008 Rule 8-4-1 to detect use of variadic functions.

## Examples

### char Used as Function Argument Type and va_arg argument

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, unsigned char);
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

In this example, func takes an unsigned char argument, which undergoes default argument promotion to int. The data type in the va_arg call is still unsigned char, which does not match the int argument type.

#### Correction — Use int as va_arg Argument

One possible correction is to read an int argument with va_arg.

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

## Result Information

# Incorrect pointer scaling

Implicit scaling in pointer arithmetic might be ignored

## Description

This defect occurs when Polyspace Bug Finder considers that you are ignoring the implicit scaling in pointer arithmetic.

For instance, the defect can occur in the following situations.

| Situation | Risk | Possible Fix |
|---|---|---|
| You use the `sizeof` operator in arithmetic operations on a pointer. | The `sizeof` operator returns the size of a data type in number of bytes.<br>Pointer arithmetic is already implicitly scaled by the size of the data type of the pointed variable. Therefore, the use of `sizeof` in pointer arithmetic produces unintended results. | Do not use `sizeof` operator in pointer arithmetic. |
| You perform arithmetic operations on a pointer, and then apply a cast. | Pointer arithmetic is implicitly scaled. If you do not consider this implicit scaling, casting the result of a pointer arithmetic produces unintended results. | Apply the cast before the pointer arithmetic. |

### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Use of `sizeof` Operator

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;
    int value_in_position_2 = *(ptr + 2*(sizeof(int)));
}
```

In this example, the operation `2*(sizeof(int))` returns twice the size of an `int` variable in bytes. However, because pointer arithmetic is implicitly scaled, the number of bytes by which `ptr` is offset is `2*(sizeof(int))*(sizeof(int))`.

In this example, the incorrect scaling shifts `ptr` outside the bounds of the array. Therefore, a **Pointer access out of bounds** error appears on the * operation.

#### Correction — Remove `sizeof` Operator

One possible correction is to remove the `sizeof` operator.

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;

    int value_in_position_2 = *(ptr + 2);
}
```

### Cast Following Pointer Arithmetic

```
int func(void) {
    int x = 0;
    char r = *(char *)(&x + 1);
    return r;
}
```

In this example, the operation `&x + 1` offsets `&x` by `sizeof(int)`. Following the operation, the resulting pointer points outside the allowed buffer. When you dereference the pointer, a **Pointer access out of bounds** error appears on the * operation.

#### Correction — Apply Cast Before Pointer Arithmetic

If you want to access the second byte of `x`, first cast `&x` to a `char*` pointer and then perform the pointer arithmetic. The resulting pointer is offset by `sizeof(char)` bytes and still points within the allowed buffer, whose size is `sizeof(int)` bytes.

```
int func(void) {
    int x = 0;
    char r = *((char *)(&x )+ 1);
    return r;
}
```

# Incorrect type data passed to va_start

Data type of second argument to `va_start` macro leads to undefined behavior

## Description

This defect occurs when the second argument of the `va_start` macro has one of these data types:

- A data type that changes when undergoing default argument promotion.

  For instance, `char` and `short` undergo promotion to `int` or `unsigned int` and `float` undergoes promotion to `double`. The types `int` and `double` do not change under default argument promotion.
- (C only) A register type or a data type declared with the `register` qualifier.
- (C++ only) A reference data type.
- (C++ only) A data type that has a nontrivial copy constructor or a nontrivial move constructor.

### Risk

In a variadic function or function with variable number of arguments:

```
void multipleArgumentFunction(int someArg, short rightmostFixedArg, ...) {
    va_list myList;
    va_start(myList, rightmostFixedArg);
    ...
    va_end(myList);
}
```

The `va_start` macro initializes a variable argument list so that additional arguments to the variadic function after the fixed parameters can be captured in the list. According to the C11 and C++14 Standards, if you use one of the flagged data types for the second argument of the `va_start` macro (for instance, `rightmostFixedArg` in the preceding example), the behavior is undefined.

If the data type involves a nontrivial copy constructor, the behavior is implementation-defined. For instance, whether the copy constructor is invoked in the call to `va_start` depends on the compiler.

### Fix

When using the `va_start` macro, try to use the types `int`, `unsigned int` or `double` for the rightmost named parameter of the variadic function. Then, use this parameter as the second argument of the `va_start` macro.

For instance, in this example, the rightmost named parameter of the variadic function has a supported data type `int`:

```
void multipleArgumentFunction(int someArg, int rightmostFixedArg, ...) {
    va_list myList;
    va_start(myList, rightmostFixedArg);
    ...
    va_end(myList);
}
```

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for MISRA C:2012 Rule 17.1 or MISRA C++:2008 Rule 8-4-1 to detect use of variadic functions.

## Examples

### Incorrect Data Types for Second Argument of va_start

```
#include <string>
#include <cstdarg>

double addVariableNumberOfDoubles(double* weight, short num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}

double addVariableNumberOfFloats(float* weight, int num, std::string s, ...) {
    float sum=0.0;
    va_list list;
    va_start(list, s);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, float);
    }
    va_end(list);
    return sum;
}
```

In this example, the checker flags the call to va_start in:

- addVariableNumberOfDoubles because the argument has type short, which undergoes default argument promotion to int.
- addVariableNumberOfFloats because the argument has type std::string, which has a nontrivial copy constructor.

#### Correction — Fix Data Type for Second Argument of va_start

Make sure that the second argument of the va_start macro has a supported data type. In the following corrected example:

- In addVariableNumberOfDoubles, the data type of the last named parameter of the variadic function is changed to int.
- In addVariableNumberOfFloats, the second and third parameters of the variadic function are switched so that data type of the last named parameter is int.

```
#include <string>
#include <cstdarg>

double addVariableNumberOfDoubles(double* weight, int num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}

double addVariableNumberOfFloats(double* weight, std::string s, int num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}
```

## Result Information

# Incorrect use of offsetof in C++

Incorrect arguments to `offsetof` macro causes undefined behavior

## Description

This defect occurs when you pass arguments to the `offsetof` macro for which the behavior of the macro is not defined.

The `offsetof` macro:

```
offsetof(classType, aMember)
```

returns the offset in bytes of the data member `aMember` from the beginning of an object of type `classType`. For use in `offsetof`, `classType` and `aMember` have certain restrictions:

- `classType` must be a standard layout class.

  For instance, it must not have `virtual` member functions. For more information on the requirements for a standard layout class, see C++ named requirements: StandardLayoutType.
- `aMember` must not be static.
- `aMember` must not be a member function.

The checker flags uses of the `offsetof` macro where the arguments violate one or more of these restrictions.

### Risk

Violating the restrictions on the arguments of the `offsetof` macro leads to undefined behavior.

### Fix

Use the `offsetof` macro only on nonstatic data members of a standard layout class.

The result details state which restriction on the `offsetof` macro is violated. Fix the violation.

## Examples

### Use of `offsetof` Macro with Nonstandard Layout Class

```
#include <cstddef>

class myClass {
     int member1;
  public:
     int member2;
};

void func() {
  size_t off = offsetof(myClass, member2);
  // ...
}
```

In this example, the class `myClass` has two data members with different access control, one private and the other public. Therefore, the class does not satisfy the requirements of a standard layout class and cannot be used with the `offsetof` macro.

#### Correction — Use Uniform Access Control for All Data Members

If the use of `offsetof` is important for the application, make sure that the first argument is a class with a standard layout. For instance, see if you can work around the need for a public data member.

```
#include <cstddef>

class myClass {
     int member1;
     int member2;
  public:
     int getMember2(void) { return member2;}
     friend void func(void);
};

void func() {
  size_t off = offsetof(myClass, member2);
  // ...
}
```

## Result Information

**Group:** Programming
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `OFFSETOF_MISUSE`
**Impact:** Medium

# Version History

# Incorrect use of va_start

`va_start` is called in a non-variadic function or called with a second argument that is not the rightmost parameter of a variadic function

## Description

This defect occurs when you use the `va_start` macro in a way that violates its specifications.

In a variadic function or function with variable number of arguments:

```
void multipleArgumentFunction(int someArg, int rightmostFixedArg, ...) {
    va_list myList;
    va_start(myList, rightmostFixedArg);
    ...
    va_end(myList);
}
```

The `va_start` macro initializes a variable argument list so that additional arguments to the variadic function after the fixed parameters can be captured in the list. In the preceding example, the `va_start` macro initializes `myList` so that it can capture arguments after `rightmostFixedArg`.

You can violate the specifications of `va_start` in multiple ways. For instance:

- You call `va_start` in a non-variadic function.
- The second argument of `va_start` is not the rightmost fixed parameter of the variadic function.

### Risk

Violating the specifications of the `va_start` macro can result in compilation errors. If the compiler fails to detect the violation, the violation can result in undefined behavior.

### Fix

Make sure that:

- The `va_start` macro is used in a variadic function
- The second argument of the `va_start` macro is the rightmost fixed parameter of the variadic function.

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for `MISRA C:2012 Rule 17.1` or `MISRA C++:2008 Rule 8-4-1` to detect use of variadic functions.

## Examples

### Incorrect Argument to va_start

```
#include <stdarg.h>

double addVariableNumberOfDoubles(int num, double* weight, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}
```

In this example, the rightmost fixed parameter to the `addVariableNumberOfDoubles` function is `weight`. However, a different parameter is used as the second argument to the `va_start` macro.

**Correction — Switch Order of Fixed Parameters of Variadic Function**

One possible correction is to modify the order of fixed parameters to the variadic function so that the rightmost fixed parameter is used for the `va_start` macro.

```
#include <stdarg.h>

double addVariableNumberOfDoubles(double* weight, int num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `VA_START_MISUSE`
**Impact:** Medium

# Incorrect value forwarding

Forwarded object might be modified unexpectedly

## Description

This defect occurs when:

- You use `std::move` to forward a forwarding reference to a function, including objects of type `auto&&` or `T&&`.
- You use `std::forward` to forward an `rvalue` reference to a function.

Consider the following code. In the function template `callMethod`, the parameter `param1` is a forwarding reference and the parameter `param2` is an `rvalue` reference. When forwarding these parameters to the function `foo()`, the code incorrectly uses `std::move` on the forwarding reference `param1` and `std::forward` on the `rvalue` reference `param2`.

```
#include<string>
#include<iostream>

template <class T> class  bar{};

template<typename T>
void foo(std::string&& s, bar<T>&&){
    //...
}

template <typename T>
void callMethod(T&& param1, bar<T>&& param2) {

    foo(std::move(param1),std::forward<bar<T>&&>(param2));
}
```

Forwarding references are declared as `T&&` or `auto&&`, and `rvalue` references are declared as `&&`. Confusing forwarding references with `rvalue` references results in incorrect value forwarding.

Polyspace does not report this defect if `std::move` or `std::forward` does not forward a reference to a function. For instance, this code does not forward the `rvalue` reference `b1` and the forwarding reference `b2` to another function. Using `std::move` with `b2` or using `std::forward` with `b1` does not cause a defect.

```
template <typename T1, typename T2>
void func(T1& b1, T2&& b2)
{
    const T1& b10 = std::forward<B>(b1);
    const T2& b20 = std::forward<B>(b2);
    const T1& b11 = std::move(b1);
    const T2& b21 = std::move(b2);
}
```

### Risk

Using `std::move` with forwarding references can result in an unexpected modification of an lvalue. Using `std::forward` with `rvalue` references is error-prone and can increase the complexity of your code.

### Fix

- If you forward an `rvalue` reference to a function, use `std::move` to cast the reference to an `rvalue`.
- If you forward a forwarding or universal reference to a function, use `std::forward` to cast the reference to an `rvalue` only if the object is bound to an `rvalue`.

## Examples

### Values Forwarded Incorrectly

```
#include <cstdint>
#include <string>
#include <utility>

class A
{
public:
    explicit A(std::string&& s)
        : str(std::move(s))
    {
    }

private:
    std::string str;
};

template <typename ...T>
void f1(T...t);

template <typename T1, typename T2>
void func(T1&& t1, T2& t2)
{
    f1(std::move(t1));
    f1(std::forward<T1>(t1));//Suggested fix

    f1(std::forward<T2>(t2));
    f1(std::move(t2));//Suggested fix
}

void func_auto(A& var)
{
    auto&& var1 = var;
    f1(std::move(var1));
    f1(std::forward<decltype(var1)>(var1));//Suggested fix
}
```

```
void main()
{
    int32_t i;
    func(0, i);
}
```

In this example, the template function `func` forwards parameters `t1` and `t2` to function `f1`.

- Because the `rvalue` reference `t2` is forwarded by calling `std::forward`, Polyspace reports a defect.
- Because the forwarding reference `t1` is forwarded by calling `std::move`, Polyspace reports a defect. If `t1` is initialized with an lvalue, the move might result in an unexpected modification of the parameter.
- Similarly, Polyspace reports a defect on the use of `std::move` in `func_auto` because objects of type `auto`&& are considered as forwarding references.

For each defect, the subsequent lines of code shows the suggested fix.

# Inline constraint not respected

Modifiable static variable is modified in nonstatic inline function

## Description

This defect occurs when you refer to a file scope modifiable static variable or define a local modifiable static variable in a nonstatic inlined function. The checker considers a variable as modifiable if it is not `const`-qualified.

For instance, `var` is a modifiable `static` variable defined in an `inline` function `func`. `g_step` is a file scope modifiable static variable referred to in the same inlined function.

```
static int g_step;
inline void func (void) {
   static int var = 0;
   var += g_step;
}
```

### Risk

When you modify a static variable in multiple function calls, you expect to modify the same variable in each call. For instance, each time you call `func`, the same instance of `var1` is incremented but a separate instance of `var2` is incremented.

```
void func(void) {
   static var1 = 0;
   var2 = 0;
   var1++;
   var2++;
}
```

If a function has an inlined and non-inlined definition (in separate files), when you call the function, the C standard allows compilers to use either the inlined or the non-inlined form (see ISO/IEC 9899:2011, sec. 6.7.4). If your compiler uses an inlined definition in one call and the non-inlined definition in another, you are no longer modifying the same variable in both calls. This behavior defies the expectations from a static variable.

### Fix

Use one of these fixes:

- If you do not intend to modify the variable, declare it as `const`.

  If you do not modify the variable, there is no question of unexpected modification.
- Make the variable non-`static`. Remove the `static` qualifier from the declaration.

  If the variable is defined in the function, it becomes a regular local variable. If defined at file scope, it becomes an extern variable. Make sure that this change in behavior is what you intend.
- Make the function `static`. Add a `static` qualifier to the function definition.

If you make the function `static`, the file with the inlined definition always uses the inlined definition when the function is called. Other files use another definition of the function. The question of which function definition gets used is not left to the compiler.

## Examples

### Static Variable Use in Inlined and External Definition

```
/* file1. c  : contains inline definition of get_random()*/

inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}

/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

In this example, `get_random()` has an inline definition in `file1.c` and an external definition in `file2.c`. When `get_random` is called in `file1.c`, compilers are free to choose whether to use the inline or the external definition.

Depending on the definition used, you might or might not modify the version of `m_z` and `m_w` in the inlined version of `get_random()`. This behavior contradicts the usual expectations from a static variable. When you call `get_random()`, you expect to always modify the same `m_z` and `m_w`.

### Correction — Make Inlined Function Static

One possible correction is to make the inlined `get_random()` static. Irrespective of your compiler, calls to `get_random()` in `file1.c` then use the inlined definition. Calls to `get_random()` in other files use the external definition. This fix removes the ambiguity about which definition is used and whether the static variables in that definition are modified.

```
/* file1. c  : contains inline definition of get_random()*/

static inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}

/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

## Result Information

# Invalid assumptions about memory organization

Address is computed by adding or subtracting from address of a variable

## Description

This defect occurs when you compute the address of a variable in the stack by adding or subtracting from the address of another non-array variable.

### Risk

When you compute the address of a variable in the stack by adding or subtracting from the address of another variable, you assume a certain memory organization. If your assumption is incorrect, accessing the computed address can be invalid.

### Fix

Do not perform an access that relies on assumptions about memory organization.

## Examples

### Reliance on Memory Organization

```
void func(void) {
    int var1 = 0x00000011, var2;
    *(&var1 + 1) = 0;
}
```

In this example, the programmer relies on the assumption that `&var1 + 1` provides the address of `var2`. Therefore, an **Invalid assumptions about memory organization** appears on the `+` operation. In addition, a **Pointer access out of bounds** error also appears on the dereference.

#### Correction — Do Not Rely on Memory Organization

One possible correction is not perform direct computation on addresses to access separately declared variables.

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `INVALID_MEMORY_ASSUMPTION`
**Impact:** Medium

# Invalid file position

`fsetpos()` is invoked with a file position argument not obtained from `fgetpos()`

## Description

This defect occurs when the file position argument of `fsetpos()` uses a value that is not obtained from `fgetpos()`.

### Risk

The function `fgetpos(FILE *stream, fpos_t *pos)` gets the current file position of the stream. When you use any other value as the file position argument of `fsetpos(FILE *stream, const fpos_t *pos)`, you might access an unintended location in the stream.

### Fix

Use the value returned from a successful call to `fgetpos()` as the file position argument of `fsetpos()`.

## Examples

### `memset()` Sets File Position Argument

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset' */
    (void)memset(&offset, 0, sizeof(offset));

    /* Read data from file */

    /* Return to the initial position. offset was not
    returned from a call to fgetpos()    */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

In this example, `fsetpos()` uses `offset` as its file position argument. However, the value of `offset` is set by `memset()`. The preceding code might access the wrong location in the stream.

### Correction — Use a File Position Returned From `fgetpos()`

Call `fgetpos()`, and if it returns successfully, use the position argument in your call to `fsetpos()`.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset'
    using fgetpos() */
    if (fgetpos(file, &offset) != 0)
    {
        /* Handle error */
    }

    /* Read data from file */

    /* Back to the initial position */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

## Result Information

# Invalid use of = operator

Assignment in conditional statement

## Description

This defect occurs when an assignment is made inside the predicate of a conditional, such as `if` or `while`.

In C and C++, a single equal sign is an assignment not a comparison. Using a single equal sign in a conditional statement can indicate a typo or a mistake.

### Risk

- Conditional statement tests the wrong values— The single equal sign operation assigns the value of the right operand to the left operand. Then, because this assignment is inside the predicate of a conditional, the program checks whether the new value of the left operand is nonzero or not NULL.
- Maintenance and readability issues — Even if the assignment is intended, someone reading or updating the code can misinterpret the assignment as an equality comparison instead of an assignment.

### Fix

- If the assignment is a bug, to check for equality, add a second equal sign (==).
- If the assignment inside the conditional statement was intentional, to improve readability, separate the assignment and the test. Move the assignment outside the control statement. In the control statement, simply test the result of the assignment.

  If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

  - “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
  - “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
  - “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Single Equal Sign Inside an `if` Condition

```
#include <stdio.h>

void bad_equals_ex(int alpha, int beta)
{
    if(alpha = beta)
    {
        printf("Equal\n");
    }
}
```

The equal sign is flagged as a defect because the assignment operator is used within the predicate of the if-statement. The predicate assigns the value `beta` to `alpha`, then implicitly tests whether `alpha` is true or false.

#### Correction — Change Expression to Comparison

One possible correction is adding an additional equal sign. This correction changes the assignment to a comparison. The if condition compares whether `alpha` and `beta` are equal.

```
#include <stdio.h>

void equality_test(int alpha, int beta)
{
    if(alpha == beta)
    {
        printf("Equal\n");
    }
}
```

#### Correction — Assignment and Comparison Inside the `if` Condition

If an assignment must be made inside the predicate, a possible correction is adding an explicit comparison. This correction assigns the value of `beta` to `alpha`, then explicitly checks whether `alpha` is nonzero. The code is clearer.

```
#include <stdio.h>

int assignment_not_zero(int alpha, int beta)
{
    if((alpha = beta) != 0)
    {
        return alpha;
    }
    else
    {
        return 0;
    }
}
```

#### Correction — Move Assignment Outside the `if` Statement

If the assignment can be made outside the control statement, one possible correction is to separate the assignment and comparison. This correction assigns the value of `beta` to `alpha` before the if. Inside the if-condition, only `alpha` is given to test if `alpha` is nonzero or not NULL.

```
#include <stdio.h>

void assign_and_print(int alpha, int beta)
{
    alpha = beta;
    if(alpha)
    {
        printf("%d", alpha);
    }
}
```

## Result Information

**Group:** Programming
**Language:** C | C++

# Invalid use of == operator

Equality operation in assignment statement

## Description

This defect occurs when you use an equality operator instead of an assignment operator in a simple statement.

### Risk

The use of == operator instead of an = operator can silently produce incorrect results. If you intended to assign a value to a variable, the assignment does not occur. The variable retains its previous value or if not initialized previously, stays uninitialized.

### Fix

Use the = (assignment) operator instead of the == (equality) operator.

The check appears on chained assignment and equality operators such as:

```
compFlag = val1 == val2;
```

For better readability of your code, place the equality check in parenthesis.

```
compFlag = (val1 == val2);
```

If the use of == operator is intended, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Equality Evaluation in for-Loop

```
void populate_array(void)
{
    int i = 0;
    int j = 0;
    int array[4];

    for (j == 5; j < 9; j++) {
        array[i] = j;
        i++;
    }
}
```

Inside the `for`-loop, the statement `j == 5` tests whether `j` is equal to 5 instead of setting `j` to 5. The `for`-loop iterates from 0 to 8 because `j` starts with a value of 0, not 5. A by-product of the invalid equality operator is an out-of-bounds array access in the next line.

#### Correction — Change to Assignment Operator

One possible correction is to change the == operator to a single equal sign (=). Changing the == sign resolves both defects because the `for`-loop iterates the intended number of times.

```
void populate_array(void)
{
    int i = 0;
    int j = 0;
    int array[4];

    for (j = 5; j < 9; j++) {
        array[i] = j;
        i++;
    }
}
```

### Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `BAD_EQUAL_EQUAL_USE`
**Impact:** High

## Version History

**Introduced in R2013b**

# Invalid use of standard library routine

Wrong arguments to standard library function

## Description

This defect occurs when you use invalid arguments with a function from the standard library. This defect picks up errors related to other functions not covered by float, integer, memory, or string standard library routines.

### Risk

Invalid arguments to a standard library function result in undefined behavior.

### Fix

The fix depends on the root cause of the defect. For instance, the argument to a `printf` function can be `NULL` because a pointer was initialized with `NULL` and the initialization value was not overwritten along a specific execution path.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Calling `printf` Without a String

```
#include <stdio.h>
#include <stdlib.h>

void print_null(void) {

  printf(NULL);
}
```

The function `printf` takes only string input arguments or format specifiers. In this function, the input value is NULL, which is not a valid string.

#### Correction — Use Compatible Input Arguments

One possible correction is to change the input arguments to fit the requirements of the standard library routine. In this example, the input argument was changed to a character.

```
#include <stdio.h>
```

```
void print_null(void) {
    char zero_val = '0';
    printf((const char*)zero_val);
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `OTHER_STD_LIB`
**Impact:** High

# Version History

**Introduced in R2013b**

# Invalid va_list argument

Variable argument list used after invalidation with `va_end` or not initialized with `va_start` or `va_copy`

## Description

This defect occurs when you use a `va_list` variable as an argument to a function in the `vprintf` group but:

- You do not initialize the variable previously using `va_start` or `va_copy`.
- You invalidate the variable previously using `va_end` and do not reinitialize it.

For instance, you call the function `vsprintf` as `vsprintf (buffer,format, args)`. However, before the function call, you do not initialize the `va_list` variable `args` using either of the following:

- `va_start(args, paramName)`. `paramName` is the last named argument of a variable-argument function. For instance, for the function definition `void func(int n, char c, ...) {}`, `c` is the last named argument.
- `va_copy(args, anotherList)`. `anotherList` is another valid `va_list` variable.

### Risk

The behavior of an uninitialized `va_list` argument is undefined. Calling a function with an uninitialized `va_list` argument can cause stack overflows.

### Fix

Before using a `va_list` variable as function argument, initialize it with `va_start` or `va_copy`.

Clean up the variable using `va_end` only after all uses of the variable.

## Examples

### `va_list` Variable Used Following Call to va_end

```
#include <stdarg.h>
#include <stdio.h>

int call_vfprintf(int line, const char *format, ...) {
    va_list ap;
    int r=0;

    va_start(ap, format);
    r = vfprintf(stderr, format, ap);
    va_end(ap);

    r += vfprintf(stderr, format, ap);
    return r;
}
```

In this example, the `va_list` variable `ap` is used in the `vfprintf` function, after the `va_end` macro is called.

#### Correction — Call va_end After Using va_list Variable

One possible correction is to call `va_end` only after all uses of the `va_list` variable.

```
#include <stdarg.h>
#include <stdio.h>

int call_vfprintf(int line, const char *format, ...) {
    va_list ap;
    int r=0;

    va_start(ap, format);
    r = vfprintf(stderr, format, ap);
    r += vfprintf(stderr, format, ap);
    va_end(ap);

    return r;
}
```

## Result Information

**Group:** Programming

# Memory comparison of float-point values

Object representation of floating-point values can be different (same) for equal (not equal) floating-point values

## Description

This defect occurs when you compare the object representation of floating-point values or the object representation of structures containing floating-point members. When you use the functions memcmp, bcmp, or wmemcmp to perform the bit pattern comparison, the defect is raised.

### Risk

The object representation of floating-point values uses specific bit patterns to encode those values. Floating-point values that are equal, for instance -0.0 and 0.0 in the IEC 60559 standard, can have different bit patterns in their object representation. Similarly, floating-point values that are not equal can have the same bit pattern in their object representation.

### Fix

When you compare structures containing floating-point members, compare the structure members individually.

To compare two floating-point values, use the == or != operators. If you follow a standard that discourages the use of these operators, such as MISRA, ensure that the difference between the floating-point values is within an acceptable range.

## Examples

### Using memcmp to Compare Structures with Floating-Point Members

```
#include <string.h>

typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

int func_cmp(myStruct *s1, myStruct *s2) {
/* Comparison between structures containing
* floating-point members */
    return memcmp
        ((const void *)s1, (const void *)s2, sizeof(myStruct));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

In this example, `func_cmp()` calls `memcmp()` to compare the object representations of structures `s1` and `s2`. The comparison might be inaccurate because the structures contain floating-point members.

#### Correction — Compare Structure Members Individually

One possible correction is to compare the structure members individually and to ensure that the difference between the floating-point values is within an acceptable range defined by `ESP`.

```
#include <string.h>
#include <math.h>

typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

#define ESP 0.00001

int func_cmp(myStruct *s1, myStruct *s2) {

/*Structure members are compared individually */
    return ((s1->i == s2->i) &&
            (fabsf(s1->f - s2->f) <= ESP));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

## Result Information

# Memory comparison of padding data

memcmp compares data stored in structure padding

## Description

This defect occurs when you use the memcmp function to compare two structures as a whole. In the process, you compare meaningless data stored in the structure padding.

For instance:

```
struct structType {
    char member1;
    int member2;
    .
    .
};

structType var1;
structType var2;
.
.
if(memcmp(&var1,&var2,sizeof(var1)))
{...}
```

### Risk

If members of a structure have different data types, your compiler introduces additional padding for data alignment in memory. For an example of padding, see Higher Estimate of Size of Local Variables.

The content of these extra padding bytes is meaningless. The C Standard allows the content of these bytes to be indeterminate, giving different compilers latitude to implement their own padding. If you perform a byte-by-byte comparison of structures with memcmp, you compare even the meaningless data stored in the padding. You might reach the false conclusion that two data structures are not equal, even if their corresponding members have the same value.

### Fix

Instead of comparing two structures in one attempt, compare the structures member by member.

For efficient code, write a function that does the comparison member by member. Use this function for comparing two structures.

You can use memcmp for byte-by-byte comparison of structures only if you know that the structures do not contain padding. Typically, to prevent padding, you use specific attributes or pragmas such as #pragma pack. However, these attributes or pragmas are not supported by all compilers and make your code implementation-dependent. If your structures contain bit-fields, using these attributes or pragmas cannot prevent padding.

## Examples

### Structures Compared with memcmp

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{

    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    if (0 == memcmp(left, right, sizeof(S_Padding)))
    {
        return 1;
    }
    else
        return 0;
}
```

In this example, `memcmp` compares byte-by-byte the two structures that `left` and `right` point to. Even if the values stored in the structure members are the same, the comparison can show an inequality if the meaningless values in the padding bytes are not the same.

#### Correction — Compare Structures Member by Member

One possible correction is to compare individual structure members.

**Note** You can compare entire arrays by using `memcmp`. All members of an array have the same data type. Padding bytes are not required to store arrays.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
```

```
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{
    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    return ((left->c == right->c) &&
            (left->i == right->i) &&
            (left->bf1 == right->bf1) &&
            (left->bf2 == right->bf2) &&
            (memcmp(left->buffer, right->buffer, 20) == 0));
}
```

### Result Information

# Memory comparison of strings

memcmp compares data stored in strings after the null terminator

## Description

This defect occurs when:

- You compare two strings byte-by-byte with the memcmp function.
- The number of bytes compared is such that you compare meaningless data stored after the null terminator.

For instance:

```
memcmp(string1, string2, sizeof(string1))
```

can compare bytes in the string after the null terminator.

### Risk

The null terminator signifies the end of a string. Comparison of bytes after the null terminator is meaningless. You might reach the false conclusion that two strings are not equal, even if the bytes before the null terminator store the same value.

### Fix

Use strcmp for string comparison. The function compares strings only up to the null terminator.

If you use memcmp for a byte-by-byte comparison of two strings, avoid comparison of bytes after the null terminator. Determine the number of bytes to compare by using the strlen function.

## Examples

### Strings Compared with memcmp

```
#include <stdio.h>
#include <string.h>

#define SIZE20 20

int func()
{
    char s1[SIZE20] =  "abc";
    char s2[SIZE20] =  "abc";

    return memcmp(s1, s2, sizeof(s1));
}
```

In this example, sizeof returns the length of the entire array s1, which is 20. However, only the first three bytes of the string are relevant.

Even though s1 and s2 hold the same value, the comparison with memcmp can show a false inequality.

#### Correction — Use `strlen` to Determine Number of Bytes to Compare

One possible correction is to determine the number of bytes to compare using the `strlen` function. `strlen` returns the number of bytes *before* the null terminator (and excluding the null terminator itself).

```
#include <stdio.h>
#include <string.h>

#define SIZE20 20

int func()
{
    char s1[SIZE20] =  "abc";
    char s2[SIZE20] =  "abc";

    return memcmp(s1, s2, strlen(s1));
}
```

# Missing byte reordering when transferring data

Different endianness of host and network

## Description

This defect occurs when you do not use a byte ordering function:

- Before sending data to a network socket.
- After receiving data from a network socket.

### Risk

Some system architectures implement little endian byte ordering (least significant byte first), and other systems implement big endian (most significant byte first). If the endianness of the sent data does not match the endianness of the receiving system, the value returned when reading the data is incorrect.

### Fix

After receiving data from a socket, use a byte ordering function such as `ntohl()`. Before sending data to a socket, use a byte ordering function such as `htonl()` .

## Examples

### Data Transferred Without Byte Reordering

```
#include <stdio.h>
#include <stdlib.h>
#include <stdint.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <byteswap.h>
#include <unistd.h>
#include <string.h>

unsigned int func(int sock, int server)
{
    unsigned int num;   /* assume int is 32-bits */
    if (server)
    {
        /* Server side */
        num = 0x17;
        /* Endianness of server host may not match endianness of network. */
        if (send(sock, (void *)&num, sizeof(num), 0) < (int)sizeof(num))
        {
            /* Handle error */
        }
        return 0;
    }
    else {
        /* Endianness of client host may not match endianness of network. */
        if (recv (sock, (void *)&num, sizeof(num), 0) < (int) sizeof(num))
        {
            /* Handle error */
        }

        /* Comparison may be inaccurate */
        if (num> 255)
        {
            return 255;
        }
        else
        {
            return num;
        }
    }
}
```

In this example, variable `num` is assigned hexadecimal value `0x17` and is sent over a network to the client from the server. If the server host is little endian and the network is big endian, `num` is transferred as `0x17000000`. The client then reads an incorrect value for `num` and compares it to a local numeric value.

**Correction — Use Byte Ordering Function**

Before sending `num` from the server host, use `htonl()` to convert from host to network byte ordering. Similarly, before reading `num` on the client host, use `ntohl()` to convert from network to host byte ordering.

```
#include <stdio.h>
#include <stdlib.h>
#include <stdint.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <byteswap.h>
#include <unistd.h>
#include <string.h>

unsigned int func(int sock, int server)
{
    unsigned int num;   /* assume int is 32-bits */
    if (server)
    {
        /* Server side */
        num = 0x17;

        /* Convert to network byte order. */
        num = htonl(num);
        if (send(sock, (void *)&num, sizeof(num), 0) < (int)sizeof(num))
        {
            /* Handle error */
        }
        return 0;
    }
    else {
        if (recv (sock, (void *)&num, sizeof(num), 0) < (int) sizeof(num))
        {
            /* Handle error */
        }

        /* Convert to host byte order. */
        num = ntohl(num);
        if (num > 255)
        {
            return 255;
        }
        else
        {
            return num;
        }
    }
}
```

# Missing null in string array

String does not terminate with null character

## Description

This defect occurs when a string does not have enough space to terminate with a null character `'\0'`.

This defect applies only for projects in C.

### Risk

A buffer overflow can occur if you copy a string to an array without assuming the implicit null terminator.

### Fix

If you initialize a character array with a literal, avoid specifying the array bounds.

```
char three[]  = "THREE";
```

The compiler automatically allocates space for a null terminator. In the preceding example, the compiler allocates sufficient space for five characters and a null terminator.

If the issue occurs after initialization, you might have to increase the size of the array by one to account for the null terminator.

In certain circumstances, you might want to initialize the character array with a sequence of characters instead of a string. In this situation, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Array size is too small

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[5] = "THREE";
}
```

The character array `three` has a size of 5 and 5 characters `'T'`, `'H'`, `'R'`, `'E'`, and `'E'`. There is no room for the null character at the end because `three` is only five bytes large.

#### Correction — Increase Array Size

One possible correction is to change the array size to allow for the five characters plus a null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[6] = "THREE";
}
```

#### Correction — Change Initialization Method

One possible correction is to initialize the string by leaving the array size blank. This initialization method allocates enough memory for the five characters and a terminating-null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[]  = "THREE";
}
```

## Result Information

# Misuse of a FILE object

Use of copy of FILE object

## Description

This defect occurs when:

- You dereference a pointer to a FILE object, including indirect dereference by using `memcmp()`.
- You modify an entire FILE object or one of its components through its pointer.
- You take the address of FILE object that was not returned from a call to an `fopen`-family function. No defect is raised if a macro defines the pointer as the address of a built-in FILE object, such as `#define ptr (&__stdout)`.

### Risk

In some implementations, the address of the pointer to a FILE object used to control a stream is significant. A pointer to a copy of a FILE object is interpreted differently than a pointer to the original object, and can potentially result in operations on the wrong stream. Therefore, the use of a copy of a FILE object can cause the software to stop responding, which an attacker might exploit in denial-of-service attacks.

### Fix

Do not make a copy of a FILE object. Do not use the address of a FILE object that was not returned from a successful call to an `fopen`-family function.

## Examples

### Copy of FILE Object Used in `fputs()`

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /*'stdout' dereferenced and contents
        copied to 'my_stdout'. */
    FILE my_stdout = *stdout;

    /* Address of 'my_stdout' may not point to correct stream. */
    if (fputs("Hello, World!\n", &my_stdout) == EOF)
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

In this example, FILE object `stdout` is dereferenced and its contents are copied to `my_stdout`. The contents of `stdout` might not be significant. `fputs()` is then called with the address of `my_stdout` as an argument. Because no call to `fopen()` or a similar function was made, the address of `my_stdout` might not point to the correct stream.

**Correction — Copy the FILE Object Pointer**

Declare `my_stdout` to point to the same address as `stdout` to ensure that you write to the correct stream when you call `fputs()`.

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /* 'my_stdout' and 'stdout' point to the same object. */
    FILE *my_stdout = stdout;
    if (fputs("Hello, World!\n", my_stdout) == EOF)
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

## Result Information

# Misuse of errno

errno incorrectly checked for error conditions

## Description

This defect occurs when you check errno for error conditions in situations where checking errno does not guarantee the absence of errors. In some cases, checking errno can lead to false positives.

For instance, you check errno following calls to the functions:

- fopen: If you follow the ISO Standard, the function might not set errno on errors.
- atof: If you follow the ISO Standard, the function does not set errno.
- signal: The errno value indicates an error only if the function returns the SIG_ERR error indicator.

### Risk

The ISO C Standard does not enforce that these functions set errno on errors. Whether the functions set errno or not is implementation-dependent.

To detect errors, if you check errno alone, the validity of this check also becomes implementation-dependent.

In some cases, the errno value indicates an error only if the function returns a specific error indicator. If you check errno before checking the function return value, you can see false positives.

### Fix

For information on how to detect errors, see the documentation for that specific function.

Typically, the functions return an out-of-band error indicator to indicate errors. For instance:

- fopen returns a null pointer if an error occurs.
- signal returns the SIG_ERR error indicator and sets errno to a positive value. Check errno only after you have checked the function return value.

## Examples

### Incorrectly Checking for errno After fopen Call

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    errno = 0;
    fileptr = fopen(temp_filename, "w+b");
    if (errno != 0) {
        if (fileptr != NULL) {
            (void)fclose(fileptr);
        }
        /* Handle error */
        fatal_error();
    }
    return fileptr;
}
```

In this example, errno is the first variable that is checked after a call to fopen. You might expect that fopen changes errno to a nonzero value if an error occurs. If you run this code with an implementation of fopen that does not set errno on errors, you might miss an error condition. In this situation, fopen can return a null pointer that escapes detection.

**Correction — Check Return Value of fopen After Call**

One possible correction is to only check the return value of fopen for a null pointer.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    fileptr = fopen(temp_filename, "w+b");
    if (fileptr == NULL) {
        fatal_error();
    }
    return fileptr;
}
```

## Result Information

# Misuse of errno in a signal handler

You read `errno` after calling an `errno`-setting function in a signal handler

## Description

This defect occurs when you call one of these functions in a signal handler:

- `signal`: You call the `signal` function in a signal handler and then read the value of `errno`.

  For instance, the signal handler function `handler` calls `signal` and then calls `perror`, which reads `errno`.

  ```
  typedef void (*pfv)(int);

  void handler(int signum) {
    pfv old_handler = signal(signum, SIG_DFL);
    if (old_handler == SIG_ERR) {
      perror("SIGINT handler");
    }
  }
  ```
- `errno`-setting POSIX function: You call an `errno`-setting POSIX function in a signal handler but do not restore `errno` when returning from the signal handler.

  For instance, the signal handler function `handler` calls `waitpid`, which changes `errno`, but does not restore `errno` before returning.

  ```
  #include <stddef.h>
  #include <errno.h>
  #include <sys/wait.h>

  void handler(int signum) {
    int rc = waitpid(-1, NULL, WNOHANG);
    if (ECHILD != errno) {
    }
  }
  ```

### Risk

In each case that the checker flags, you risk relying on an indeterminate value of `errno`.

- `signal`: If the call to `signal` in a signal handler fails, the value of `errno` is indeterminate (see C11 Standard, Sec. 7.14.1.1). If you rely on a specific value of `errno`, you can see unexpected results.
- `errno`-setting POSIX function: An `errno`-setting function sets `errno` on failure. If you read `errno` after a signal handler is called and the signal handler itself calls an `errno`-setting function, you can see unexpected results.

### Fix

Avoid situations where you risk relying on an indeterminate value of `errno`.

- `signal`: After calling the `signal` function in a signal handler, do not read `errno` or use a function that reads `errno`.
- `errno`-setting POSIX function: Before calling an `errno`-setting function in a signal handler, save `errno` to a temporary variable. Restore `errno` from this variable before returning from the signal handler.

## Examples

### Reading errno After signal Call in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()

void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        perror("SIGINT handler");
    }
}

int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

In this example, the function `handler` is called to handle the `SIGINT` signal. In the body of `handler`, the `signal` function is called. Following this call, the value of `errno` is indeterminate. The checker raises a defect when the `perror` function is called because `perror` relies on the value of `errno`.

#### Correction — Avoid Reading errno After signal Call

One possible correction is to not read `errno` after calling the `signal` function in a signal handler. The corrected code here calls the `abort` function via the `fatal_error` macro instead of the `perror` function.

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()

void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        fatal_error();
    }
}
```

```
int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

### Result Information

# Misuse of narrow or wide character string

Narrow (wide) character string passed to wide (narrow) string function

## Description

This defect occurs when you pass a narrow character string to a wide string function, or a wide character string to a narrow string function.

**Misuse of narrow or wide character string** raises no defect on operating systems where narrow and wide character strings have the same size.

### Risk

Using a narrow character string with a wide string function, or vice versa, can result in unexpected or undefined behavior.

If you pass a wide character string to a narrow string function, you can encounter these issues:

- Data truncation. If the string contains null bytes, a copy operation using `strncpy()` can terminate early.
- Incorrect string length. `strlen()` returns the number of characters of a string up to the first null byte. A wide string can have additional characters after its first null byte.

If you pass a narrow character string to a wide string function, you can encounter this issue:

- Buffer overflow. In a copy operation using `wcsncpy()`, the destination string might have insufficient memory to store the result of the copy.

### Fix

Use the narrow string functions with narrow character strings. Use the wide string functions with wide character strings.

## Examples

### Passing Wide Character Strings to `strncpy()`

```
#include <string.h>
#include <wchar.h>

void func(void)
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    strncpy(wide_str2, wide_str1, 10);
}
```

In this example, `strncpy()` copies 10 wide characters from `wide_strt1` to `wide_str2`. If `wide_str1` contains null bytes, the copy operation can end prematurely and truncate the wide character string.

#### Correction — Use `wcsncpy()` to Copy Wide Character Strings

One possible correction is to use `wcsncpy()` to copy `wide_str1` to `wide_str2`.

```
#include <string.h>
#include <wchar.h>

void func(void)
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    wcsncpy(wide_str2, wide_str1, 10);
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `NARROW_WIDE_STR_MISUSE`
**Impact:** High

# Misuse of return value from non-reentrant standard function

Pointer to static buffer from previous call is used despite a subsequent call that modifies the buffer

## Description

This defect occurs when these events happen in this sequence:

1. You point to the buffer returned from a nonreentrant standard function such as `getenv` or `setlocale`.

   ```
   user = getenv("USER");
   ```
2. You call that nonreentrant standard function again.

   ```
   user2 = getenv("USER2");
   ```
3. You use or dereference the pointer from the first step expecting the buffer to remain unmodified since that step. In the meantime, the call in the second step has modified the buffer.

   For instance:

   ```
   var=*user;
   ```

In some cases, the defect might appear even if you do not call the `getenv` function a second time but simply return the pointer. For instance:

```
char* func() {
     user=getenv("USER");
     .
     .
     return user;
}
```

For information on which functions are covered by this defect, see documentation on nonreentrant standard functions.

### Risk

The C Standard allows nonreentrant functions such as `getenv` to return a pointer to a *static* buffer. Because the buffer is static, a second call to `getenv` modifies the buffer. If you continue to use the pointer returned from the first call past the second call, you can see unexpected results. The buffer that it points to no longer has values from the first call.

The defect appears even if you do not call `getenv` a second time but simply return the pointer. The reason is that someone calling your function might use the returned pointer *after* a second call to `getenv`. By returning the pointer from your call to `getenv`, you make your function unsafe to use.

The same rationale is true for other nonreentrant functions covered by this defect.

### Fix

After the first call to getenv, make a copy of the buffer that the returned pointer points to. After the second call to getenv, use this copy. Even if the second call modifies the buffer, your copy is untouched.

## Examples

### Return from getenv Used After Second Call to getenv

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");   /* First call */
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');

        if (user_name_from_home != NULL) {
            user = getenv("USER");   /* Second call */
            if ((user != NULL) &&
                (strcmp(user, user_name_from_home) == 0))
            {
                result = 1;
            }
        }
    }
    return result;
}
```

In this example, the pointer user_name_from_home is derived from the pointer home. home points to the buffer returned from the first call to getenv. Therefore, user_name_from_home points to a location in the same buffer.

After the second call to getenv, the buffer is modified. If you continue to use user_name_from_home, you can get unexpected results.

#### Correction — Make Copy of Buffer Before Second Call

If you want to access the buffer from the first call to getenv past the second call, make a copy of the buffer after the first call. One possible correction is to use the strdup function to make the copy.

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');
        if (user_name_from_home != NULL) {
            /* Make copy before second call */
            char *saved_user_name_from_home = strdup(user_name_from_home);
            if (saved_user_name_from_home != NULL) {
                user = getenv("USER");
                if ((user != NULL) &&
                    (strcmp(user, saved_user_name_from_home) == 0))
                {
                    result = 1;
                }
                free(saved_user_name_from_home);
            }
        }
    }
    return result;
}
```

## Result Information

# Misuse of sign-extended character value

Data type conversion with sign extension causes unexpected behavior

## Description

This defect occurs when you convert a signed or plain `char` variable containing possible negative values to a wider integer data type (or perform an arithmetic operation that does the conversion) and then use the resulting value in one of these ways:

- For comparison with `EOF` (using == or `!=`)
- As array index
- As argument to a character-handling function in `ctype.h`, for instance, `isalpha()` or `isdigit()`

If you convert a signed `char` variable with a negative value to a wider type such as `int`, the sign bit is preserved (sign extension). This can lead to specific problems even in situations where you think you have accounted for the sign bit.

For instance, the signed `char` value of -1 can represent the character `EOF` (end-of-file), which is an invalid character. Suppose a `char` variable `var` acquires this value. If you treat `var` as a `char` variable, you might want to write special code to account for this invalid character value. However, if you perform an operation such as `var++` (involving integer promotion), it leads to the value 0, which represents a valid value `'\0'` by accident. You transitioned from an invalid to a valid value through the arithmetic operation.

Even for negative values other than -1, a conversion from signed `char` to signed `int` can lead to other issues. For instance, the signed `char` value -126 is equivalent to the `unsigned char` value 130 (corresponding to an extended character `'\202'`). If you convert the value from `char` to `int`, the sign bit is preserved. If you then cast the resulting value to `unsigned int`, you get an unexpectedly large value, 4294967170 (assuming 32-bit `int`). If your code expects the `unsigned char` value of 130 in the final `unsigned int` variable, you can see unexpected results.

The underlying cause of this issue is the sign extension during conversion to a wider type. Most architectures use two's complement representation for storing values. In this representation, the most significant bit indicates the sign of the value. When converted to a wider type, the conversion is done by copying this sign bit to all the leading bits of the wider type, so that the sign is preserved. For instance, the `char` value of -3 is represented as `11111101` (assuming 8-bit `char`). When converted to `int`, the representation is:

```
11111111 11111111 11111111  11111101
```

The value -3 is preserved in the wider type `int`. However, when converted to `unsigned int`, the value (4294967293) is no longer the same as the `unsigned char` equivalent of the original `char` value. If you are not aware of this issue, you can see unexpected results in your code.

### Risk

In the following cases, Bug Finder flags use of variables after a conversion from `char` to a wider data type or an arithmetic operation that implicitly converts the variable to a wider data type:

- *If you compare the variable value with EOF*:

  A char value of -1 can represent the invalid character EOF or the valid extended character value '\377' (corresponding to the unsigned char equivalent, 255). After a char variable is cast to a wider type such as int, because of sign extension, the char value -1, representing one of EOF or '\377' becomes the int value -1, representing only EOF. The unsigned char value 255 can no longer be recovered from the int variable. Bug Finder flags this situation so that you can cast the variable to unsigned char first (or avoid the char-to-int conversion or converting operation before comparison with EOF). Only then, a comparison with EOF is meaningful. See “Sign-Extended Character Value Compared with EOF” on page 11-125.
- *If you use the variable value as an array index*:

  After a char variable is cast to a wider type such as int, because of sign extension, all negative values retain their sign. If you use the negative values directly to access an array, you cause buffer overflow/underflow. Even when you account for the negative values, the way you account for them might result in incorrect elements being read from the array. See “Sign-Extended Character Value Used as Array Index” on page 11-126.
- *If you pass the variable value as argument to a character-handling function*:

  According to the C11 standard (Section 7.4), if you supply an integer argument that cannot be represented as unsigned char or EOF, the resulting behavior is undefined. Bug Finder flags this situation because negative char values after conversion can no longer be represented as unsigned char or EOF. For instance, the signed char value -126 is equivalent to the unsigned char value 130, but the signed int value -126 cannot be represented as unsigned char or EOF.

### Fix

Before conversion to a wider integer data type, cast the signed or plain char value explicitly to unsigned char.

If you use the char data type to not represent characters but simply as a smaller data type to save memory, your use of sign-extended char values might avoid the risks mentioned earlier. If so, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Sign-Extended Character Value Compared with EOF

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];

static int parser(char *buf)
```

```
{
    int c = EOF;
    if (buf && *buf) {
        c = *buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

In this example, the function `parser` can traverse a string input `buf`. If a character in the string has the value -1, it can represent either `EOF` or the valid character value `'\377'` (corresponding to the `unsigned char` equivalent 255). When converted to the `int` variable `c`, its value becomes the integer value -1, which is always `EOF`. The later comparison with `EOF` will not detect if the value returned from `parser` is actually `EOF`.

#### Correction — Cast to `unsigned char` Before Conversion

One possible correction is to cast the plain `char` value to `unsigned char` before conversion to the wider `int` type. Only then can you test if the return value of `parser` is really `EOF`.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];

static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = (unsigned char)*buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

### Sign-Extended Character Value Used as Array Index

```
#include <limits.h>
#include <stddef.h>
#include <stdio.h>

#define NUL '\0'
#define SOH 1    /* start of heading */
```

```
#define STX 2    /* start of text */
#define ETX 3    /* end of text */
#define EOT 4    /* end of transmission */
#define ENQ 5    /* enquiry */
#define ACK 6    /* acknowledge */

static const int ascii_table[UCHAR_MAX + 1] =
{
      [0]=NUL,[1]=SOH, [2]=STX, [3]=ETX, [4]=EOT, [5]=ENQ,[6]=ACK,
      /* ... */
      [126] = '~',
      /* ... */
      [130/*-126*/]='\202',
      /* ... */
      [255 /*-1*/]='\377'
};

int lookup_ascii_table(char c)
{
    int i;
    i = (c < 0 ? -c : c);
    return ascii_table[i];
}
```

In this example, the `char` variable `c` is converted to the `int` variable `i`. If `c` has negative values, they are converted to positive values before assignment to `i`. However, this conversion can lead to unexpected values when `i` is used as array index. For instance:

- If `c` has the value -1 representing the invalid character `EOF`, you want to probably treat this value separately. However, in this example, a value of `c` equal to -1 leads to a value of `i` equal to 1. The function `lookup_ascii_table` returns the value `ascii_table[1]` (or `SOH`) without the invalid character value `EOF` being accounted for.

  If you use the `char` data type to not represent characters but simply as a smaller data type to save memory, you need not worry about this issue.
- If `c` has a negative value, when assigned to `i`, its sign is reversed. However, if you access the elements of `ascii_table` through `i`, this sign reversal can result in unexpected values being read.

  For instance, if `c` has the value -126, `i` has the value 126. The function `lookup_ascii_table` returns the value `ascii_table[126]` (or `'~'`) but you probably expected the value `ascii_table[130]` (or `'\202'`).

#### Correction – Cast to `unsigned char`

To correct the issues, avoid the conversion from `char` to `int`. First, check `c` for the value `EOF`. Then, cast the value of the `char` variable `c` to `unsigned char` and use the result as array index.

```
#include <limits.h>
#include <stddef.h>
#include <stdio.h>

#define NUL '\0'
#define SOH 1    /* start of heading */
#define STX 2    /* start of text */
#define ETX 3    /* end of text */
```

```
#define EOT 4    /* end of transmission */
#define ENQ 5    /* enquiry */
#define ACK 6    /* acknowledge */

static const int ascii_table[UCHAR_MAX + 1] =
{
      [0]=NUL,[1]=SOH, [2]=STX, [3]=ETX, [4]=EOT, [5]=ENQ,[6]=ACK,
      /* ... */
      [126] = '~',
      /* ... */
      [130/*-126*/]='\202',
      /* ... */
      [255 /*-1*/]='\377'
};

int lookup_ascii_table(char c)
{
    int r = EOF;
    if (c != EOF) /* specific handling EOF, invalid character */
        r = ascii_table[(unsigned char)c]; /* cast to 'unsigned char' */
    return r;
}
```

### Result Information

**Group:** Programming
**Language:** C | C++

# Misuse of structure with flexible array member

Memory allocation ignores flexible array member

## Description

This defect occurs when:

- You define an object with a flexible array member of unknown size at compilation time.
- You make an assignment between structures with a flexible array member without using `memcpy()` or a similar function.
- You use a structure with a flexible array member as an argument to a function and pass the argument by value.
- Your function returns a structure with a flexible array member.

A flexible array member has no array size specified and is the last element of a structure with at least two named members.

### Risk

If the size of the flexible array member is not defined, it is ignored when allocating memory for the containing structure. Accessing such a structure has undefined behavior.

### Fix

- Use `malloc()` or a similar function to allocate memory for a structure with a flexible array member.
- Use `memcpy()` or a similar function to copy a structure with a flexible array member.
- Pass a structure with a flexible array member as a function argument by pointer.

## Examples

### Structure Passed By Value to Function

```
#include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <unistd.h>

struct example_struct
{
    size_t num;
    int data[];
};

extern void arg_by_value(struct example_struct s);

void func(void)
```

```
{
    struct example_struct *flex_struct;
    size_t i;
    size_t array_size = 4;
    /* Dynamically allocate memory for the struct */
    flex_struct = (struct example_struct *)
        malloc(sizeof(struct example_struct) + sizeof(int) * array_size);
    if (flex_struct == NULL)
    {
        /* Handle error */
    }
    /* Initialize structure */
    flex_struct->num = array_size;
    for (i = 0; i < array_size; ++i)
    {
        flex_struct->data[i] = 0;
    }
    /* Handle structure */

    /* Argument passed by value. 'data' not
    copied to passed value. */
    arg_by_value(*flex_struct);

    /* Free dynamically allocated memory */
    free(flex_struct);
}
```

In this example, `flex_struct` is passed by value as an argument to `arg_by_value`. As a result, the flexible array member data is not copied to the passed argument.

**Correction — Pass Structure by Pointer to Function**

To ensure that all the members of the structure are copied to the passed argument, pass `flex_struct` to `arg_by_pointer` by pointer.

```
#include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <unistd.h>

struct example_struct
{
    size_t num;
    int data[];
};

extern void arg_by_pointer(struct example_struct *s);

void func(void)
{
    struct example_struct *flex_struct;
    size_t i;
    size_t array_size = 4;
    /* Dynamically allocate memory for the struct */
    flex_struct = (struct example_struct *)
        malloc(sizeof(struct example_struct) + sizeof(int) * array_size);
    if (flex_struct == NULL)
    {
        /* Handler error */
    }
    /* Initialize structure */
    flex_struct->num = array_size;
    for (i = 0; i < array_size; ++i)
    {
        flex_struct->data[i] = 0;
    }
    /* Handle structure */

    /* Structure passed by pointer */
    arg_by_pointer(flex_struct);

    /* Free dynamically allocated memory */
    free(flex_struct);
}
```

## Result Information

**Group:** Programming
**Language:** C | C++

# Modification of internal buffer returned from non-reentrant standard function

Function attempts to modify internal buffer returned from a nonreentrant standard function

## Description

This defect occurs when the following happens:

- A nonreentrant standard function returns a pointer.
- You attempt to write to the memory location that the pointer points to.

Nonreentrant standard functions that return a non `const`-qualified pointer to an internal buffer include `getenv`, `getlogin`, `crypt`, `setlocale`, `localeconv`, `strerror` and others.

### Risk

Modifying the internal buffer that a nonreentrant standard function returns can cause the following issues:

- It is possible that the modification does not succeed or alters other internal data.

  For instance, `getenv` returns a pointer to an environment variable value. If you modify this value, you alter the environment of the process and corrupt other internal data.
- Even if the modification succeeds, it is possible that a subsequent call to the same standard function does not return your modified value.

  For instance, you modify the environment variable value that `getenv` returns. If another process, thread, or signal handler calls `setenv`, the modified value is overwritten. Therefore, a subsequent call to `getenv` does not return your modified value.

### Fix

Avoid modifying the internal buffer using the pointer returned from the function.

## Examples

### Modification of `getenv` Return Value

```
#include <stdlib.h>
#include <string.h>

void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        strncpy(env, "C", 1);
        printstr(env);
    }
}
```

In this example, the first argument of `strncpy` is the return value from a nonreentrant standard function `getenv`. The behavior can be undefined because `strncpy` modifies this argument.

#### Correction - Copy Return Value of getenv and Modify Copy

One possible solution is to copy the return value of `getenv` and pass the copy to the `strncpy` function.

```
#include <stdlib.h>
#include <string.h>
enum {
    SIZE20 = 20
};

void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        char env_cp[SIZE20];
        strncpy(env_cp, env, SIZE20);
        strncpy(env_cp, "C", 1);
        printstr(env_cp);
    }
}
```

## Result Information

# Overlapping assignment

Memory overlap between left and right sides of an assignment

## Description

This defect occurs when there is a memory overlap between the left and right sides of an assignment. For instance, a variable is assigned to itself or one member of a union is assigned to another.

### Risk

If the left and right sides of an assignment have memory overlap, the behavior is either redundant or undefined. For instance:

- Self-assignment such as `x=(int)(long)x;` is redundant unless `x` is `volatile`-qualified.
- Assignment of one union member to another causes undefined behavior.

  For instance, in the following code:

  - The result of the assignment `u1.a = u1.b` is undefined because `u1.b` is not initialized.
  - The result of the assignment `u2.b = u2.a` depends on the alignment and endianness of the implementation. It is not defined by C standards.

  ```
  union {
     char a;
     int b;
  }u1={'a'}, u2={'a'}; //'u1.a' and 'u2.a' are initialized

  u1.a = u1.b;
  u2.b = u2.a;
  ```

### Fix

Avoid assignment between two variables that have overlapping memory.

## Examples

### Assignment of Union Members

```
#include <string.h>

union Data {
    int i;
    float f;
};

int main( ) {
    union Data data;
    data.i = 0;
    data.f = data.i;
```

```
    return 0;
}
```

In this example, the variables `data.i` and `data.f` are part of the same `union` and are stored in the same location. Therefore, part of their memory storage overlaps.

### Result Information

# Possible misuse of sizeof

Use of `sizeof` operator can cause unintended results

## Description

This defect occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

### Fix

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

  The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.
- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

## Examples

### `sizeof` Used Incorrectly to Determine Array Size

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++)    {
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

#### Correction — Determine Array Size in Another Way

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

# Possibly unintended evaluation of expression because of operator precedence rules

Operator precedence rules cause unexpected evaluation order in arithmetic expression

## Description

This defect occurs when an arithmetic expression result is possibly unintended because operator precedence rules dictate an evaluation order that you do not expect.

The defect highlights expressions of the form `x` *`op_1`* `y` *`op_2`* `z`. Here, *op_1* and *op_2* are operator combinations that commonly induce this error. For instance, `x == y | z`.

The checker does not flag all operator combinations. For instance, `x == y || z` is not flagged because you most likely intended to perform a logical OR between `x == y` and `z`. Specifically, the checker flags these combinations:

- && and `||`: For instance, `x || y && z` or `x && y || z`.
- Assignment and bitwise operations: For instance, `x = y | z`.
- Assignment and comparison operations: For instance, `x = y != z` or `x = y > z`.
- Comparison operations: For instance, `x > y > z` (except when one of the comparisons is an equality `x == y > z`).
- Shift and numerical operation: For instance, `x << y + 2`.
- Pointer dereference and arithmetic: For instance, `*p++`.

### Risk

The defect can cause the following issues:

- If you or another code reviewer reviews the code, the intended order of evaluation is not immediately clear.
- It is possible that the result of the evaluation does not meet your expectations. For instance:
  - In the operation `*p++`, it is possible that you expect the dereferenced value to be incremented. However, the pointer `p` is incremented before the dereference.
  - In the operation `(x == y | z)`, it is possible that you expect `x` to be compared with `y | z`. However, the == operation happens before the `|` operation.

### Fix

See if the order of evaluation is what you intend. If not, apply parentheses to implement the evaluation order that you want.

For better readability of your code, it is good practice to apply parenthesis to implement an evaluation order even when operator precedence rules impose that order.

## Examples

### Expressions with Possibly Unintended Evaluation Order

```
int test(int a, int b, int c) {
    return(a & b == c);
}
```

In this example, the == operation happens first, followed by the & operation. If you intended the reverse order of operations, the result is not what you expect.

#### Correction — Parenthesis For Intended Order

One possible correction is to apply parenthesis to implement the intended evaluation order.

```
int test(int a, int b, int c) {
    return((a & b) == c);
}
```

## Result Information

C++ Operator Precedence

# Predefined macro used as an object

You use standard library macros such as `assert` and `errno` as objects

## Description

This defect occurs when you use certain identifiers in a way that requires an underlying object to be present. These identifiers are defined as macros. The C Standard does not allow you to redefine them as objects. You use the identifiers in such a way that macro expansion of the identifiers cannot occur.

For instance, you refer to an external variable `errno`:

```
extern int errno;
```

However, `errno` does not occur as a variable but a macro.

The defect applies to these macros: `assert`, `errno`, `math_errhandling`, `setjmp`, `va_arg`, `va_copy`, `va_end`, and `va_start`. The checker looks for the defect only in source files (not header files).

### Risk

The C11 Standard (Sec. 7.1.4) allows you to redefine most macros as objects. To access the object and not the macro in a source file, you do one of these:

- Redeclare the identifier as an external variable or function.
- For function-like macros, enclose the identifier name in parentheses.

If you try to use these strategies for macros that cannot be redefined as objects, an error occurs.

### Fix

Do not use the identifiers in such a way that a macro expansion is suppressed.

- Do not redeclare the identifiers as external variables or functions.
- For function-like macros, do not enclose the macro name in parentheses.

## Examples

### Use of `assert` as Function

```
#include<assert.h>
typedef void (*err_handler_func)(int);

extern void demo_handle_err(err_handler_func, int);

void func(int err_code) {
    extern void assert(int);
    demo_handle_err(&(assert), err_code);
}
```

In this example, the `assert` macro is redefined as an external function. When passed as an argument to `demo_handle_err`, the identifier `assert` is enclosed in parentheses, which suppresses use of the `assert` macro.

#### Correction — Use `assert` as Macro

One possible correction is to directly use the `assert` macro from `assert.h`. A different implementation of the function `demo_handle_err` directly uses the `assert` macro instead of taking the address of an `assert` function.

```
#include<assert.h>
void demo_handle_err(int err_code) {
    assert(err_code == 0);
}

void func(int err_code) {
    demo_handle_err(err_code);
}
```

## Result Information

# Preprocessor directive in macro argument

You use a preprocessor directive in the argument to a function-like macro

## Description

This defect occurs when you use a preprocessor directive in the argument to a function-like macro or a function that might be implemented as a function-like macro.

For instance, a `#ifdef` statement occurs in the argument to a `memcpy` function. The `memcpy` function might be implemented as a macro.

```
memcpy(dest, src,
    #ifdef PLATFORM1
      12
    #else
      24
    #endif
  );
```

The checker flags similar usage in `printf` and `assert`, which can also be implemented as macros.

### Risk

During preprocessing, a function-like macro call is replaced by the macro body and the parameters are replaced by the arguments to the macro call (argument substitution). Suppose a macro `min()` is defined as follows.

```
#define min(X, Y)  ((X) < (Y) ? (X) : (Y))
```

When you call `min(1,2)`, it is replaced by the body `((X) < (Y) ? (X) : (Y))`. `X` and `Y` are replaced by 1 and 2.

According to the C11 Standard (Sec. 6.10.3), if the list of arguments to a function-like macro itself has preprocessing directives, the argument substitution during preprocessing is undefined.

### Fix

To ensure that the argument substitution happens in an unambiguous manner, use the preprocessor directives outside the function-like macro.

For instance, to execute `memcpy` with different arguments based on a `#ifdef` directive, call `memcpy` multiple times within the `#ifdef` directive branches.

```
#ifdef PLATFORM1
    memcpy(dest, src, 12);
#else
    memcpy(dest, src, 24);
#endif
```

## Examples

### Directives in Function-Like Macros

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
    print(
#ifdef SW
          "Message 1"
#else
          "Message 2"
#endif
         );
}
```

In this example, the preprocessor directives `#ifdef` and `#endif` occur in the argument to the function-like macro `print()`.

#### Correction — Use Directives Outside Macro

One possible correction is to use the function-like macro multiple times in the branches of the `#ifdef` directive.

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
#ifdef SW
        print("Message 1");
#else
        print("Message 2");
#endif
}
```

# Qualifier removed in conversion

Variable qualifier is lost during conversion

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs during a pointer conversion when one pointer has a qualifier and the other does not. For example, when converting from a `const int*` to an `int*`, the conversion removes the `const` qualifier.

This defect applies only for projects in C.

### Risk

Qualifiers such as `const` or `volatile` in a pointer declaration:

```
const int* ptr;
```

imply that the underlying object is `const` or `volatile`. These qualifiers act as instructions to the compiler. For instance, a `const` object is not supposed to be modified in the code and a `volatile` object is not supposed to be optimized away by the compiler.

If a second pointer points to the same object but does not use the same qualifier, the qualifier on the first pointer is no longer valid. For instance, if a `const int*` pointer and an `int*` pointer point to the same object, you can modify the object through the second pointer and violate the contract implied by the `const` qualifier in the first pointer.

### Fix

If you intend to convert from one pointer to another, declare both pointers with the same qualifiers.

## Examples

### Cast of Character Pointers

```
void read(char *);

void implicit_cast(void) {
    const char  cc, *pcc = &cc;
    char * quo;

    quo = &cc;
    quo = pcc;

    read(quo);
}
```

During the assignment to the character `q`, the variables, `cc` and `pcc`, are converted from `const char` to `char`. The `const` qualifier is removed during the conversion causing a defect.

#### Correction — Add Qualifiers

One possible correction is to add the same qualifiers to the new variables. In this example, changing `q` to a `const char` fixes the defect.

```
void read(char *);

void implicit_cast(void) {
    const char  cc, *pcc = &cc;
    const char * quo;

    quo = &cc;
    quo = pcc;

    read(quo);
}
```

#### Correction — Remove Qualifiers

One possible correction is to remove the qualifiers in the converted variable. In this example, removing the `const` qualifier from the `cc` and `pcc` initialization fixes the defect.

```
void read(char *);

void implicit_basic_cast(void) {
    char  cc, *pcc = &cc;
    char * quo;

    quo = &cc;
    quo = pcc;

    read(quo);
}
```

## Result Information

# Return from computational exception signal handler

Undefined behavior when signal handler returns normally from program error

## Description

This defect occurs when a signal handler returns after catching a computational exception signal SIGFPE, SIGILL, or SIGSEGV.

### Risk

A signal handler that returns normally from a computational exception is undefined behavior. Even if the handler attempts to fix the error that triggered the signal, the program can behave unexpectedly.

### Fix

Check the validity of the values of your variables before the computation to avoid using a signal handler to catch exceptions. If you cannot avoid a handler to catch computation exception signals, call abort(), quick_exit(), or _Exit() in the handler to stop the program.

## Examples

### Signal Handler Return from Division by Zero

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */
void sig_handler(int s)
{
    int s0 = s;
    if (denom == 0)
    {
        denom = 1;
    }
    /* Normal return from computation exception
    signal */
    return;
}

long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

In this example, `sig_handler` is declared to handle a division by zero computation error. The handler changes the value of `denom` if it is zero and returns, which is undefined behavior.

**Correction — Call `abort()` to Terminate Program**

After catching a computational exception, call `abort()` from `sig_handler` to exit the program without further error.

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */

void sig_handler(int s)
{
    int s0 = s;
    /* call to abort() to exit the program */
    abort();
}

long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

## Result Information

# Shared data access within signal handler

Access or modification of shared data causes inconsistent state

## Description

This defect occurs when you access or modify a shared object inside a signal handler.

### Risk

When you define a signal handler function to access or modify a shared object, the handler accesses or modifies the shared object when it receives a signal. If another function is already accessing the shared object, that function causes a race condition and can leave the data in an inconsistent state.

### Fix

To access or modify shared objects inside a signal handler, check that the objects are lock-free atomic, or, if they are integers, declare them as `volatile sig_atomic_t`.

## Examples

### `int` Variable Access in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* declare global variable. */
int e_flag;

void sig_handler(int signum)
{
    /* Signal handler accesses variable that is not
    of type volatile sig_atomic_t. */
    e_flag = signum;
}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

In this example, sig_handler accesses e_flag, a variable of type int. A concurrent access by another function can leave e_flag in an inconsistent state.

#### Correction — Declare Variable of Type volatile sig_atomic_t

Before you access a shared variable from a signal handler, declare the variable with type volatile sig_atomic_t instead of int. You can safely access variables of this type asynchronously.

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* Declare variable of type volatile sig_atomic_t. */
volatile sig_atomic_t e_flag;
void sig_handler(int signum)
{
    /* Use variable of proper type inside signal handler. */
    e_flag = signum;

}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** SIG_HANDLER_SHARED_OBJECT
**Impact:** Medium

# Version History

# Side effect in arguments to unsafe macro

Macro contains arguments that can be evaluated multiple times or not evaluated

## Description

This defect occurs when you call an unsafe macro with an expression that has a side effect.

- *Unsafe macro*: When expanded, an unsafe macro evaluates its arguments multiple times or does not evaluate its argument at all.

  For instance, the `ABS` macro evaluates its argument `x` twice.

  ```
  #define ABS(x) (((x) < 0) ? -(x) : (x))
  ```
- *Side effect*: When evaluated, an expression with a side effect modifies at least one of the variables in the expression.

  For instance, `++n` modifies `n`, but `n+1` does not modify `n`.

  The checker does not consider side effects in nested macros. The checker also does not consider function calls or volatile variable access as side effects.

### Risk

If you call an unsafe macro with an expression that has a side effect, the expression is evaluated multiple times or not evaluated at all. The side effect can occur multiple times or not occur at all, causing unexpected behavior.

For instance, in the call `MACRO(++n)`, you expect only one increment of the variable `n`. If `MACRO` is an unsafe macro, the increment happens more than once or does not happen at all.

The checker flags expressions with side effects in the `assert` macro because the `assert` macro is disabled in non-debug mode. To compile in non-debug mode, you define the `NDEBUG` macro during compilation. For instance, in GCC, you use the flag `-DNDEBUG`.

### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result as a macro argument.

For instance, instead of:

```
MACRO(++n);
```

perform the operation in two steps:

```
++n;
MACRO(n);
```

Alternatively, use an inline function instead of a macro. Pass the expression with side effect as argument to the inline function.

The checker considers modifications of a local variable defined only in the block scope of a macro body as a side effect. This defect cannot happen since the variable is visible only in the macro body. If you see a defect of this kind, ignore the defect.

## Examples

### Macro Argument with Side Effects

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  int m = ABS(++n);

  /* ... */
}
```

In this example, the ABS macro evaluates its argument twice. The second evaluation can result in an unintended increment.

#### Correction — Separate Evaluation of Expression from Macro Usage

One possible correction is to first perform the increment, and then pass the result to the macro.

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  ++n;
  int m = ABS(n);

  /* ... */
}
```

#### Correction — Evaluate Expression in Inline Function

Another possible correction is to evaluate the expression in an inline function.

```
static inline int iabs(int x) {
  return (((x) < 0) ? -(x) : (x));
}

void func(int n) {
  /* Validate that n is within the desired range */

int m = iabs(++n);

  /* ... */
}
```

# Side effect of expression ignored

`sizeof`, `_Alignof`, or `_Generic` operates on expression with side effect

## Description

This defect occurs when the `sizeof`, `_Alignof`, or `_Generic` operator operates on an expression with a side effect. When evaluated, an expression with side effect modifies at least one of the variables in the expression.

For instance, the defect checker does not flag `sizeof(n+1)` because `n+1` does not modify `n`. The checker flags `sizeof(n++)` because `n++` is intended to modify `n`.

The check also applies to the C++ operator `alignof` and its C extensions, `__alignof__` and `__typeof__`.

### Risk

The expression in a `_Alignof` or `_Generic` operator is not evaluated. The expression in a `sizeof` operator is evaluated only if it is required for calculating the size of a variable-length array, for instance, `sizeof(a[n++])`.

When an expression with a side effect is not evaluated, the variable modification from the side effect does not happen. If you rely on the modification, you can see unexpected results.

### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result in a `sizeof`, `_Alignof`, or `_Generic` operator.

For instance, instead of:

```
a = sizeof(n++);
```

perform the operation in two steps:

```
n++;
a = sizeof(n);
```

The checker considers a function call as an expression with a side effect. Even if the function does not have side effects now, it might have side effects on later additions. The code is more maintainable if you call the function outside the `sizeof` operator.

## Examples

### Increment Operator in `sizeof`

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    unsigned int b = (unsigned int)sizeof(++a);
    printf ("%u, %u\n", a, b);
}
```

In this example, `sizeof` operates on `++a`, which is intended to modify `a`. Because the expression is not evaluated, the modification does not happen. The `printf` statement shows that `a` still has the value `1`.

#### Correction — Perform Increment Outside `sizeof`

One possible correction is to perform the increment first, and then provide the result to the `sizeof` operator.

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    ++a;
    unsigned int b = (unsigned int)sizeof (a);
    printf ("%u, %u\n", a, b);
}
```

# Signal call from within signal handler

Nonpersistent signal handler calling `signal()` in Windows system causes race condition

## Description

This defect occurs when you call the function `signal()` from a signal handler on Windows platforms.

The defect is detected only if you specify a Visual Studio compiler. See `Compiler (-compiler)`.

### Risk

The function `signal()` associates a signal with a signal handler function. On platforms such as Windows, which removes this association after receiving the signal, you might call the function `signal()` again *within the signal handler* to re-establish the association.

However, this attempt to make a signal handler persistent is prone to race conditions. On Windows platforms, from the time the signal handler begins execution to when the `signal` function is called again, it is the default signal handling, `SIG_DFL`, that is active. If a second signal is received within this time window, you see the default signal handling and not the custom signal handler, but you might expect otherwise.

### Fix

Do not call `signal()` from a signal handler on Windows platforms.

## Examples

### `signal()` Called from Signal Handler

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;

    /* Call signal() to reestablish sig_handler
    upon receiving SIG_ERR. */

    if (signal(s0, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
}
```

```
void func(void)
{
        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
  /* more code */
}
```

In this example, the definition of `sig_handler()` includes a call to `signal()` when the handler catches `SIG_ERR`. On Windows platforms, signal handlers are nonpersistent. This code can result in a race condition.

The issue is detected only if you specify a compiler such as `visual15.x` for the analysis.

**Correction — Do Not Call `signal()` from Signal Handler**

Avoid attempting to make a signal handler persistent on Windows. If your code requires the use of a persistent signal handler on a Windows platform, use a persistent signal handler after performing a thorough risk analysis.

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;
    /* No call to signal() */
}

int main(void)
{

        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code

**Command-Line Syntax:** `SIG_HANDLER_CALLING_SIGNAL`
**Impact:** Medium

## Version History

# Standard function call with incorrect arguments

Argument to a standard function does not meet requirements for use in the function

## Description

This defect occurs when the arguments to certain standard functions do not meet the requirements for their use in the functions.

For instance, the arguments to these functions can be invalid in the following ways.

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| String manipulation functions such as `strlen` and `strcpy` | The pointer arguments do not point to a `NULL`-terminated string. | The behavior of the function is undefined. | Pass a `NULL`-terminated string to string manipulation functions. |
| File handling functions in `stdio.h` such as `fputc` and `fread` | The `FILE*` pointer argument can have the value `NULL`. | The behavior of the function is undefined. | Test the `FILE*` pointer for `NULL` before using it as function argument. |
| File handling functions in `unistd.h` such as `lseek` and `read` | The file descriptor argument can be -1. | The behavior of the function is undefined.<br>Most implementations of the `open` function return a file descriptor value of -1. In addition, they set `errno` to indicate that an error has occurred when opening a file. | Test the return value of the `open` function for -1 before using it as argument for `read` or `lseek`.<br>If the return value is -1, check the value of `errno` to see which error has occurred. |
| | The file descriptor argument represents a closed file descriptor. | The behavior of the function is undefined. | Close the file descriptor only after you have completely finished using it. Alternatively, reopen the file descriptor before using it as function argument. |
| Directory name generation functions such as `mkdtemp` and `mkstemps` | The last six characters of the string template are not `XXXXXX`. | The function replaces the last six characters with a string that makes the file name unique. If the last six characters are not `XXXXXX`, the function cannot generate a unique enough directory name. | Test if the last six characters of a string are `XXXXXX` before using the string as function argument. |

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| Functions related to environment variables such as `getenv` and `setenv` | The string argument is `""`. | The behavior is implementation-defined. | Test the string argument for `""` before using it as `getenv` or `setenv` argument. |
| | The string argument terminates with an equal sign, =. For instance, `"C="` instead of `"C"`. | The behavior is implementation-defined. | Do not terminate the string argument with =. |
| String handling functions such as `strtok` and `strstr` | • `strtok`: The delimiter argument is `""`.<br>• `strstr`: The search string argument is `""`. | Some implementations do not handle these edge cases. | Test the string for `""` before using it as function argument. |

### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### `NULL` Pointer Passed as `strnlen` Argument

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};

int func() {
    char* s = NULL;
    return strnlen(s, SIZE20);
}
```

In this example, a `NULL` pointer is passed as `strnlen` argument instead of a `NULL`-terminated string.

Before running analysis on the code, specify a GNU compiler. See `Compiler (-compiler)`.

#### Correction — Pass NULL-terminated String

Pass a `NULL`-terminated string as the first argument of `strnlen`.

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};

int func() {
    char* s = "";
    return strnlen(s, SIZE20);
}
```

### Result Information

# Stream argument with possibly unintended side effects

Stream argument side effects occur more than once

## Description

This defect occurs when you call `getc()`, `putc()`, `getwc()`, or `putwc()` with a stream argument that has side effects.

**Stream argument with possibly unintended side effects** considers the following as stream side effects:

- Any assignment of a variable of a stream, such as `FILE *`, or any assignment of a variable of a deeper stream type, such as an array of `FILE *`.
- Any call to a function that manipulates a stream or a deeper stream type.

The number of defects raised corresponds to the number of side effects detected. When a stream argument is evaluated multiple times in a function implemented as a macro, a defect is raised for each evaluation that has a side effect.

A defect is also raised on functions that are not implemented as macros but that can be implemented as macros on another operating system.

### Risk

If the function is implemented as an unsafe macro, the stream argument can be evaluated more than once, and the stream side effect happens multiple times. For instance, a stream argument calling `fopen()` might open the same file multiple times, which is unspecified behavior.

### Fix

To ensure that the side effect of a stream happens only once, use a separate statement for the stream argument.

## Examples

### Stream Argument of `getc()` Has Side Effect `fopen()`

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;
    /* getc() has stream argument fptr with
    * 2 side effects: call to fopen(), and assignment
    * of fptr
    */
    c = getc(fptr = fopen(myfile, "r"));
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

In this example, `getc()` is called with stream argument `fptr`. The stream argument has two side effects: the call to `fopen()` and the assignment of `fptr`. If `getc()` is implemented as an unsafe macro, the side effects happen multiple times.

**Correction — Use Separate Statement for `fopen()`**

One possible correction is to use a separate statement for `fopen()`. The call to `fopen()` and the assignment of `fptr` happen in this statement so there are no side effects when you pass `fptr` to `getc()`.

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;

    /* Separate statement for fopen()
    * before call to getc()
    */
    fptr = fopen(myfile, "r");
    if (fptr == NULL) {
        /* Handle error */
        fatal_error();
    }
    c = getc(fptr);
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

# Too many va_arg calls for current argument list

Number of calls to va_arg exceeds number of arguments passed to variadic function

## Description

This defect occurs when the number of calls to va_arg exceeds the number of arguments passed to the corresponding variadic function. The analysis raises a defect only when the variadic function is called.

**Too many va_arg calls for current argument list** does not raise a defect when:

- The number of calls to va_arg inside the variadic function is indeterminate. For example, if the calls are from an external source.
- The va_list used in va_arg is invalid.

### Risk

When you call va_arg and there is no next argument available in va_list, the behavior is undefined. The call to va_arg might corrupt data or return an unexpected result.

### Fix

Ensure that you pass the correct number of arguments to the variadic function.

## Examples

### No Argument Available When Calling va_arg

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/
int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {
/* No further argument available
* in va_list when calling va_arg
*/

            result += va_arg(ap, int);
        }
    }
    va_end(ap);
    return result;
}

void func(void) {

    (void)variadic_func(2, 100);

}
```

In this example, the named argument and only one variadic argument are passed to `variadic_func()` when it is called inside `func()`. On the second call to `va_arg`, no further variadic argument is available in `ap` and the behavior is undefined.

#### Correction — Pass Correct Number of Arguments to Variadic Function

One possible correction is to ensure that you pass the correct number of arguments to the variadic function.

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/

int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {

/* The correct number of arguments is
* passed to va_list when variadic_func()
* is called inside func()
*/
            result += va_arg(ap, int);
        }
    }
    va_end(ap);
    return result;
}

void func(void) {

    (void)variadic_func(2, 100, 200);

}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code

**Command-Line Syntax:** `TOO_MANY_VA_ARG_CALLS`<br>
**Impact:** Medium

# Typedef mismatch

Mismatch between typedef statements

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when typedef statements lead to conflicting underlying types for one of these data types:

- size_t
- ssize_t
- wchar_t
- ptrdiff_t

### Risk

If you change the underlying type of size_t, ssize_t, wchar_t, or ptrdiff_t, you have inconsistent definitions of the same type. Compilation units with different include paths can potentially use different-sized types causing conflicts in your program.

For example, say that you define a function in one compilation unit that redefines size_t as unsigned long. But in another compilation unit that uses the size_t definition from <stddef.h>, you use the same function as an extern declaration. Your program will encounter a mismatch between the function declaration and function definition.

### Fix

Use consistent type definitions. For example:

- Remove custom type definitions for these fundamental types. Only use system definitions.
- Use the same size for all compilation units. Move your typedef to a shared header file.

## Examples

### Two Definitions of size_t

file1.c:

```
#include <stddef.h>

void func1()
{
    size_t var = 0;
    /*... more code ... */
}
```

file2.c:

```
typedef unsigned char size_t;

void func2()
{
    size_t var = 0;
    /*... more code ... */
}
```

In this example, Polyspace flags the definition of `size_t` in `file2.c` as a defect. This definition is a `typedef` mismatch because another file in your project, `file1.c`, includes `stddef.h`, which defines `size_t` as unsigned long.

### Correction — Use System Definition

One possible correction is to use the system definition of `size_t` in `stddef.h` to avoid conflicting type definitions.

`file1.c`:

```
#include <stddef.h>

void func1()
{
    size_t var = 0;
    /*... more code ... */
}
```

`file2.c`:

```
#include <stddef.h>

void func2()
{
    size_t var = 0;
    /*... more code ... */
}
```

### Correction — Use Shared Header File

One possible correction is to use a shared header file to store your type definition that gets included in both files.

`types.h`:

```
typedef unsigned char size_t;
```

`file1.c`:

```
#include "types.h"

void func1()
{
    size_t var = 0;
    /*... more code ... */
}
```

`file2.c`:

```
#include "types.h"
```

```
void func2()
{
    size_t var = 0;
    /*... more code ... */
}
```

### Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `TYPEDEF_MISMATCH`
**Impact:** High

## Version History

**Introduced in R2016b**

# Universal character name from token concatenation

You create a universal character name by joining tokens with ## operator

## Description

This defect occurs when two preprocessing tokens joined with a ## operator create a universal character name. A universal character name begins with `\u` or `\U` followed by hexadecimal digits. It represents a character not found in the basic character set.

For instance, you form the character `\u0401` by joining two tokens:

```
#define assign(uc1, uc2, val) uc1##uc2 = val
...
assign(\u04, 01, 4);
```

### Risk

The C11 Standard (Sec. 5.1.1.2) states that if a universal character name is formed by token concatenation, the behavior is undefined.

### Fix

Use the universal character name directly instead of producing it through token concatenation.

## Examples

### Universal Character Name from Token Concatenation

```
#define assign(uc1, uc2, val) uc1##uc2 = val

int func(void) {
    int \u0401 = 0;
    assign(\u04, 01, 4);
    return \u0401;
}
```

In this example, the `assign` macro, when expanded, joins the two tokens `\u04` and `01` to form the universal character name `\u0401`.

#### Correction — Use Universal Character Name Directly

One possible correction is to use the universal character name `\u0401` directly. The correction redefines the `assign` macro so that it does not join tokens.

```
#define assign(ucn, val) ucn = val

int func(void) {
    int \u0401 = 0;
    assign(\u0401, 4);
    return \u0401;
}
```

### Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `PRE_UCNAME_JOIN_TOKENS`
**Impact:** Low

# Unnamed namespace in header file

Header file contains unnamed namespace leading to multiple definitions

## Description

This defect occurs when an unnamed namespace is used in a header file, which can lead to multiple definitions of objects in the namespace.

### Risk

According to the C++ standard, names in an unnamed namespace, for instance, `aVar`:

```
namespace {
   int aVar;
}
```

have internal linkage by default. If a header file contains an unnamed namespace, each translation unit with a source file that `#include`-s the header file defines its own instance of objects in the namespace. The multiple definitions are probably not what you intended and can lead to unexpected results, unwanted excess memory usage, or inadvertently violating the one-definition rule.

### Fix

Specify names for namespaces in header files or avoid using namespaces in header files.

## Examples

### Unexpected Results from Unnamed Namespaces in Header Files

Header File: `aHeader.h`

```
namespace {
   int aVar;
}
```

First source file: `aSource.cpp`

```
#include "aHeader.h"
#include <iostream>

void setVar(int arg) {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = arg;
    std::cout << "Value set at: " << aVar << std::endl;
}
```

Second source file: `anotherSource.cpp`

```
#include "aHeader.h"
#include <iostream>

extern void setVar(int);
```

```
void resetVar() {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = 0;
    std::cout << "Value set at: 0" << std::endl;
}

void main() {
    setVar(1);
    resetVar();
}
```

In this example, the unnamed namespace leads to two definitions of `aVar` in the translation unit from `aSource.cpp` and the translation unit from `anotherSource.cpp`. The two definitions lead to possible unexpected output:

```
Current value: 0
Value set at: 1
Current value: 0
Value set at: 0
```

**Correction – Avoid the Unnamed Namespace**

One possible correction is to avoid a namespace in the header file.

Header File: `aHeader.h`

```
extern int aVar;
```

First source file: `aSource.cpp`

```
#include "aHeader.h"
#include <iostream>

void setVar(int arg) {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = arg;
    std::cout << "Value set at: " << aVar << std::endl;
}
```

Second source file: `anotherSource.cpp`

```
#include "aHeader.h"
#include <iostream>

extern void setVar(int);
int aVar;

void resetVar() {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = 0;
    std::cout << "Value set at: 0" << std::endl;
}

void main() {
    setVar(1);
    resetVar();
}
```

You now see the expected sequence in the output:

```
Current value: 0
Value set at: 1
Current value: 1
Value set at: 0
```

## Result Information

# Unsafe conversion between pointer and integer

Misaligned or invalid results from conversions between pointer and integer types

## Description

This defect occurs when you convert between a pointer type, such as `intptr_t`, or `uintprt_t`, and an integer type, such as `enum`, `ptrdiff_t`, or `pid_t`, or vice versa.

### Risk

The mapping between pointers and integers is not always consistent with the addressing structure of the environment.

Converting from pointers to integers can create:

- Truncated or out of range integer values.
- Invalid integer types.

Converting from integers to pointers can create:

- Misaligned pointers or misaligned objects.
- Invalid pointer addresses.

### Fix

Where possible, avoid pointer-to-integer or integer-to-pointer conversions. If you want to convert a `void` pointer to an integer, so that you do not change the value, use types:

- C99 — `intptr_t` or `uintptr_t`
- C90 — `size_t` or `ssize_t`

## Examples

### Integer to Pointer Conversions

```
 unsigned int *badintptrcast(void)
{
    unsigned int *ptr0 = (unsigned int *)0xdeadbeef;
    char *ptr1 = (char *)0xdeadbeef;
    unsigned int *explicit_ptr = reinterpret_cast<unsigned int*>(0xdeadbeef);
    return (unsigned int *)(ptr0 - (unsigned int *)ptr1);
}
```

In this example, there are four conversions, three unsafe conversions and one safe conversion.

- The conversion of `0xdeadbeef` to an `unsigned int*` causes alignment issues for the pointer. Polyspace flags this conversion.
- The conversion of `0xdeadbeef` to a `char *` is not flagged because there are no alignment issues for `char`.

- The explicit reinterpret_cast of 0xdeadbeef to an unsigned int* causes alignment issues for the pointer. Polyspace flags this conversion.
- The conversion in the return casts ptrdiff_t to a pointer. This pointer might point to an invalid address. Polyspace flags this conversion.

#### Correction — Use intptr_t

One possible correction is to use intptr_t types to store the pointer address 0xdeadbeef. Also, you can change the second pointer to an integer offset so that there is no longer a conversion from ptrdiff_t to a pointer.

```
#include <stdint.h>

unsigned int *badintptrcast(void)
{
    intptr_t iptr0 = (intptr_t)0xdeadbeef;
    int offset = 0;
    return (unsigned int *)(iptr0 - offset);
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** BAD_INT_PTR_CAST
**Impact:** Medium

# Version History

**Introduced in R2016b**

# Unsafe conversion from string to numerical value

String to number conversion without validation checks

## Description

This defect occurs when you perform conversions from strings to integer or floating-point values and your conversion method does not include robust error handling.

### Risk

Converting a string to numerical value can cause data loss or misinterpretation. Without validation of the conversion or error handling, your program continues with invalid values.

### Fix

- Add additional checks to validate the numerical value.
- Use a more robust string-to-numeric conversion function such as `strtol`, `strtoll`, `strtoul`, or `strtoull`.

## Examples

### Conversion With `atoi`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char* argv1)
{
    int s = 0;
    if (demo_check_string_not_empty(argv1))
    {
        s = atoi(argv1);
    }
    return s;
}
```

In this example, `argv1` is converted to an integer with `atoi`. `atoi` does not provide errors for an invalid integer string. The conversion can fail unexpectedly.

#### Correction — Use `strtol` instead

One possible correction is to use `strtol` to validate the input string and the converted integer.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>
#include <errno.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char *argv1)
{
    char *c_str = argv1;
    char *end;
    long sl;

    if (demo_check_string_not_empty(c_str))
    {
        errno = 0; /* set errno for error check */
        sl = strtol(c_str, &end, 10);
        if (end == c_str)
        {
            (void)fprintf(stderr, "%s: not a decimal number\n", c_str);
        }
        else if ('\0' != *end)
        {
            (void)fprintf(stderr, "%s: extra characters: %s\n", c_str, end);
        }
        else if ((LONG_MIN == sl || LONG_MAX == sl) && ERANGE == errno)
        {
            (void)fprintf(stderr, "%s out of range of type long\n", c_str);
        }
        else if (sl > INT_MAX)
        {
            (void)fprintf(stderr, "%ld greater than INT_MAX\n", sl);
        }
        else if (sl < INT_MIN)
        {
            (void)fprintf(stderr, "%ld less than INT_MIN\n", sl);
        }
        else
        {
            return (int)sl;
        }
    }
    return 0;
}
```

## Result Information

# Use of indeterminate string

Use of unvalidated buffer from fgets-family function

## Description

This defect occurs when you do not check if a write operation using an `fgets`-family function such as:

```
char * fgets(char* buf, int n, FILE *stream)
```

succeeded and the buffer written has valid content, or you do not reset the buffer on failure. You then perform an operation that assumes a buffer with valid content. For instance, if the buffer with possibly indeterminate content is `buf` (as shown above), the checker raises a defect if:

- You pass `buf` as argument to standard functions that print or manipulate strings or wide strings.
- You return `buf` from a function.
- You pass `buf` as argument to external functions with parameter type `const char *` or `const wchar_t *`.
- You read `buf` as `buf[index]` or `*(buf + offset)`, where `index` or `offset` is a numerical value representing the distance from the beginning of the buffer.

### Risk

If an `fgets`-family function fails, the content of its output buffer is indeterminate. Use of such a buffer has undefined behavior and can result in a program that stops working or other security vulnerabilities.

### Fix

Reset the output buffer of an `fgets`-family function to a known string value when the function fails.

## Examples

### Output of `fgets()` Passed to External Function

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func(void) {
    char buf[SIZE20];

    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* 'buf' may contain an indeterminate string.  */
        ;
    }
    /* 'buf passed to external function */
    display_text(buf);
}
```

In this example, the output `buf` is passed to the external function `display_text()`, but its value is not reset if `fgets()` fails.

#### Correction — Reset `fgets()` Output on Failure

If `fgets()` fails, reset `buf` to a known value before you pass it to an external function.

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func1(void) {
    char buf[SIZE20];
    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* value of 'buf' reset after fgets() failure. */
        buf[0] = '\0';
    }
    /* 'buf' passed to external function */
    display_text(buf);
}
```

## Result Information

# Use of memset with size argument zero

Size argument of function in `memset` family is zero

## Description

This defect occurs when you call a function in the `memset` family with size argument zero. Functions include `memset`, `wmemset`, `bzero`, `SecureZeroMemory`, `RtlSecureZeroMemory`, and so on.

### Risk

`void *memset (void *ptr, int value, size_t num)` fills the first `num` bytes of the memory block that `ptr` points to with the specified `value`. A zero value of `num` renders the call to `memset` redundant. The memory that `ptr` points to:

- Remains uninitialized, if not previously initialized.
- Is not cleared and can contain sensitive data, if previously initialized.

### Fix

Determine if the zero size argument occurs because of a previous error in your code. Fix the error.

## Examples

### Zero Size Argument of memset

```
#include <stdio.h>
#include <string.h>

void func (unsigned int size)
{
    char str[] = "Buffer to be filled.";
    memset (str,'-',size);
    puts (str);
}

void calling_func(void) {
    unsigned int buf_size=0;
    func(buf_size);
}
```

In this example, the argument `size` of `memset` is zero.

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `MEMSET_INVALID_SIZE`
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Variable length array with non-positive size

Size of variable-length array is zero or negative

## Description

This defect occurs when size of a variable-length array is zero or negative.

### Risk

If the size of a variable-length array is zero or negative, unexpected behavior can occur, such as stack overflow.

### Fix

When you declare a variable-length array as a local variable in a function:

- If you use a function parameter as the array size, check that the parameter is positive.
- If you use the result of a computation on a function parameter as the array size, check that the result is positive.

You can place a test for positive value either before the function call or the array declaration in the function body.

## Examples

### Nonpositive Array Size

```
int input(void);

void add_scalar(int n, int m) {
    int r=0;
    int arr[m][n];
    for (int i=0; i<m; i++) {
        for (int j=0; j<n; j++) {
            arr[i][j] = input();
            r += arr[i][j];
        }
    }
}

void main() {
    add_scalar(2,2);
    add_scalar(-1,2);
    add_scalar(2,0);
}
```

In this example, the second and third calls to `add_scalar` result in a negative and zero size of `arr`.

#### Correction — Make Array Size Positive

One possible correction is fix or remove calls that result in a nonpositive array size.

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `NON_POSITIVE_VLA_SIZE`
**Impact:** High

# Writing to const qualified object

Object declared with a `const` qualifier is modified

## Description

This defect occurs when you do one of the following:

- Use a `const`-qualified object as the destination of an assignment.
- Pass a `const`-qualified object to a function that modifies the argument.

For instance, the defect can occur in the following situations:

- You pass a `const`-qualified object as first argument of one of the following functions:
  - `mkstemp`
  - `mkostemp`
  - `mkostemps`
  - `mkdtemp`
- You pass a `const`-qualified object as the destination argument of one of the following functions:
  - `strcpy`
  - `strncpy`
  - `strcat`
  - `memset`
- You perform a write operation on a `const`-qualified object.

### Risk

The risk depends upon the modifications made to the `const`-qualified object.

| Situation | Risk |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | These functions replace the last six characters of their first argument with a string. Therefore, they expect a modifiable `char` array as their first argument. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | These functions modify their destination argument. Therefore, they expect a modifiable `char` array as their destination argument. |
| Writing to the object | The `const` qualifier implies an agreement that the value of the object will not be modified. By writing to a `const`-qualified object, you break the agreement. The result of the operation is undefined. |

### Fix

The fix depends on the modification made to the `const`-qualified object.

| Situation | Fix |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | Pass a non-`const` object as first argument of the function. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | Pass a non-`const` object as destination argument of the function. |
| Writing to the object | Perform the write operation on a non-`const` object. |

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Writing to `const`-Qualified Object

```
#include <string.h>

const char* buffer = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

In this example, because `buffer` is `const`-qualified, `strchr(buffer,'X')` returns a `const`-qualified `char*` pointer. When this `char*` pointer is used as the destination argument of `strcpy`, a **Writing to const qualified object** error appears.

#### Correction — Copy `const`-Qualified Object to Non-`const` Object

One possible correction is to assign the constant string to a non-`const` object and use the non-`const` object as destination argument of `strchr`.

```
#include <string.h>

char buffer[] = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

## Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `CONSTANT_OBJECT_WRITE`
**Impact:** High

# Wrong type used in sizeof

`sizeof` argument does not match pointed type

## Description

This defect occurs when both of the following conditions hold:

1. You assign the address of a block of memory to a pointer, or transfer data between two blocks of memory. The assignment or copy uses the `sizeof` operator.

   For instance, you initialize a pointer using `malloc(sizeof(`*`type`*`))` or copy data between two addresses using `memcpy(`*`destination_ptr`*`, `*`source_ptr`*`, sizeof(`*`type`*`))`.
2. You use an incorrect type as argument of the `sizeof` operator. For instance:

   - You might be using the pointer type instead of the type that the pointer points to. For example, to initialize a *`type`*`*` pointer, you might be using `malloc(sizeof(`*`type`*`*))` instead of `malloc(sizeof(`*`type`*`))`.
   - You might be using a completely unrelated type as `sizeof` argument. For example, to initialize a *`type`*`*` pointer, you might be using `malloc(sizeof(`*`anotherType`*`))`.

### Risk

Irrespective of what *`type`* stands for, the expression `sizeof(`*`type`*`*)` always returns a fixed size. The size returned is the pointer size on your platform in bytes. The appearance of `sizeof(`*`type`*`*)` often indicates an unintended usage. The error can cause allocation of a memory block that is much smaller than what you need and lead to weaknesses such as buffer overflows.

For instance, assume that `structType` is a structure with ten `int` variables. If you initialize a `structType*` pointer using `malloc(sizeof(structType*))` on a 32-bit platform, the pointer is assigned a memory block of four bytes. However, to be allocated completely for one `structType` variable, the `structType*` pointer must point to a memory block of `sizeof(structType) = 10 * sizeof(int)` bytes. The required size is much greater than the actual allocated size of four bytes.

### Fix

To initialize a *`type`*`*` pointer, replace `sizeof(`*`type`*`*)` in your pointer initialization expression with `sizeof(`*`type`*`)`.

## Examples

### Allocate a Char Array With `sizeof`

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char*) * 5);
    free(str);
}
```

In this example, memory is allocated for the character pointer `str` using a `malloc` of five char pointers. However, `str` is a pointer to a character, not a pointer to a character pointer. Therefore the `sizeof` argument, `char*`, is incorrect.

#### Correction — Match Pointer Type to `sizeof` Argument

One possible correction is to match the argument to the pointer type. In this example, `str` is a character pointer, therefore the argument must also be a character.

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char) * 5);
    free(str);

}
```

### Result Information

**Group:** Programming
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `PTR_SIZEOF_MISMATCH`
**Impact:** High

## Version History

# Non-compliance with AUTOSAR specification

An RTE API function is used with arguments that violate the AUTOSAR standard specification

## Description

This defect occurs when you use an RTE API function with arguments that violate the AUTOSAR standard specifications.

For instance, checks on `Rte_Write_*` or `Rte_Byps_Write_*` function calls determine if the pointer-to-data argument in the call:

- Is NULL valued.
- Points to a memory buffer.
- Points to an initialized memory buffer.
- For buffers with enum values, values are within the enum range.

For more information on the RTE API specifications, see AUTOSAR documentation (Specification of RTE Software).

To enable this check, use the value `autosar` for the option `Libraries used (-library)`.

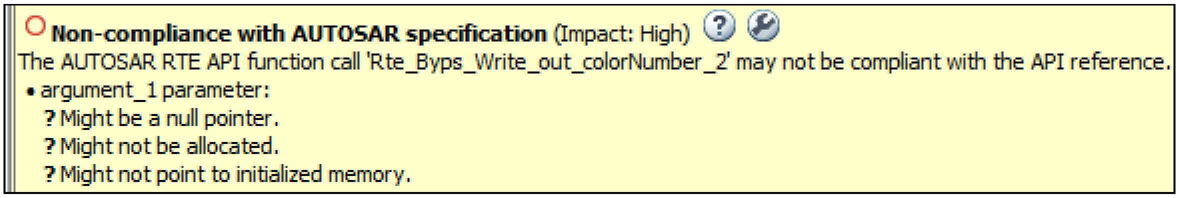
A more exhaustive version of the same checker is available with Code Prover. When checking for AUTOSAR standard violations on an `Rte_` function call, the Code Prover checker considers *all* execution paths that lead to the function call (subject to verification assumptions).

### Risk

The RTE function usage might lead to run-time errors.

### Fix

The fix depends on the root cause of the defect. To diagnose this check, read the message on the **Result Details** pane. The message shows all checks performed on the RTE API function, along with information about whether the check passed. For instance, this message:



○ **Non-compliance with AUTOSAR specification** (Impact: High)
The AUTOSAR RTE API function call 'Rte_Byps_Write_out_colorNumber_2' may not be compliant with the API reference.
- argument_1 parameter:
  **?** Might be a null pointer.
  **?** Might not be allocated.
  **?** Might not point to initialized memory.

Shows the results of three checks, all three of which might fail. The first argument of the function might be a null pointer, might not be allocated and might not point to initialized memory.

Investigate the root cause of the issue further.

## Examples

### Rte_Byps_Write_* Argument Pointing to Statically Allocated Noninitialized Buffer

```
#include <stdlib.h>

// Type declarations that are typically in AUTOSAR header Rte_type.h
typedef unsigned char uint8_T;
typedef unsigned int uint32_T;
typedef uint8_T Std_ReturnType;

typedef struct {
    uint8_T color;
    uint32_T number;
}
colorNumber;

extern Std_ReturnType Rte_Byps_Write_out_colorNumber_1(colorNumber*);

void SendData() {
    colorNumber aColor;
    uint8_T copyColor;
    uint32_T copyNumber;

    colorNumber* aPtrColor = &aColor;
    Rte_Byps_Write_out_colorNumber_1(aPtrColor);

    copyColor = aColor.color;
    copyNumber = aColor.number;
}
```

In this example, the function `Rte_Byps_Write_out_colorNumber_1` takes a pointer to a noninitialized variable. The checker flags the function call because the pointer does not point to initialized memory. To run this example, use the option `-library autosar`.

### Rte_Byps_Write_* Argument Pointing to Dynamically Allocated Noninitialized Buffer

```
#include <stdlib.h>

// Type declarations that are typically in AUTOSAR header Rte_type.h
typedef unsigned char uint8_T;
typedef unsigned int uint32_T;
typedef uint8_T Std_ReturnType;

typedef struct {
    uint8_T color;
    uint32_T number;
}
colorNumber;
extern Std_ReturnType Rte_Byps_Write_out_colorNumber_2(colorNumber*);

void SendData() {
    colorNumber* arrayColorNumber = (colorNumber*) malloc(2*sizeof(colorNumber));
    uint8_T copyColor;
    uint32_T copyNumber;
    Rte_Byps_Write_out_colorNumber_2(arrayColorNumber);

    copyColor = arrayColorNumber[0].color;
    copyNumber = arrayColorNumber[0].number;
}
```

In this example, the function `Rte_Byps_Write_out_colorNumber_2` takes a pointer returned from a memory allocation with `malloc`. The checker flags the function call because the pointer does not point to initialized memory. To run this example, use the option `-library autosar`.

## Result Information

# Result of `string::c_str()` compared to another pointer

The C string obtained from `std::string::c_str()` is compared to a pointer (or NULL)

## Description

This defect occurs when a C string that is obtained by calling the `std::string::c_str` function is compared to a pointer or a NULL. For instance, Polyspace flags the comparison operations in the `if` statements in this code:

```
void foo(){
    //...
    std::string str{"loren ipsum"};
    //...
    const char pStr[] = "loren ipsum";
    const char* p = str.c_str();
    if(p==NULL){//Defect: Unnecessary

    }
    if(p==pStr){ //Defect: Compares pointer address
    //..
    }
    //..
}
```

### Risk

Comparing a pointer to the C string obtained from a `string` has these risks:

- When you compare the output of `std::string::c_str` to a pointer, the addresses of the pointers are compared. You might expect the compiler to compare the content of the pointers. For instance, in the preceding code, you might expect that `(p==pStr)` evaluates to `true` because both pointers contains `loren ipsum`. The compiler compares the addresses `p` and `pStr`, which evaluates to `false`. Comparing pointers as a method of comparing strings produces unexpected results.
- The C string `p` that is obtained by calling `std::string::c_str()` is always non-NULL. The expression `(p==NULL)` always evaluates to `false`. Comparing such a C string to NULL might produce unexpected results and indicates a logic error in the code.

### Fix

To fix this issue:

- To compare the content of strings, use string functions or use operators with the string objects directly.
- Because `std::string::c_str()` always returns a non-NULL value, remove the comparison to NULL or refactor your logic.

## Examples

### Avoid Comparing C Strings from string::c_str() to NULL

```
#include<string>
extern void setCategoryName(const char *);

void setName(const std::string &s)
{
    if (s.c_str() != NULL)//Defect
    {
        setCategoryName(s.c_str());
    }
}
```

In this example, the function setName sets the category name when the C string obtained from the string s is non-NULL. You might expect the condition (s.c_str() != NULL) to evaluate to true only when s contains a string of nonzero length. Because std::string::c_str() returns a non-NULL value regardless of the content of the string object, the condition always evaluates to true. As a result, this comparison is unnecessary and cannot detect empty strings.

#### Correction — Use string::empty to Detect Empty

To fix this defect, remove the comparison of the C string to NULL. To detect empty string, use std::string::empty().

```
#include<string>

extern void setCategoryName(const char *);
void setName_possibleFix1(const std::string &s)
{
    setCategoryName(s.c_str());
}

void setName_possibleFix2(const std::string &s)
{
    if (!s.empty())
    {
        setCategoryName(s.c_str());
    }
}
```

### Avoid Comparing C Strings From string::c_str() to Other Pointers

```
#include<string>
bool is_same(const std::string &s1, const std::string &s2)
{
    const char* pStr1 = s1.c_str();
    const char* pStr2 = s2.c_str();
    return (pStr1 == pStr2);//Defect
}
bool is_different(const std::string &s1, const char* Cstr)
{
    const char* pStr1 = s1.c_str();
    return (pStr1 != Cstr);//Defect
}
```

In this example, C strings pStr1 and pStr2 are obtained by calling string::c_str() and then compared to other pointers. In is_same, you might expect (pStr1 == pStr2) to evaluate to true if the contents of s1 and s2 contains the same string. Because this operation is a pointer comparison, it compares the address of the pointers pStr1 and pStr2 instead of the content of the string, producing unexpected results.

When comparing string objects and C strings, you might expects comparison operations such as (pStr1 != Cstr) to compare the content of the string and char pointer. Because this operation compares the addresses of the pointers instead of the string contents, the results might be unexpected.

#### Correction — Use Member Functions and Overloaded Operators of std::string

To fix this defect, use the member functions and overloaded operators of std::string to compare strings and C strings.

```
#include <string>

bool is_same(const std::string &s1, const std::string &s2)
{
    return (s1 == s2);
}
bool is_different(const std::string &s1, const char* Cstr)
{
    return (s1!= Cstr);
}
```

## Result Information

# Improper erase-remove idiom

Container's `erase()` is not called or called improperly following a call to `std::remove()`

## Description

This defect occurs when any of these conditions are true:

- The function `std::remove()` or `std::remove_if()` is called and the output is not passed to a container's `erase()` method.
- The container's `erase()` method is called by using the output of `std::remove` but without passing the second parameter.

### Risk

You might expect `std::remove()` or `std::remove_if` to remove entries from a container. Instead, these functions partition a container and move the entries that match the removal criteria to the right side. This right side content might not be meaningful. If you do not pass the output of `std::remove()` and `std::remove_if` to the container's `erase()` method, the entries are not removed and the container might remain in an indeterminate state.

When you call a container's `erase()` by using the output of `std::remove` but do not specify the second parameter, the call to `erase()` might lead to unexpected or undefined behavior. For instance, such a call to `erase()` removes only the first entry on the right side of the container instead of removing all of them. If `std::remove()` returns the `end()` iterator, such a malformed `erase()` results in undefined behavior.

### Fix

To remove entries from a container, use these two steps:

1. First, call `std::remove()` or `std::remove_if` to move the entries that you want to remove to the right side of the container.
2. Then, call the container's `erase()` method to remove the entries on the right side of the container.

Avoid using `std::remove()` without a following call to `erase()`. Some containers implement their own `remove()` methods. For these containers, it might be sufficient to use these `remove()` methods instead of `std::remove()`.

If you want to partition a container, use `std::partition()`.

If you use C++20, use the functions `std:erase()` and `std::erase_if()`. These functions implement the erase-remove idiom in a single call.

When calling the containers `erase()` with the output of `std::remove()`, specify the second parameter of `erase()` to avoid undefined behaviors. Generally, the second parameter of `erase()` matches the second parameter of `std::remove()`.

## Examples

### Use Erase-Remove Idiom to Remove Entries from Containers Efficiently

```
#include <vector>
#include<string>
#include <algorithm>
typedef std::string V;

void removeValues(std::vector<V> &vec, const V &value)
{
    std::remove(vec.begin(), vec.end(), value);
}
void removeValues_improper(std::vector<V> &vec, const V &value)
{
    vec.erase(std::remove(vec.begin(), vec.end(), value));
}
```

In this example, Polyspace flags improper use of the erase-remove idiom.

- In the function `removeValues`, Polyspace flags the use of `std::remove` because its output is not used. Because the output is not passed to `vec.erase()`, the entries are not erased from the vector and the vector remains in an indeterminate state.
- In the function `removeValues_improper`, Polyspace flags the improper call to `vec.erase()`. Because the call has no second parameter, `vec.erase()` might erase only the first element of the range that is returned by `std::remove()`. If `std::remove()` returns the `end()` iterator, this call to `vec.erase()` is undefined behavior.

#### Correction — Proper implementation of erase-remove idiom

To fix this defect, pass the output of `std::remove()` to `vec.erase()`. Specify a second parameter when calling `vec.erase()`. The second parameter for `vec.erase()` might be the same as the second parameter to `std::remove()`.

```
#include <vector>
#include<string>
#include <algorithm>
typedef std::string V;
void removeValues_FIXED(std::vector<V> &vec, const V &value)
{
    vec.erase(std::remove(vec.begin(), vec.end(), value), vec.end());
}
```

## Result Information

# Invalid iterator usage

Mismatched or uninitialized iterators are used in standard algorithm functions and comparison operations

## Description

This checker flags invalid use of iterators. For instance, this checker is raised when:

- Iterators from mismatched containers are compared to each other.
- Iterators from mismatched containers are passed to algorithms that expect iterators from the same container.
- Uninitialized iterators are passed to a standard algorithm function or used in a comparison operation.
- The `end()` iterator is passed as the only argument to the `vector::erase()` method.

### Risk

The preceding invalid uses of iterators might result in unexpected behavior.

- Calling standard algorithms by using mismatched or uninitialized iterators might lead to segmentation faults or undefined behaviors.
- Because mismatched iterators point to different containers, comparing them fails silently. This behavior might be unexpected and lead to bugs that are difficult to diagnose.

### Fix

The preceding invalid use of iterators might indicate typographical errors or logic errors in your code. To fix such defects, use initialized iterators from the same container in standard algorithms and comparison operations.

## Examples

### Mismatched Iterators in Standard Algorithm Function

```
#include <vector>
#include <algorithm>
#include <string>
typedef const std::vector<std::string>  VS;

bool bothHaveKey(VS& v1, VS& v2, const std::string& key)
{
    bool b1 = (std::find(v1.begin(), v2.end(), key) != v1.end());

    bool b2 = (std::find(v2.begin(), v1.end(), key) != v2.end());
    return b1 && b2;
}
```

In this example, the function `std::find` expects a first/last pair of iterators from the same container. Because this function is called by using mismatched iterators from different containers `v1` and `v2`, Polyspace flags these function calls.

#### Correction — Use Iterators from Same Container

To fix this defect, use iterators that point to the same container when calling `std::find`.

```
#include <vector>
#include <algorithm>
#include <string>
typedef const std::vector<std::string> VS;

bool bothHaveKey(VS& v1, VS& v2, const std::string& key)
{
    bool b1 = (std::find(v1.begin(), v1.end(), key) != v1.end());

    bool b2 = (std::find(v2.begin(), v2.end(), key) != v2.end());

    return b1 && b2;
}
```

### Uninitialized Iterators in Standard Algorithm Function

```
#include <vector>
#include <algorithm>
#include <string>
typedef std::vector<std::string>::iterator vs_it;
vs_it first;
vs_it last;

//first and last are uninitialized
auto findBetween(std::string key)
{
    return std::find(first, last, key); //Noncompliant
}
```

In this example, the `std::find` method is called by using uninitialized iterators `first` and `last`. Such a call might lead to undefined behaviors. Polyspace flags the call.

#### Correction — Initialize Iterators Before Use

To fix this defect, initialize the iterators before calling `std::find`.

```
#include <vector>
#include <algorithm>
#include <string>

typedef std::vector<std::string>::iterator vs_it;
std::vector<std::string> V;

vs_it first = V.begin();
vs_it last = V.end();

auto findBetween(std::string key)
{
    return std::find(first, last, key);
}
```

### Comparing Mismatched Iterators

```
#include <vector>
#include <algorithm>
#include <string>
typedef std::vector<std::string> VS;

std::string key;

bool foo(VS v1, VS v2)
{
    return std::find(v1.begin(), v1.end(), key) == v2.end();
}
```

In this example, iterators from the containers `v1` and `v2` are compared in the function `foo`. This operation always returns false, which might be unexpected. Polyspace flags the operation.

#### Correction — Compare Iterators from Same Container

To fix this defect, compare iterators from the same container.

```
#include <vector>
#include <algorithm>
#include <string>
typedef std::vector<std::string> VS;

std::string key;

bool foo(VS v1, VS v2)
{
    return std::find(v1.begin(), v1.end(), key) == v1.end();
}
```

## Result Information

# std::string_view initialized with dangling pointer

An `std::string_view` object is initialized by using an unnamed temporary object

## Description

This defect occurs when you construct an `std::string_view` object by using an unnamed temporary object.

```
std::string get();
std::string_view s = get(); // Defect
```

In the preceding code, `get()` returns a temporary string that goes out of scope after the semicolon. The `string_view` object `s` remains in scope, but it points to memory that is already released. Polyspace flags initializing `string_view` objects with such dangling pointers.

This defect is relevant for C++17 or later.

### Risk

An `std::string_view` object typically contains a pointer to a `const char` array. When you initialize an `std::string_view` object by using an unnamed temporary, the pointer in the `std::string_view` object points to the memory block containing the temporary. The unnamed temporary goes out of scope at the end of the statement where it is created, and releases the memory. The `std::string_view` object then contains a dangling pointer, which leads to bugs that are difficult to find.

### Fix

Avoid using unnamed temporaries when initializing `std::string_view` objects. Use named variables instead.

## Examples

### Avoid Initializing `std::string_view` Objects by Using Unnamed Temporaries

```
#include <string_view>
#include <string>

extern std::string getString();

extern void useStringView(std::string_view s);

void foo()
{
    std::string_view sv = getString();

    useStringView(sv);
}
```

In this example, the `std::string_view` object `sv` is initialized by the temporary object returned by `getString`. The temporary goes out of scope at the end of the initialization statement. The function `useStringView()` is called with a dangling `std::string_view`. This call might result in unexpected behavior. Polyspace raises a defect on the initialization statement.

#### Correction — Use Named Variables When Initializing `std::string_view`

To fix this defect, initialize `std::string_view` objects by using named variables.

```
#include <string_view>
#include <string>

extern std::string getString();

extern void useStringView(std::string_view s);

void foo()
{
    const std::string s = getString();
    std::string_view sv = s;
    useStringView(sv);
}
```

## Result Information

# Data Flow Defects

# Code deactivated by constant false condition

Code segment deactivated by `#if 0` directive or `if(0)` condition

## Description

This defect occurs when a block of code is deactivated using a `#if 0` directive or `if(0)` condition.

### Risk

A `#if 0` directive or `if(0)` condition is used to temporarily deactivate segments of code. If your production code contains these directives, it means that the deactivation has not been lifted before shipping the code.

### Fix

If the segment of code is present for debugging purposes only, remove the segment from production code. If the deactivation occurred by accident, remove the `#if 0` and `#endif` statements.

Often, a segment of code is deactivated for specific conditions, for instance, a specific operating system. Use macros with the `#if` directive to indicate these conditions instead of deactivating the code completely with a `#if 0` directive. For instance, GCC provides macros to detect the Windows operating system:

```
#ifdef _WIN32
   //Code deactivated for all operating systems
   //Other than 32-bit Windows
#endif
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Code Deactivated by Constant False Condition Error

```
#include<stdio.h>
int Trim_Value(int* Arr,int Size,int Cutoff)
{
    int Count=0;

    for(int i=0;i < Size;i++){
        if(Arr[i]>Cutoff){
            Arr[i]=Cutoff;
            Count++;
        }
    }

    #if 0
    /* Defect: Code Segment Deactivated */

    if(Count==0){
        printf("Values less than cutoff.");
    }
     #endif

    return Count;
}
```

In the preceding code, the `printf` statement is placed within a `#if #endif` directive. The software treats the portion within the directive as code comments and not compiled.

**Correction — Change `#if 0` to `#if 1`**

Unless you intended to deactivate the `printf` statement, one possible correction is to reactivate the block of code in the `#if #endif` directive. To reactivate the block, change `#if 0` to `#if 1`.

```
#include<stdio.h>
int Trim_Value(int* Arr,int Size,int Cutoff)
{
 int Count=0;

 for(int i=0;i < Size;i++)
     {
      if(Arr[i]>Cutoff)
            {
             Arr[i]=Cutoff;
             Count++;
            }
     }

 /* Fix: Replace #if 0 by #if 1 */
 #if 1
      if(Count==0)
           {
            printf("Values less than cutoff.");
           }
 #endif

 return Count;
}
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** off
**Command-Line Syntax:** `DEACTIVATED_CODE`
**Impact:** Low

## Version History

**Introduced in R2013b**

# Dead code

Code does not execute

## Description

This defect occurs when a block of code cannot be reached because of a condition that is always true or false. This defect excludes:

- `Code deactivated by constant false condition`, which checks for directives with compile-time constants such as `#if 0` or `if(0)`.
- `Unreachable code`, which checks for code after a control escape such as `goto`, `break`, or `return`.
- `Useless if`, which checks for if statements that are always true.

### Risk

Dead code wastes development time, memory and execution cycles. Developers have to maintain code that is not being executed. Instructions that are not executed still have to be stored and cached.

Dead code often represents legacy code that is no longer used. Cleaning up dead code periodically reduces future maintenance.

### Fix

The fix depends on the root cause of the defect. For instance, the root cause can be an error condition that is checked twice on the same execution path, making the second check redundant and the corresponding block dead code.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you see dead code from use of functions such as `isinf` and `isnan`, enable an analysis mode that takes into account non-finite values. See `Consider non finite floats (-allow-non-finite-floats)`.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Dead Code from if-Statement

```
#include <stdio.h>

int Return_From_Table(int ch){

    int table[5];

    /* Create a table */
    for(int i=0;i<=4;i++){
        table[i]=i^2+i+1;
    }

    if(table[ch]>100){ /* Defect: Condition always false */
         return 0;
    }
    return table[ch];
}
```

The maximum value in the array `table` is `4^2+4+1=21`, so the test expression `table[ch]>100` always evaluates to false. The `return 0` in the `if` statement is not executed.

#### Correction — Remove Dead Code

One possible correction is to remove the `if` condition from the code.

```
#include <stdio.h>

int Return_From_Table(int ch){

    int table[5];

    /* Create a table */
    for(int i=0;i<=4;i++){
        table[i]=i^2+i+1;
    }

    return table[ch];
}
```

### Dead Code for if with Enumerated Type

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS))
        card = UNKNOWN_SUIT;

    if (card > 7) {
        do_something(card);
    }
}
```

The type `suit` is enumerated with five options. However, the conditional expression `card > 7` always evaluates to false because `card` can be at most 5. The content in the `if` statement is not executed.

#### Correction — Change Condition

One possible correction is to change the if-condition in the code. In this correction, the 7 is changed to `HEART` to relate directly to the type of `card`.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS))
        card = UNKNOWN_SUIT;

    if (card > HEARTS) {
        do_something(card);
    }
}
```

### Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `DEAD_CODE`
**Impact:** Low

## Version History

# Infinite loop

Loop termination condition might never be satisfied

## Description

This defect occurs when a loop termination condition is never satisfied after the loop is entered.

The checker skips intentional infinite loops such as `while(1)`. Code following intentional infinite loops are flagged by the `Unreachable code` checker.

### Risk

Unintended infinite loops often indicate an error in the program logic. For instance, one of the following programming errors might have occurred:

- The loop index is never updated inside the loop.
- The loop index is updated in branches inside the loop that are unreachable.
- The loop index is updated in a way that the index never satisfies the loop termination condition.

### Fix

Fix the programming error if any. Make sure that the loop index update is reachable, and the loop index eventually acquires a value that makes the loop terminate.

If you determine that the loop termination condition is satisfied under certain circumstances (false positive), add comments to your result or code to avoid another review. See

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Loop Index Not Updated

```
void cleanArray(int* fullArray, int* finalArray, int lenFullArray, int lenfinalArray) {
    int i,j;
    for(i = 0, j = 0; i < lenFullArray; j++) {
        if(fullArray[i] >= 0 && j < lenfinalArray) {
            finalArray[j] = fullArray[i];
            j++;
        }
    }
}
```

In this example, the loop uses two indices to cycle through two arrays. The index used in the loop termination condition is never updated inside the loop, possibly because of a programming error (the other index is updated twice).

**Correction – Update Loop Index**

Make sure to update the loop index used in the loop termination condition.

```
void cleanArray(int* fullArray, int* finalArray, int lenFullArray, int lenfinalArray) {
    int i,j;
    for(i = 0, j = 0; i < lenFullArray; i++) {
        if(fullArray[i] >= 0 && j < lenfinalArray) {
            finalArray[j] = fullArray[i];
            j++;
        }
    }
}
```

### Loop Index Not Updated in Code Under Analysis

```
#include <stdint.h>

uint32_t idx;

void func(void);

void foo() {
    while(idx) {
        func();
    }
}
```

In this example, the variable `idx` is seemingly not updated in the `while` loop, leading to the detection of an infinite loop.

The issue happens because the definition of the function `func()` is not available to the Bug Finder analysis. Therefore, the analysis stubs the function and assumes that the function does not update global variables, including the variable `idx`.

### Loop Index Updated in Unreachable Branch

```
int addNTimes(int elem, int addNegative, int addPositive, int init, int final) {
    int i = init, sum = elem;
    while (i <= final) {
        if(i < 0) {
            sum += addNegative;
            i++;
        }
        else {
            sum += addPositive;
        }
    }
    return sum;
}
```

In this example, if the fourth argument `init` and the fifth argument `final` are both positive, the loop index is never updated. The loop index update occurs in the branch `if(i < 0)`, which is never reached.

Note that Bug Finder can find the issue only if you analyze the code with the fourth and fifth arguments constrained to positive values. In other words, specify the following constraints on `arg4` and `arg5`:

- **Init Mode**: `INIT`
- **Init Range**: `0..max`

See also “Specify External Constraints for Polyspace Analysis” and “External Constraints for Polyspace Analysis”.

#### Correction – Update Loop Index Outside Branches

Unless specifically needed, update loop indices outside branches of a condition. You reduce the chances of a loop being infinite because the index was not updated due to conditional logic.

```
int addNTimes(int elem, int addNegative, int addPositive, int init, int final) {
    int i = init, sum = elem;
    while (i <= final) {
        if(i < 0) {
            sum += addNegative;
        }
        else {
            sum += addPositive;
        }
        i++;
    }
    return sum;
}
```

## Result Information

# Missing return statement

Function with non-`void` return type does not return value on some paths

## Description

This defect occurs when a function does not return a value along at least one execution path. This defect does not occur if:

- The return type of the function is `void`.
- The execution path is terminated by a function that does not return the flow of execution, such as a `[[noreturn]]` function.
- If you use C version above C99 or C++. From C version C99 and above, as well as for C++, the `main` function implicitly returns a `0` if a return value is not specified.

### Risk

If a function has a non-`void` return value in its signature, it is expected to return a value. The return value of this function can be used in later computations. If the execution of the function body goes through a path where a `return` statement is missing, the function return value is indeterminate. Computations with this return value can lead to unpredictable results.

### Fix

In most cases, you can fix this defect by placing the `return` statement at the end of the function body. If your code has execution paths that do not return the flow of execution, specify them by using the attribute `[[noreturn]]`.

Alternatively, you can identify which execution paths through the function body do not have a `return` statement and add a `return` statement on those paths. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

If the analysis flags a missing `return` statement on a path where a process termination function exists, you can make the analysis aware of the process termination function using the option `-termination-functions`.

## Examples

### Missing or invalid return statement error

```
int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }
 }
/* Defect: No return value if n is not 0*/
```

If n is equal to 0, the code does not enter the if statement. Therefore, the function AddSquares does not return a value if n is 0.

#### Correction — Place Return Statement on Every Execution Path

One possible correction is to return a value in every branch of the if...else statement.

```
 int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }

   /*Fix: Place a return statement on branches of if-else */
   else
     return 0;
  }
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** MISSING_RETURN
**Impact:** Low

# Non-initialized pointer

Pointer not initialized before dereference

## Description

This defect occurs when a pointer is not assigned an address before dereference.

### Risk

Unless a pointer is explicitly assigned an address, it points to an unpredictable location.

### Fix

The fix depends on the root cause of the defect. For instance, you assigned an address to the pointer but the assignment is unreachable.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below. It is a good practice to initialize a pointer to NULL when declaring the pointer.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

If a pointer in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Non-initialized pointer error

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;
    if (prev == NULL)
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j;
    /* Defect: Writing to uninitialized pointer */

    return pi;
}
```

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not.

**Correction — Initialize Pointer on Every Execution Path**

One possible correction is to assign an address to `pi` when `prev` is not `NULL`.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
       {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
       }
    /* Fix: Initialize pi in branches of if statement  */
    else
        pi = prev;

    *pi = j;

    return pi;
}
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `NON_INIT_PTR`
**Impact:** High

# Non-initialized variable

Variable not initialized before use

## Description

This defect occurs when a variable is not initialized before its value is read.

### Risk

Unless a variable is explicitly initialized, the variable value is unpredictable. You cannot rely on the variable having a specific value.

### Fix

The fix depends on the root cause of the defect. For instance, you assigned a value to the variable but the assignment is unreachable or you assigned a value to the variable in one of two branches of a conditional statement. Fix the unreachable code or missing assignment.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below. It is a good practice to initialize a variable at declaration.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See “Extend Checkers for Initialization to Check Function Arguments Passed by Pointers”.
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Non-initialized variable error

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
    /* Defect: val does not have a value if command is not 2 */
}
```

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

#### Correction — Initialize During Declaration

One possible correction is to initialize `val` during declaration so that the initialization is not bypassed on some execution paths.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    /* Fix: Initialize val */
    int val=0;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
 }
```

`val` is assigned an initial value of 0. When `command` is not equal to 2, the function `get_sensor_value` returns this value.

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `NON_INIT_VAR`
**Impact:** High

# Partially accessed array

Array partly read or written before end of scope

## Description

This defect occurs when an array is partially read or written before the end of array scope. For arrays local to a function, the end of scope occurs when the function ends.

### Risk

A partially accessed array often indicates an omission in coding. For instance, when sorting an array using a loop, you used a number of loop iterations such that one array element is never read. The implementation can result in an array that is not fully sorted.

### Fix

The fix depends on the root cause of the defect. For instance, if the root cause is a loop with an incorrect number of iterations, change the loop bound or add a step after the loop to access the unread or unwritten elements.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Partially accessed array error

```
int Calc_Sum(void)
{
  int tab[5]={0,1,2,3,4},sum=0;
  /* Defect: tab[4] is not read */

  for (int i=0; i<4;i++) sum+=tab[i];

  return(sum);

 }
```

The array `tab` is only partially read before end of function `Calc_Sum`. While calculating `sum`, `tab[4]` is not included.

#### Correction — Access Every Array Element

One possible correction is to read every element in the array `tab`.

```
int Calc_Sum(void)
{
  int tab[5]={0,1,2,3,4},sum=0;

  /* Fix: Include tab[4] in calculating sum */
  for (int i=0; i<5;i++) sum+=tab[i];

  return(sum);

 }
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `PARTIALLY_ACCESSED_ARRAY`
**Impact:** Low

# Version History

**Introduced in R2013b**

# Pointer to non initialized value converted to const pointer

Pointer to constant assigned address that does not contain a value

## Description

This defect occurs when a pointer to a constant (`const int*`, `const char*`, etc.) is assigned an address that does not yet contain a value.

For instance:

```
int x; const int * ptr = &x;
```

### Risk

A pointer to a constant stores a value that must not be changed later in the program. If you assign the address of a non-initialized variable to the pointer, it now points to an address with garbage values for the remainder of the program.

### Fix

Initialize a variable before assigning its address to a pointer to a constant.

### Extend Checker

If a `const` pointer is initialized incorrectly only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Address of Noninitialized Variable Assigned to `const` Pointer

```
#include<stdio.h>

void Display_Parity()
 {
  int num,parity;
  const int* num_ptr = &num;
  /* Defect: Address &num does not store a value */

  printf("Enter a number\n:");
  scanf("%d",&num);

  parity=((*num_ptr)%2);
  if(parity==0)
    printf("The number is even.");
  else
    printf("The number is odd.");
 }
```

num_ptr is declared as a pointer to a constant. However the variable num does not contain a value when num_ptr is assigned the address &num.

#### Correction — Initialize Variable Before Assigning Its Address to const Pointer

One possible correction is to obtain the value of num from the user before &num is assigned to num_ptr.

```
#include<stdio.h>

void Display_Parity()
 {
  int num,parity;
  const int* num_ptr;

  printf("Enter a number\n:");
  scanf("%d",&num);

 /* Fix: Assign &num to pointer after it receives a value */
  num_ptr=&num;
  parity=((*num_ptr)%2);
  if(parity==0)
    printf("The number is even.");
  else
    printf("The number is odd.");
 }
```

The scanf statement stores a value in &num. Once the value is stored, it is legitimate to assign &num to num_ptr.

### Address of Dynamically Allocated Memory Assigned to const Pointer

```
#include <stdlib.h>

int isElementInArray(const int* arr, const int elem);
void fillArray(int *);

void createArray(int elem) {
    int* arr = (int*) malloc (100*sizeof(int));
    isElementInArray(arr, elem);
}
```

In this example, the function isElementInArray takes a pointer to a const variable as first argument. The const specifier indicates that the function intends to read and not modify the pointed values. However, the array passed to this function is not initialized. The function isElementInArray, which can only read the array elements, reads non-initialized elements.

#### Correction – Initialize Memory Before Assigning to const Pointer

Initialize dynamically allocated memory before assigning its address to a const pointer. In this example, the array initialization is done using the fillArray function.

```
#include <stdlib.h>
```

```
int isElementInArray(const int* arr, const int elem);
void fillArray(int *);

void createArray(int elem) {
    int* arr = (int*) malloc (100*sizeof(int));
    fillArray(arr);
    isElementInArray(arr, elem);
}
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `NON_INIT_PTR_CONV`
**Impact:** Medium

# Version History

**Introduced in R2013b**

# Static uncalled function

Function with static scope not called in file

## Description

This defect occurs when a `static` function is not called in the same file where it is defined.

### Risk

Uncalled functions often result from legacy code and cause unnecessary maintenance.

### Fix

If the function is not meant to be called, remove the function. If the function is meant for debugging purposes only, wrap the function definition in a debug macro.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Uncalled function error

Save the following code in the file `Initialize_Value.c`

```
#include <stdlib.h>
#include <stdio.h>

static int Initialize(void)
/* Defect: Function not called */
  {
   int input;
   printf("Enter an integer:");
   scanf("%d",&input);
   return(input);
  }

 void main()
  {
   int num;

   num=0;
   printf("The value of num is %d",num);
  }
```

The `static` function `Initialize` is not called in the file `Initialize_Value.c`.

**Correction — Call Function at Least Once**

One possible correction is to call `Initialize` at least once in the file `Initialize_Value.c`.

```
#include <stdlib.h>
#include <stdio.h>

static int Initialize(void)
  {
   int input;
   printf("Enter an integer:");
   scanf("%d",&input);
   return(input);
  }

 void main()
  {
   int num;

   /* Fix: Call static function Initialize */
   num=Initialize();

   printf("The value of num is %d",num);
  }
```

## Result Information

# Unreachable code

Code not executed because of preceding control-flow statements

## Description

This defect occurs when a section of code cannot be reached because of a previous break in control flow.

Statements such as `break`, `goto`, and `return`, move the flow of the program to another section or function. Because of this flow escape, the statements following the control-flow code, statistically, do not execute, and therefore the statements are unreachable.

This check also finds code following trivial infinite loops, such as `while(1)`. These types of loops only release the flow of the program by exiting the program. This type of exit causes code after the infinite loop to be unreachable.

### Risk

Unreachable code wastes development time, memory and execution cycles. Developers have to maintain code that is not being executed. Instructions that are not executed still have to be stored and cached.

### Fix

The fix depends on the intended functionality of the unreachable code. If you want the code to be executed, check the placement of the code or the prior statement that diverts the control flow. For instance, if the unreachable code follows a `return` statement, you might have to switch their order or remove the `return` statement altogether.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Unreachable Code After Return

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void guess(suit s);

suit deal(void){
    suit card = nextcard();
    if( (card < SPADES) || (card > CLUBS) )
        card = UNKNOWN_SUIT;
        return card;
    if (card < HEARTS) {
        guess(card);
    }
    return card;
}
```

In this example, there are missing braces and misleading indentation. The first `return` statement changes the flow of code back to where the function was called. Because of this return statement, the `if`-block and second `return` statement do not execute.

If you correct the indentation and the braces, the error becomes clearer.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void guess(suit s);

suit deal(void){
    suit card = nextcard();
    if( (card < SPADES) || (card > CLUBS) ){
        card = UNKNOWN_SUIT;
    }
    return card;

    if (card < HEARTS) {
        guess(card);
    }
    return card;
}
```

**Correction — Remove Return**

One possible correction is to remove the escape statement. In this example, remove the first `return` statement to reach the final `if` statement.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void guess(suit s);

suit deal(void){
    suit card = nextcard();
    if( (card < SPADES) || (card > CLUBS) )
    {
        card = UNKNOWN_SUIT;
    }

    if(card < HEARTS)
    {
        guess(card);
    }
    return card;
}
```

**Correction — Remove Unreachable Code**

Another possible correction is to remove the unreachable code if you do not need it. Because the function does not reach the second `if`-statement, removing it simplifies the code and does not change the program behavior.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void guess(suit s);

suit deal(void){
    suit card = nextcard();
    if( (card < SPADES) || (card > CLUBS) )
    {
        card = UNKNOWN_SUIT;
    }
    return card;
}
```

### Infinite Loop Causing Unreachable Code

```
int add_apples(int apple) {
    int count = 1;
    while(1) {
        if(apple < 99){
            apple++;
            count++;
        }else{
            count--;
        }
    }
    return count;
}
```

In this example, the `while(1)` statement creates an infinite loop. The `return count` statement following this infinite loop is unreachable because the only way to exit this infinite loop is to exit the program.

#### Correction — Rewrite Loop Condition

One possible correction is to change the loop condition to make the `while` loop finite. In the example correction here, the loop uses the statement from the `if` condition: `apple < 99`.

```
int add_apples1(int apple) {
    int count = 0;
    while(apple < 99) {
        apple++;
        count++;
    }
    if(count == 0)
        count = -1;
    return count;
}
```

#### Correction — Add a Break Statement

Another possible correction is to add a break from the infinite loop, so there is a possibility of reaching code after the infinite loop. In this example, a `break` is added to the `else` block making the `return count` statement reachable.

```
int add_apples(int apple) {
    int count = 1;
    while(1) {
        if(apple < 99)
        {
            apple++;
            count++;
        }else{
            count--;
            break;
        }
    }
    return count;
}
```

#### Correction — Remove Unreachable Code

Another possible correction is to remove the unreachable code. This correction cleans up the code and makes it easier to review and maintain. In this example, remove the return statement and change the function return type to `void`.

```
void add_apples(int apple) {
    int count = 1;
    while(1) {
        if(apple < 99)
        {
            apple++;
            count++;
        }else{
            count--;
        }
    }
}
```

### Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On
**Command-Line Syntax:** `UNREACHABLE`
**Impact:** Medium

## Version History

**Introduced in R2013b**

# Useless if

Unnecessary if conditional

## Description

This defect occurs on `if`-statements where the condition is always true. This defect occurs only on if-statements that do not have an else-statement.

This defect shows unnecessary `if`-statements when there is no difference in code execution if the `if`-statement is removed.

### Risk

Unnecessary `if` statements often indicate a coding error. Perhaps the `if` condition is coded incorrectly or the `if` statement is not required at all.

### Fix

The fix depends on the root cause of the defect. For instance, the root cause can be an error condition that is checked twice on the same execution path, making the second check redundant.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If the redundant condition represents defensive coding practices and you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### `if` with Enumerated Type

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }

    if (card < 7) {
        do_something(card);
    }
}
```

The type `suit` is enumerated with five options. However, the conditional expression `card < 7` always evaluates to true because `card` can be at most 5. The `if` statement is unnecessary.

**Correction — Change Condition**

One possible correction is to change the if-condition in the code. In this correction, the 7 is changed to `UNKNOWN_SUIT` to relate directly to the type of `card`.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }

    if (card > UNKNOWN_SUIT) {
        do_something(card);
    }
}
```

**Correction — Remove If**

Another possible correction is to remove the if-condition in the code. Because the condition is always true, you can remove the condition to simplify your code.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }

    do_something(card);
}
```

## Result Information

# Variable shadowing

Variable hides another variable of same name with nested scope

## Description

This defect occurs when a variable hides another variable of the same name in an outer scope.

For instance, if a local variable has the same name as a global variable, the local variable hides the global variable during its lifetime.

### Risk

When two variables with the same name exist in an inner and outer scope, any reference to the variable name uses the variable in the inner scope. However, a developer or reviewer might incorrectly expect that the variable in the outer scope was used.

### Fix

The fix depends on the root cause of the defect. For instance, suppose you refactor a function such that you use a local static variable in place of a global variable. In this case, the global variable is redundant and you can remove its declaration. Alternatively, if you are not sure if the global variable is used elsewhere, you can modify the name of the local static variable and all references within the function.

If the shadowing is intended and you do not want to fix the issue, add comments to your result or code to avoid another review. See

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Variable Shadowing Error

```
#include <stdio.h>

int fact[5]={1,2,6,24,120};

int factorial(int n)
 {
  int fact=1;
  /*Defect: Local variable hides global array with same name */

  for(int i=1;i<=n;i++)
    fact*=i;
  return(fact);
 }
```

Inside the `factorial` function, the integer variable `fact` hides the global integer array `fact`.

#### Correction — Change Variable Name

One possible correction is to change the name of one of the variables, preferably the one with more local scope.

```
#include <stdio.h>

int fact[5]={1,2,6,24,120};

int factorial(int n)
 {
  /* Fix: Change name of local variable */
  int f=1;

  for(int i=1;i<=n;i++)
    f*=i;

  return(f);
 }
```

### Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `VAR_SHADOWING`
**Impact:** Low

# Write without a further read

Variable never read after assignment

## Description

This defect occurs when a value assigned to a variable is never read.

For instance, you write a value to a variable and then write a second value before reading the previous value. The first write operation is redundant.

### Risk

Redundant write operations often indicate programming errors. For instance, you forgot to read the variable between two successive write operations or unintentionally read a different variable.

### Fix

Identify the reason why you write to the variable but do not read it later. Look for common programming errors such as accidentally reading a different variable with a similar name.

If you determine that the write operation is redundant, remove the operation.

## Examples

### Write Without Further Read Error

```
void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();
    /* Defect: Useless write */
}
```

After the variable `level` gets assigned the value `4 * getsensor()`, it is not read.

#### Correction — Use Value After Assignment

One possible correction is to use the variable `level` after the assignment.

```
#include <stdio.h>

void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();

    /* Fix: Use level after assignment */
    printf("The value is %d", level);

}
```

The variable `level` is printed, reading the new value.

### Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `USELESS_WRITE`
**Impact:** Low

# Useless preprocessor conditional directive

Preprocessor conditional directive is always true or always false

## Description

This defect occurs when a preprocessor conditional directive always evaluates to the same logical value. For instance, you might be testing for the condition in a previous conditional directive. Consider this code:

```
long sensorFlag;
#if cond1
  sensorFlag = 0x0001;

#elif cond2
  sensorFlag = 0x00AA;

#else
    #if cond1 //Always false
        sensorFlag = 0xFF00;
    #endif
#endif
```

In the `#else` block, the conditional directive `#if cond1` is executed only when `cond1` is false. This directive is always `false`. Polyspace flags conditional directive that always evaluates to the same logical value.

### Risk

If a conditional directive is always true or always false, it might indicate an inadvertent error. For instance, the conditional directive might be unexpectedly impacted by a change elsewhere in your code. Alternatively, your conditional directive design might contain unexpected errors. In the preceding code, the statement `#if cond1` might be a typographical error. The developer intent might have been to use `#if cond3`.

### Fix

To fix this defect, remove the flagged conditional directive. If the useless conditional is unexpected, review and refactor your code.

## Examples

### Avoid Useless Preprocessor Conditional Directives

```
#define THE_ANSWER 42

#if defined(UNIVERSE)
    #define STARS 1
    #define MILKY_WAY 1
    #if defined(UNIVERSE) // Defect
        #define SUN 1
    #endif
```

```
#else
    #define STARS 0
    #define MILKY_WAY 0

    #if defined(UNIVERSE) // Defect
        #define SUN 0
    #endif
#endif
```

In this example, Polyspace flags two useless preprocessor conditional directives.

- The conditional directive `if defined(UNIVERSE)` on line six is placed inside the conditional block that starts with the same conditional. The flagged conditional is reached only when it is always `true`. Because this conditional is always `true`, you can remove it without changing code behavior. Polyspace flags the useless preprocessor directive.
- The conditional directive `if defined(UNIVERSE)` on line 13 is reached only when the same conditional evaluates to false. Because this conditional is always false, you can remove it without changing code behavior. Polyspace flags the useless preprocessor directive.

#### Correction — Remove Useless Preprocessor Conditional Directives

To fix this defect, remove the useless conditional directives. Alternatively, redesign your code. For instance, when the token `UNIVERSE` is undefined, you might set the value of `SUN` to zero without performing another check on `UNIVERSE`.

```
#define THE_ANSWER 42

#if defined(UNIVERSE)
    #define STARS 1
    #define MILKY_WAY 1
    #define SUN 1
#else
    #define STARS 0
    #define MILKY_WAY 0
    #define SUN 0
#endif
```

## Result Information

**Group:** Data flow
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `USELESS_PREPROC_CONDITION`
**Impact:** Low

# Security Defects

# Bad order of dropping privileges

Dropped higher elevated privileges before dropping lower elevated privileges

## Description

This defect occurs when you use functions such as `setuid` and `setgid` in the incorrect order, dropping higher elevated privileges before dropping lower elevated privileges. For example, you drop elevated primary group privileges before dropping elevated ancillary group privileges.

### Risk

If you drop privileges in the wrong order, you can potentially drop higher privileges that you need to drop lower privileges. The incorrect order can mean that privileges are not dropped compromising the security of your program.

### Fix

Respect this order of dropping elevated privileges:

- Drop (elevated) ancillary group privileges, then drop (elevated) primary group privileges.
- Drop (elevated) primary group privileges, then drop (elevated) user privileges.

## Examples

### Dropping User Privileges First

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()

static void sanitize_privilege_drop_check(uid_t olduid, gid_t oldgid)
{
    if (seteuid(olduid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
    if (setegid(oldgid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
}
void badprivilegedroporder(void) {
    uid_t
        newuid = getuid(),
        olduid = geteuid();
    gid_t
```

```
        newgid = getgid(),
        oldgid = getegid();

    if (setuid(newuid) == -1) {
        /* handle error condition */
        fatal_error();
    }
    if (setgid(newgid) == -1)  {
        /* handle error condition */
        fatal_error();
    }
    if (olduid == 0) {
        /* drop ancillary groups IDs only possible for root */
        if (setgroups(1, &newgid) == -1) {
            /* handle error condition */
            fatal_error();
        }
    }

    sanitize_privilege_drop_check(olduid, oldgid);
}
```

In this example, there are two privilege drops made in the incorrect order. `setgid` attempts to drop group privileges. However, `setgid` requires the user privileges, which were dropped previously using `setuid`, to perform this function. After dropping group privileges, this function attempts to drop ancillary groups privileges by using `setgroups`. This task requires the higher primary group privileges that were dropped with `setgid`. At the end of this function, it is possible to regain group privileges because the order of dropping privileges was incorrect.

#### Correction — Reverse Privilege Drop Order

One possible correction is to drop the lowest level privileges first. In this correction, ancillary group privileges are dropped, then primary group privileges are dropped, and finally user privileges are dropped.

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()

static void sanitize_privilege_drop_check(uid_t olduid, gid_t oldgid)
{
    if (seteuid(olduid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
    if (setegid(oldgid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
}
void badprivilegedroporder(void) {
    uid_t
        newuid = getuid(),
        olduid = geteuid();
    gid_t
        newgid = getgid(),
        oldgid = getegid();

    if (olduid == 0) {
        /* drop ancillary groups IDs only possible for root */
        if (setgroups(1, &newgid) == -1) {
            /* handle error condition */
            fatal_error();
        }
    }
    if (setgid(getgid()) == -1)  {
        /* handle error condition */
        fatal_error();
    }
    if (setuid(getuid()) == -1) {
        /* handle error condition */
        fatal_error();
    }

    sanitize_privilege_drop_check(olduid, oldgid);
}
```

### Result Information

# Deterministic random output from constant seed

Seeding routine uses a constant seed making the output deterministic

## Description

This defect occurs when you use standard random number generator functions that have deterministic output given a constant seed.

The checker detects this issue with the following random number generator functions:

- C Standard Library functions such as `srand`, `srandom` and `initstate`
- OpenSSL functions such as `RAND_seed` and `RAND_add`
- C++ Standard Library functions such as `std::linear_congruential_engine<>::seed()` and `std::mersenne_twister_engine<>::seed()` (and also the constructors of these class templates)

### Risk

With constant seeds, random number generator functions produce the same output every time your program is run. A hacker can disrupt your program if they know how your program behaves.

### Fix

Use a different random standard function or use a nonconstant seed.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

## Examples

### Random Number Generator Initialization

```
#include <stdlib.h>

void random_num(void)
{
    srand(12345U);
    /* ... */
}
```

This example initializes a random number generator using `srand` with a constant seed. The random number generation is deterministic, making this function cryptographically weak.

#### Correction — Use Different Random Number Generator

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S
```

```
#include <stdlib.h>
#include <stdio.h>

unsigned int random_num_time(void)
{

    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `RAND_SEED_CONSTANT`
**Impact:** Medium

# Version History

**Introduced in R2015b**

# Errno not checked

errno is not checked for error conditions following function call

## Description

This defect occurs when you call a function that sets errno to indicate error conditions, but do not check errno after the call. For these functions, checking errno is the only reliable way to determine if an error occurred.

Functions that set errno on errors include:

- fgetwc, strtol, and wcstol.

  For a comprehensive list of functions, see documentation about errno.
- POSIX errno-setting functions such as encrypt and setkey.

### Risk

To see if the function call completed without errors, check errno for error values.

The return values of these errno-setting functions do not indicate errors. The return value can be one of the following:

- void
- Even if an error occurs, the return value can be the same as the value from a successful call. Such return values are called in-band error indicators.

You can determine if an error occurred only by checking errno.

For instance, strtol converts a string to a long integer and returns the integer. If the result of conversion overflows, the function returns LONG_MAX and sets errno to ERANGE. However, the function can also return LONG_MAX from a successful conversion. Only by checking errno can you distinguish between an error and a successful conversion.

### Fix

Before calling the function, set errno to zero.

After the function call, to see if an error occurred, compare errno to zero. Alternatively, compare errno to known error indicator values. For instance, strtol sets errno to ERANGE to indicate errors.

The error message in the Polyspace result shows the error indicator value that you can compare to.

## Examples

### errno Not Checked After Call to strtol

```
#include<stdio.h>
#include<stdlib.h>
```

```
#include<errno.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    long val = strtol(str, &endptr, base);
    printf("Return value of strtol() = %ld\n", val);
}
```

You are using the return value of `strtol` without checking `errno`.

**Correction — Check `errno` After Call**

Before calling `strtol`, set `errno` to zero . After a call to `strtol`, check the return value for `LONG_MIN` or `LONG_MAX` and `errno` for `ERANGE`.

```
#include<stdlib.h>
#include<stdio.h>
#include<errno.h>
#include<limits.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    errno = 0;
    long val = strtol(str, &endptr, base);
    if((val == LONG_MIN || val == LONG_MAX) && errno == ERANGE) {
         printf("strtol error");
         exit(EXIT_FAILURE);
    }
    printf("Return value of strtol() = %ld\n", val);
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `ERRNO_NOT_CHECKED`
**Impact:** Medium

# Version History

# Execution of a binary from a relative path can be controlled by an external actor

Command with relative path is vulnerable to malicious attack

## Description

This defect occurs when you call an external command with a relative path or without a path.

This defect also finds results that the **Execution of externally controlled command** defect checker finds.

### Risk

By using a relative path or no path to call an external command, your program uses an unsafe search process to find the command. An attacker can control the search process and replace the intended command with a command of their own.

### Fix

When you call an external command, specify the full path.

## Examples

### Call Command with Relative Path

```
# define _GNU_SOURCE
# include <sys/types.h>
# include <sys/socket.h>
# include <unistd.h>
# include <stdio.h>
# include <stdlib.h>
# include <wchar.h>
# include <string.h>
# define MAX_BUFFER 100

void rel_path()
{
    char * data;
    char data_buf[MAX_BUFFER] = "";
    data = data_buf;

    strcpy(data, "ls -la");
    FILE *pipe;
    pipe = popen(data, "wb");
    if (pipe != NULL) pclose(pipe);
}
```

In this example, Bug Finder flags `popen` because it tries to call `ls -la` using a relative path to the `ls` command. An attacker can manipulate the command to use a malicious version.

#### Correction — Use Full Path

One possible correction is to use the full path when calling the command.

```
# define _GNU_SOURCE
# include <sys/types.h>
# include <sys/socket.h>
# include <unistd.h>
# include <stdio.h>
# include <stdlib.h>
# include <wchar.h>
# include <string.h>
# define MAX_BUFFER 100

void rel_path()
{
    char * data;
    char data_buf[MAX_BUFFER] = "";
    data = data_buf;

    strcpy(data, "/usr/bin/ls -la");
    FILE *pipe;
    pipe = popen(data, "wb");
    if (pipe != NULL) pclose(pipe);
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `RELATIVE_PATH_CMD`
**Impact:** Medium

# Version History

**Introduced in R2015b**

# File access between time of check and use (TOCTOU)

File or folder might change state due to access race

## Description

This defect occurs when a race condition happens between checking the existence of a file or folder, and using the file or folder.

### Risk

An attacker can access and manipulate your file between your check for the file and your use of a file. Symbolic links are particularly risky because an attacker can change where your symbolic link points.

### Fix

Before using a file, do not check its status. Instead, use the file and check the results afterward.

## Examples

### Check File Before Using

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    if (access(log_path, W_OK)==0) {
        FILE* f = fopen(log_path, "w");
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

In this example, before opening and using the file, the function checks if the file exists. However, an attacker can change the file between the first and second lines of the function.

#### Correction — Open Then Check

One possible correction is to open the file, and then check the existence and contents afterward.

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);
```

```
void toctou(char * log_path) {
    int fd = open(log_path, O_WRONLY);
    if (fd!=-1) {
        FILE *f = fdopen(fd, "w");
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

## Result Information

# File descriptor exposure to child process

Copied file descriptor used in multiple processes

## Description

This defect occurs when a process is forked and the child process uses file descriptors inherited from the parent process.

### Risk

When you fork a child process, file descriptors are copied from the parent process, which means that you can have concurrent operations on the same file. Use of the same file descriptor in the parent and child processes can lead to race conditions that may not be caught during standard debugging. If you do not properly manage the file descriptor permissions and privileges, the file content is vulnerable to attacks targeting the child process.

### Fix

Check that the file has not been modified before forking the process. Close all inherited file descriptors and reopen them with stricter permissions and privileges, such as read-only permission.

## Examples

### File Descriptor Accessed from Forked Process

```
# include <stdio.h>
# include <stdlib.h>
# include <string.h>
# include <unistd.h>
# include <fcntl.h>
# include <sys/types.h>
# include <sys/stat.h>

const char *test_file="/home/user/test.txt";

void func(void)
{
    char c;
    pid_t pid;
    /* create file descriptor in read and write mode */
    int fd = open(test_file, O_RDWR);
    if (fd == -1)
    {
        /* Handle error */
        abort();
    }
    /* fork process */
    pid = fork();
    if (pid == -1)
    {
        /* Handle error */
        abort();
    }
    else if (pid == 0)
    {   /* Child process accesses file descriptor inherited
        from parent process */
        (void)read(fd, &c, 1);
    }
    else
    {   /* Parent process access same file descriptor as
        child process */
        (void)read(fd, &c, 1);
    }
}
```

In this example, a file descriptor `fd` is created in read and write mode. The process is then forked. The child process inherits and accesses `fd` with the same permissions as the parent process. A race condition exists between the parent and child processes. The contents of the file is vulnerable to attacks through the child process.

**Correction — Close and Reopen Inherited File Descriptor**

After you create the file descriptor, check the file for tampering. Then, close the inherited file descriptor in the child process and reopen it in read-only mode.

```
# include <stdio.h>
# include <stdlib.h>
# include <string.h>
# include <unistd.h>
# include <fcntl.h>
# include <sys/types.h>
# include <sys/stat.h>

const char *test_file="/home/user/test.txt";

void func(void)
{
    char c;
    pid_t pid;

    /* Get the state of file for further file tampering checking */

    /* create file descriptor in read and write mode */
    int fd = open(test_file, O_RDWR);
    if (fd == -1)
    {
        /* Handle error */
        abort();
    }

    /* Be sure the file was not tampered with while opening */

    /* fork process */

    pid = fork();
    if (pid == -1)
    {
        /* Handle error */
        (void)close(fd);
        abort();
    }
    else if (pid == 0)
    {  /* Close file descriptor in child process and repoen
        it in read only mode */

        (void)close(fd);
        fd = open(test_file, O_RDONLY);
        if (fd == -1)
        {
            /* Handle error */
            abort();
        }

        (void)read(fd, &c, 1);
        (void)close(fd);
    }
    else
    {  /* Parent acceses original file descriptor */
        (void)read(fd, &c, 1);
        (void)close(fd);
    }
}
```

# File manipulation after chroot() without chdir("/")

Path-related vulnerabilities for file manipulated after call to chroot

## Description

This defect occurs when you have access to a file system outside of the jail created by chroot. By calling chroot, you create a file system jail that confines access to a specific file subsystem. However, this jail is ineffective if you do not call chdir("/").

### Risk

If you do not call chdir("/") after creating a chroot jail, file manipulation functions that takes a path as an argument can access files outside of the jail. An attacker can still manipulate files outside the subsystem that you specified, making the chroot jail ineffective.

### Fix

After calling chroot, call chdir("/") to make your chroot jail more secure.

## Examples

### Open File in chroot-jail

```
#include <unistd.h>
#include <stdio.h>

const char root_path[] = "/var/ftproot";
const char log_path[] = "file.log";
FILE* chrootmisuse() {
    FILE* res;
    chroot(root_path);
    chdir("base");
    res = fopen(log_path, "r");
    return res;
}
```

This example uses chroot to create a chroot-jail. However, to use the chroot jail securely, you must call chdir("\") afterward. This example calls chdir("base"), which is not equivalent. Bug Finder also flags fopen because fopen opens a file in the vulnerable chroot-jail.

#### Correction — Call chdir("/")

Before opening files, call chdir("/").

```
#include <unistd.h>
#include <stdio.h>

const char root_path[] = "/var/ftproot";
const char log_path[] = "file.log";
FILE* chrootmisuse() {
    FILE* res;
    chroot(root_path);
    chdir("/");
    res = fopen(log_path, "r");
    return res;
}
```

### Result Information

# Function pointer assigned with absolute address

Constant expression is used as function address is vulnerable to code injection

## Description

This defect occurs when a function pointer is assigned an absolute address.

Bug Finder considers expressions with any combination of literal constants as an absolute address. The one exception is when the value of the expression is zero.

### Risk

Using a fixed address is not portable because it is possible that the address is invalid on other platforms.

An attacker can inject code at the absolute address, causing your program to execute arbitrary, possibly malicious, code.

### Fix

Do not use an absolute address with function pointers.

## Examples

### Function Pointer Address Assignment

```
extern int func0(int i, char c);
typedef int (*FuncPtr) (int, char);

FuncPtr funcptrabsoluteaddr() {
    return (FuncPtr)0x08040000;
}
```

In this example, the function returns a function pointer to the address `0x08040000`. If an attacker knows this absolute address, an attacker can compromise your program.

#### Correction — Function Address

One possible correction is to use the address of an existing function instead.

```
extern int func0(int i, char c);
typedef int (*FuncPtr) (int, char);

FuncPtr funcptrabsoluteaddr() {
    return &func0;
}
```

## Result Information

**Group:** Security
**Language:** C | C++

**Default:** Off
**Command-Line Syntax:** `FUNC_PTR_ABSOLUTE_ADDR`
**Impact:** Low

## Version History

# Hard-coded sensitive data

Sensitive data is exposed in code, for instance as string literals

## Description

This defect occurs when data that is potentially sensitive is directly exposed in the code, for instance, as string literals. The checker identifies certain data as sensitive from their use in certain functions such as password encryption functions.

Following data can be potentially sensitive.

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Host name | • sethostname, setdomainname, gethostbyname, gethostbyname2, getaddrinfo, gethostbyname_r, gethostbyname2_r (string argument)<br>• inet_aton, inet_pton, inet_net_pton, inet_addr, inet_network (string argument)<br>• mysql_real_connect, mysql_real_connect_nonblocking, mysql_connect (2nd argument) |
| Password | • CreateProcessWithLogonW, LogonUser (1st argument)<br>• mysql_real_connect, mysql_real_connect_nonblocking, mysql_connect (3rd argument) |
| Database | • MySQL: mysql_real_connect, mysql_real_connect_nonblocking, mysql_connect (4th argument)<br>• SQLite: sqlite3_open, sqlite3_open16, sqlite3_open_v2 (1st argument)<br>• PostgreSQL: PQconnectdb<br>• Microsoft SQL: SQLDriverConnect (3rd argument) |
| User name | • getpw, getpwnam, getpwnam_r, getpwuid, getpwuid_r |
| Salt | crypt, crypt_r (2nd argument) |

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Cryptography keys and initialization vectors | OpenSSL:<br>- EVP_CipherInit, EVP_EncryptInit, EVP_DecryptInit (3rd argument)<br>- EVP_CipherInit_ex, EVP_EncryptInit_ex, EVP_DecryptInit_ex (4th argument) |
| Seed | - srand, srandom, initstate (1st argument)<br>- OpenSSL: RAND_seed, RAND_add |

#### Risk

Information that is hardcoded can be queried from binaries generated from the code.

#### Fix

Avoid hard coding sensitive information.

## Examples

### Sensitive Data Exposed Through String Literals

```
// Typically, you include the header "mysql.h" with function and type declarations.
// In this example, only the required lines from the header are quoted.

typedef struct _MYSQL MYSQL;

MYSQL *mysql_real_connect(MYSQL *mysql,
                          const char *host, const char *user, const char *passwd,
                          const char *db, unsigned int port, const char *unix_socket,
                          unsigned long client_flag);

typedef void * DbHandle;
extern MYSQL *sql;

// File that uses functions from "mysql.h"
const char *host = "localhost";
char *user = "guest";
char *passwd;

DbHandle connect_to_database_server(const char *db)
{
    passwd = (char*)"guest";
    return (DbHandle)
        mysql_real_connect (sql, host, user, passwd, db, 0, 0x0, 0);
}
```

In this example, the arguments host (host name), user (user name), and passwd (password) are string literals and directly exposed in the code.

Querying the generated binary for ASCII strings can reveal this information.

#### Correction – Read Sensitive Data from Secured Configuration Files

One possible correction is to read the data from a configuration file. In the following corrected example, the call to function `connect_to_database_server_init` presumably reads the host name, user name, and password into its arguments from a secured configuration file.

```
// Typically, you include the header "mysql.h" with function and type declarations.
// In this example, only the required lines from the header are quoted.

typedef struct _MYSQL MYSQL;

MYSQL *mysql_real_connect(MYSQL *mysql,
                          const char *host, const char *user, const char *passwd,
                          const char *db, unsigned int port, const char *unix_socket,
                          unsigned long client_flag);

typedef void * DbHandle;
extern MYSQL *sql;

// File that uses functions from "mysql.h"

int connect_to_database_server_init(const char **host,
                                    const char **user,
                                    const char **passwd,
                                    const char **db);

DbHandle connect_to_database_server(const char *db)
{
    const char *host_from_cfg;
    const char *user_from_cfg;
    const char *passwd_from_cfg;
    const char *db_from_cfg;
    if (connect_to_database_server_init(&host_from_cfg,
                                        &user_from_cfg,
                                        &passwd_from_cfg,
                                        &db_from_cfg))
    {
        return (DbHandle)
            mysql_real_connect (sql, host_from_cfg, user_from_cfg,
                        passwd_from_cfg, db_from_cfg,  0, 0x0, 0);
    }
    else
        return (DbHandle)0x0;
}
```

## Result Information

# Inappropriate I/O operation on device files

Operation can result in security vulnerabilities or a system failure

## Description

This defect occurs when you do not check whether a file name parameter refers to a device file before you pass it to these functions:

- `fopen()`
- `fopen_s()`
- `freopen()`
- `remove()`
- `rename()`
- `CreateFile()`
- `CreateFileA()`
- `CreateFileW()`
- `_wfopen()`
- `_wfopen_s()`

Device files are files in a file system that provide an interface to device drivers. You can use these files to interact with devices.

**Inappropriate I/O operation on device files** does not raise a defect when:

- You use `stat` or `lstat`-family functions to check the file name parameter before calling the previously listed functions.
- You use a string comparison function to compare the file name against a list of device file names.

### Risk

Operations appropriate only for regular files but performed on device files can result in denial-of-service attacks, other security vulnerabilities, or system failures.

### Fix

Before you perform an I/O operation on a file:

- Use `stat()`, `lstat()`, or an equivalent function to check whether the file name parameter refers to a regular file.
- Use a string comparison function to compare the file name against a list of device file names.

## Examples

### Using `fopen()` Without Checking `file_name`

```
#include <stdio.h>
#include <string.h>
```

```
#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";

    if ((f = fopen(file_name, "w")) == NULL) {
        /*handle error */
    };
    /*operate on file */
}
```

In this example, `func()` operates on the file `file_name` without checking whether it is a regular file. If `file_name` is a device file, attempts to access it can result in a system failure.

**Correction — Check File with `lstat()` Before Calling `fopen()`**

One possible correction is to use `lstat()` and the `S_ISREG` macro to check whether the file is a regular file. This solution contains a `TOCTOU` race condition that can allow an attacker to modify the file after you check it but before the call to fopen(). To prevent this vulnerability, ensure that `file_name` refers to a file in a secure folder.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <sys/stat.h>

#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";
    struct stat orig_st;
    if ((lstat(file_name, &orig_st) != 0) ||
        (!S_ISREG(orig_st.st_mode))) {
        exit(0);
    }
    if ((f = fopen(file_name, "w")) == NULL) {
        /*handle error */
    };
    /*operate on file */
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INAPPROPRIATE_IO_ON_DEVICE`

# Incorrect order of network connection operations

Socket is not correctly established due to bad order of connection steps or missing steps

## Description

This defect occurs when you perform operations on a network connection at the wrong point of the connection lifecycle.

### Risk

Sending or receiving data to an incorrectly connected socket can cause unexpected behavior or disclosure of sensitive information.

If you do not connect your socket correctly or change the connection by mistake, you can send sensitive data to an unexpected port. You can also get unexpected data from an incorrect socket.

### Fix

During socket connection and communication, check the return of each call and the length of the data.

Before reading, writing, sending, or receiving information, create sockets in this order:

- For a connection-oriented server socket (SOCK_STREAM or SOCK_SEQPACKET):

  ```
  socket(...);
  bind(...);
  listen(...);
  accept(...);
  ```
- For a connectionless server socket (SOCK_DGRAM):

  ```
  socket(...);
  bind(...);
  ```
- For a client socket (connection-oriented or connectionless):

  ```
  socket(...);
  connect(...);
  ```

## Examples

### Connecting a Connection-Oriented Server Socket

```
# include <stdio.h>
# include <string.h>
# include <time.h>
# include <arpa/inet.h>
# include <unistd.h>

enum { BUF_SIZE=1025 };

volatile int rd;
```

```
int stream_socket_server(int argc, char *argv[])
{
    int listenfd = 0, connfd = 0;
    struct sockaddr_in serv_addr;

    char sendBuff[BUF_SIZE];
    time_t ticks;
    struct tm * timeinfo;

    listenfd = socket(AF_INET, SOCK_STREAM, 0);
    memset(&serv_addr, 48, sizeof(serv_addr));
    memset(sendBuff, 48, sizeof(sendBuff));

    serv_addr.sin_family = AF_INET;
    serv_addr.sin_addr.s_addr = htonl(INADDR_ANY);
    serv_addr.sin_port = htons(5000);

    bind(listenfd, (struct sockaddr*)&serv_addr, sizeof(serv_addr));

    listen(listenfd, 10);

    while(1)
    {
        connfd = accept(listenfd, (struct sockaddr*)NULL, NULL);

        ticks = time(NULL);
        timeinfo = localtime(&ticks);
        strftime (sendBuff,BUF_SIZE,"%I:%M%p.",timeinfo);

        write(listenfd, sendBuff, strlen(sendBuff));

        close(connfd);
        sleep(1);
    }
}
```

This example creates a connection-oriented network connection. The function calls the correct functions in the correct order: `socket`, `bind`, `listen`, `accept`. However, the program should write to the `connfd` socket instead of the `listenfd` socket.

**Correction — Use Safe Socket**

One possible correction is to write to the `connfd` function instead of the `listenfd` socket.

```
# include <stdio.h>
# include <string.h>
# include <time.h>
# include <arpa/inet.h>
# include <unistd.h>

enum { BUF_SIZE=1025 };

volatile int rd;

int stream_socket_server_good(int argc, char *argv[])
{
    int listenfd = 0, connfd = 0;
    struct sockaddr_in serv_addr;

    char sendBuff[BUF_SIZE];
    time_t ticks;
    struct tm * timeinfo;

    listenfd = socket(AF_INET, SOCK_STREAM, 0);
    memset(&serv_addr, 48, sizeof(serv_addr));
    memset(sendBuff, 48, sizeof(sendBuff));

    serv_addr.sin_family = AF_INET;
    serv_addr.sin_addr.s_addr = htonl(INADDR_ANY);
    serv_addr.sin_port = htons(5000);

    bind(listenfd, (struct sockaddr*)&serv_addr, sizeof(serv_addr));
    listen(listenfd, 10);

    while(1)
    {
        connfd = accept(listenfd, (struct sockaddr*)NULL, NULL);
        ticks = time(NULL);
        timeinfo = localtime(&ticks);
        strftime (sendBuff,BUF_SIZE,"%I:%M%p.",timeinfo);
        write(connfd, sendBuff, strlen(sendBuff));
        close(connfd);
        sleep(1);
    }
}
```

### Result Information

# Information leak via structure padding

Padding bytes can contain sensitive information

## Description

This defect occurs when you do not initialize the padding data of a structure or union before passing it across a trust boundary. A compiler adds padding bytes to the structure or union to ensure a proper memory alignment of its members. The bit-fields of the storage units can also have padding bits.

**Information leak via structure padding** raises a defect when:

- You call an untrusted function with structure or union pointer type argument containing uninitialized padding data.

  All external functions are considered untrusted.
- You copy or assign a structure or union containing uninitialized padding data to an untrusted object.

  All external structure or union objects, the output parameters of all externally linked functions, and the return pointer of all external functions are considered untrusted objects.

### Risk

The padding bytes of the passed structure or union might contain sensitive information that an untrusted source can access.

### Fix

- Prevent the addition of padding bytes for memory alignment by using the `pack` pragma or attribute supported by your compiler.
- Explicitly declare and initialize padding bytes as fields within the structure or union.
- Explicitly declare and initialize bit-fields corresponding to padding bits, even if you use the `pack` pragma or attribute supported by your compiler.

## Examples

### Structure with Padding Bytes Passed to External Function

```
#include <stddef.h>
#include <stdlib.h>
#include <string.h>

typedef struct s_padding
{
 /* Padding bytes may be introduced between
 * 'char c' and 'int i'
 */
        char c;
    int i;
/*Padding bits may be introduced around the bit-fields
* even if you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/

    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
/*Padding bytes not initialized*/

    S_Padding s = {'A', 10, 1, 3, {}};
/*Structure passed to external function*/

    copy_object((void *)out_buffer, (void *)&s, sizeof(s));
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

In this example, structure `s1` can have padding bytes between the `char c` and `int i` members. The bit-fields of the storage units of the structure can also contain padding bits. The content of the padding bytes and bits is accessible to an untrusted source when `s1` is passed to `func`.

**Correction — Use pack Pragma to Prevent Padding Bytes**

One possible correction in Microsoft Visual Studio is to use `#pragma pack()` to prevent padding bytes between the structure members. To prevent padding bits in the bit-fields of `s1`, explicitly declare and initialize the bit-fields even if you use `#pragma pack()`.

```
 #include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>

#define CHAR_BIT 8

#pragma pack(push, 1)

typedef struct s_padding
{
/*No Padding bytes when you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
/* Padding bits explicitely declared */
```

```
    unsigned int bf_filler : sizeof(unsigned) * CHAR_BIT - 3;
    unsigned char buffer[20];
}

    S_Padding;

#pragma pack(pop)

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
    S_Padding s = {'A', 10, 1, 3, 0 /* padding bits */, {}};
    copy_object((void *)out_buffer, (void *)&s, sizeof(s));
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `PADDING_INFO_LEAK`
**Impact:** Low

# LDAP injection

Data read from an untrusted source is used in the construction of an LDAP query

## Description

This defect occurs when data read from an untrusted source such as standard input is used in the construction of an LDAP query.

This defect checker detects the flow of data from an untrusted source to a function that constructs an LDAP query. The checker recognizes OpenLDAP search functions such as `ldap_search()`, `ldap_search_ext()`, and so on. In all search functions, the checker considers the second parameter (base) and the fourth parameter (search filter) as sensitive to untrusted inputs. Untrusted sources can include read operations on the standard input `stdin` using the `fread()` or `fgets()` function.

Note that the defect checker is not available in the Polyspace user interface and is disabled even if you select the value `all` for the option `Find defects (-checkers)`. For the issue to be detected, the checker must be enabled explicitly using the option `-checkers LDAP_INJECTION`.

### Risk

If you construct the search base or search filters in an LDAP query from user inputs but use the inputs directly in the LDAP query without any validation or sanitization, they are vulnerable to LDAP injection. A malicious user can inject unintended LDAP queries masquerading as input, which can compromise secure user information.

For instance, in this LDAP search filter, the variable *`username`* is obtained from user inputs. The search filter is vulnerable to LDAP injection.

`(&(name=`*`username`*`)(pass=`*`password`*`))`

If the user enters `*)(name=*))(|(name=*` for *`username`*, the search filter becomes:

`(&(name=*)(name=*))(|(name=*)(pass=`*`password`*`))`

The resulting search filter is trivially true and bypasses the authentication mechanism built into the search filter using the variable *`password`*.

### Fix

Validate user inputs if you use them in the construction of the search base or search filters in an LDAP query.

If you validate user inputs using dedicated functions, you can make the LDAP injection checker aware of your validation functions. Suppose that the function `ldap_validate_inputs` checks user inputs for malicious entries.

```
int ldap_validate_inputs(
     char *,    /* String to check */
     int);      /* Length of string */
```

Suppose that the *n*-th parameter of this function is the user input to validate. For instance, the first argument in the above signature could be the string to validate.

To make the LDAP injection checker aware of this function:

1. In a file with extension `.dl`, add:

   ```
   .include "models/interfaces/ldap.dl"

   Ldap.Basic.sanitizing("ldap_validate_inputs", $OutParameterDeref(n-1)).
   ```

   If *n* is 1 (that is, the first parameters of the function is the parameter of interest), then the statement becomes:

   ```
   .include "models/interfaces/ldap.dl"

   Ldap.Basic.sanitizing("ldap_validate_inputs", $OutParameterDeref(0)).
   ```
2. Specify this file using the option `-code-behavior-specifications`. For instance, if the file is named `ldapAdditionalFunctions.dl`, use the analysis option:

   ```
   -code-behavior-specifications ldapAdditionalFunctions.dl
   ```

## Examples

### LDAP Filter Created from Untrusted User Input

```
#include <stdio.h>
#include <stddef.h>
#include <sys/time.h>
#include <ldap.h>

int LDAPSearch()
{
    const char* hostName = "fabrikam.com";
    LDAP* ld;

    // Creating LDAP search parameters
    ld = ldap_open(hostName, LDAP_PORT);

    const char* base = "DC=fabrikam,DC=com";
    const int scope = LDAP_SCOPE_SUBTREE;
    char* attrs[6];
    attrs[0] = "cn";
    attrs[1] = "company";
    attrs[2] = "department";
    attrs[3] = "telephoneNumber";
    attrs[4] = "memberOf";
    attrs[5] = NULL;
    const int attrsonly = 0;

    // Creating LDAP search filter from untrusted source
    char filter[1024] = "";
    char idToSearch[512];
    char password[512];

    fread(idToSearch, sizeof(idToSearch), 1, stdin);
    fread(password, sizeof(password), 1, stdin);
```

```
    strcat(filter, "(&(uid=");
    strcat(filter, idToSearch);
    strcat(filter, ")(pass=");
    strcat(filter, password);
    strcat(filter, "))");

    // Performing LDAP search
    ldap_search(ld, base, scope, filter, attrs, attrsonly);

    return 0;
}
```

In this example, the fourth argument to `ldap_search()`, that is, the variable `filter` (representing the LDAP search filter), is constructed from untrusted user inputs. The user inputs comes from the variables `idToSearch` and `password`.

**Correction – Validate User Input Before Use in LDAP Query**

You can write your own sanitization function to validate or sanitize the input before using the input to construct an LDAP search filter. In this example, assume that the function `ldap_validate_inputs()` validates the user input and removes elements that do not belong to an allowlist.

```
#include <stdio.h>
#include <stddef.h>
#include <sys/time.h>
#include <ldap.h>

extern void ldap_validate_inputs(char* s, size_t n);

int LDAPSearch()
{
    const char* hostName = "fabrikam.com";
    LDAP* ld;

    // Creating LDAP search parameters
    ld = ldap_open(hostName, LDAP_PORT);

    const char* base = "DC=fabrikam,DC=com";
    const int scope = LDAP_SCOPE_SUBTREE;
    char* attrs[6];
    attrs[0] = "cn";
    attrs[1] = "company";
    attrs[2] = "department";
    attrs[3] = "telephoneNumber";
    attrs[4] = "memberOf";
    attrs[5] = NULL;
    const int attrsonly = 0;

    // Creating LDAP search filter from untrusted source
    char filter[1024] = "";
    char idToSearch[512];
    char password[512];

    fread(idToSearch, sizeof(idToSearch), 1, stdin);
    fread(password, sizeof(password), 1, stdin);
    strcat(filter, "(&(uid=");
    strcat(filter, idToSearch);
    strcat(filter, ")(pass=");
    strcat(filter, password);
    strcat(filter, "))");

    // Sanitize filter
    ldap_validate_inputs(filter, sizeof(filter));

    // Performing LDAP search
    ldap_search(ld, base, scope, filter, attrs, attrsonly);

    return 0;
}
```

To make the Polyspace analysis aware of the nature of your sanitization function:

1. Specify this code in a file with extension `.dl` (for instance, `sanitizeFunctions.dl`):

   ```
   .include "models/interfaces/ldap.dl"

   Ldap.Basic.sanitizing("ldap_validate_inputs", $OutParameterDeref(0)).
   ```
2. Specify this option with the analysis:

   ```
   -code-behavior-specifications sanitizeFunctions.dl
   ```

   See also `-code-behavior-specifications`.

# Load of library from a relative path can be controlled by an external actor

Library loaded with relative path is vulnerable to malicious attacks

## Description

This defect occurs when library loading routines that load an external library use a relative path or do not use a path at all.

### Risk

By using a relative path or no path to load an external library, your program uses an unsafe search process to find the library. An attacker can control the search process and replace the intended library with a library of their own.

### Fix

When you load an external library, specify the full path.

## Examples

### Open Library with Library Name

```
#include <dlfcn.h>
#include <stdlib.h>
#include <string.h>
#include <malloc.h>
#include <stdio.h>

void relative_path()
{
    dlopen("liberty.dll",RTLD_LAZY);
}
```

In this example, `dlopen` opens the `liberty` library by calling only the name of the library. However, this call to the library uses a relative path to find the library, which is unsafe.

#### Correction — Use Full Path to Library

One possible correction is to use the full path to the library when you load it into your program.

```
#include <dlfcn.h>
#include <stdlib.h>
#include <string.h>
#include <malloc.h>
#include <stdio.h>

void relative_path()
{
    dlopen("/home/my_libs/library/liberty.dll",RTLD_LAZY);
}
```

## Result Information

# Mismatch between data length and size

Data size argument is not computed from actual data length

## Description

This defect occurs when you do not check the length argument and data buffer argument of memory copying functions such as `memcpy`, `memset`, or `memmove`, to protect against buffer overflows.

### Risk

If an attacker can manipulate the data buffer or length argument, the attacker can cause buffer overflow by making the actual data size smaller than the length.

This mismatch in length allows the attacker to copy memory past the data buffer to a new location. If the extra memory contains sensitive information, the attacker can now access that data.

This defect is similar to the SSL Heartbleed bug.

### Fix

When copying or manipulating memory, compute the length argument directly from the data so that the sizes match.

## Examples

### Copy Buffer of Data

```
#include <stdlib.h>
#include <string.h>

typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    memcpy(&(beta.data[num]), os->data + 2, length);

    return(1);
}
```

This function copies the buffer `alpha` into a buffer `beta`. However, the `length` variable is not related to `data+2`.

#### Correction — Check Buffer Length

One possible correction is to check the length of your buffer against the maximum value minus 2. This check ensures that you have enough space to copy the data to the `beta` structure.

```
#include <stdlib.h>
#include <string.h>

typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    if (length<(os->max -2)) {
        memcpy(&(beta.data[num]), os->data + 2, length);
    }

    return(1);

}
```

## Result Information

# Missing case for switch condition

switch variable not covered by cases and default case is missing

## Description

This defect occurs when the switch variable can take values that are not covered by a case statement.

**Note** Bug Finder only raises a defect if the switch variable is not full range.

### Risk

If the switch variable takes a value that is not covered by a case statement, your program can have unintended behavior.

A switch-statement that makes a security decision is particularly vulnerable when all possible values are not explicitly handled. An attacker can use this situation to deviate the normal execution flow.

### Fix

It is good practice to use a default statement as a catch-all for values that are not covered by a case statement. Even if the switch variable takes an unintended value, the resulting behavior can be anticipated.

## Examples

### Missing Default Condition

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}
```

```
int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    }

    printf("Welcome!\n");
    return r;
}
```

In this example, the `enum` parameter `User` can take a value `UNKNOWN` that is not covered by a `case` statement.

#### Correction — Add a Default Condition

One possible correction is to add a default condition for possible values that are not covered by a `case` statement.

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}

int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    break;
    default:
        printf("Invalid login credentials!\n");
    }

    printf("Welcome!\n");
    return r;
}
```

## Result Information

# Misuse of readlink()

Third argument of `readlink` does not leave space for null terminator in buffer

## Description

This defect occurs when you pass a buffer size argument to `readlink()` that does not leave space for a null terminator in the buffer.

For instance:

```
ssize_t len = readlink("/usr/bin/perl", buf, sizeof(buf));
```

The third argument is exactly equal to the size of the second argument. For large enough symbolic links, this use of `readlink()` does not leave space to enter a null terminator.

### Risk

The `readlink()` function copies the content of a symbolic link (first argument) to a buffer (second argument). However, the function does not append a null terminator to the copied content. After using `readlink()`, you must explicitly add a null terminator to the buffer.

If you fill the entire buffer when using `readlink`, you do not leave space for this null terminator.

### Fix

When using the `readlink()` function, make sure that the third argument is one less than the buffer size.

Then, append a null terminator to the buffer. To determine where to add the null terminator, check the return value of `readlink()`. If the return value is -1, an error has occurred. Otherwise, the return value is the number of characters (bytes) copied.

## Examples

### Incorrect Size Argument of `readlink`

```
#include <unistd.h>

#define SIZE1024 1024

extern void display_path(const char *);

void func() {
    char buf[SIZE1024];
    ssize_t len = readlink("/usr/bin/perl", buf, sizeof(buf));
    if (len > 0) {
        buf[len - 1] = '\0';
    }
    display_path(buf);
}
```

In this example, the third argument of `readlink` is exactly the size of the buffer (second argument). If the first argument is long enough, this use of `readlink` does not leave space for the null terminator.

Also, if no characters are copied, the return value of `readlink` is 0. The following statement leads to a buffer underflow when `len` is 0.

```
buf[len - 1] = '\0';
```

**Correction — Make Sure Size Argument is One Less Than Buffer Size**

One possible correction is to make sure that the third argument of `readlink` is one less than size of the second argument.

The following corrected code also accounts for `readlink` returning 0.

```
#include <stdlib.h>
#include <unistd.h>

#define fatal_error() abort()
#define SIZE1024 1024

extern void display_path(const char *);

void func() {
    char buf[SIZE1024];
    ssize_t len = readlink("/usr/bin/perl", buf, sizeof(buf) - 1);
    if (len != -1) {
        buf[len] = '\0';
        display_path(buf);
    }
    else {
        /* Handle error */
        fatal_error();
    }
}
```

## Result Information

# Predictable random output from predictable seed

Seeding routine uses a predictable seed making the output predictable

## Description

This defect occurs when you use standard random number generator functions with a nonconstant but predictable seed. Examples of predictable seed generators are `time`, `gettimeofday`, and `getpid`.

The checker detects this issue with the following random number generator functions:

- C Standard Library functions such as `srand`, `srandom` and `initstate`
- C++ Standard Library functions such as `std::linear_congruential_engine<>::seed()` and `std::mersenne_twister_engine<>::seed()` (and also the constructors of these class templates)

### Risk

When you use predictable seed values for random number generation, your random numbers are also predictable. A hacker can disrupt your program if they know how your program behaves.

### Fix

You can use a different function to generate less predictable seeds.

You can also use a different random number generator that does not require a seed. For example, the Windows API function `rand_s` seeds itself by default. It uses information from the entire system, for example, system time, thread ids, system counter, and memory clusters. This information is more random and a user cannot access this information.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

## Examples

### Seed as an Argument

```
#include <stdlib.h>
#include <time.h>

void seed_rng(int seed)
{
    srand(seed);
}

int generate_num(void)
{
    seed_rng(time(NULL) + 3);
    /* ... */
}
```

This example uses `srand` to start the random number generator with `seed` as the seed. However, `seed` is predictable because the function `time` generates it. So, an attacker can predict the random numbers generated by `srand`.

#### Correction — Use Different Random Number Generator

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S

#include <stdlib.h>
#include <stdio.h>
#include <errno.h>

int generate_num(void)
{
    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

### Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `RAND_SEED_PREDICTABLE`
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Privilege drop not verified

Attacker can gain unintended elevated access to program

## Description

This defect occurs when you relinquish privileges using functions such as `setuid` but do not verify that the privileges were actually dropped before exiting your function.

### Risk

If privilege relinquishment fails, an attacker can regain elevated privileges and have more access to your program than intended. This security hole can cause unexpected behavior in your code if left open.

### Fix

Before the end of scope, verify that the privileges that you dropped were actually dropped.

## Examples

### Drop Privileges Within a Function

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()
extern int need_more_privileges;

void missingprivilegedropcheck()
{
    /* Code intended to run with elevated privileges */

    /* Temporarily drop elevated privileges */
    if (seteuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges */

    if (need_more_privileges) {
        /* Restore elevated privileges */
        if (seteuid(0) != 0) {
            /* Handle error */
            fatal_error();
        }
        /* Code intended to run with elevated privileges */
    }

    /* ... */
    /* Permanently drop elevated privileges */
    if (setuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges */
}
```

In this example, privileges are elevated and dropped to run code with the intended privilege level. When privileges are dropped, the privilege level before exiting the function body is not verified. A malicious attacker can regain their elevated privileges.

**Correction — Verify Privilege Drop**

One possible correction is to use `setuid` to verify that the privileges were dropped.

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()
extern int need_more_privileges;

void missingprivilegedropcheck()
{
    /* Store the privileged ID for later verification */
    uid_t privid = geteuid();

    /* Code intended to run with elevated privileges   */

    /* Temporarily drop elevated privileges */
    if (seteuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges  */

    if (need_more_privileges) {
        /* Restore elevated Privileges */
        if (seteuid(privid) != 0) {
            /* Handle error */
            fatal_error();
        }
        /* Code intended to run with elevated privileges   */
    }

    /* ... */

    /* Restore privileges if needed */
    if (geteuid() != privid) {
        if (seteuid(privid) != 0) {
            /* Handle error */
            fatal_error();
        }
    }

    /* Permanently drop privileges */
    if (setuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    if (setuid(0) != -1) {
        /* Privileges can be restored, handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges; */
}
```

### Result Information

# Returned value of a sensitive function not checked

Sensitive functions called without checking for unexpected return values and errors

## Description

This defect occurs when you call sensitive standard functions that return information about possible errors and you do one of the following:

- Ignore the return value.

  You simply do not assign the return value to a variable, or explicitly cast the return value to `void`.
- Use an output from the function (return value or argument passed by reference) without testing the return value for errors.

The checker considers a function as sensitive if the function call is prone to failure because of reasons such as:

- Exhausted system resources (for example, when allocating resources).
- Changed privileges or permissions.
- Tainted sources when reading, writing, or converting data from external sources.
- Unsupported features despite an existing API.

The checker only considers functions where the *return value* indicates if the function completed without errors.

Some of these functions can perform critical tasks such as:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

### Risk

If you do not check the return value of functions that perform sensitive tasks and indicate error information through their return values, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

### Fix

Before continuing with the program, test the return value of critical sensitive functions.

For sensitive functions that are not critical, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

## Examples

### Sensitive Function Return Ignored

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    pthread_attr_init(&attr);//Noncompliant
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r");
  return 0; //Noncompliant

}
```

This example shows calls to the sensitive POSIX functions `pthread_attr_init` and `fmemopen`. Their return values are ignored, causing defect.

#### Correction — Cast Function to (void)

One possible correction is to cast the function to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of the sensitive function.

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    (void)pthread_attr_init(&attr);//Compliant
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  (void)fmemopen (argv[1], strlen (argv[1]), "r"); //Compliant

  return 0;
}
```

#### Correction — Test Return Value

One possible correction is to test the return value of `pthread_attr_init` and `fmemopen` to check for errors.

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    int result = pthread_attr_init(&attr);//Compliant
    if(result != 0){
        //Handle fatal error
    }
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r");
  if (in==NULL){
      // Handle error
  }
  return 0;//Compliant
}
```

### Critical Function Return Ignored

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0));
    pthread_join(thread_id,  &res);
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), Polyspace does not ignore this *Return value of a sensitive function not checked* defect. The other critical function, `pthread_join`, returns value that is ignored implicitly. `pthread_join` uses the return value of `pthread_create`, which was not checked.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

### Result Information

# Sensitive data printed out

Function prints sensitive data

## Description

This defect occurs when print functions such as `stdout` or `stderr` print sensitive information.

The checker considers the following as sensitive information:

- Return values of password manipulation functions such as `getpw`, `getpwnam` or `getpwuid`.
- Input values of functions such as the Windows-specific function `LogonUser`.

### Risk

Printing sensitive information, such as passwords or user information, allows an attacker additional access to the information.

### Fix

One fix for this defect is to not print out sensitive information.

If you are saving your logfile to an external file, set the file permissions so that attackers cannot access the logfile information.

## Examples

### Printing Passwords

```
#include <sys/types.h>
#include <pwd.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

extern void verify_null(const char* buf);
void bug_sensitivedataprint(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    puts("Name\n");
    puts(pwd.pw_name);
    puts("PassWord\n");
    puts(pwd.pw_passwd);
    memset(buf, 0, sizeof(buf));
    verify_null(buf);
}
```

In this example, Bug Finder flags `puts` for printing out the password `pwd.pw_passwd`.

#### Correction — Obfuscate the Password

One possible correction is to obfuscate the password information so that the information is not visible.

```
#include <sys/types.h>
#include <pwd.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

extern void verify_null(const char* buf);

void sensitivedataprint(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    puts("Name\n");
    puts(pwd.pw_name);
    puts("PassWord\n");
    puts("XXXXXXXX\n");
    memset(buf, 0, sizeof(buf));
    verify_null(buf);
}
```

## Result Information

# Sensitive heap memory not cleared before release

Sensitive data not cleared or released by memory routine

## Description

This defect occurs when dynamically allocated memory contains sensitive data and you do not clear the data before you free the memory.

### Risk

If the memory zone is reallocated, an attacker can still inspect the sensitive data in the old memory zone.

### Fix

Before calling `free`, clear out the sensitive data using `memset` or `SecureZeroMemory`.

## Examples

### Sensitive Buffer Freed, Not Cleared

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>

void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    free(buf);
}
```

In this example, the function uses a buffer of passwords and frees the memory before the end of the function. However, the data in the memory is not cleared by using the `free` command.

#### Correction — Nullify Data

One possible correction is to write over the data to clear out the sensitive information. This example uses `memset` to write over the data with zeros.

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0;i<(sizeof(arr)/sizeof(arr[0]));i++) assert(arr[i]==0)
```

```
void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);

    if (buf) {
        getpwnam_r(my_user, &pwd, buf, bufsize, &result);
        memset(buf, 0, (size_t)1024);
        isNull(buf);
        free(buf);
    }
}
```

### Result Information

# SQL injection

Data read from an untrusted source is used in the construction of an SQL query

## Description

This defect occurs when data read from an untrusted source such as standard input is used in the construction of an SQL query.

This defect checker detects the flow of data from an untrusted source to a function that executes an SQL query (or prepares an SQL query to execute later). The checker flags functions from the following API-s:

- MySQL C API – SQL query functions such as `mysql_query()` and `mysql_real_query()`.
- SQLite API – SQL query functions such as `sqlite3_exec()` or SQL statement preparation functions such as `sqlite3_prepare()` and `sqlite3_prepare_v2()`.

Untrusted sources include strings read from the standard input `stdin` using the `fread()` or `fgets()` function or from files opened with `fopen()`.

Note that the defect checker is not available in the Polyspace user interface and is disabled even if you select the value `all` for the option `Find defects (-checkers)`. For the issue to be detected, the checker must be enabled explicitly using the option `-checkers SQL_INJECTION`.

### Risk

If you construct SQL queries from user inputs but use the inputs directly in the query construction without any sanitization, the queries are vulnerable to SQL injection. A malicious user can inject code masquerading as input, resulting in:

- Bypassing of logic that secures part of the database.
- Execution of malicious SQL queries or shell commands.

For instance, this SQL query, where the variables *`username`* and *`itemName`* are obtained from user inputs, is vulnerable to SQL injection:

```
SELECT * FROM items WHERE owner = 'userName' AND itemname = 'itemName';
```

If a malicious user enters two inputs such as `john` and `anItem' OR 'a' = 'a`, the query translates to:

```
SELECT * FROM items WHERE owner = 'john' AND itemname = 'anItem' OR 'a' = 'a';
```

The query effectively means that the `WHERE` clause is always true. This allows the user to access the entire database even if they do not have the requisite permissions.

### Fix

Depending on the API you are using, follow these sanitization approaches to sanitize user inputs before using them in SQL queries. For instance:

- MySQL C API – Escape values in the SQL query string using `mysql_real_escape_string()` or `mysql_real_escape_string_quote()`.
- SQLite API – Create parametrized queries using the functions `sqlite3_prepare_*()` with parameters and then bind the parameters using the functions `sqlite3_bind_*()`.

You can also write your own sanitization functions to validate or clean up the user input. For information on how to make the checker aware of custom sanitization functions, see the next section.

### Extend Checker

You can extend this checker by specifying your own SQL statement execution and sanitization functions.

Suppose you want to specify that:

- Function `sql_exec` executes an SQL statement or prepares an SQL statement for execution:

  ```
  int sql_exec
      (char*,           /* SQL query */
       sqlite3* ,       /* Database */
       int (*callback)(void*,int,char**,char**),
       void*,
       char**);
  ```

  Suppose the *`n_exec`*-th argument of this function is the SQL query string. For instance, the first argument in the above signature could be the SQL query string.
- Function `sql_sanitize` sanitizes the untrusted (tainted) data that is later used in an SQL statement.

  ```
  int sql_sanitize(
       char *,    /* String to sanitize */
       int);      /* Length of string */
  ```

  Suppose the *`n_sanitize`*-th argument of this function is the data string to sanitize. For instance, the first argument in the above signature could be the data to sanitize.

To make the SQL injection checker aware of these functions:

1. In a file with extension `.dl`, add this code:

   ```
   .include "models/interfaces/sql.dl"

   Sql.Basic.execution("sql_exec", $InParameterDeref(n_exec-1)).
   Sql.Basic.sanitizing("sql_sanitize", $OutParameterDeref(n_sanitize-1)).
   ```

   If *`n_exec`* and *`n_sanitize`* are both 1 (that is, the first parameters of each function are the parameters of interest), then the statements become:

   ```
   .include "models/interfaces/sql.dl"

   Sql.Basic.execution("sql_exec", $InParameterDeref(0)).
   Sql.Basic.sanitizing("sql_sanitize", $OutParameterDeref(0)).
   ```
2. Specify this file using the option `-code-behavior-specifications`. For instance, if the file is named `sqlAdditionalFunctions.dl`, use the analysis option:

   ```
   -code-behavior-specifications sqlAdditionalFunctions.dl
   ```

## Examples

### Execution of SQL Query Created from Untrusted User Input

```
#include <stdio.h>
#include <string.h>
#include <sqlite3.h>

// Function to insert names into database
void insertIntoDatabase(void)
{
    sqlite3* db;
    char query[256] = "";
    char name[256];
    char* error_message;
    int nameLength;

    sqlite3_open("userCredentials.db", &db);

    fread(name, 1, 128, stdin);

    strcat(query, "INSERT INTO privatenames (name) VALUES ('");
    strcat(query, name);
    strcat(query, "');");

    if (sqlite3_exec(db, query, NULL, NULL, &error_message))
        {
            sqlite3_free(error_message);
        }
}
```

In this example, the function `sqlite3_exec()` creates an SQL query by concatenating parts of an SQL command with a user input. The final query is the following:

```
INSERT INTO privatenames (name) VALUES ('name')
```

A malicious user can pass SQL commands inside the user input so that the overall SQL query performs additional operations (other SQL operations or shell commands). For instance, if the user passes an input like this:

```
john'); DELETE FROM privatenames;--
```

The SQL query becomes:

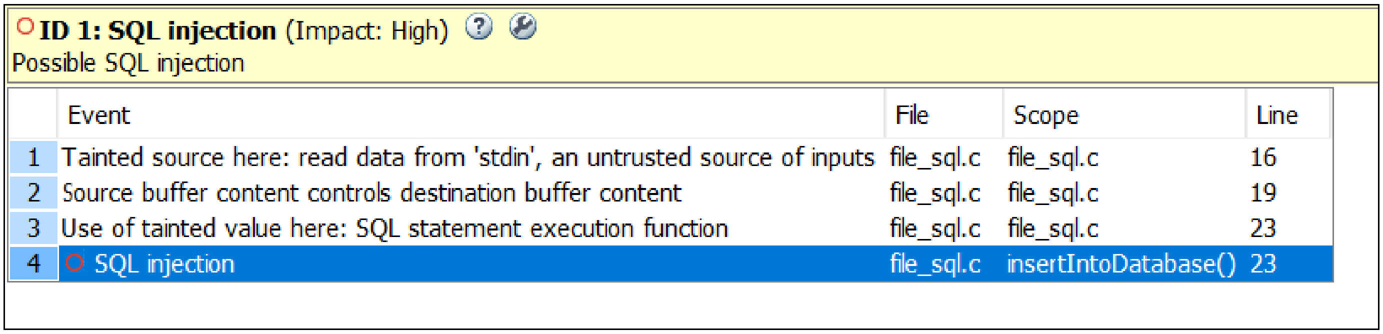
```
INSERT INTO privatenames (name) VALUES ('john');
DELETE FROM privatenames;
--');
```

The `--` results in the remainder of the line being commented out. The resulting SQL query consists of two statements: the first statement is the query that you intended and the second one results in an unintended deletion of all items from the database.

The event list on the **Result Details** pane shows how tainted data propagates into an SQL query. For instance, in this example:

- The first event points to where the tainted data is obtained.
- The second event points to where the tainted data flows to another variable.
- The third event points to where the tainted data is eventually used.

Click on an event to navigate to the corresponding location in the source code.



○ **ID 1: SQL injection** (Impact: High)

Possible SQL injection

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Tainted source here: read data from 'stdin', an untrusted source of inputs | file_sql.c | file_sql.c | 16 |
| 2 | Source buffer content controls destination buffer content | file_sql.c | file_sql.c | 19 |
| 3 | Use of tainted value here: SQL statement execution function | file_sql.c | file_sql.c | 23 |
| 4 | ○ SQL injection | file_sql.c | insertIntoDatabase() | 23 |

**Correction – Write Custom Sanitization Function**

You can write your own sanitization function to validate or sanitize the input before using the input to construct an SQL query. In this example, the function `sanitizeString()` performs some basic sanitization such as removing semicolons from the input string.

```
#include <stdio.h>
#include <string.h>
#include <sqlite3.h>

void sanitizeString(char *, int);

// Function to insert names into database
void insertIntoDatabase(void)
{
    sqlite3* db;
    char query[256] = "";
    char name[256];
    char* error_message;
    int nameLength;

    sqlite3_open("userCredentials.db", &db);

    fread(name, 1, 128, stdin);

    nameLength = sizeof(name)/sizeof(char);
    sanitizeString(name, nameLength);

    strcat(query, "INSERT INTO privatenames (name) VALUES (");
    strcat(query, name);
    strcat(query, ");");

    if (sqlite3_exec(db, query, NULL, NULL, &error_message))
        {
            sqlite3_free(error_message);
        }
}
```

```
void sanitizeString(char *name, int len)
{
    for (int i = 0; i < len; i++)
        {
            // Remove semicolons
            if(name[i] == ';')
                {
                    name[i] = ' ';
                }
            // Other sanitization of string
        }
}
```

To make the Polyspace analysis aware of the nature of your sanitization function:

1 Specify this code in a file with extension `.dl` (for instance, `sanitizeFunctions.dl`):

   ```
   .include "models/interfaces/sql.dl"

   Sql.Basic.sanitizing("sanitizeString", $OutParameterDeref(0)).
   ```

2 Specify this option with the analysis:

   ```
   -code-behavior-specifications sanitizeFunctions.dl
   ```

   See also `-code-behavior-specifications`.

# Umask used with chmod-style arguments

Argument to umask allows external user too much control

## Description

This defect occurs when umask commands have arguments specified in the style of arguments to chmod and provide possibly unintended permissions. For instance:

- The umask command provides more permissions to the group than the current user.
- The umask command provides more permissions to other users than the group.

For new files, the umask argument or the mask value specifies which permissions *not* to set, in other words, which permissions to remove. The mask is bitwise-negated and then applied to new file permissions. In contrast, chmod sets the permissions as you specify them.

### Risk

If you use chmod-style arguments, you specify opposite permissions of what you want. This mistake can give external users unintended read/write access to new files and folders.

### Fix

To fix this defect, perform both of these tasks:

- Enable read permission for the user.
- Set the mask value so that the user (u) has equal or fewer permissions turned off than the group (g) and the group has equal or fewer permissions turned off than other users (o), or u <= g <= o.

You can see the umask value by calling,

```
umask
```

or the symbolic value by calling,

```
umask -S
```

## Examples

### Setting the Default Mask

```
#include <stdio.h>
#include <assert.h>
#include <sys/types.h>
#include <sys/stat.h>

typedef mode_t (*umask_func)(mode_t);

const mode_t default_mode = (
    S_IRUSR    /* 00400 */
    | S_IWUSR  /* 00200 */
    | S_IRGRP  /* 00040 */
    | S_IWGRP  /* 00020 */
    | S_IROTH  /* 00004 */
    | S_IWOTH  /* 00002 */
    );         /* 00666 (i.e. -rw-rw-rw-) */

static void my_umask(mode_t mode)
{
    umask(mode);
}

int umask_use(mode_t m)
{
    my_umask(default_mode);
    return 0;
}
```

This example uses a function called `my_umask` to set the default mask mode. However, the `default_mode` variable gives the permissions 666 or `-rw-rw-rw`. `umask` negates this value. However, this negation means the default mask mode turns off read/write permissions for the user, group users, and other outside users.

#### Correction — Negate Preferred Permissions

One possible correction is to negate the `default_mode` argument to `my_umask`. This correction nullifies the negation `umask` for new files.

```
#include <stdio.h>
#include <assert.h>
#include <sys/types.h>
#include <sys/stat.h>

typedef mode_t (*umask_func)(mode_t);

const mode_t default_mode = (
    S_IRUSR    /* 00400 */
    | S_IWUSR  /* 00200 */
    | S_IRGRP  /* 00040 */
    | S_IWGRP  /* 00020 */
    | S_IROTH  /* 00004 */
    | S_IWOTH  /* 00002 */
    );         /* 00666 (i.e. -rw-rw-rw-) */

static void my_umask(mode_t mode)
{
    umask(mode);
}

int umask_use(mode_t m)
{
    my_umask(~default_mode);
    return 0;
}
```

## Result Information

**Group:** Security

# Uncleared sensitive data in stack

Variable in stack is not cleared and contains sensitive data

## Description

This defect occurs when statically allocated memory contains sensitive data and you do not clear the data before exiting a function or program.

### Risk

Leaving sensitive information in your stack, such as passwords or user information, allows an attacker additional access to the information after your program has ended.

### Fix

Before exiting a function or program, clear out the memory zones that contain sensitive data by using `memset` or `SecureZeroMemory`.

## Examples

### Static Buffer of Password Information

```
#include <unistd.h>
#include <sys/types.h>
#include <pwd.h>

void bug_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
}
```

In this example, a static buffer is filled with password information. The program frees the stack memory at the end of the program. However, the data is still accessible from the memory.

#### Correction — Clear Memory

One possible correction is to write over the memory before exiting the function. This example uses `memset` to clear the data from the buffer memory.

```
#include <unistd.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0;i<(sizeof(arr)/sizeof(arr[0]));i++) assert(arr[i]==0)

void corrected_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    memset(buf, 0, (size_t)1024);
    isNull(buf);
}
```

### Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `SENSITIVE_STACK_NOT_CLEARED`
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Unsafe call to a system function

Unsanitized command argument has exploitable vulnerabilities

## Description

This defect occurs when you use a function that invokes an implementation-defined command processor. These functions include:

- The C standard `system()` function.
- The POSIX `popen()` function.
- The Windows `_popen()` and `_wpopen()` functions.

### Risk

If the argument of a function that invokes a command processor is not sanitized, it can cause exploitable vulnerabilities. An attacker can execute arbitrary commands or read and modify data anywhere on the system.

### Fix

Do not use a `system`-family function to invoke a command processor. Instead, use safer functions such as POSIX `execve()` and WinAPI `CreateProcess()`.

## Examples

### `system()` Called

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
    char buf[SIZE512];
    int retval=sprintf(buf, "/usr/bin/any_cmd %s", arg);

    if (retval<=0 || retval>SIZE512){
        /* Handle error */
        abort();
    }
    /* Use of system() to pass any_cmd with
    unsanitized argument to command processor */

    if (system(buf) == -1) {
    /* Handle error */
```

```
  }
}
```

In this example, `system()` passes its argument to the host environment for the command processor to execute. This code is vulnerable to an attack by command-injection.

#### Correction — Sanitize Argument and Use execve()

In the following code, the argument of `any_cmd` is sanitized, and then passed to `execve()` for execution. `exec`-family functions are not vulnerable to command-injection attacks.

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
  char *const args[SIZE3] = {"any_cmd", arg, NULL};
  char  *const env[] = {NULL};

  /* Sanitize argument */

  /* Use execve() to execute any_cmd. */

  if (execve("/usr/bin/time", args, env) == -1) {
    /* Handle error */
  }
}
```

## Result Information

# Unsafe standard encryption function

Function is not reentrant or uses a risky encryption algorithm

## Description

This defect occurs when a standard encryption function uses a broken or weak cryptographic algorithm. For example, `crypt` is not reentrant and is based on the risky Data Encryption Standard (DES).

### Risk

The use of a broken, weak, or nonstandard algorithm can expose sensitive information to an attacker. A determined hacker can access the protected data using various techniques.

If the weak function is nonreentrant, when you use the function in concurrent programs, there is an additional race condition risk.

### Fix

Avoid functions that use these encryption algorithms. Instead, use a reentrant function that uses a stronger encryption algorithm.

**Note** Some implementations of `crypt` support additional, possibly more secure, encryption algorithms.

## Examples

### Decrypting Password Using `crypt`

```
#define _GNU_SOURCE
#include <pwd.h>
#include <string.h>
#include <crypt.h>

volatile int rd = 1;

const char *salt = NULL;
struct crypt_data input, output;

int verif_pwd(const char *pwd, const char *cipher_pwd, int safe)
{
    int r = 0;
    char *decrypted_pwd = NULL;

    switch(safe)
    {
      case 1:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;
      case 2:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      default:
        decrypted_pwd = crypt(pwd, cipher_pwd);
        break;
    }

    r = (strcmp(cipher_pwd, decrypted_pwd) == 0);

    return r;
}
```

In this example, `crypt_r` and `crypt` decrypt a password. However, `crypt` is nonreentrant and uses the unsafe Data Encryption Standard algorithm.

**Correction — Use `crypt_r`**

One possible correction is to replace `crypt` with `crypt_r`.

```
#define _GNU_SOURCE
#include <pwd.h>
#include <string.h>
#include <crypt.h>

volatile int rd = 1;

const char *salt = NULL;
struct crypt_data input, output;

int verif_pwd(const char *pwd, const char *cipher_pwd, int safe)
{
    int r = 0;
    char *decrypted_pwd = NULL;

    switch(safe)
    {
      case 1:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      case 2:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      default:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;
    }

    r = (strcmp(cipher_pwd, decrypted_pwd) == 0);

    return r;
}
```

## Result Information

# Unsafe standard function

Function unsafe for security-related purposes

## Description

This defect occurs when you use standard functions that are unsafe and must not be used for security-related programming. Functions can be unsafe for many reasons. Some functions are unsafe because they are nonreentrant. Other functions change behavior depending on the target or platform, making some implementations unsafe.

### Risk

Some unsafe functions are not reentrant, meaning that the contents of the function are not locked during a call. So, an attacker can change the values midstream.

`getlogin` specifically can be unsafe depending on the implementation. Some implementations of `getlogin` return only the first eight characters of a log-in name. An attacker can use a different login with the same first eight characters to gain entry and manipulate the program.

### Fix

Avoid unsafe functions for security-related purposes. If you cannot avoid unsafe functions, use a safer version of the function instead. For `getlogin`, use `getlogin_r`.

## Examples

### Using `getlogin`

```
#include <stdio.h>
#include <unistd.h>
#include <sys/types.h>
#include <pwd.h>
#include <string.h>
#include <stdlib.h>

volatile int rd = 1;

int login_name_check(char *user)
{
    int r = -2;
    char *name = getlogin();
    if (name != NULL)
    {
        if (strcmp(name, user) == 0)
        {
            r = 0;
        }
        else
            r = -1;
    }
    return r;
}
```

This example uses getlogin to compare the user name of the current user to the given user name . However, getlogin can return something other than the current user name because a parallel process can change the string.

#### Correction — Use getlogin_r

One possible correction is to use getlogin_r instead of getlogin. getlogin_r is reentrant, so you can trust the result.

```
#define _POSIX_C_SOURCE 199506L // use of getlogin_r
#include <stdio.h>
#include <unistd.h>
#include <sys/types.h>
#include <pwd.h>
#include <string.h>
#include <stdlib.h>

volatile int rd = 1;

enum {  NAME_MAX_SIZE=64  };

int login_name_check(char *user)
{
    int r;
    char name[NAME_MAX_SIZE];

    if (getlogin_r(name, sizeof(name)) == 0)
    {
        if ((strlen(user) < sizeof(name)) &&
                     (strncmp(name, user, strlen(user)) == 0))
        {
            r = 0;
        }
        else
            r = -1;
    }
    else
        r = -2;
    return r;
}
```

## Result Information

# Use of dangerous standard function

Dangerous functions cause possible buffer overflow in destination buffer

## Description

This issue occurs when your code uses standard functions that write data to a buffer in a way that can result in buffer overflows.

The following table lists dangerous standard functions, the risks of using each function, and what function to use instead. The checker flags:

- Any use of an inherently dangerous function.
- An use of a possibly dangerous function only if the size of the buffer to which data is written can be determined at compile time. The checker does not flag an use of such a function with a dynamically allocated buffer.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `std::cin::operator>>` and `std::wcin::operator>>` | Inherently dangerous — You cannot control the length of input from the console. | Preface calls to `cin` by `cin.width` to control the input length. This method can result in truncated input.<br>To avoid potential buffer overflow and truncated input, use `std::string` objects as destinations for >> operator. |
| `strcpy` | Possibly dangerous — If the size of the destination buffer is too small to accommodate the source buffer and a null terminator, a buffer overflow might occur. | Use the function `strlen()` to determine the size of the source buffer, and allocate sufficient memory so that the destination buffer can accommodate the source buffer and a null terminator. Instead of `strcpy`, use the function `strncpy`. |
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| lstrcat or StrCat | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | StringCbCat, StringCchCat, strncay, strcat_s, or strlcat |
| wcpcpy | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | wcpncpy |
| wcscat | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | wcsncat, wcslcat, or wcncat_s |
| wcscpy | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | wcsncpy |
| sprintf | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | snprintf |
| vsprintf | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | vsnprintf |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Using sprintf

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
```

```
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

**Correction — Use `snprintf` with Buffer Size**

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Destination Buffer Too Small

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[128];
  strcpy(source, destination);

  return 0;
}
```

### Correction — Allocate Sufficient Memory for Destination

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char* destination = (char *)malloc(strlen(source)+ 1);
  if(destination!=NULL){
      strncpy(source, destination,sizeof(source));//No defect
  }else{
      /*Handle Error*/
  }
  //...
  free(destination);
  return 0;
}
```

## Result Information

# Use of non-secure temporary file

Temporary generated file name not secure

## Description

This defect occurs when you use temporary file routines that are not secure.

### Risk

If an attacker guesses the file name generated by a standard temporary file routine, the attacker can:

- Cause a race condition when you generate the file name.
- Precreate a file of the same name, filled with malicious content. If your program reads the file, the attacker's file can inject the malicious code.
- Create a symbolic link to a file storing sensitive data. When your program writes to the temporary file, the sensitive data is deleted.

### Fix

To create temporary files, use a more secure standard temporary file routine, such as `mkstemp` from POSIX.1-2001.

Also, when creating temporary files with routines that allow flags, such as `mkostemp`, use the exclusion flag `O_EXCL` to avoid race conditions.

## Examples

### Temp File Created With `tempnam`

```
#define _BSD_SOURCE
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

int test_temp()
{
    char tpl[] = "abcXXXXXX";
    char suff_tpl[] = "abcXXXXXXsuff";
    char *filename = NULL;
    int fd;

    filename = tempnam("/var/tmp", "foo_");

    if (filename != NULL)
    {
        printf("generated tmp name (%s) in (%s:%s:%s)\n",
               filename, getenv("TMPDIR") ? getenv("TMPDIR") : "$TMPDIR",
               "/var/tmp", P_tmpdir);

        fd = open(filename, O_CREAT, S_IRWXU|S_IRUSR);
        if (fd != -1)
        {
            close(fd);
            unlink(filename);
            return 1;
        }
    }
    return 0;
}
```

In this example, Bug Finder flags `open` because it tries to use an unsecure temporary file. The file is opened without exclusive privileges. An attacker can access the file causing various risks on page 13-84.

#### Correction — Add O_EXCL Flag

One possible correction is to add the `O_EXCL` flag when you open the temporary file.

```
#define _BSD_SOURCE
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

int test_temp()
{
    char tpl[] = "abcXXXXXX";
    char suff_tpl[] = "abcXXXXXXsuff";
    char *filename = NULL;
    int fd;

    filename = tempnam("/var/tmp", "foo_");

    if (filename != NULL)
    {
        printf("generated tmp name (%s) in (%s:%s:%s)\n",
               filename, getenv("TMPDIR") ? getenv("TMPDIR") : "$TMPDIR",
               "/var/tmp", P_tmpdir);

        fd = open(filename, O_CREAT|O_EXCL, S_IRWXU|S_IRUSR);
        if (fd != -1)
        {
            close(fd);
            unlink(filename);
            return 1;
        }
    }
    return 0;
}
```

## Result Information

**Group:** Security  
**Language:** C | C++  
**Default:** Off  
**Command-Line Syntax:** `NON_SECURE_TEMP_FILE`  
**Impact:** High

# Use of obsolete standard function

Obsolete routines can cause security vulnerabilities and portability issues

## Description

This defect occurs when you use standard function routines that are considered legacy, removed, deprecated, or obsolete by C/C++ coding standards.

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `asctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |
| `asctime_r` | Deprecated in POSIX.1-2008 | Implementation based on unsafe function `sprintf`. | `strftime` or `asctime_s` |
| `bcmp` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcmp` |
| `bcopy` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcpy` or `memmove` |
| `brk` and `sbrk` | Marked as legacy in SUSv2 and POSIX.1-2001. | | `malloc` |
| `bsd_signal` | Removed in POSIX.1-2008 | | `sigaction` |
| `bzero` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | `memset` |
| `ctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |
| `ctime_r` | Deprecated in POSIX.1-2008 | Implementation based on unsafe function `sprintf`. | `strftime` or `asctime_s` |
| `cuserid` | Removed in POSIX.1-2001. | Not reentrant. Precise functionality not standardized causing portability issues. | `getpwuid` |
| `ecvt` and `fcvt` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | Not reentrant | `snprintf` |
| `ecvt_r` and `fcvt_r` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | | `snprintf` |
| `ftime` | Removed in POSIX.1-2008 | | `time`, `gettimeofday`, `clock_gettime` |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| gamma, gammaf, gammal | Function not specified in any standard because of historical variations | Portability issues. | tgamma, lgamma |
| gcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | snprintf |
| getcontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| getdtablesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_OPEN _MAX ) |
| gethostbyaddr | Removed in POSIX.1-2008 | Not reentrant | getaddrinfo |
| gethostbyname | Removed in POSIX.1-2008 | Not reentrant | getnameinfo |
| getpagesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_PAGE SIZE ) |
| getpass | Removed in POSIX.1-2001. | Not reentrant. | getpwuid |
| getw | Not present in POSIX.1-2001. | | fread |
| getwd | Marked legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | getcwd |
| index | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strchr |
| makecontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| memalign | Appears in SunOS 4.1.3. Not in 4.4 BSD or POSIX.1-2001 | | posix_memalign |
| mktemp | Removed in POSIX.1-2008. | Generated names are predictable and can cause a race condition. | mkstemp removes race risk |
| pthread_attr_ getstackaddr and pthread_attr_ setstackaddr | | Ambiguities in the specification of the stackaddr attribute cause portability issues | pthread_attr_ getstack and pthread_attr_ setstack |
| putw | Not present in POSIX.1-2001. | Portability issues. | fwrite |
| qecvt and qfcvt | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| qecvt_r and qfcvt_r | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| rand_r | Marked as obsolete in POSIX.1-2008 | | |
| re_comp | BSD API function | Portability issues | regcomp |
| re_exes | BSD API function | Portability issues | regexec |
| rindex | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strrchr |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| scalb | Removed in POSIX.1-2008 | | scalbln, scalblnf, or scalblnl |
| sigblock | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigsetmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigstack | Interface is obsolete and not implemented on most platforms. | Portability issues. | sigaltstack |
| sigvec | 4.3BSD signal API whose origin is unclear | | sigaction |
| swapcontext | Removed in POSIX.1-2008 | Portability issues. | Use POSIX threads. |
| tmpnam and tmpnam_r | Marked as obsolete in POSIX.1-2008. | This function generates a different string each time it is called, up to TMP_MAX times. If it is called more than TMP_MAX times, the behavior is implementation-defined. | mkstemp, tmpfile |
| ttyslot | Removed in POSIX.1-2001. | | |
| ualarm | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | Errors are under-specified | setitimer or POSIX timer_create |
| usleep | Removed in POSIX.1-2008. | | nanosleep |
| utime | SVr4, POSIX.1-2001. POSIX.1-2008 marks as obsolete. | | |
| valloc | Marked as obsolete in 4.3BSD.<br>Marked as legacy in SUSv2.<br>Removed from POSIX.1-2001 | | posix_memalign |
| vfork | Removed from POSIX.1-2008 | Under-specified in previous standards. | fork |
| wcswcs | This function was not included in the final ISO/IEC 9899:1990/ Amendment 1:1995 (E). | | wcsstr |
| WinExec | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |
| LoadModule | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |

#### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

## Examples

### Printing Out Time

```
#include <stdio.h>
#include <time.h>

void timecheck_bad(int argc, char *argv[])
{
    time_t ticks;

    ticks = time(NULL);
    printf("%.24s\r\n", ctime(&ticks));
}
```

In this example, the function `ctime` formats the current time and prints it out. However, `ctime` was removed after C99 because it does not work on multithreaded programs.

#### Correction — Different Time Function

One possible correction is to use `strftime` instead because this function uses a set buffer size.

```
#include <stdio.h>
#include <string.h>
#include <time.h>

void timecheck_good(int argc, char *argv[])
{
    char outBuff[1025];
    time_t ticks;
    struct tm * timeinfo;

    memset(outBuff, 0, sizeof(outBuff));

    ticks = time(NULL);
    timeinfo = localtime(&ticks);
    strftime(outBuff,sizeof(outBuff),"%I:%M%p.",timeinfo);
    fprintf(stdout, outBuff);
}
```

# Vulnerable path manipulation

Path argument with `/../`, `/abs/path/`, or other unsecure elements

## Description

This defect occurs when you create a relative or absolute path from a tainted source and you then use the path to open/create files.

### Risk

Relative path elements, such as `".."` can resolve to locations outside the intended folder. Absolute path elements, such as `"/abs/path"` can also resolve to locations outside the intended folder.

An attacker can use these types of path traversal elements to traverse to the rest of the file system and access other files or folders.

### Fix

Avoid vulnerable path traversal elements such as `/../` and `/abs/path/`. Use fixed file names and locations wherever possible.

## Examples

### Relative Path Traversal

```
# include <stdio.h>
# include <string.h>
# include <wchar.h>
# include <sys/types.h>
# include <sys/stat.h>
# include <fcntl.h>
# include <unistd.h>
# include <stdlib.h>
# define BASEPATH "/tmp/"
# define FILENAME_MAX 512

static void Relative_Path_Traversal(void)
{
    char * data;
    char data_buf[FILENAME_MAX] = BASEPATH;
    char sub_buf[FILENAME_MAX];

    if (fgets(sub_buf, FILENAME_MAX, stdin) == NULL) exit (1);
    data = data_buf;
    strcat(data, sub_buf);

    FILE *file = NULL;
    file = fopen(data, "wb+");
    if (file != NULL) fclose(file);
}
```

```
int path_call(void){
    Relative_Path_Traversal();
}
```

This example opens a file from `"/tmp/"`, but uses a relative path to the file. An external user can manipulate this relative path when `fopen` opens the file.

**Correction — Use Fixed File Name**

One possible correction is to use a fixed file name instead of a relative path. This example uses `file.txt`.

```
# include <stdio.h>
# include <string.h>
# include <wchar.h>
# include <sys/types.h>
# include <sys/stat.h>
# include <fcntl.h>
# include <unistd.h>
# include <stdlib.h>
# define BASEPATH "/tmp/"
# define FILENAME_MAX 512

static void Relative_Path_Traversal(void)
{
    char * data;
    char data_buf[FILENAME_MAX] = BASEPATH;
    data = data_buf;

    /* FIX: Use a fixed file name */
    strcat(data, "file.txt");
    FILE *file = NULL;
    file = fopen(data, "wb+");
    if (file != NULL) fclose(file);
}

int path_call(void){
    Relative_Path_Traversal();
}
```

## Result Information

# Vulnerable permission assignments

Argument gives read/write/search permissions to external users

## Description

This defect occurs when functions that can change resource permissions, such as `chmod`, `umask`, `creat`, or `open`, specify permissions that allow unintended actors to modify or read the resource.

### Risk

If you give outside users or outside groups a wider range or permissions than required, you potentially expose your sensitive information and your modifications. This defect is especially dangerous for permissions related to:

- Program configurations
- Program executions
- Sensitive user data

### Fix

Set your permissions so that the user (`u`) has more permissions than the group (`g`), and so the group has more permissions than other users (`o`), or `u >= g >= o`.

## Examples

### Create File with Other Permissions

```
#include <unistd.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

void bug_dangerouspermissions(const char * log_path) {
    mode_t mode = S_IROTH | S_IXOTH | S_IWOTH;
    int fd = creat(log_path, mode);

    if (fd) {
        write(fd, "Hello\n", 6);
    }
    close(fd);
    unlink(log_path);
}
```

In this example, the `log_path` file is created with more rights for the other outside users, than the current user. The permissions are `---------rwx`.

#### Correction — Modify User Permissions

One possible correction is to modify the user permissions for the file. In this correction, the user has read/write/execute permissions, but other users do not.

```
#include <unistd.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

void corrected_dangerouspermissions(const char * log_path) {
    mode_t mode = S_IRUSR | S_IXUSR | S_IWUSR;
    int fd = creat(log_path, mode);

    if (fd) {
        write(fd, "Hello\n", 6);
    }
    close(fd);
    unlink(log_path);
}
```

### Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `DANGEROUS_PERMISSIONS`
**Impact:** Medium

# Vulnerable pseudo-random number generator

Using a cryptographically weak pseudo-random number generator

## Description

This defect occurs when you use cryptographically weak pseudo-random number generator (PRNG) routines.

The list of cryptographically weak routines flagged by this checker include:

- `rand`, `random`
- `drand48`, `lrand48`, `mrand48`, `erand48`, `nrand48`, `jrand48`, and their `_r` equivalents such as `drand48_r`
- `RAND_pseudo_bytes`

### Risk

These cryptographically weak routines are predictable and must not be used for security purposes. When a predictable random value controls the execution flow, your program is vulnerable to malicious attacks.

### Fix

Use more cryptographically sound random number generators, such as `CryptGenRandom` (Windows), `OpenSSL/RAND_bytes`(Linux/UNIX).

## Examples

### Random Loop Numbers

```
#include <stdio.h>
#include <stdlib.h>

volatile int rd = 1;
int main(int argc, char *argv[])
{
    int j, r, nloops;
    struct random_data buf;
    int i = 0;

    nloops = rand();

    for (j = 0; j < nloops; j++) {
        if (random_r(&buf, &i))
            exit(1);
        printf("random_r: %ld\n", (long)i);
    }
    return 0;
}
```

This example uses rand and random_r to generate random numbers. If you use these functions for security purposes, these PRNGs can be the source of malicious attacks.

#### Correction — Use Stronger PRNG

One possible correction is to replace the vulnerable PRNG with a stronger random number generator.

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/rand.h>

volatile int rd = 1;
int main(int argc, char* argv[])
{
    int j, r, nloops;
    unsigned char buf;
    unsigned int seed;
    int i = 0;

    if (argc != 3)
    {
        fprintf(stderr, "Usage: %s <seed> <nloops>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    seed = atoi(argv[1]);
    nloops = atoi(argv[2]);

    for (j = 0; j < nloops; j++) {
        if (RAND_bytes(&buf, i) != 1)
            exit(1);
        printf("RAND_bytes: %u\n", (unsigned)buf);
    }
    return 0;
}
```

### Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** VULNERABLE_PRNG
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Critical data member is not private

A critical data member is declared `public`

## Description

This defect occurs when you declare a critical nonstatic data member of a class to be `public`. By default, Polyspace assumes that no data member is critical. Specify the critical data members in your code by using the code behavior `CRITICAL_DATA`. See “Specifying Critical Data Members”. If you do not specify any critical data members, Polyspace raises a warning during the analysis.

### Risk

Declaring the critical data members as `public` allows the clients of a class to modify critical data members. You can inadvertently introduce vulnerabilities when critical data members are public. The vulnerabilities of such code are difficult to find and time-consuming to fix.

### Fix

To fix this defect, determine which data members are critical and declare them as `private` or `protected`.

## Examples

### Declare Critical Data Members as Private

```
#include <string.h>
#define MAX_PASSWORD_LENGTH 15
#define MAX_USERNAME_LENGTH 15

class UserAccount
{
public:
  UserAccount(char *username, char *password)
  {
    //...
  }

  int authorizeAccess(char *username, char *password)
  {
    //...
  }

  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

In this example, the data members `username` and `password` are declared as `public`. Specify these variables as critical in a code behavior XML file:

```
<specifications>
   <members>
```

```
    <member name="password" kind="variable">
        <behavior name="CRITICAL_DATA"/>
    </member>
    <member name="username" kind="variable">
        <behavior name="CRITICAL_DATA"/>
    </member>
   </members>
</specifications>
```

After you specify the variables as critical, Polyspace flags the public critical data members. If you do not specify the critical data members, Polyspace assumes that no data members are critical and the defect is not raised.

### Correction — Declare Critical Variables as Private

To fix this defect, declare the critical variables as `private`

```
#include <string.h>

#define MAX_PASSWORD_LENGTH 15
#define MAX_USERNAME_LENGTH 15

class UserAccount
{
public:
  UserAccount(char *username, char *password)
  {
    //...
  }

  int authorizeAccess(char *username, char *password)
  {
    //...
  }
private:
  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

## Result Information

**Group:** Security
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `CRITICAL_DATA_MEMBER_DECLARED_PUBLIC`
**Impact:** High

# Uncertain memory cleaning

The code clears information that might be sensitive from memory but compiler optimization might leave the information untouched

## Description

This defect occurs when you clean memory by writing `0` into it but the memory is not read after the cleaning operation. Because the memory is not read after the cleaning, a compiler might skip the cleaning operation when optimizing the code. For instance, consider this code:

```
void foo(){
    void* buffer = getSensitiveData();
    //...
    memset(buffer, 0, sizeof(buffer));
}
```

Here, `buffer` might contain sensitive data. The call to `memset()` is intended to scrub the data. Because buffer is not read after the scrubbing, the compiler optimization process might ignore the `memset()` command. The data in `buffer` might remain uncleaned. Polyspace flags such uncertain memory cleaning. Polyspace does not raise this defect if either of these conditions are true:

- The return value of the memory cleaning function is assigned to a variable.
- The memory cleaning function scrubs a global object.

### Risk

When a variable is written with no further read, compilers might consider it as a deadstore. To optimize the code, the compiler might remove any assignments to deadstore variables.

If such code optimization removes code that scrubs sensitive information from memory, then sensitive information might remain uncleaned in your system. An attacker can then access the sensitive information and use it to further erode the protection mechanisms in your code.

### Fix

When scrubbing memory, use code that the compiler cannot remove. For instance, instead of `memset`, use secure functions, such as `memset_s` or `fill_n`. If you use an older version of C or C++ where these functions are unavailable, consider updating your code to a more recent version. Alternatively, you might implement your own secure memory-scrubbing function. When using your own implementation, review the compiled code to make sure that the memory-cleaning operations are untouched by the compiler.

## Examples

### Avoid Uncertainty in Cleaning Sensitive Memory

```
#include <string.h>

extern int getSensitiveData(char*, size_t);
extern int writeDB(char*, char*);
char Gbuffer[64];
void Job(char *key) {
    char buffer[64];
    if (getSensitiveData(buffer, sizeof(buffer))) {
        if (writeDB(key, buffer)) {
            // Record data
        }
    }
    (void) memset(buffer, 0, sizeof(buffer)); // Defect
}

void manageGBuffer(char *key) {
    //...
    memset(Gbuffer, 0, sizeof(Gbuffer)); // No Defect
}
```

In this example, the command `memset()` is used in `Job()` to clean the memory in `buffer`. Because `buffer` is not read after the cleaning, the compiler might remove this code when optimizing the code. Polyspace flags the uncertain cleaning. In the function `manage()`, `memset()` is used to clean the global array `Gbuffer`. Polyspace does not flag this cleaning operation.

#### Correction — Use Secure Functions to Clean Sensitive Memory

To fix this defect, use secure functions, such as `memset_s()`, to clean uncertain memory.

```
#include <string.h>

extern int getSensitiveData(char*, size_t);
extern int writeDB(char*, char*);

void Job(char *key) {
    char buffer[64];
    if (getSensitiveData(buffer, sizeof(buffer))) {
        if (writeDB(key, buffer)) {
            // Record data
        }
    }
    memset_s(buffer, 0, sizeof(buffer)); // No Defect
}
```

## Result Information

**Group:** Security
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `UNCERTAIN_MEMORY_CLEANING`
**Impact:** Medium

# Cryptography Defects

# Constant block cipher initialization vector

Initialization vector is constant instead of randomized

## Description

This defect occurs when you use a constant for the initialization vector (IV) during encryption.

### Risk

Using a constant IV is equivalent to not using an IV. Your encrypted data is vulnerable to dictionary attacks.

Block ciphers break your data into blocks of fixed size. Block cipher modes such as CBC (Cipher Block Chaining) protect against dictionary attacks by XOR-ing each block with the encrypted output from the previous block. To protect the first block, these modes use a random initialization vector (IV). If you use a constant IV to encrypt multiple data streams that have a common beginning, your data becomes vulnerable to dictionary attacks.

### Fix

Produce a random IV by using a strong random number generator.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

## Examples

### Constants Used for Initialization Vector

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

/* Using the cryptographic routines */

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16] = {'1', '2', '3', '4','5','6','b','8','9',
                                 '1','2','3','4','5','6','7'};
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

In this example, the initialization vector `iv` has constants only. The constant initialization vector makes your cipher vulnerable to dictionary attacks.

#### Correction — Use Random Initialization Vector

One possible correction is to use a strong random number generator to produce the initialization vector. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

/* Using the cryptographic routines */

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_CONSTANT_IV`
**Impact:** Medium

# Version History

**Introduced in R2017a**

# Constant cipher key

Encryption or decryption key is constant instead of randomized

## Description

This defect occurs when you use a constant for the encryption or decryption key.

### Risk

If you use a constant for the encryption or decryption key, an attacker can retrieve your key easily.

You use a key to encrypt and later decrypt your data. If a key is easily retrieved, data encrypted using that key is not secure.

### Fix

Produce a random key by using a strong random number generator.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

## Examples

### Constants Used for Key

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16] = {'1', '2', '3', '4','5','6','b','8','9',
                                 '1','2','3','4','5','6','7'};
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

In this example, the cipher key, `key`, has constants only. An attacker can easily retrieve a constant key.

#### Correction — Use Random Key

Use a strong random number generator to produce the cipher key. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16
```

```
int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_CONSTANT_KEY`
**Impact:** Medium

## Version History

**Introduced in R2017a**

# Context initialized incorrectly for cryptographic operation

Context used for public key cryptography operation is initialized for a different operation

## Description

This defect occurs when you initialize an EVP_PKEY_CTX object for a specific public key cryptography operation but use the object for a different operation.

For instance, you initialize the context for encryption.

```
ret = EVP_PKEY_encrypt_init(ctx);
```

However, you use the context for decryption without reinitializing the context.

```
ret = EVP_PKEY_decrypt(ctx, out, &out_len, in, in_len);
```

The checker detects if the context object used in these functions has been initialized by using the corresponding initialization functions: EVP_PKEY_paramgen, EVP_PKEY_keygen, EVP_PKEY_encrypt, EVP_PKEY_verify, EVP_PKEY_verify_recover,EVP_PKEY_decrypt, EVP_PKEY_sign, EVP_PKEY_derive,and EVP_PKEY_derive_set_peer.

### Risk

Mixing up different operations on the same context can lead to obscure code. It is difficult to determine at a glance whether the current object is used for encryption, decryption, signature, or another operation. The mixup can also lead to a failure in the operation or unexpected ciphertext.

### Fix

After you set up a context for a certain family of operations, use the context for only that family of operations.For instance, use these pairs of functions for initialization and usage of the EVP_PKEY_CTX context object.

- For encryption with EVP_PKEY_encrypt, initialize the context with EVP_PKEY_encrypt_init.
- For signature verification with EVP_PKEY_verify, initialize the context with EVP_PKEY_verify_init.
- For key generation with EVP_PKEY_keygen, initialize the context with EVP_PKEY_keygen_init.

If you want to reuse an existing context object for a different family of operations, reinitialize the context.

## Examples

### Encryption Using Context Initialized for Decryption

```
#include <openssl/evp.h>
```

```
#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf10;
size_t out_len10;
int func(unsigned char *src, size_t len, EVP_PKEY_CTX *ctx){
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_decrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf10, &out_len10, src, len);
}
```

In this example, the context is initialized for decryption but used for encryption.

**Correction — Use One Family of Operations**

One possible correction is to initialize the object for encryption.

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf10;
size_t out_len10;
int func(unsigned char *src, size_t len, EVP_PKEY_CTX *ctx){
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf10, &out_len10, src, len);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_PKEY_INCORRECT_INIT`
**Impact:** Medium

# Version History

# Context initialized incorrectly for digest operation

Context used for digest operation is initialized for a different digest operation

## Description

This defect occurs when you initialize an `EVP_MD_CTX` context object for a specific digest operation but use the context for a different operation.

For instance, you initialize the context for creating a message digest only.

```
ret = EVP_DigestInit(ctx, EVP_sha256())
```

However, you perform a final step for signing:

```
ret = EVP_SignFinal(&ctx, out, &out_len, pkey);
```

The error is shown only if the final step is not consistent with the initialization of the context. If the intermediate update steps are inconsistent, it does not trigger an error because the intermediate steps do not depend on the nature of the operation. For instance, `EVP_DigestUpdate` works identically to `EVP_SignUpdate`.

### Risk

Mixing up different operations on the same context can lead to obscure code. It is difficult to determine at a glance whether the current object is used for message digest creation, signing, or verification. The mixup can also lead to a failure in the operation or unexpected message digest.

### Fix

After you set up a context for a certain family of operations, use the context for only that family of operations. For instance, use these pairs of functions for initialization and final steps.

- `EVP_DigestInit` : `EVP_DigestFinal`
- `EVP_DigestInit_ex` : `EVP_DigestFinal_ex`
- `EVP_DigestSignInit` : `EVP_DigestSignFinal`

If you want to reuse an existing context object for a different family of operations, reinitialize the context.

## Examples

### Inconsistent Initial and Final Digest Operation

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf16;
unsigned int out_len16;
```

```
void func(unsigned char *src, size_t len){
  EVP_MD_CTX* ctx = EVP_MD_CTX_create();

  ret = EVP_SignInit_ex(ctx, EVP_sha256(), NULL);
  if (ret != 1) fatal_error();

  ret = EVP_SignUpdate(ctx, src, len);
  if (ret != 1) fatal_error();

  ret = EVP_DigestSignFinal(ctx, out_buf16, (size_t*) out_len16);

  if (ret != 1) fatal_error();
}
```

In this example, the context object is initialized for signing only with EVP_SignInit but the final step attempts to create a signed digest with EVP_DigestSignFinal.

#### Correction — Use One Family of Operations

One possible correction is to use the context object for signing only. Change the final step to EVP_SignFinal in keeping with the initialization step.

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf16;
unsigned int out_len16;

void corrected_cryptomdbadfunction(unsigned char *src, size_t len, EVP_PKEY* pkey){
  EVP_MD_CTX* ctx = EVP_MD_CTX_create();

  ret = EVP_SignInit_ex(ctx, EVP_sha256(), NULL);
  if (ret != 1) fatal_error();

  ret = EVP_SignUpdate(ctx, src, len);
  if (ret != 1) fatal_error();

  ret = EVP_SignFinal(ctx, out_buf16, &out_len16, pkey);
  if (ret != 1) fatal_error();
}
```

## Result Information

# Incompatible padding for RSA algorithm operation

Cryptography operation is not supported by the padding type set in context

## Description

This defect occurs when you perform an RSA algorithm operation on a context object that is not compatible with the padding previously associated with the object.

For instance, you associate the OAEP padding scheme with a context object but later use the context for signature verification, an operation that the padding scheme does not support.

```
ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
...
ret = EVP_PKEY_verify(ctx, out, out_len, in, in_len);
```

### Risk

Padding schemes remove determinism from the RSA algorithm and protect RSA operations from certain kinds of attack.

When you use an incorrect padding scheme, the RSA operation can fail or result in unexpected ciphertext.

### Fix

Before performing an RSA operation, associate the context object with a padding scheme that is compatible with the operation.

- Encryption: Use the OAEP padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_OAEP_PADDING` or the `RSA_padding_add_PKCS1_OAEP` function.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
  ```

  You can also use the PKCS#1v1.5 or SSLv23 schemes. Be aware that these schemes are considered insecure.

  You can then use functions such as `EVP_PKEY_encrypt` / `EVP_PKEY_decrypt` or `RSA_public_encrypt` / `RSA_private_decrypt` on the context.
- Signature: Use the RSA-PSS padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_PSS_PADDING`.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_PSS_PADDING);
  ```

  You can also use the ANSI X9.31, PKCS#1v1.5, or SSLv23 schemes. Be aware that these schemes are considered insecure.

  You can then use functions such as the `EVP_PKEY_sign`-`EVP_PKEY_verify` pair or the `RSA_private_encrypt`-`RSA_public_decrypt` pair on the context.

If you perform two kinds of operation with the same context, after the first operation, reset the padding scheme in the context before the second operation.

## Examples

### OAEP Padding for Signature Operation

```
#include <stddef.h>
#include <openssl/rsa.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;

int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();
  return RSA_private_encrypt(len, src, out_buf, rsa, RSA_PKCS1_OAEP_PADDING);
}
```

In this example, the function `RSA_private_encrypt` performs a signature operation by using the OAEP padding scheme, which supports encryption operations only.

#### Correction — Use Padding Scheme That Supports Signature

One possible correction is to use the RSA-PSS padding scheme. The corrected example uses the function `RSA_padding_add_PKCS1_PSS` to associate the padding scheme with the context.

```
#include <stddef.h>
#include <openssl/evp.h>
#include <openssl/rsa.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *msg_pad;
unsigned char *out_buf;

int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();

  ret = RSA_padding_add_PKCS1_PSS(rsa, msg_pad, src, EVP_sha256(), -2);
  if (ret <= 0) fatal_error();

  return RSA_private_encrypt(len, msg_pad, out_buf, rsa, RSA_NO_PADDING);
}
```

# Inconsistent cipher operations

You perform encryption and decryption steps in succession with the same cipher context without a reinitialization in between

## Description

This defect occurs when you perform an encryption and decryption step with the same cipher context. You do not reinitialize the context in between those steps. The checker applies to symmetric encryption only.

For instance, you set up a cipher context for decryption using `EVP_DecryptInit_ex`.

```
EVP_DecryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);
```

However, you use the context for encryption using `EVP_EncryptUpdate`.

```
EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
```

### Risk

Mixing up encryption and decryption steps can lead to obscure code. It is difficult to determine at a glance whether the current cipher context is used for encryption or decryption. The mixup can also lead to race conditions, failed encryption, and unexpected ciphertext.

### Fix

After you set up a cipher context for a certain family of operations, use the context for only that family of operations.

For instance, if you set up a cipher context for decryption using `EVP_DecryptInit_ex`, use the context afterward for decryption only.

## Examples

### Encryption Step Following Decryption Step

```
#include <openssl/evp.h>
#include <stdlib.h>

/* Using the cryptographic routines */

unsigned char *out_buf;
int out_len;
unsigned char g_key[16];
unsigned char g_iv[16];
void func(unsigned char* src, int len) {

    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Cipher context set up for decryption*/
    EVP_DecryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, g_key, g_iv);

    /* Update step for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

In this example, the cipher context `ctx` is set up for decryption using `EVP_DecryptInit_ex`. However, immediately afterward, the context is used for encryption using `EVP_EncryptUpdate`.

#### Correction — Change Setup Step

One possible correction is to change the setup step. If you want to use the cipher context for encryption, set it up using `EVP_EncryptInit_ex`.

```
#include <openssl/evp.h>
#include <stdlib.h>

unsigned char *out_buf;
int out_len;
unsigned char g_key[16];
unsigned char g_iv[16];

void func(unsigned char* src, int len) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Cipher context set up for encryption*/
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, g_key, g_iv);

    /* Update step for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

### Result Information

# Incorrect key for cryptographic algorithm

Public key cryptography operation is not supported by the algorithm used in context initialization

## Description

This defect occurs when you initialize a context object with a key for a specific algorithm but perform an operation that the algorithm does not support.

For instance, you initialize the context with a key for the DSA algorithm.

```
ret = EVP_PKEY_set1_DSA(pkey,dsa);
ctx = EVP_PKEY_CTX_new(pkey, NULL);
```

However, you use the context for encrypting data, an operation that the DSA algorithm does not support.

```
ret = EVP_PKEY_encrypt(ctx,out, &out_len, in, in_len);
```

### Risk

If the algorithm does not support your cryptographic operation, you do not see the expected results. For instance, if you use the DSA algorithm for encryption, you might get unexpected ciphertext.

### Fix

Use the algorithm that is appropriate for the cryptographic operation that you want to perform:

- Diffie-Hellman (DH): For key derivation.
- Digital Signature Algorithm (DSA): For signature.
- RSA: For encryption and signature.
- Elliptic curve (EC): For key derivation and signature.

## Examples

### Encryption with DSA Algorithm

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len, DSA * dsa){
  EVP_PKEY_CTX *ctx;
  EVP_PKEY *pkey = NULL;

  pkey = EVP_PKEY_new();
  if(pkey == NULL) fatal_error();
  ret = EVP_PKEY_set1_DSA(pkey,dsa);
  if (ret <= 0) fatal_error();

  ctx = EVP_PKEY_CTX_new(pkey, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

In this example, the context object is initialized with a key associated with the DSA algorithm. However, the object is used for encryption, an operation that the DSA algorithm does not support.

#### Correction — Use RSA Algorithm

One possible correction is to initialize the context object with a key associated with the RSA algorithm.

```
#include <openssl/evp.h>
#include <openssl/rsa.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len, RSA * rsa){
  EVP_PKEY_CTX *ctx;
  EVP_PKEY *pkey = NULL;

  pkey = EVP_PKEY_new();
  if(pkey == NULL) fatal_error();

  ret = EVP_PKEY_set1_RSA(pkey,rsa);
  if (ret <= 0) fatal_error();

  ctx = EVP_PKEY_CTX_new(pkey, NULL); /* RSA key is set in the context */
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx); /* Encryption operation is set in the context */
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

# Missing blinding for RSA algorithm

Context used in decryption or signature verification is not blinded against timing attacks

## Description

This defect occurs when you do not enable blinding for an RSA context object before using the object for decryption or signature verification.

For instance, you do not turn on blinding in the context object `rsa` before this decryption step:

```
  ret = RSA_public_decrypt(in_len, in, out, rsa, RSA_PKCS1_PADDING)
```

### Risk

Without blinding, the time it takes for the cryptographic operation to be completed has a correlation with the key value. An attacker can gather information about the RSA key by measuring the time for completion. Blinding removes this correlation and protects the decryption or verification operation against timing attacks.

### Fix

Before performing RSA decryption or signature verification, enable blinding.

```
ret = RSA_blinding_on(rsa, NULL);
```

## Examples

### Blinding Disabled Before Decryption

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();

  RSA_blinding_off(rsa);
  return RSA_private_decrypt(len, src, out_buf, rsa, RSA_PKCS1_OAEP_PADDING);
}
```

In this example, blinding is disabled for the context object `rsa`. Decryption with this context object can be vulnerable to timing attacks.

#### Correction — Enable Blinding Before Decryption

One possible correction is to explicitly enable blinding before decryption. Even if blinding might be enabled previously or by default, explicitly enabling blinding ensures that the security of the current decryption step is not reliant on the caller of `func`.

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();

  ret = RSA_blinding_on(rsa, NULL);
  if (ret <= 0) fatal_error();
  return RSA_private_decrypt(len, src, out_buf, rsa, RSA_PKCS1_OAEP_PADDING);
}
```

### Result Information

# Missing block cipher initialization vector

Context used for encryption or decryption is associated with NULL initialization vector or not associated with an initialization vector

## Description

This defect occurs when you encrypt or decrypt data using a NULL initialization vector (IV).

**Note** You can initialize your cipher context with a NULL initialization vector (IV). However, if your algorithm requires an IV, before the encryption or decryption step, you must associate the cipher context with a non-NULL IV.

### Risk

Many block cipher modes use an initialization vector (IV) to prevent dictionary attacks. If you use a NULL IV, your encrypted data is vulnerable to such attacks.

Block ciphers break your data into blocks of fixed size. Block cipher modes such as CBC (Cipher Block Chaining) protect against dictionary attacks by XOR-ing each block with the encrypted output from the previous block. To protect the first block, these modes use a random initialization vector (IV). If you use a NULL IV, you get the same ciphertext when encrypting the same plaintext. Your data becomes vulnerable to dictionary attacks.

### Fix

Before your encryption or decryption steps

```
 ret = EVP_EncryptUpdate(&ctx, out_buf, &out_len, src, len)
```

associate your cipher context `ctx` with a non-NULL initialization vector.

```
ret = EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv)
```

## Examples

### NULL Initialization Vector Used for Encryption

```
#include <openssl/evp.h>
#include <stdlib.h>
#define fatal_error() abort()

unsigned char *out_buf;
int out_len;

int func(EVP_CIPHER_CTX *ctx, unsigned char *key, unsigned char *src, int len){
    if (key == NULL)
        fatal_error();
    /* Last argument is initialization vector */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, NULL);

    /* Update step with NULL initialization vector */
    return EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

In this example, the initialization vector associated with the cipher context `ctx` is NULL. If you use this context to encrypt your data, your data is vulnerable to dictionary attacks.

#### Correction — Use Random Initialization Vector

Use a strong random number generator to produce the initialization vector. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define fatal_error() abort()
#define SIZE16 16

unsigned char *out_buf;
int out_len;

int func(EVP_CIPHER_CTX *ctx, unsigned char *key, unsigned char *src, int len){
    if (key == NULL)
        fatal_error();
    unsigned char iv[SIZE16];
    RAND_bytes(iv, 16);

    /* Last argument is initialization vector */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update step with non-NULL initialization vector */
    return EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

## Result Information

# Missing certification authority list

Certificate for authentication cannot be trusted

## Description

This defect occurs when you use a context to handle TLS/SSL connections with these functions, but you do not load a certification authority (CA) list into the context.

- `SSL_connect`
- `SSL_accept`
- `SSL_do_handshake`
- `SSL_write`
- `SSL_read`
- `BIO_do_connect`
- `BIO_do_accept`
- `BIO_do_handshake`

A CA is a trusted third party entity that issues digital certificates to other entities. The certificate contains information about its owner. Server or clients use this information to authenticate connections to the certificate owner.

The checker raises a defect if:

- For server authentication, the client has no CA list to determine whether the server certificate is from a trusted source.
- For client authentication, the server has no CA list to determine whether the client certificate is from a trusted source.

### Risk

Without a CA list, you cannot determine if the certificate is issued by a trusted CA. The entity that presents the certificate for authentication might not be the entity described in the certificate. Your connection is vulnerable to man-in-the-middle (MITM) attacks.

### Fix

Load a certification authority list into the context you create to handle TLS/SSL connections.

## Examples

### Missing CA List When `SSL_connect` Initiates TLS/SSL Handshake

```
#include <openssl/ssl.h>
#include <arpa/inet.h>
#include <unistd.h>
#include <openssl/err.h>
```

```
unsigned char* buf;

int OpenConnection(char* hostname, int port)
{
    /* Open the connection */
}

SSL_CTX* InitCTX(void)
{
    SSL_CTX* ctx;
    OpenSSL_add_all_algorithms();
    ctx = SSL_CTX_new(TLSv1_2_client_method());
    if (ctx == NULL) {
        /*handle errors */
    }
    return ctx;
}

void func()
{
    SSL_CTX* ctx;
    int server;
    SSL* ssl;
    char buf[1024];
    int bytes;
    char* hostname, *portnum;
    int ret;

    SSL_library_init();
    hostname = "localhost";
    portnum = "4433";

    ctx = InitCTX();
    server = OpenConnection(hostname, atoi(portnum));
    ssl = SSL_new(ctx);
    SSL_set_fd(ssl, server);
    ret = SSL_connect(ssl);
    if (SSL_get_error(ssl, ret) <= 0) {
        char* msg = "Hello???";
        printf("Connected with %s encryption\n", SSL_get_cipher(ssl));
        SSL_write(ssl, msg, strlen(msg));
        bytes = SSL_read(ssl, buf, sizeof(buf));
        buf[bytes] = 0;
        printf("Received: \"%s\"\n", buf);
        SSL_free(ssl);
    } else
        ERR_print_errors_fp(stderr);
    close(server);
    SSL_CTX_free(ctx);
}
```

In this example, a context `ctx` is initialized to handle TLS/SSL connections. When `SSL_connect` initializes the TLS/SSL handshake with the server by using the SSL structure `ssl` created from `ctx`, there is no CA list to check the validity of the server certificate.

#### Correction — Before Initiating the TLS/SSL Handshake, Load a CA List into the Context

One possible correction is to, before you initialize the SSL structure, specify a list of CA certificates for the context `ctx`, for instance with `SSL_CTX_load_verify_locations`.

```
#include <openssl/ssl.h>
#include <arpa/inet.h>
#include <unistd.h>
#include <openssl/err.h>

unsigned char* buf;

int OpenConnection(char* hostname, int port)
{
    /* Open the connection */
}

SSL_CTX* InitCTX(void)
{
    SSL_CTX* ctx;
    OpenSSL_add_all_algorithms();
    ctx = SSL_CTX_new(TLSv1_2_client_method());
    if (ctx == NULL) {
        /*handle errors */
    }
    return ctx;
}

void LoadCA(SSL_CTX* ctx, char* CertFile, char* CertPath)
{
    if (SSL_CTX_load_verify_locations(ctx, CertFile, CertPath) <= 0) {
        /* handle errors */
    }
}

void func()
{
    SSL_CTX* ctx;
    int server;
    SSL* ssl;
    char buf[1024];
    int bytes;
    char* hostname, *portnum;
    int ret;

    SSL_library_init();
    hostname = "localhost";
    portnum = "4433";

    ctx = InitCTX();
    LoadCA(ctx, "cacert.pem", "ca/");
    server = OpenConnection(hostname, atoi(portnum));
    ssl = SSL_new(ctx);
    SSL_set_fd(ssl, server);
    ret = SSL_connect(ssl);
    if (SSL_get_error(ssl, ret) <= 0) {
        char* msg = "Hello???";
        printf("Connected with %s encryption\n", SSL_get_cipher(ssl));
        SSL_write(ssl, msg, strlen(msg));
        bytes = SSL_read(ssl, buf, sizeof(buf));
        buf[bytes] = 0;
        printf("Received: \"%s\"\n", buf);
        SSL_free(ssl);
    } else
        ERR_print_errors_fp(stderr);
    close(server);
    SSL_CTX_free(ctx);
}
```

## Result Information

# Missing cipher algorithm

An encryption or decryption algorithm is not associated with the cipher context

## Description

This defect occurs when you do not assign a cipher algorithm when setting up your cipher context.

You can initialize your cipher context without an algorithm. However, before you encrypt or decrypt your data, you must associate the cipher context with a cipher algorithm.

### Risk

A missing cipher algorithm can lead to run-time errors or at least, non-secure ciphertext.

Before encryption or decryption, you set up a cipher context that has the information required for encryption: the cipher algorithm and mode, an encryption or decryption key and an initialization vector (for modes that require initialization vectors).

```
ret = EVP_EncryptInit(&ctx, EVP_aes_128_cbc(), key, iv)
```

The function `EVP_aes_128_cbc()` specifies that the Advanced Encryption Standard (AES) algorithm must be used for encryption. The function also specifies a block size of 128 bits and the Cipher Bloch Chaining (CBC) mode.

Instead of specifying the algorithm, you can use NULL in the initialization step. However, before using the cipher context for encryption or decryption, you must perform an additional initialization that associates an algorithm with the context. Otherwise, the update steps for encryption or decryption can lead to run-time errors.

### Fix

Before your encryption or decryption steps

```
 ret = EVP_EncryptUpdate(&ctx, out_buf, &out_len, src, len)
```

associate your cipher context `ctx` with an algorithm.

```
ret = EVP_EncryptInit(ctx, EVP_aes_128_cbc(), key, iv)
```

## Examples

### Algorithm Missing During Context Initialization

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char key[SIZE16];
unsigned char iv[SIZE16];
void func(void) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);
    EVP_EncryptInit_ex(ctx, NULL, NULL, key, iv);
}
```

In this example, an algorithm is not provided when the cipher context `ctx` is initialized.

Before you encrypt or decrypt your data, you have to provide a cipher algorithm. If you perform a second initialization to provide the algorithm, the cipher context is completely re-initialized. Therefore, the current initialization statement using `EVP_EncryptInit_ex` is redundant.

#### Correction — Provide Algorithm During Initialization

One possible correction is to provide an algorithm when you initialize the cipher context. In the corrected code below, the routine `EVP_aes_128_cbc` invokes the Advanced Encryption Standard (AES) algorithm. The routine also specifies a block size of 128 bits and the Cipher Block Chaining (CBC) mode for encryption.

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char key[SIZE16];
unsigned char iv[SIZE16];
void func(unsigned char *src, int len, unsigned char *out_buf, int out_len) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Initialization of cipher context */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update steps for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

### Result Information

# Missing cipher data to process

Final encryption or decryption step is performed without previous update steps

## Description

This defect occurs when you perform the final step of a block cipher encryption or decryption incorrectly.

For instance, you do one of the following:

- You do not perform update steps for encrypting or decrypting the data before performing a final step.

```
/* Initialization of cipher context */
ret = EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);
...
/* Missing update step */
...
/* Final step */
ret = EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
```

- You perform consecutive final steps without intermediate initialization and update steps.

```
/* Initialization of cipher context */
ret = EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);
...
/* Update step(s) */
ret = EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
...
/* Final step */
ret = EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
...
/* Missing initialization and update */
...
/* Second final step */
ret = EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
```

- You perform a cleanup of the cipher context and then perform a final step.

```
/* Initialization of cipher context */
ret = EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);
...
/* Update step(s) */
ret = EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
...
/* Cleanup of cipher context */
EVP_CIPHER_CTX_cleanup(ctx);
...
/* Second final step */
ret = EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
```

### Risk

Block ciphers break your data into blocks of fixed size. During encryption or decryption, the update step encrypts or decrypts your data in blocks. Any leftover data is encrypted or decrypted by the final step. The final step adds padding to the leftover data so that it occupies one block, and then encrypts or decrypts the padded data.

If you perform the final step before performing the update steps, or perform the final step when there is no data to process, the behavior is undefined. You can also encounter run-time errors.

### Fix

Perform encryption or decryption in this sequence:

- Initialization of cipher context
- Update steps
- Final step
- Cleanup of context

## Examples

### Missing Update Steps for Encryption Before Final Step

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char *out_buf;
int out_len;
unsigned char key[SIZE16];
unsigned char iv[SIZE16];

void func(void) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Initialization of cipher context */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Missing update steps for encryption */

    /* Final encryption step */
    EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
}
```

In this example, after the cipher context is initialized, there are no update steps for encrypting the data. The update steps are supposed to encrypt one or more blocks of data, leaving the final step to encrypt data that is left over in a partial block. If you perform the final step without previous update steps, the behavior is undefined.

#### Correction — Perform Update Steps for Encryption Before Final Step

Perform update steps for encryption before the final step. In the corrected code below, the routine `EVP_EncryptUpdate` performs the update steps.

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char *out_buf;
int out_len;
unsigned char key[SIZE16];
unsigned char iv[SIZE16];

void func(unsigned char *src, int len) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Initialization of cipher context */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update steps for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);

    /* Final encryption step */
    EVP_EncryptFinal_ex(ctx, out_buf, &out_len);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_NO_DATA`
**Impact:** Medium

# Missing cipher final step

You do not perform a final step after update steps for encrypting or decrypting data

## Description

This defect occurs when you do not perform a final step after your update steps for encrypting or decrypting data.

For instance, you do the following:

```
/* Initialization of cipher context */
ret = EVP_EncryptInit_ex(&ctx, EVP_aes_128_cbc(), NULL, key, iv);
...
/* Update step */
ret = EVP_EncryptUpdate(&ctx, out_buf, &out_len, src, len);
...
/* Missing final step */
...
/* Cleanup of cipher context */
EVP_CIPHER_CTX_cleanup(ctx);
```

### Risk

Block ciphers break your data into blocks of fixed size. During encryption or decryption, the update step encrypts or decrypts your data in blocks. Any leftover data is encrypted or decrypted by the final step. The final step adds padding to the leftover data so that it occupies one block, and then encrypts or decrypts the padded data.

If you do not perform the final step, leftover data remaining in a partial block is not encrypted or decrypted. You can face incomplete or unexpected output.

### Fix

After your update steps for encryption or decryption, perform a final step to encrypt or decrypt leftover data.

```
/* Initialization of cipher context */
ret = EVP_EncryptInit_ex(&ctx, EVP_aes_128_cbc(), NULL, key, iv);
...
/* Update step(s) */
ret = EVP_EncryptUpdate(&ctx, out_buf, &out_len, src, len);
...
/* Final step */
ret = EVP_EncryptFinal_ex(&ctx, out_buf, &out_len);
...
/* Cleanup of cipher context */
EVP_CIPHER_CTX_cleanup(ctx);
```

## Examples

### Cleanup of Cipher Context Before Final Step

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char *out_buf;
int out_len;
unsigned char key[SIZE16];
unsigned char iv[SIZE16];

void func(unsigned char *src, int len) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Initialization of cipher context */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update steps for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);

    /* Missing final encryption step */

    /* Cleanup of cipher context */
    EVP_CIPHER_CTX_cleanup(ctx);
}
```

In this example, the cipher context `ctx` is cleaned up before a final encryption step. The final step is supposed to encrypt leftover data. Without the final step, the encryption is incomplete.

#### Correction — Perform Final Encryption Step

After your update steps for encryption, perform a final encryption step to encrypt leftover data. In the corrected code below, the routine `EVP_EncryptFinal_ex` is used to perform this final step.

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

unsigned char *out_buf;
int out_len;
unsigned char key[SIZE16];
unsigned char iv[SIZE16];

void func(unsigned char *src, int len) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);

    /* Initialization of cipher context */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update steps for encryption */
    EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);

    /* Final encryption step */
    EVP_EncryptFinal_ex(ctx, out_buf, &out_len);

    /* Cleanup of cipher context */
    EVP_CIPHER_CTX_cleanup(ctx);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_NO_FINAL`
**Impact:** Medium

# Missing cipher key

Context used for encryption or decryption is associated with NULL key or not associated with a key

## Description

This defect occurs when you encrypt or decrypt data using a NULL encryption or decryption key.

**Note** You can initialize your cipher context with a NULL key. However, before you encrypt or decrypt your data, you must associate the cipher context with a non-NULL key.

### Risk

Encryption or decryption with a NULL key can lead to run-time errors or at least, non-secure ciphertext.

### Fix

Before your encryption or decryption steps

```
 ret = EVP_EncryptUpdate(&ctx, out_buf, &out_len, src, len)
```

associate your cipher context `ctx` with a non-NULL key.

```
ret = EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv)
```

Sometimes, you initialize your cipher context with a non-NULL key

```
ret = EVP_EncryptInit_ex(&ctx, cipher_algo_1, NULL, key, iv)
```

but change the cipher algorithm later. When you change the cipher algorithm, you use a NULL key.

```
 ret = EVP_EncryptInit_ex(&ctx, cipher_algo_2, NULL, NULL, NULL)
```

The second statement reinitializes the cipher context completely but with a NULL key. To avoid this issue, every time you initialize a cipher context with an algorithm, associate it with a key.

## Examples

### NULL Key Used for Encryption

```
#include <openssl/evp.h>
#include <stdlib.h>
#define fatal_error() abort()

unsigned char *out_buf;
int out_len;

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv, unsigned char *src, int len){
    if (iv == NULL)
        fatal_error();

    /* Fourth argument is cipher key */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, NULL, iv);

    /* Update step with NULL key */
    return EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

In this example, the cipher key associated with the context `ctx` is NULL. When you use this context to encrypt your data, you can encounter run-time errors.

**Correction — Use Random Cipher Key**

Use a strong random number generator to produce the cipher key. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define fatal_error() abort()
#define SIZE16 16

unsigned char *out_buf;
int out_len;

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv, unsigned char *src, int len){
    if (iv == NULL)
        fatal_error();
    unsigned char key[SIZE16];
    RAND_bytes(key, 16);

    /* Fourth argument is cipher key */
    EVP_EncryptInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv);

    /* Update step with non-NULL cipher key */
    return EVP_EncryptUpdate(ctx, out_buf, &out_len, src, len);
}
```

## Result Information

# Missing data for encryption, decryption or signing operation

Data provided for public key cryptography operation is NULL or data length is zero

## Description

This defect occurs when the data provided for an encryption, decryption, signing, or authentication operation is NULL or the data length is zero.

For instance, you unintentionally provide a NULL value for `in` or a zero value for `in_len` in this decryption operation:

```
ret = EVP_PKEY_decrypt(ctx, out, &out_len, in, in_len);
```

Or, you provide a NULL value for `md` or `sig`, or a zero value for `md_len` or `sig_len` in this verification operation:

```
ret = EVP_PKEY_verify(ctx, md, mdlen, sig, siglen);
```

### Risk

With NULL data or zero length, the operation does not occur. The redundant operation often indicates a coding error.

### Fix

Check the placement of the encryption, decryption, or signing operation. If the operation is intended to happen, make sure that the data provided is non-NULL. Set the data length to a nonzero value.

## Examples

### Zero Data Length for Signing Operation

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY_CTX * ctx){
  if (ctx == NULL) fatal_error();
  unsigned char* sig = (unsigned char*) "0123456789";
  unsigned char* md = (unsigned char*) "0123456789";

  ret = EVP_PKEY_verify_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_signature_md(ctx, EVP_sha256());
  if (ret <= 0) fatal_error();
  return EVP_PKEY_verify(ctx, sig, 0, md, 0);
}
```

In this example, the data lengths (third and fifth arguments to `EVP_PKEY_verify`) are zero. The operation fails.

#### Correction — Use Nonzero Data Length

One possible correction is to use a nonzero length for the signature and the data believed to be signed.

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY_CTX * ctx){
  if (ctx == NULL) fatal_error();
  unsigned char* sig = (unsigned char*) "0123456789";
  unsigned char* md = (unsigned char*) "0123456789";

  ret = EVP_PKEY_verify_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_signature_md(ctx, EVP_sha256());
  if (ret <= 0) fatal_error();
  return EVP_PKEY_verify(ctx, sig, 10, md, 10);
}
```

## Result Information

# Missing final step after hashing update operation

Hash is incomplete or non-secure

## Description

The defect occurs when, after an update operation on a message digest context, you do not perform a final step before you clean up or reinitialize the context.

When you use message digest functions, you typically initialize a message digest context and perform at least one update step to add data into the context. You then sign, verify, or retrieve the data in the context as a final step.

### Risk

A missing final step might indicate that the hash is incomplete or is non-secure.

### Fix

Perform a final step to sign, verify, or retrieve date from the message digest context before you clean up or reinitialize the context.

## Examples

### Missing Final Step Before Context Cleanup

```
#include <stdlib.h>
#include <openssl/evp.h>

void func(unsigned char* src, int len, EVP_PKEY* pkey)
{
    int ret;

    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    ret = EVP_DigestVerifyInit(&ctx, NULL, EVP_sha256(), NULL, pkey);
    if (ret != 1) handle_error();

    ret = EVP_DigestVerifyUpdate(&ctx, src, len);
    if (ret != 1) handle_error();

    EVP_MD_CTX_cleanup(&ctx);
}
```

In this example, a verification context `ctx` is initialized and updated with data. The context is then cleaned up without being verified in a final step. Typically, you create a verification context to validate a previously signed message. Without the final step the signature on the message cannot be validated.

#### Correction — Perform Final Step Before Context Cleanup

One possible correction is to perform a final step to verify the signature of the verification context before you clean up the context.

```
#include <stdlib.h>
#include <openssl/evp.h>

unsigned char out_buf[EVP_MAX_MD_SIZE];
unsigned int out_len;

void handle_error()
{
    exit(-1);
}

void func(unsigned char* src, int len, EVP_PKEY* pkey)
{
    int ret;

    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    ret = EVP_DigestVerifyInit(&ctx, NULL, EVP_sha256(), NULL, pkey);
    if (ret != 1) handle_error();

    ret = EVP_DigestVerifyUpdate(&ctx, src, len);
    if (ret != 1) handle_error();

    ret = EVP_DigestVerifyFinal(&ctx, out_buf, out_len);
    if (ret != 1) handle_error();

    EVP_MD_CTX_cleanup(&ctx);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_MD_NO_FINAL`
**Impact:** Medium

## Version History

**Introduced in R2020a**

# Missing hash algorithm

Context in EVP routine is initialized without a hash algorithm

## Description

This defect occurs when you use a message digest context in these EVP routines, but you initialize the context without specifying a hash algorithm.

- `EVP_DigestFinal`
- `EVP_DigestSignFinal`
- `EVP_SignFinal`
- `EVP_VerifyFinal`

### Risk

Using a message digest context that was initialized without an algorithm to perform a hashing operation might result in a run-time error. Even if the hashing operation is successful, the resulting digest is not secure.

### Fix

Specify a hash algorithm when you initial a message digest context that you use in an EVP routine.

## Examples

### Context Used in EVP Routine After Context Cleanup

```
#include <openssl/evp.h>

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    EVP_VerifyInit(&ctx, EVP_sha256());
    EVP_MD_CTX_cleanup(&ctx);
    EVP_VerifyUpdate(&ctx, src, len);
}
```

In this example, context `ctx` is initialized with secure hash algorithm SHA-256. But, `ctx` is cleaned up before it is used by `EVP_VerifyUpdate`. The clean up of `ctx` frees up its resources and reinitializes it without a hash algorithm. The hashing operation of `EVP_VerifyUpdate` might result in a run-time error.

#### Correction — Clean Up Context Only After You No Longer Need It

One possible correction is to clean up the digest context only after you no longer need it.

```
#include <openssl/evp.h>

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    EVP_VerifyInit(&ctx, EVP_sha256());
    EVP_VerifyUpdate(&ctx, src, len);
    EVP_MD_CTX_cleanup(&ctx);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_MD_NO_ALGORITHM`
**Impact:** Medium

## Version History

**Introduced in R2019b**

# Missing padding for RSA algorithm

Context used in encryption or signing operation is not associated with any padding

## Description

This defect occurs when you perform RSA encryption or signature by using a context object without associating the object with a padding scheme.

For instance, you perform encryption by using a context object that was initially not associated with a specific padding.

```
ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_NO_PADDING);
...
ret = EVP_PKEY_encrypt(ctx, out, &out_len, in, in_len)
```

### Risk

Padding schemes remove determinism from the RSA algorithm and protect RSA operations from certain kinds of attack. Padding ensures that a given message does not lead to the same ciphertext each time it is encrypted. Without padding, an attacker can launch chosen-plaintext attacks against the cryptosystem.

### Fix

Before performing an RSA operation, associate the context object with a padding scheme that is compatible with the operation.

- Encryption: Use the OAEP padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_OAEP_PADDING` or the `RSA_padding_add_PKCS1_OAEP` function.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
  ```

  You can also use the PKCS#1v1.5 or SSLv23 schemes. Be aware that these schemes are considered insecure.

  You can then use functions such as `EVP_PKEY_encrypt` / `EVP_PKEY_decrypt` or `RSA_public_encrypt` / `RSA_private_decrypt` on the context.
- Signature: Use the RSA-PSS padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_PSS_PADDING`.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_PSS_PADDING);
  ```

  You can also use the ANSI X9.31, PKCS#1v1.5, or SSLv23 schemes. Be aware that these schemes are considered insecure.

  You can then use functions such as the `EVP_PKEY_sign`-`EVP_PKEY_verify` pair or the `RSA_private_encrypt`-`RSA_public_decrypt` pair on the context.

If you perform two kinds of operation with the same context, after the first operation, reset the padding scheme in the context before the second operation.

## Examples

### Encryption Without Padding

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len){
  EVP_PKEY_CTX *ctx;
  EVP_PKEY* pkey;

  /* Key generation */
  ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA,NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_keygen(ctx, &pkey);
  if (ret <= 0) fatal_error();

  /* Encryption */
  EVP_PKEY_CTX_free(ctx);
  ctx = EVP_PKEY_CTX_new(pkey,NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

In this example, before encryption with `EVP_PKEY_encrypt`, a specific padding is not associated with the context object `ctx`.

#### Correction — Set Padding in Context Before Encryption

One possible correction is to set the OAEP padding scheme in the context.

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)
```

```
int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len){
  EVP_PKEY_CTX *ctx;
  EVP_PKEY* pkey;

  /* Key generation */
  ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA,NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_keygen(ctx, &pkey);
  if (ret <= 0) fatal_error();

  /* Encryption */
  EVP_PKEY_CTX_free(ctx);
  ctx = EVP_PKEY_CTX_new(pkey,NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
  if (ret <= 0) fatal_error();
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++

# Missing parameters for key generation

Context used for key generation is associated with NULL parameters

## Description

This defect occurs when you perform a key generation step with a context object without first associating the object with required parameters.

For instance, you associate a `EVP_PKEY_CTX` context object with an empty `EVP_PKEY` object `params` before key generation :

```
EVP_PKEY * params = EVP_PKEY_new();
...
EVP_PKEY_CTX * ctx = EVP_PKEY_CTX_new(params, NULL);
...
EVP_PKEY_keygen(ctx, &pkey);
```

### Risk

Without appropriate parameters, the key generation step does not occur. The redundant operation often indicates a coding error.

### Fix

Check the placement of the key generation step. If the operation is intended, make sure that the parameters are set before key generation.

Certain algorithms use default parameters. For instance, if you specify the DSA algorithm when creating the `EVP_PKEY_CTX` object, a default key length of 1024 bits is used:

```
kctx = EVP_PKEY_CTX_new_id(EVP_PKEY_DSA, NULL);
```

Specifying the algorithm during context creation is sufficient to avoid this defect. Only if you use the Elliptic Curve (EC) algorithm, you must also specify the curve explicitly before key generation.

However, the default parameters can generate keys that are too weak for encryption. Weak parameters can trigger another defect. To change default parameters, use functions specific to the algorithm. For instance, to set parameters, you can use these functions:

- Diffie-Hellman (DH): Use `EVP_PKEY_CTX_set_dh_paramgen_prime_len` and `EVP_PKEY_CTX_set_dh_paramgen_generator`.
- Digital Signature Algorithm (DSA): Use `EVP_PKEY_CTX_set_dsa_paramgen_bits`.
- RSA: Use `EVP_PKEY_CTX_set_rsa_padding`, `EVP_PKEY_CTX_set_rsa_pss_saltlen`, `EVP_PKEY_CTX_set_rsa_rsa_keygen_bits`, and `EVP_PKEY_CTX_set_rsa_keygen_pubexp`.
- Elliptic curve (EC): Use `EVP_PKEY_CTX_set_ec_paramgen_curve_nid` and `EVP_PKEY_CTX_set_ec_param_enc`.

## Examples

### Empty Parameters During Key Generation

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  EVP_PKEY * params = EVP_PKEY_new();
  if (params == NULL) fatal_error();

  EVP_PKEY_CTX * ctx = EVP_PKEY_CTX_new(params, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_keygen(ctx, &pkey);
}
```

In this example, the context object `ctx` is associated with an empty parameter object `params`. The context object does not have the required parameters for key generation.

#### Correction — Specify Algorithm During Context Creation

One possible correction is to specify an algorithm, such as RSA, during context creation. For stronger encryption, use 2048 bits for key length instead of the default 1024 bits.

```
#include <openssl/evp.h>
#include <openssl/rsa.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  EVP_PKEY_CTX * ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();

  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();

  return EVP_PKEY_keygen(ctx, &pkey);
}
```

# Missing peer key

Context used for shared secret derivation is associated with NULL peer key or not associated with a peer key at all

## Description

This defect occurs when you use a context object for shared secret derivation but you have not previously associated the object with a non-NULL peer key.

For instance, you initialize the context object, and then use the object for shared secret derivation without an intermediate step where the object is associated with a peer key:

```
EVP_PKEY_derive_init(ctx);
/* Missing step for associating peer key with context */
ret = EVP_PKEY_derive(ctx, out_buf, &out_len);
```

The counterpart checker `Missing private key` checks for a private key in shared secret derivation.

### Risk

Without a peer key, the shared secret derivation step does not occur. The redundant operation often indicates a coding error.

### Fix

Check the placement of the shared secret derivation step. If the operation is intended, make sure that you have completed these steps prior to the operation:

- Generate a non-NULL peer key.

  For instance:

  ```
  EVP_PKEY* peerkey = NULL;
  EVP_PKEY_keygen(EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL), &peerkey);
  ```
- Associate a non-NULL context object with the peer key.

  For instance:

  ```
  EVP_PKEY_derive_set_peer(ctx,peerkey);
  ```

## Examples

### Missing Step for Associating Peer Key with Context

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)
```

```
int ret;
unsigned char *out_buf;
size_t out_len;

int func(EVP_PKEY *pkey){
  if (pkey == NULL) fatal_error();

  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new(pkey, NULL);
  if (ctx == NULL) fatal_error();
  ret = EVP_PKEY_derive_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_derive(ctx, out_buf, &out_len);
}
```

In this example, the context object `ctx` is associated with a private key but not a peer key. The `EVP_PKEY_derive` function uses this context object for shared secret derivation.

#### Correction — Set Peer Key in Context

One possible correction is to use the function `EVP_PKEY_derive_set_peer` and associate a peer key with the context object. Make sure that the peer key is non-NULL.

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(EVP_PKEY *pkey,  EVP_PKEY* peerkey){
  if (pkey == NULL) fatal_error();
  if (peerkey == NULL) fatal_error();

  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new(pkey, NULL);
  if (ctx == NULL) fatal_error();
  ret = EVP_PKEY_derive_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_derive_set_peer(ctx,peerkey);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_derive(ctx, out_buf, &out_len);
}
```

## Result Information

# Missing private key

Context used for cryptography operation is associated with NULL private key or not associated with a private key at all

## Description

This defect occurs when you use a context object for decryption, signature, or shared secret derivation but you have not previously associated the object with a non-NULL private key.

For instance, you initialize the context object with a NULL private key and use the object for decryption later.

```
ctx = EVP_PKEY_CTX_new(pkey, NULL);
...
ret = EVP_PKEY_decrypt_init(ctx);
...
ret = EVP_PKEY_decrypt(ctx, out, &out_len, in, in_len);
```

The counterpart checker `Missing public key` checks for a public key in encryption and authentication operations. The checker `Missing peer key` checks for a peer key in shared secret derivation.

### Risk

Without a private key, the decryption, signature, or shared secret derivation step does not occur. The redundant operation often indicates a coding error.

### Fix

Check the placement of the operation (decryption, signature, or shared secret derivation). If the operation is intended, make sure you have completed these steps prior to the operation:

- Generate a non-NULL private key.

  For instance:

  ```
  EVP_PKEY *pkey = NULL;
  kctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);

  EVP_PKEY_keygen_init(kctx);
  EVP_PKEY_CTX_set_rsa_keygen_bits(kctx, RSA_2048BITS);
  EVP_PKEY_keygen(kctx, &pkey);
  ```
- Associate a non-NULL context object with the private key.

  For instance:

  ```
  ctx = EVP_PKEY_CTX_new(pkey, NULL);
  ```

  Note: If you use `EVP_PKEY_CTX_new_id` instead of `EVP_PKEY_CTX_new`, you are not associating the context object with a private key.

## Examples

### Missing Step for Associating Private Key with Context

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len){
  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_decrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_decrypt(ctx, out_buf, &out_len, src, len);
}
```

In this example, the context object ctx is initialized with EVP_PKEY_CTX_new_id instead of EVP_PKEY_CTX_new. The function EVP_PKEY_CTX_new_id does not associate the context object with a key. However, the EVP_PKEY_decrypt function uses this object for decryption.

#### Correction — Associate Private Key with Context During Initialization

One possible correction is to use the EVP_PKEY_CTX_new function for context initialization and associate a private key with the context object. In the following correction, the private key pkey is obtained from an external source and checked for NULL before use.

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len, EVP_PKEY *pkey){
  if (pkey == NULL) fatal_error();

  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new(pkey, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_decrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_decrypt(ctx, out_buf, &out_len, src, len);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_PKEY_NO_PRIVATE_KEY`
**Impact:** Medium

# Missing private key for X.509 certificate

Missing key might result in run-time error or non-secure encryption

## Description

The defect occurs when you load a X.509 certificate file into the SSL context but you do not load the corresponding private key, or the key that you load into the context is null.

Typically, in a TLS/SSL exchange, the server proves its identity during a TLS/SSL handshake by sending a X.509 certificate that contains information about the server and a public key. The client that receives the certificate uses the public key to encrypt and send a pre-master secret that can only be decrypted with the corresponding private key. The server uses the decrypted pre-master secret and other exchanged messages to generate session keys that are used to encrypt the communication session.

The checker raises no defect if:

- You pass the SSL context as an argument to the function that calls `SSL_new`.
- You declare the SSL context outside the scope of the function handling the connection.

### Risk

Not loading the private key for a X.509 certificate might result in a run-time error on non-secure encryption.

### Fix

Load the private key of the X.509 certificate into the SSL context by calling `SSL_CTX_use_PrivateKey_file` or load the private key into the SSL structure by calling `SSL_use_PrivateKey_file`.

## Examples

### No Private Key Loaded Into SSL Context

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>
#define SSL_SERVER_CRT "server.pem"

#define fatal_error() exit(-1)

void load_cert(SSL_CTX* ctx, const char* certfile)
{
    int ret = SSL_CTX_use_certificate_file(ctx, certfile, SSL_FILETYPE_PEM);
    if (ret <= 0) fatal_error();
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_server_method());
    if (ctx == NULL) fatal_error();
    /* context configuration */
    load_cert(ctx, SSL_SERVER_CRT);

    /* Handle connection */
    ssl = SSL_new(ctx);
    ret = SSL_accept(ssl);
    if (ret <= 0) fatal_error();

    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

In this example, SSL context `ctx` is initiated with server role and the function `load_cert` loads the server certificate into `ctx`. The server then waits for a client to initiate a handshake. However, since the private key is not loaded into the SSL structure, the server cannot decrypt the pre-master secret that a client sends, and the handshake fails.

#### Correction — Load Private Key into SSL Context

One possible correction is to load the private key into the SSL context after you load the server certificate file.

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>
#define SSL_SERVER_CRT "server.pem"
#define SSL_SERVER_KEY "server.key"

#define fatal_error() exit(-1)

void load_cert(SSL_CTX* ctx, const char* certfile)
{
    int ret = SSL_CTX_use_certificate_file(ctx, certfile, SSL_FILETYPE_PEM);
    if (ret <= 0) fatal_error();

    ret = SSL_CTX_use_PrivateKey_file(ctx, SSL_SERVER_KEY, SSL_FILETYPE_PEM);
    if (ret <= 0) fatal_error();
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_server_method());
    if (ctx == NULL) fatal_error();

    /* context configuration */
    load_cert(ctx, SSL_SERVER_CRT);

    /* Handle connection */
    ssl = SSL_new(ctx);
    ret = SSL_accept(ssl);
    if (ret <= 0) fatal_error();

    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

## Result Information

# Missing public key

Context used for cryptography operation is associated with NULL public key or not associated with a public key at all

## Description

This defect occurs when you use a context object for encryption or signature authentication but you have not previously associated the object with a non-NULL public key.

For instance, you initialize the context object with a NULL public key and use the object for encryption later.

```
ctx = EVP_PKEY_CTX_new(pkey, NULL);
...
ret = EVP_PKEY_encrypt_init(ctx);
...
ret = EVP_PKEY_encrypt(ctx, out, &out_len, in, in_len);
```

The counterpart checker `Missing private key` checks for a private key in decryption and signature operations.

### Risk

Without a public key, the encryption or signature authentication step does not happen. The redundant operation often indicates a coding error.

### Fix

Check the placement of the operation (encryption or signature authentication). If the operation is intended to happen, make sure you have done these steps prior to the operation:

- You generated a non-NULL public key.

  For instance:

  ```
  EVP_PKEY *pkey = NULL;
  kctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);

  EVP_PKEY_keygen_init(kctx);
  EVP_PKEY_CTX_set_rsa_keygen_bits(kctx, RSA_2048BITS);
  EVP_PKEY_keygen(kctx, &pkey);
  ```
- You associated a non-NULL context object with the public key.

  For instance:

  ```
  ctx = EVP_PKEY_CTX_new(pkey, NULL);
  ```

  Note: If you use `EVP_PKEY_CTX_new_id` instead of `EVP_PKEY_CTX_new`, you are not associating the context object with a public key.

## Examples

### Missing Step for Associating Private Key with Context

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len){
  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

In this example, the context object ctx is initialized with EVP_PKEY_CTX_new_id instead of EVP_PKEY_CTX_new. The function EVP_PKEY_CTX_new_id does not associate the context object with a key. However, the EVP_PKEY_encrypt function uses this object for decryption.

**Correction — Associate Public Key with Context During Initialization**

One possible correction is to use the EVP_PKEY_CTX_new function for context initialization and associate a public key with the context object. In the following correction, the public key pkey is obtained from an external source and checked for NULL before use.

```
#include <stddef.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
size_t out_len;

int func(unsigned char *src, size_t len, EVP_PKEY *pkey){
  if (pkey == NULL) fatal_error();

  EVP_PKEY_CTX *ctx = EVP_PKEY_CTX_new(pkey, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_encrypt_init(ctx);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_encrypt(ctx, out_buf, &out_len, src, len);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_PKEY_NO_PUBLIC_KEY`
**Impact:** Medium

# Missing salt for hashing operation

Hashed data is vulnerable to rainbow table attack

## Description

This defect occurs when you use a digest context in these functions, but you hash data into the context only once or you use a null salt in all subsequent hashing operations. A salt is random data that you use to improve the security of a hashing operation. The hashing operation takes the salt as an input to produce a more secure hashed value.

- `EVP_DigestFinal`
- `EVP_DigestSignUpdate`
- `EVP_DigestVerifyUpdate`
- `SHA*_Final` family of functions

**Missing salt for hashing operation** raises no defect if no information is available about the context. For instance, if the context is passed as an argument to the function that calls the hashing operation or if the context is declared outside the scope of the function. For example, no defect is raised in this code snippet.

```
EVP_MD_CTX ctx_global;

void foo(EVP_MD_CTX* ctx) {
//ctx passed as argument of func()
    EVP_DigestFinal(ctx, out_buf, &out_len); //no defect
}

void bar() {
// ctx_global declared outside of bar()
    EVP_DigestFinal(&ctx_glob, out_buf, &out_len); //no defect
}
```

### Risk

Hashing the same data without a salt results in the same hashed value. For instance, if you hash user passwords and two users have the same passwords, the hashed passwords are identical. The hashing is then vulnerable to precomputed rainbow attacks.

### Fix

Provide a salt when you hash data.

## Examples

### Data Hashed Into Context Only Once

```
#include <openssl/evp.h>
#include <cstring>
```

```
unsigned char* out_buf;
unsigned int out_len;

void func()
{
    const char* src = "toto";
    EVP_MD_CTX ctx;

    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, strlen(src));
    EVP_DigestFinal(&ctx, out_buf, &out_len);
    EVP_cleanup();
}
```

In this example, context `ctx` is initialized with secure hashing algorithm SHA-256, then `EVP_DigestUpdate` hashes `src` into `ctx`. Because `EVP_DigestUpdate` is called only once, no salt can be provided to improve the security of the hashing operation. The digest value that `EVP_DigestFinal` retrieves is then vulnerable to precomputed rainbow attacks.

#### Correction — Hash Salt Into Context After Initial Data Hash

One possible correction is to hash a salt into the context `ctx` after the first hashing operation. The resulting digest value that `EVP_DigestFinal` retrieves is more secure.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <cstring>

#define BUFF_SIZE_32 32

unsigned char* out_buf;
unsigned int out_len;

void func()
{
    const char* src = "toto";
    const char* salt;

    RAND_bytes((unsigned char*)salt, BUFF_SIZE_32);
    EVP_MD_CTX ctx;

    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, strlen(src));
    EVP_DigestUpdate(&ctx, salt, BUFF_SIZE_32);
    EVP_DigestFinal(&ctx, out_buf, &out_len);
    EVP_cleanup();
}
```

## Result Information

**Group:** Cryptography<br>
**Language:** C | C++<br>
**Default:** Off<br>

# Missing X.509 certificate

Server or client cannot be authenticated

## Description

This defect occurs when you use a context to handle TLS/SSL connections with these functions, but you do not load an X.509 certificate into the context.

- `SSL_accept`
- `SSL_connect`
- `SSL_do_handshake`
- `SSL_write`
- `SSL_read`
- `BIO_do_accept`
- `BIO_do_connect`
- `BIO_do_handshake`

An X.509 certificate is a digital certificate that is issued to an entity. It contains information that identifies the entity. The certificate is used to authenticate connections to the entity identified in the certificate.

The checker raises a defect if:

- For a server authentication, no certificate is loaded before handling a connection.
- For a client authentication, the client attempts to connect to a server a second time after getting an `SSL_ERROR_WANT_X509_LOOKUP` error on the first connection attempt.

### Risk

When you do not load an X.509 certificate into the context to handle TLS/SSL connections, the connection is not secure and is vulnerable to man-in-the-middle (MITM) attacks.

### Fix

Load an X.509 certificate into the context you create to handle TLS/SSL connections.

## Examples

### SSL Structure Created From Context with Missing Certificate

```
#include <openssl/ssl.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <unistd.h>
#include <openssl/err.h>

unsigned char* buf;
int len;

SSL_CTX* InitServerCTX(void)
```

```
{
    SSL_CTX* ctx;
    OpenSSL_add_all_algorithms();
    ctx = SSL_CTX_new(SSLv23_server_method());
    SSL_CTX_set_options(ctx, SSL_OP_NO_SSLv2 | SSL_OP_NO_SSLv3 | SSL_OP_NO_TLSv1);
    if (ctx == NULL) {
        /*handle errors */
    }
    return ctx;
}

int OpenListener(int port)
{
    /* Create server socket */
}

void func()
{
    SSL_CTX* ctx;
    int server, port;
    int ret;
    SSL_library_init();

    ctx = InitServerCTX();
    server = OpenListener(port);
    while (1) {
        struct sockaddr_in addr;
        socklen_t len = sizeof(addr);
        SSL* ssl;

        int client = accept(server, (struct sockaddr*)&addr, &len);
        printf("Connection: %s:%d\n", inet_ntoa(addr.sin_addr), ntohs(addr.sin_port));
        ssl = SSL_new(ctx);
        SSL_set_fd(ssl, client);
        ret = SSL_accept(ssl);
        if (SSL_get_error(ssl, ret) <= 0)
            /* Serve connection */;
        else
            SSL_free(ssl);
    }
    close(server);
    SSL_CTX_free(ctx);
}
```

In this example, `InitServerCTX()` initializes context `ctx` for TLS/SSL connections, but no certificate is loaded into `ctx`. When `SSL_accept` checks the TLS/SLL handshake for the SSL structure created from `ctx`, there is no certificate available to authenticate the server.

### Correction — Before Creating a SSL Structure, Load Certificate Into Context

One possible correction is to, before you create a SSL structure, load a certificate into the context you create for TLS/SSL connections, for instance with `SSL_CTX_use_certificate_file`.

```
#include <openssl/ssl.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <unistd.h>
#include <openssl/err.h>

unsigned char* buf;
int len;

SSL_CTX* InitServerCTX(void)
{
    SSL_CTX* ctx;
    OpenSSL_add_all_algorithms();
    ctx = SSL_CTX_new(SSLv23_server_method());
    SSL_CTX_set_options(ctx, SSL_OP_NO_SSLv2 | SSL_OP_NO_SSLv3 | SSL_OP_NO_TLSv1);
    if (ctx == NULL) {
        /*handle errors */
    }
    return ctx;
}

void LoadCertificates(SSL_CTX* ctx, char* CertFile, char* KeyFile)
{
    if (SSL_CTX_use_certificate_file(ctx, CertFile, SSL_FILETYPE_PEM) <= 0) {
        /* Handle errors */
    }
}

int OpenListener(int port)
{
    /* Create server socket */
}

void func()
{
    SSL_CTX* ctx;
    int server, port;
    int ret;
    SSL_library_init();

    ctx = InitServerCTX();
    LoadCertificates(ctx, "mycert.pem", "mycert.pem");
    server = OpenListener(port);
    while (1) {
        struct sockaddr_in addr;
        socklen_t len = sizeof(addr);
        SSL* ssl;

        int client = accept(server, (struct sockaddr*)&addr, &len);
        printf("Connection: %s:%d\n", inet_ntoa(addr.sin_addr), ntohs(addr.sin_port));
        ssl = SSL_new(ctx);
        SSL_set_fd(ssl, client);
        ret = SSL_accept(ssl);
        if (SSL_get_error(ssl, ret) <= 0)
            /* Serve connection */;
        else
            SSL_free(ssl);
    }
    close(server);
    SSL_CTX_free(ctx);
}
```

# No data added into context

Performing hash operation on empty context might cause run-time errors

## Description

The defect occurs when you only update a message digest context with null data, or you perform a final step on a message digest context without performing any update step.

When you use message digest functions, you typically initialize a message digest context and perform at least one update step to add data into the context. You then sign, verify, or retrieve the data in the context as a final step.

The checker raises no defect if no information is available about the context. For instance, if the context is passed as an argument to the function that calls the hashing operation or if the context is declared outside the scope of the function. For example, no defect is raised in this code snippet.

```
void bar(unsigned char* src, int len, EVP_MD_CTX *ctx) {
    //ctx passed as argument of bar()
    EVP_DigestFinal(ctx, out_buf, &out_len); //no defect
}
EVP_MD_CTX glob_ctx;
void foo(unsigned char* src, int len) {
    //glob_ctx declared outside scope of foo()
    EVP_DigestFinal(&glob_ctx, out_buf, &out_len); //no defect
}
```

### Risk

Performing an update step on a context with null data might result in a run-time error.

Performing a final step on a context with no data might result in unexpected behavior.

### Fix

Perform at least one update operation with non-null data on a message digest context before you sign, verify, or retrieve the data in the context.

## Examples

### No Update Step Before Final Step

```
#include <openssl/evp.h>
#include <stdio.h>

unsigned char out_buf[EVP_MAX_MD_SIZE];
unsigned int out_len;

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);
    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, len);
    EVP_MD_CTX_init(&ctx);
    EVP_DigestFinal(&ctx, out_buf, &out_len);
}
```

In this example, the message digest context `ctx` is initialized and an update operation is performed to add data `src` into the context. The context is then reinitialized but no data is added to `ctx` before `EVP_DigestFinal` attempts to retrieve data from `ctx`, which results in an error.

#### Correction — Perform Final Step Before Reinitializing Context

One possible correction is to perform the final step that retrieves data from the context before you reinitialize the context.

```
#include <openssl/evp.h>
#include <stdio.h>

unsigned char out_buf[EVP_MAX_MD_SIZE];
unsigned int out_len;

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, len);
    EVP_DigestFinal(&ctx, out_buf, &out_len);
    EVP_MD_CTX_init(&ctx);
}
```

### No Data Added to Context

```
#include <openssl/evp.h>
#include <stdio.h>

unsigned char out_buf[EVP_MAX_MD_SIZE];
unsigned int out_len;

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);
    size_t cnt = 0;

    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, cnt);
    EVP_DigestFinal(&ctx, out_buf, &out_len);
}
```

In this example, zero bytes of data is hashed into the message digest context during the update operation. Retrieving data from the context in the final step results in unexpected behavior.

#### Correction — Add non-Null Data Into Context

A possible correction is to add data into the context during the update step before you retrieve data from the context.

```
#include <openssl/evp.h>
#include <stdio.h>

unsigned char out_buf[EVP_MAX_MD_SIZE];
unsigned int out_len;

void func(unsigned char* src, int len)
{
    EVP_MD_CTX ctx;
    EVP_MD_CTX_init(&ctx);

    EVP_DigestInit(&ctx, EVP_sha256());
    EVP_DigestUpdate(&ctx, src, len);
    EVP_DigestFinal(&ctx, out_buf, &out_len);
}
```

# Nonsecure hash algorithm

Context used for message digest creation is associated with weak algorithm

## Description

This defect occurs when you use a cryptographic hash function that is proven to be weak against certain forms of attack.

The hash functions flagged by this checker include SHA-0, SHA-1, MD4, MD5, and RIPEMD-160. The checker detects the use of these hash functions in:

- Functions from the EVP API such as `EVP_DigestUpdate` or `EVP_SignUpdate`.
- Functions from the low level API such as `SHA1_Update` or `MD5_Update`.

### Risk

You use a hash function to create a message digest from input data and thereby ensure integrity of your data. The hash functions flagged by this checker use algorithms with known weaknesses that an attacker can exploit. The attacks can comprise the integrity of your data.

### Fix

Use a more secure hash function. For instance, use the later SHA functions such as SHA-224, SHA-256, SHA-384, and SHA-512.

## Examples

### Use of MD5 Algorithm

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
unsigned int out_len;

void func(unsigned char *src, size_t len, EVP_PKEY* pkey){
  EVP_MD_CTX* ctx = EVP_MD_CTX_create();

  ret = EVP_SignInit_ex(ctx, EVP_md5(), NULL);
  if (ret != 1) fatal_error();

  ret = EVP_DigestUpdate(ctx,src,len);

  if (ret != 1) fatal_error();

  ret = EVP_SignFinal(ctx, out_buf, &out_len, pkey);
  if (ret != 1) fatal_error();
}
```

In this example, during initialization with `EVP_SignInit_ex`, the context object is associated with the weak hash function MD5. The checker flags the usage of this context in the update step with `EVP_DigestUpdate`.

#### Correction — Use SHA-2 Family Function

One possible correction is to use a hash function from the SHA-2 family, such as SHA-256.

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;
unsigned int out_len;

void func(unsigned char *src, size_t len, EVP_PKEY* pkey){
  EVP_MD_CTX* ctx = EVP_MD_CTX_create();

  ret = EVP_SignInit_ex(ctx, EVP_sha256(), NULL);
  if (ret != 1) fatal_error();

  ret = EVP_SignUpdate(ctx, src, len);
  if (ret != 1) fatal_error();

  ret = EVP_SignFinal(ctx, out_buf, &out_len, pkey);
  if (ret != 1) fatal_error();
}
```

# Nonsecure parameters for key generation

Context used for key generation is associated with weak parameters

## Description

This defect occurs when you attempt key generation by using an EVP_PKEY_CTX context object that is associated with weak parameters. What constitutes a weak parameter depends on the public key algorithm used. In the DSA algorithm, a weak parameter can be the result of setting an insufficient parameter length.

For instance, you set the number of bits used for DSA parameter generation to 512 bits, and then use the parameters for key generation:

```
EVP_PKEY_CTX *pctx,*kctx;
EVP_PKEY *params, *pkey;

/* Initializations for parameter generation */
pctx = EVP_PKEY_CTX_new_id(EVP_PKEY_DSA, NULL);
params = EVP_PKEY_new();

/* Parameter generation */
ret = EVP_PKEY_paramgen_init(pctx);
ret = EVP_PKEY_CTX_set_dsa_paramgen_bits(pctx, KEYLEN_512BITS);
ret = EVP_PKEY_paramgen(pctx, &params);

/* Initializations for key generation */
kctx = EVP_PKEY_CTX_new(params, NULL);
pkey = EVP_PKEY_new();

/* Key generation */
ret = EVP_PKEY_keygen_init(kctx);
ret = EVP_PKEY_keygen(kctx, &pkey);
```

### Risk

Weak parameters lead to keys that are not sufficiently strong for encryption and expose sensitive information to known ways of attack.

### Fix

Depending on the algorithm, use these parameters:

- Diffie-Hellman (DH): Set the length of the DH prime parameter to 2048 bits.

  ```
  ret = EVP_PKEY_CTX_set_dh_paramgen_prime_len(pctx, 2048);
  ```

  Set the DH generator to 2 or 5.

  ```
  ret = EVP_PKEY_CTX_set_dh_paramgen_generator(pctx, 2);
  ```
- Digital Signature Algorithm (DSA): Set the number of bits used for DSA parameter generation to 2048 bits.

  ```
  ret = EVP_PKEY_CTX_set_dsa_paramgen_bits(pctx, 2048);
  ```

- RSA: Set the RSA key length to 2048 bits.

  ```
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(kctx, 2048);
  ```
- Elliptic curve (EC): Avoid using curves that are known to be broken, for instance, `X9_62_prime256v1`. Use, for instance, `sect239k1`.

  ```
  ret = EVP_PKEY_CTX_set_ec_paramgen_curve_nid(pctx, NID_sect239k1);
  ```

## Examples

### Insufficient Bits for RSA Key Generation

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  EVP_PKEY_CTX * ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 512);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_keygen(ctx, &pkey);
}
```

In this example, the RSA key generation uses 512 bits, which makes the generated key vulnerable to attacks.

**Correction — Use 2048 bits**

Use 2048 bits for RSA key generation.

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  EVP_PKEY_CTX * ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_keygen(ctx, &pkey);
}
```

## Result Information

# Nonsecure RSA public exponent

Context used in key generation is associated with low exponent value

## Description

This defect occurs when you attempt RSA key generation by using a context object that is associated with a low public exponent.

For instance, you set a public exponent of 3 in the context object, and then use it for key generation.

```
/* Set public exponent */
ret = BN_dec2bn(&pubexp, "3");

/* Initialize context */
ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
pkey = EVP_PKEY_new();
ret = EVP_PKEY_keygen_init(kctx);

/* Set public exponent in context */
ret = EVP_PKEY_CTX_set_rsa_keygen_pubexp(ctx, pubexp);

/* Generate key */
ret = EVP_PKEY_keygen(kctx, &pkey);
```

### Risk

A low RSA public exponent makes certain kinds of attacks more damaging, especially when a weak padding scheme is used or padding is not used at all.

### Fix

It is recommended to use a public exponent of 65537. Using a higher public exponent can make the operations slower.

## Examples

### Using RSA Public Exponent of 3

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  BIGNUM* pubexp;
  EVP_PKEY_CTX* ctx;

  pubexp = BN_new();
  if (pubexp == NULL) fatal_error();
  ret = BN_set_word(pubexp, 3);
  if (ret <= 0) fatal_error();

  ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_pubexp(ctx, pubexp);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_keygen(ctx, &pkey);
}
```

In this example, an RSA public exponent of 3 is associated with the context object `ctx`. The low exponent makes operations that use the generated key vulnerable to certain attacks.

**Correction — Use Public Exponent of 65537**

One possible correction is to use the recommended public exponent 65537.

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
int func(EVP_PKEY *pkey){
  BIGNUM* pubexp;
  EVP_PKEY_CTX* ctx;

  pubexp = BN_new();
  if (pubexp == NULL) fatal_error();
  ret = BN_set_word(pubexp, 65537);
  if (ret <= 0) fatal_error();

  ctx = EVP_PKEY_CTX_new_id(EVP_PKEY_RSA, NULL);
  if (ctx == NULL) fatal_error();

  ret = EVP_PKEY_keygen_init(ctx);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_bits(ctx, 2048);
  if (ret <= 0) fatal_error();
  ret = EVP_PKEY_CTX_set_rsa_keygen_pubexp(ctx, pubexp);
  if (ret <= 0) fatal_error();
  return EVP_PKEY_keygen(ctx, &pkey);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_RSA_LOW_EXPONENT`

**Impact:** Medium

# Nonsecure SSL/TLS protocol

Context used for handling SSL/TLS connections is associated with weak protocol

## Description

This defect occurs when you do not disable nonsecure protocols in an SSL_CTX or SSL context object before using the object for handling SSL/TLS connections.

For instance, you disable the protocols SSL2.0 and TLS1.0 but forget to disable the protocol SSL3.0, which is also considered weak.

```
/* Create and configure context */
ctx = SSL_CTX_new(SSLv23_method());
SSL_CTX_set_options(ctx, SSL_OP_NO_SSLv2|SSL_OP_NO_TLSv1);

/* Use context to handle connection */
ssl = SSL_new(ctx);
SSL_set_fd(ssl, NULL);
ret = SSL_connect(ssl);
```

### Risk

The protocols SSL2.0, SSL3.0, and TLS1.0 are considered weak in the cryptographic community. Using one of these protocols can expose your connections to cross-protocol attacks. The attacker can decrypt an RSA ciphertext without knowing the RSA private key.

### Fix

Disable the nonsecure protocols in the context object before using the object to handle connections.

```
/* Create and configure context */
ctx = SSL_CTX_new(SSLv23_method());
SSL_CTX_set_options(ctx, SSL_OP_NO_SSLv2|SSL_OP_NO_SSLv3|SSL_OP_NO_TLSv1);
```

## Examples

### Nonsecure Protocols Not Disabled

```
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <openssl/ssl.h>
#include <openssl/err.h>

#define fatal_error() exit(-1)

int ret;
int func(){
  SSL_CTX *ctx;
  SSL *ssl;

  SSL_library_init();

  /* context configuration */
  ctx = SSL_CTX_new(SSLv23_client_method());
  if (ctx==NULL) fatal_error();

  ret = SSL_CTX_use_certificate_file(ctx, "cert.pem", SSL_FILETYPE_PEM);
  if (ret <= 0) fatal_error();

  ret = SSL_CTX_load_verify_locations(ctx, NULL, "ca/path");
  if (ret <= 0) fatal_error();

  /* Handle connection */
  ssl = SSL_new(ctx);
  if (ssl==NULL) fatal_error();
  SSL_set_fd(ssl, NULL);

  return SSL_connect(ssl);
}
```

In this example, the protocols SSL2.0, SSL3.0, and TLS1.0 are not disabled in the context object before the object is used for a new connection.

**Correction — Disable Nonsecure Protocols**

Disable nonsecure protocols before using the objects for a new connection. Use the function `SSL_CTX_set_options` to disable the protocols SSL2.0, SSL3.0, and TLS1.0.

```
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <openssl/ssl.h>
#include <openssl/err.h>

#define fatal_error() exit(-1)

int ret;
int func(){
  SSL_CTX *ctx;
  SSL *ssl;

  SSL_library_init();

  /* context configuration */
  ctx = SSL_CTX_new(SSLv23_client_method());
  if (ctx==NULL) fatal_error();

  SSL_CTX_set_options(ctx, SSL_OP_NO_SSLv2|SSL_OP_NO_SSLv3|SSL_OP_NO_TLSv1);

  ret = SSL_CTX_use_certificate_file(ctx, "cert.pem", SSL_FILETYPE_PEM);
  if (ret <= 0) fatal_error();
  ret = SSL_CTX_load_verify_locations(ctx, NULL, "ca/path");
  if (ret <= 0) fatal_error();

  /* Handle connection */
  ssl = SSL_new(ctx);
  if (ssl==NULL) fatal_error();
  SSL_set_fd(ssl, NULL);

  return SSL_connect(ssl);
}
```

# Predictable block cipher initialization vector

Initialization vector is generated from a weak random number generator

## Description

This defect occurs when you use a weak random number generator for the block cipher initialization vector.

### Risk

If you use a weak random number generator for the initiation vector, your data is vulnerable to dictionary attacks.

Block ciphers break your data into blocks of fixed size. Block cipher modes such as CBC (Cipher Block Chaining) protect against dictionary attacks by XOR-ing each block with the encrypted output from the previous block. To protect the first block, these modes use a random initialization vector (IV). If you use a weak random number generator for your IV, your data becomes vulnerable to dictionary attacks.

### Fix

Use a strong pseudo-random number generator (PRNG) for the initialization vector. For instance, use:

- OS-level PRNG such as `/dev/random` on UNIX or `CryptGenRandom()` on Windows
- Application-level PRNG such as Advanced Encryption Standard (AES) in Counter (CTR) mode, HMAC-SHA1, etc.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

## Examples

### Predictable Initialization Vector

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_pseudo_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

In this example, the function `RAND_pseudo_bytes` declared in `openssl/rand.h` produces the initialization vector. The byte sequences that `RAND_pseudo_bytes` generates are not necessarily unpredictable.

#### Correction — Use Strong Random Number Generator

Use a strong random number generator to produce the initialization vector. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

## Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_PREDICTABLE_IV`
**Impact:** Medium

# Version History

# Predictable cipher key

Encryption or decryption key is generated from a weak random number generator

## Description

This defect occurs when you use a weak random number generator for the encryption or decryption key.

### Risk

If you use a weak random number generator for the encryption or decryption key, an attacker can retrieve your key easily.

You use a key to encrypt and later decrypt your data. If a key is easily retrieved, data encrypted using that key is not secure.

### Fix

Use a strong pseudo-random number generator (PRNG) for the key. For instance:

- Use an OS-level PRNG such as /dev/random on UNIX or CryptGenRandom() on Windows
- Use an application-level PRNG such as Advanced Encryption Standard (AES) in Counter (CTR) mode, HMAC-SHA1, etc.

For a list of random number generators that are cryptographically weak, see Vulnerable pseudo-random number generator.

## Examples

### Predictable Cipher Key

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_pseudo_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

In this example, the function RAND_pseudo_bytes declared in openssl/rand.h produces the cipher key. However, the byte sequences that RAND_pseudo_bytes generates are not necessarily unpredictable.

### Correction — Use Strong Random Number Generator

One possible correction is to use a strong random number generator to produce the cipher key. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

# Server certificate common name not checked

Attacker might use valid certificate to impersonate trusted host

## Description

The defect occurs when you do not check the common name provided in the server certificate against the domain name of the server.

Typically, when a client connects to a server, the server sends a digital certificate to the client that identifies the server as a trusted entity. The certificate contains information about the server, including the common name of the server. The common name matches the server domain name that the certificate identifies as a trusted entity.

The checker raises no defect if:

- You pass the SSL context as an argument to the function that calls `SSL_new`.
- You declare the SSL context outside the scope of the function handling the connection.

### Risk

A malicious attacker might use a valid certificate to impersonate a trusted host, resulting in the client interacting with an untrusted server.

### Fix

Use one of these functions to specify the server domain name that the program checks against the common name provided in the server certificate.

- `SSL_set_tlsext_host_name`
- `SSL_set1_host`
- `SSL_add1_host`

## Examples

### Client Checks Server Certificate but not Server Domain Name

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

void check_certificate(SSL_CTX* ctx, SSL* ssl)
{
    /* Check for Client authentication error */
    if (!SSL_get_peer_certificate(ssl)) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }
    /* Check for Client authentication error */
    if (SSL_get_verify_result(ssl) != X509_V_OK) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_client_method());
    if (ctx == NULL) fatal_error();

    /* Handle connection */
    ssl = SSL_new(ctx);
    SSL_set_connect_state(ssl);
    check_certificate(ctx, ssl);
    ret = SSL_connect(ssl);
    if (ret <= 0) fatal_error();

    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

In this example, an SSL structure is initiated with a client connection method. The client validates the server certificate with `check_certificate`. However, the client does not check that the certificate common name matches the domain name of the server. An attacker might use the valid certificate to impersonate the trusted server.

**Correction — Specify a Domain Name to Check Against the Certificate Common Name**

One possible correction is to use `SSL_set1_host` to specify the expected domain name that the program checks against the server certificate common name.

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

void check_certificate(SSL_CTX* ctx, SSL* ssl)
{
    /* Check for Client authentication error */
    if (!SSL_get_peer_certificate(ssl)) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }
    /* Check for Client authentication error */
    if (SSL_get_verify_result(ssl) != X509_V_OK) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_client_method());
    if (ctx == NULL) fatal_error();

    /* Handle connection */
    ssl = SSL_new(ctx);
    SSL_set_connect_state(ssl);
    check_certificate(ctx, ssl);
    ret = SSL_set1_host(ssl, "www.mysite.com");
    if (ret <= 0) fatal_error();
    ret = SSL_connect(ssl);
    if (ret <= 0) fatal_error();

    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

## Result Information

# TLS/SSL connection method not set

Program cannot determine whether to call client or server routines

## Description

The defect occurs when you call one of these functions without explicitly setting the connection method of the TLS/SSL context.

- SSL_read
- SSL_write
- SSL_do_handshake

The communication between server and client entities that use a TLS/SSL connection begins with a handshake. During the handshake, the parties exchange information and establish the encryption algorithm and session keys the parties use during the session. The connection methods for the server and client use different routines for the handshake.

The checker raises no defect if:

- You use SSL_connect (client) and SSL_accept (server) functions. These functions set the correct handshake routines automatically.
- You pass the SSL context as an argument to the function that calls SSL_new.
- You declare the SSL context outside the scope of the function handling the connection.

### Risk

You cannot begin a handshake if the SSL engine does not know which connection method routines to call.

### Fix

- For client handshake routines, call SSL_set_connect_state before you begin the handshake.
- For server handshake routines, call SSL_set_accept_state before you begin the handshake.

## Examples

### Server Connection Method Not Set Explicitly

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

int len;
unsigned char buf;
volatile int rd;
```

```
const SSL_METHOD*  set_method()
{
    return SSLv23_server_method();
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;
    const SSL_METHOD* method =  set_method();
    ctx = SSL_CTX_new(method);
    ssl = SSL_new(ctx);

    switch (rd) {
    case 1:
        ret = SSL_read(ssl, (void*)buf, len);
        if (ret <= 0) fatal_error();
        break;
    case 2:
        ret = SSL_do_handshake(ssl);
        if (ret <= 0) fatal_error();
        break;
    default:
        ret = SSL_write(ssl, (void*)buf, len);
        if (ret <= 0) fatal_error();
        break;
    }
}
```

In this example, the SSL context `ctx` is generated with server connection method `SSLv23_server_method`. However, the connection method is not set explicitly for the SSL structure `ssl` before the attempt to read from the connection, initiate a handshake, or write to the connection.

**Correction — Set Server Connection Method Explicitly**

One possible correction is to call `SSL_set_accept_state` to set the server role for the SSL structure `ssl` before you begin the handshake.

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

int len;
unsigned char buf;
volatile int rd;

const SSL_METHOD*  set_method()
{
    return SSLv23_server_method();
}

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;
    const SSL_METHOD* method =  set_method();
    ctx = SSL_CTX_new(method);
    ssl = SSL_new(ctx);
    SSL_set_accept_state(ssl);

    switch (rd) {
    case 1:
        ret = SSL_read(ssl, (void*)buf, len);
        if (ret <= 0) fatal_error();
        break;
    case 2:
        ret = SSL_do_handshake(ssl);
        if (ret <= 0) fatal_error();
        break;
    default:
        ret = SSL_write(ssl, (void*)buf, len);
        if (ret <= 0) fatal_error();
        break;
    }
}
```

# TLS/SSL connection method set incorrectly

Program calls functions that do not match role set by connection method

## Description

The defect occurs when you call functions that do not match the role set by the connection method that you specified for the SSL context.

The functions that you call when handling a TLS/SSL connection between client and server entities are different, depending on the role of the entity. For instance, the connection between a server and a client begins with a handshake. The client always initiates the handshake. You use `SSL_accept` with a server entity to wait for a client to initiate the handshake.

Typically, you set a connection method when you initiate the SSL context. The method specifies the role of the entity.

The checker flags the use of functions that do not match the connection method specified for the SSL context. See the **Event** column in the **Results Details** pane to view connection method specified for the SSL context.

### Risk

If you set the TLS/SSL connection method incorrectly, the functions you use to handle the connection might not match the role specified by the method. For instance, you use `SSL_accept` with a client entity to wait for a client to initiate a handshake instead of `SSL_connect` to initiate the handshake with a server.

### Fix

Make sure that you use functions that match the TLS/SSL connection method to handle the connection.

## Examples

### Client Waiting for Client to Initiate Handshake

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

const SSL_METHOD*  set_method()
{
    return SSLv23_client_method();
}

void set_method_1(SSL* ssl)
{
    SSL_set_connect_state(ssl);
}
void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;
    const SSL_METHOD* method = set_method();
    ctx = SSL_CTX_new(method);
    ssl = SSL_new(ctx);
    set_method_1(ssl);
    ret = SSL_accept(ssl);
    if (ret <= 0) fatal_error();
}
```

In this example, the SSL context `ctx` is initialized with a client role. The SSL structure is also explicitly set to client role through the call to `set_method_1`. To establish a connection with the server, the client should initiate a handshake with the server. Instead, `SSL_accept` causes the client to wait for another client to initiate a handshake.

#### Correction — Use SSL_connect to Initiate Handshake with Server

One possible correction is to use `SSL_connect` to initiate the TLS/SSL handshake with the server.

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

const SSL_METHOD*  set_method()
{
    return SSLv23_client_method();
}

void set_method_1(SSL* ssl)
{
    SSL_set_connect_state(ssl);
}
void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;
    const SSL_METHOD* method = set_method();
    ctx = SSL_CTX_new(method);
    ssl = SSL_new(ctx);
    set_method_1(ssl);
    ret = SSL_connect(ssl);
    if (ret <= 0) fatal_error();
}
```

## Result Information

# Weak cipher algorithm

Encryption algorithm associated with the cipher context is weak

## Description

This defect occurs when you associate a weak encryption algorithm with the cipher context.

### Risk

Some encryption algorithms have known flaws. Though the OpenSSL library still supports the algorithms, you must avoid using them.

If your cipher algorithm is weak, an attacker can decrypt your data by exploiting a known flaw or brute force attacks.

### Fix

Use algorithms that are well-studied and widely acknowledged as secure.

For instance, the Advanced Encryption Standard (AES) is a widely accepted cipher algorithm.

## Examples

### Use of DES Algorithm

```
#include <openssl/evp.h>
#include <stdlib.h>

void func(unsigned char *key, unsigned char *iv) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);
    const EVP_CIPHER * ciph = EVP_des_cbc();
    EVP_EncryptInit_ex(ctx, ciph, NULL, key, iv);
}
```

In this example, the routine `EVP_des_cbc()` invokes the Data Encryption Standard (DES) algorithm, which is now considered as non-secure and relatively slow.

#### Correction — Use AES Algorithm

One possible correction is to use the faster and more secure Advanced Encryption Standard (AES) algorithm instead.

```
#include <openssl/evp.h>
#include <stdlib.h>

void func(unsigned char *key, unsigned char *iv) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);
    const EVP_CIPHER * ciph = EVP_aes_128_cbc();
    EVP_EncryptInit_ex(ctx, ciph, NULL, key, iv);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_WEAK_CIPHER`
**Impact:** Medium

## Version History

**Introduced in R2017a**

# Weak cipher mode

Encryption mode associated with the cipher context is weak

## Description

This defect occurs when you associate a weak block cipher mode with the cipher context.

The cipher mode that is especially flagged by this defect is the Electronic Code Book (ECB) mode.

### Risk

The ECB mode does not support protection against dictionary attacks.

An attacker can decrypt your data even using brute force attacks.

### Fix

Use a cipher mode more secure than ECB.

For instance, the Cipher Block Chaining (CBC) mode protects against dictionary attacks by:

- XOR-ing each block of data with the encrypted output from the previous block.
- XOR-ing the first block of data with a random initialization vector (IV).

## Examples

### Use of ECB Mode

```
#include <openssl/evp.h>
#include <stdlib.h>

void func(unsigned char *key, unsigned char *iv) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);
    const EVP_CIPHER * ciph = EVP_aes_128_ecb();
    EVP_EncryptInit_ex(ctx, ciph, NULL, key, iv);
}
```

In this example, the routine `EVP_aes_128_ecb()` invokes the Advanced Encryption Standard (AES) algorithm in the Electronic Code Book (ECB) mode. The ECB mode does not support protection against dictionary attacks.

#### Correction — Use CBC Mode

One possible correction is to use the Cipher Block Chaining (CBC) mode instead.

```
#include <openssl/evp.h>
#include <stdlib.h>
```

```
void func(unsigned char *key, unsigned char *iv) {
    EVP_CIPHER_CTX *ctx = EVP_CIPHER_CTX_new();
    EVP_CIPHER_CTX_init(ctx);
    const EVP_CIPHER * ciph = EVP_aes_128_cbc();
    EVP_EncryptInit_ex(ctx, ciph, NULL, key, iv);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_CIPHER_WEAK_MODE`
**Impact:** Medium

# Weak padding for RSA algorithm

Context used in encryption or signing operation is associated with insecure padding type

## Description

This defect occurs when you perform RSA encryption or signature by using a context object that was previously associated with a weak padding scheme.

For instance, you perform encryption by using a context object that is associated with the PKCS#1v1.5 padding scheme. The scheme is considered insecure and has already been broken.

```
ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_PADDING);
...
ret = EVP_PKEY_encrypt(ctx, out, &out_len, in, in_len)
```

### Risk

Padding schemes remove determinism from the RSA algorithm and protect RSA operations from certain kinds of attacks. Padding schemes such as PKCS#1v1.5, ANSI X9.31, and SSLv23 are known to be vulnerable. Do not use these padding schemes for encryption or signature operations.

### Fix

Before performing an RSA operation, associate the context object with a strong padding scheme.

- Encryption: Use the OAEP padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_OAEP_PADDING` or the `RSA_padding_add_PKCS1_OAEP` function.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_OAEP_PADDING);
  ```

  You can then use functions such as `EVP_PKEY_encrypt` / `EVP_PKEY_decrypt` or `RSA_public_encrypt` / `RSA_private_decrypt` on the context.
- Signature: Use the RSA-PSS padding scheme.

  For instance, use the `EVP_PKEY_CTX_set_rsa_padding` function with the argument `RSA_PKCS1_PSS_PADDING`.

  ```
  ret = EVP_PKEY_CTX_set_rsa_padding(ctx, RSA_PKCS1_PSS_PADDING);
  ```

  You can then use functions such as the `EVP_PKEY_sign`-`EVP_PKEY_verify` pair or the `RSA_private_encrypt`-`RSA_public_decrypt` pair on the context.

## Examples

### Encryption with PKCS#1v1.5 Padding

```
#include <stddef.h>
#include <openssl/rsa.h>
```

```
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;

int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();

  return RSA_public_encrypt(len, src, out_buf, rsa, RSA_PKCS1_PADDING);
}
```

In this example, the PKCS#1v1.5 padding scheme is used in the encryption step.

#### Correction — Use OAEP Padding Scheme

Use the OAEP padding scheme for stronger encryption.

```
#include <stddef.h>
#include <openssl/rsa.h>
#include <openssl/evp.h>

#define fatal_error() exit(-1)

int ret;
unsigned char *out_buf;

int func(unsigned char *src, size_t len, RSA* rsa){
  if (rsa == NULL) fatal_error();

  return RSA_public_encrypt(len, src, out_buf, rsa, RSA_PKCS1_OAEP_PADDING);
}
```

### Result Information

**Group:** Cryptography
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `CRYPTO_RSA_WEAK_PADDING`
**Impact:** Medium

## Version History

**Introduced in R2018a**

# X.509 peer certificate not checked

Connection might be vulnerable to man-in-the-middle attacks

## Description

The defect occurs when you do not properly check the X.509 certificate used to authenticate the TLS/SSL connection when handling the connection. To properly check the certificate, you must call these two functions together to obtain and verify the certificate.

- `SSL_get_peer_certificate`: Obtains a certificate from the client or server you are trying to authenticate. The function returns NULL if no certificate is present. Even if the function returns a certificate, the certificate must still be checked.
- `SSL_get_verify_result`: Verifies the certificate presented by the client or server. If you do not obtain a certificate before calling this function, there are no verification errors and the function returns successfully.

The checker raises a defect on the functions `SSL_read` or `SSL_write` when you attempt to read from or write to the TLS/SSL connection.

The checker raises no defect if:

- You declare the SSL context outside the scope of the function handling the connection.
- You use anonymous cypher suites.

### Risk

If you do not properly check the validity of the certificate of the peer you are attempting to authenticate, your connection is vulnerable to man-in-the-middle attacks.

### Fix

To properly check the validity of the certificate, call both `SSL_get_peer_certificate` and `SSL_get_verify_result`.

## Examples

### Client Certificate Obtained But Not Verified

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)

int len;
unsigned char buf;
```

```
void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_client_method());
    if (ctx == NULL) fatal_error();

    /* Set to require peer (client) certificate */
    SSL_CTX_set_verify(ctx, SSL_VERIFY_PEER, NULL);

    /* Handle connection */
    ssl = SSL_new(ctx);
    if (ssl == NULL) fatal_error();
    ret = SSL_set_fd(ssl, NULL);
    if (!ret) fatal_error();
    ret = SSL_connect(ssl);
    if (ret <= 0) fatal_error();

    /* Check for Client authentication error */
    if (!SSL_get_peer_certificate(ssl)) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }

    /*Read message from the client.*/
    ret = SSL_read(ssl, (void*)buf, len);
    if (ret <= 0) fatal_error();

    /* Close connection */
    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

In this example, a TLS/SSL context is created for a server connection method. The function `SSL_get_peer_certificate` then requests the client certificate to authenticate the connection. However, the server then attempts to read from the connection without checking the validity of the returned certificate. The certificate might be invalid, and the connection could be vulnerable to a man-in-the-middle attack.

**Correction — Check the Validity of the Returned Certificate**

One possible correction is to check the validity of the returned certificate by calling `SSL_get_verify_result`.

```
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <openssl/ssl.h>

#define fatal_error() exit(-1)
```

```
int len;
unsigned char buf;

void func()
{
    int ret;
    SSL_CTX* ctx;
    SSL* ssl;

    /* creation context for the SSL protocol */
    ctx = SSL_CTX_new(SSLv23_client_method());
    if (ctx == NULL) fatal_error();

    /* Set to require peer (client) certificate */
    SSL_CTX_set_verify(ctx, SSL_VERIFY_PEER, NULL);

    /* Handle connection */
    ssl = SSL_new(ctx);
    if (ssl == NULL) fatal_error();
    ret = SSL_set_fd(ssl, NULL);
    if (!ret) fatal_error();
    ret = SSL_connect(ssl);
    if (ret <= 0) fatal_error();

    /* Check for Client authentication error */
    if (!SSL_get_peer_certificate(ssl)) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }

    if (SSL_get_verify_result(ssl) != X509_V_OK) {
        printf("SSL Client Authentication error\n");
        SSL_free(ssl);
        SSL_CTX_free(ctx);
        exit(0);
    }

    /*Read message from the client.*/
    ret = SSL_read(ssl, (void*)buf, len);
    if (ret <= 0) fatal_error();

    /* Close connection */
    SSL_free(ssl);
    SSL_CTX_free(ctx);
}
```

# Tainted Data Defects

# Array access with tainted index

Array index from unsecure source possibly outside array bounds

## Description

This defect occurs when you access an array by using an index that is obtained from unsecure sources and which has not been validated.

### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];//Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The index `num` is obtained from an unsecure source and the function `taintedarrayindex` does not check to see if `num` is inside the range of `tab`.

### Correction — Check Range Before Use

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_ARRAY_INDEX`
**Impact:** Medium

# Command executed from externally controlled path

Path argument from an unsecure source

## Description

This defect occurs when the path to a command executed in the program is constructed from external sources.

### Risk

An attacker can:

- Change the command that the program executes, possibly to a command that only the attack can control.
- Change the environment in which the command executes, by which the attacker controls what the command means and does.

### Fix

Before calling the command, validate the path to make sure that it is the intended location.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Executing Path from Environment Variable

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void bug_taintedpathcmd() {
    char cmd[SIZE128] = "";
    char* userpath = getenv("MYAPP_PATH");

    strncpy(cmd, userpath, SIZE100);//Noncompliant
    strcat(cmd, "/ls *");
    /* Launching command */
    system(cmd);//Noncompliant
}
```

This example obtains a path from an environment variable MYAPP_PATH. The path string is tainted. Polyspace flags its use in the strncopy function. system runs a command from the tainted path without checking the value of the path. If the path is not the intended path, your program executes in the wrong location.

**Correction — Use Trusted Path**

One possible correction is to use a list of allowed paths to match against the environment variable path.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

/* Function to sanitize a string */
/* Any defect is localized here */
int sanitize_str(char* s, size_t n) {
    int res = 0;
    /* String is ok if */
    if (s && n>0 && n<SIZE128) {
        /* - string is not null                     */
        /* - string has a positive and limited size */
        s[n-1] = '\0';  /* Add a security \0 char at end of string *///Noncompliant
        /* Tainted pointer detected above, used as "firewall" */
        res = 1;
    }
    return res;
}

/* Authorized path ids */
enum { PATH0=1, PATH1, PATH2 };

void taintedpathcmd() {
    char cmd[SIZE128] = "";

    char* userpathid = getenv("MYAPP_PATH_ID");
    if (sanitize_str(userpathid, SIZE100)) {
        int pathid = atoi(userpathid);

        char path[SIZE128] = "";
        switch(pathid) {
            case PATH0:
                strcpy(path, "/usr/local/my_app0");
                break;
            case PATH1:
                strcpy(path, "/usr/local/my_app1");
                break;
            case PATH2:
                strcpy(path, "/usr/local/my_app2");
                break;
            default:
                /* do nothing */
        break;
        }
        if (strlen(path)>0) {
            strncpy(cmd, path, SIZE100);
            strcat(cmd, "/ls *");
            system(cmd);
        }
    }
}
```

### Result Information

# Execution of externally controlled command

Command argument from an unsecure source vulnerable to operating system command injection

## Description

This defect occurs when commands are fully or partially constructed from externally controlled input.

### Risk

Attackers can use the externally controlled input as operating system commands, or arguments to the application. An attacker could read or modify sensitive data can be read or modified, execute unintended code, or gain access to other aspects of the program.

### Fix

Validate the inputs to allow only intended input values. For example, create a list of acceptable inputs and compare the input against this list.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Call External Command

```
#include "stdlib.h"
#include "stdio.h"
#include "string.h"
#include "unistd.h"
#include "dlfcn.h"
#include "limits.h"
#define MAX 128

void taintedexternalcmd(void)
{
    char* usercmd;
    fgets(usercmd,MAX,stdin);
    char cmd[MAX] = "/usr/bin/cat ";
    strcat(cmd, usercmd);
    system(cmd);//Noncompliant
}
```

This example function calls a command from a user input without checking the command variable.

### Correction — Use a Predefined Command

One possible correction is to use a `switch` statement to run a predefined command, using the user input as the switch variable.

```
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include "stdlib.h"
#include "stdio.h"
#include "string.h"
#include "unistd.h"
#include "dlfcn.h"
#include "limits.h"

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
enum { CMD0 = 1, CMD1, CMD2 };

void taintedexternalcmd(void)
{
    int usercmd = strtol(getenv("cmd"),NULL,10);
    char cmd[SIZE128] = "/usr/bin/cat ";

    switch(usercmd) {
        case CMD0:
            strcat(cmd, "*.c");
            break;
        case CMD1:
            strcat(cmd, "*.h");
            break;
        case CMD2:
            strcat(cmd, "*.cpp");
            break;
        default:
            strcat(cmd, "*.c");
    }
    system(cmd);
}
```

## Result Information

# Host change using externally controlled elements

Changing host ID from an unsecure source

## Description

This defect occurs when routines that change the host ID, such as `sethostid` (Linux) or `SetComputerName` (Windows), use arguments that are externally controlled.

### Risk

The tainted host ID value can allow external control of system settings. This control can disrupt services, cause unexpected application behavior, or cause other malicious intrusions.

### Fix

Use caution when changing or editing the host ID. Do not allow user-provided values to control sensitive data.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Change Host ID from Function Argument

```
#include <unistd.h>
#include <stdlib.h>

void bug_taintedhostid(void) {
    long userhid = strtol(getenv("HID"),NULL,10);
    sethostid(userhid);//Noncompliant
}
```

This example sets a new host ID using the argument passed to the function. Before using the host ID, check the value passed in.

#### Correction — Predefined Host ID

One possible correction is to change the host ID to a predefined ID. This example uses the host argument as a switch variable to choose between the different, predefined host IDs.

```
#include <unistd.h>
#include <stdlib.h>

extern long called_taintedhostid_sanitize(long);
enum { HI0 = 1, HI1, HI2, HI3 };
```

```
void taintedhostid(void) {
    long host = strtol(getenv("HID"),NULL,10);
    long hid = 0;
    switch(host) {
        case HI0:
            hid = 0x7f0100;
            break;
        case HI1:
            hid = 0x7f0101;
            break;
        case HI2:
            hid = 0x7f0102;
            break;
        case HI3:
            hid = 0x7f0103;
            break;
        default:
            /* do nothing */
        break;
    }
    if (hid > 0) {
        sethostid(hid);
    }
}
```

## Result Information

# Library loaded from externally controlled path

Using a library argument from an externally controlled path

## Description

This defect occurs when libraries are loaded from fixed or externally controlled unsecure paths and unintended actors can control one or more locations on the paths.

### Risk

If an attacker knows or controls the path that you use to load a library, the attacker can change:

- The library that the program loads, replacing the intended library and commands.
- The environment in which the library executes, giving unintended permissions and capabilities to the attacker.

### Fix

When possible, use hard-coded or fully qualified path names to load libraries. It is possible the hard-coded paths do not work on other systems. Use a centralized location for hard-coded paths, so that you can easily modify the path within the source code.

Another solution is to use functions that require explicit paths. For example, `system()` does not require a full path because it can use the `PATH` environment variable. However, `execl()` and `execv()` do require the full path.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Call Custom Library

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
```

```
void* taintedpathlib() {
    void* libhandle = NULL;
    char lib[SIZE128] = "";
    char* userpath = getenv("LD_LIBRARY_PATH");
    strncpy(lib, userpath, SIZE128);//Noncompliant- userpath is tainted
    strcat(lib, "/libX.so");
    libhandle = dlopen(lib, 0x00001);//Noncompliant
    return libhandle;
}
```

This example loads the library `libX.so` from an environment variable `LD_LIBRARY_PATH`. An attacker can change the library path in this environment variable. The actual library you load could be a different library from the one that you intend.

**Correction — Change and Check Path**

One possible correction is to change how you get the library path and check the path of the library before opening the library. This example receives the path as an input argument but then performs the following checks on the path:

- The function `sanitize_str` protects against possible buffer overflows.
- The function `identified_safe_libX_folder` checks if the path belongs to a list of allowed paths.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

/* Use allowlist */
static const char *libX_safe_folder[] = {
  "/usr/",
  "/usr/lib",
  "/lib"
};

/* Return the index if the input is in the allowlist */
int identified_safe_libX_folder(const char* path)
{
  for (int i = 0; i < sizeof(libX_safe_folder) / sizeof(libX_safe_folder[0]); i ++)
    {
      if (strcmp(path, libX_safe_folder[i]) == 0)
      return i;
    }
  return -1;
}

/* Function to sanitize a string */
```

```
char *sanitize_str(char* s, size_t n) {
  /* strlen is used here as a kind of firewall for tainted string errors */
  if (strlen(s) > 0 && strlen(s) < n)
    return s;
  else
    return NULL;
}

void* taintedpathlib(char* userpath) {
  void* libhandle = NULL;
  const char *const checked_userpath = sanitize_str(userpath, SIZE128);
  if (checked_userpath != NULL) {
    int index = identified_safe_libX_folder(checked_userpath);
    if (index > 0) {
      char lib[SIZE128] = "";
      strncpy(lib, libX_safe_folder[index], SIZE128);
      strcat(lib, "/libX.so");
      libhandle = dlopen(lib, RTLD_LAZY);
    }
  }
  return libhandle;
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_PATH_LIB`
**Impact:** Medium

# Loop bounded with tainted value

Loop controlled by a value from an unsecure source

## Description

This defect occurs when a loop is bounded by values obtained from unsecure sources.

### Risk

A tainted value can cause over looping or infinite loops. Attackers can use this vulnerability to terminate your program or cause other unintended behavior.

### Fix

Before starting the loop, validate unknown boundary and iterator values by validating their low bounds and high bounds. Execute the loop only when both the lower bound and upper bound of the tainted values are validated. Explicitly check that both the lower and upper bound of the tainted value is acceptable. Alternatively, saturate or clamp the tainted value.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Loop Boundary From User Input

```
#include<stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    for (int i=0 ; i < count; ++i) {//Noncompliant
        res += i;
    }
    return res;
}
```

In this example, the function uses a user input to loop `count` times. `count` could be any number because the value is not checked before starting the `for` loop.

#### Correction: Clamp Tainted Loop Control

One possible correction is to clamp the tainted loop control. To validate the tainted loop variable `count`, this example limits `count` to a minimum value and a maximum value by using inline functions `min` and `max`. Regardless of the user input, the value of `count` remains within a known range.

```
#include<stdio.h>
#include<algorithm>
#define MIN 50
#define MAX 128
static  inline int max(int a, int b) { return a > b ? a : b;}
static inline int min(int a, int b) { return a < b ? a : b; }

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    count = max(MIN, min(count, MAX));
    for (int i=0 ; i<count ; ++i) {
        res += i;
    }
    return res;
}
```

#### Correction — Check Tainted Loop Control

Another possible correction is to check the low bound and the high bound of the tainted loop boundary variable before starting the `for` loop. This example checks the low and high bounds of `count` and executes the loop only when `count` is between 0 and 127.

```
#include<stdio.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;

    if (count>=0 && count<SIZE128) {
        for (int i=0 ; i<count ; ++i) {
            res += i;
        }
    }
    return res;
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off

**Command-Line Syntax:** `TAINTED_LOOP_BOUNDARY`
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Memory allocation with tainted size

Size argument to memory function is from an unsecure source

## Description

This defect occurs when a memory allocation function, such as `calloc` or `malloc`, uses a size argument from an unsecure source.

### Risk

Uncontrolled memory allocation can cause your program to request too much system memory. This consequence can lead to a crash due to an out-of-memory condition, or assigning too many resources.

### Fix

Before allocating memory, check the value of your arguments to check that they do not exceed the bounds.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Allocate Memory Using Input From User

```
#include<stdio.h>
#include <stdlib.h>

int* bug_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = (int*)malloc(size);//Noncompliant
    return p;
}
```

In this example, `malloc` allocates `size` bytes of memory for the pointer `p`. The variable `size` comes from the user of the program. Its value is not checked, and it could be larger than the amount of available memory. If `size` is larger than the number of available bytes, your program could crash.

#### Correction — Check Size of Memory to be Allocated

One possible correction is to check the size of the memory that you want to allocate before performing the `malloc` operation. This example checks to see if `size` is positive and less than the maximum size.

```
#include<stdio.h>
#include <stdlib.h>
```

```
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int* corrected_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = NULL;
    if (size>0 && size<SIZE128) {          /* Fix: Check entry range before use */
        p = (int*)malloc((unsigned int)size);
    }
    return p;
}
```

## Result Information

# Pointer dereference with tainted offset

Offset is from an unsecure source and dereference might be out of bounds

## Description

This defect occurs when a pointer dereference uses an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

### Fix

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Dereference Pointer Array

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset];//Noncompliant
        free(pint);
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `offset`. The value of `offset` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of `offset`. Continue with the pointer dereferencing only if `offset` is inside the valid range.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_PTR_OFFSET`
**Impact:** Low

## Version History

**Introduced in R2015b**

# Tainted division operand

Operands of division operation (`/`) come from an unsecure source

## Description

This defect occurs when one or both integer operands in a division operation comes from unsecure sources.

### Risk

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

### Fix

Before performing the division, validate the values of the operands. Check for denominators of `0` or `-1`, and numerators of the minimum integer value.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Division of Function Arguments

```
#include <limits.h>
#include <stdio.h>

extern void print_int(int);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    int r =  num/denum; //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include <limits.h>
#include <stdio.h>

extern void print_long(long);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    long res= 0;
    if (denum!=0 && !(num==INT_MIN && denum==-1)) {
        res = num/denum;
    }
    print_long(res);
    return res;
}
```

### Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_INT_DIVISION`
**Impact:** Low

## Version History

**Introduced in R2015b**

# Tainted modulo operand

Operands of remainder operation (%) come from an unsecure source

## Description

This defect occurs when one or both integer operands in a remainder operation (%) comes from unsecure sources.

### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is -1, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of 0 and -1. Check both operands for negative values.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option -consider-analysis-perimeter-as-trust-boundary.

## Examples

### Modulo with User Input

```
#include <stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem =  128%userden; //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using a user input. The input is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem = 0;
    if (userden > 0 ) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_INT_MOD`
**Impact:** Low

# Tainted NULL or non-null-terminated string

Argument is from an unsecure source and might be NULL or not NULL-terminated

## Description

This defect occurs when strings from unsecure sources are used in string manipulation routines that implicitly dereference the string buffer, for instance, `strcpy` or `sprintf`.

**Tainted NULL or non-null-terminated string** raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Getting String from Input

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));//Noncompliant
    print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

**Correction — Validate the Data**

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // Noncompliant-TAINTED_STRING only flagged here
        // - string is not null
        // - string has a positive and limited size
        // - TAINTED_STRING on strlen used as a firewall
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

**Correction — Validate the Data**

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }

  return sensorValue;
}
```

## Result Information

# Tainted sign change conversion

Value from an unsecure source changes sign

## Description

This defect occurs when values from unsecure sources are converted, implicitly or explicitly, from signed to unsigned values.

For example, functions that use `size_t` as arguments implicitly convert the argument to an unsigned integer. Some functions that implicitly convert `size_t` are:

```
bcmp
memcpy
memmove
strncmp
strncpy
calloc
malloc
memalign
```

### Risk

If you convert a small negative number to unsigned, the result is a large positive number. The large positive number can create security vulnerabilities. For example, if you use the unsigned value in:

- Memory size routines — causes allocating memory issues.
- String manipulation routines — causes buffer overflow.
- Loop boundaries — causes infinite loops.

### Fix

To avoid converting unsigned negative values, check that the value being converted is within an acceptable range. For example, if the value represents a size, validate that the value is not negative and less than the maximum value size.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Set Memory Value with Size Argument

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
```

```
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void bug_taintedsignchange(void) {
    int size;
    scanf("%d",&size);
    char str[SIZE128] = "";
    if (size<SIZE128) {
        memset(str, 'c', size); //Noncompliant
    }
}
```

In this example, a `char` buffer is created and filled using `memset`. The size argument to `memset` is an input argument to the function.

The call to `memset` implicitly converts `size` to unsigned integer. If `size` is a large negative number, the absolute value could be too large to represent as an integer, causing a buffer overflow.

#### Correction — Check Value of `size`

One possible correction is to check if `size` is inside the valid range. This correction checks if `size` is greater than zero and less than the buffer size before calling `memset`.

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void corrected_taintedsignchange(void) {
    int size;
    scanf("%d",&size);
    char str[SIZE128] = "";
    if (size>0 && size<SIZE128) {
        memset(str, 'c', size);
    }
}
```

### Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_SIGN_CHANGE`
**Impact:** Medium

## Version History

**Introduced in R2015b**

# Tainted string format

Input format argument is from an unsecure source

## Description

This defect occurs when `printf`-style functions use a format specifier constructed from unsecure sources.

### Risk

If you use externally controlled elements to format a string, you can cause buffer overflow or data-representation problems. An attacker can use these string formatting elements to view the contents of a stack using `%x` or write to a stack using `%n`.

### Fix

Pass a static string to format string functions. This fix ensures that an external actor cannot control the string.

Another possible fix is to allow only the expected number of arguments. If possible, use functions that do not support the vulnerable `%n` operator in format strings.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Get Elements from User Input

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf(userstr);//Noncompliant
}
```

This example prints the input argument `userstr`. The string is unknown. If it contains elements such as `%`, `printf` can interpret `userstr` as a string format instead of a string, causing your program to crash.

#### Correction — Print as String

One possible correction is to print `userstr` explicitly as a string so that there is no ambiguity.

```
#include "stdio.h"
#include <unistd.h>
```

```
#define MAX 40

void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf("%.20s", userstr);
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_STRING_FORMAT`
**Impact:** Low

# Version History

**Introduced in R2015b**

# Tainted size of variable length array

Size of the variable-length array (VLA) is from an unsecure source and might be zero, negative, or too large

## Description

This defect occurs when the size of a variable length array (VLA) is obtained from an unsecure source.

### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Example — User Input Argument Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
#define LIM 40

long squaredSum(int size) {

    int tabvla[size];
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

**Correction — Check VLA Size**

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 0 and less than 40, before creating the VLA

```
#include <stdio.h>
#include <stdlib.h>
#define LIM 40

long squaredSum(int size) {
    long res = 0;
    if (size>0 && size<LIM){
        int tabvla[size];
        for (int i=0 ; i<size || i<LIM-1 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }else{
        res = -1;
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_VLA_SIZE`
**Impact:** Medium

# Version History

**Introduced in R2015b**

## See Also

# Use of externally controlled environment variable

Value of environment variable is from an unsecure source

## Description

This defect occurs when functions that add or change environment variables, such as `putenv` and `setenv`, obtain new environment variable values from unsecure sources.

### Risk

If the environment variable is tainted, an attacker can control your system settings. This control can disrupt an application or service in potentially malicious ways.

### Fix

Before using the new environment variable, check its value to avoid giving control to external users.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Set Path in Environment

```
#define _XOPEN_SOURCE
#define _GNU_SOURCE
#include "stdlib.h"

void taintedenvvariable(void)
{
    char* path = getenv("APP_PATH");
    putenv(path); //Noncompliant
}
```

In this example, `putenv` changes an environment variable. The path `path` has not been checked to make sure that it is the intended path.

#### Correction — Sanitize Path

One possible correction is to sanitize the path, checking that it matches what you expect.

```
#define _POSIX_C_SOURCE
#include <stdlib.h>
#include <string.h>

/* Function to sanitize a path */
const char * sanitize_path(const char* str) {
    /* secure allowlist of paths */
    static const char *const authorized_paths[] = {
        "/bin",
        "/usr/bin"
    };
    if (str != NULL) {
        for (int i = 0; i < sizeof(authorized_paths) / sizeof(authorized_paths[0]); i++)
        if (strcmp(authorized_paths[i], str) == 0) {
            return authorized_paths[i];
        }
    }
    return NULL;
}

void taintedenvvariable(void)
{
    const char* path = getenv("APP_PATH");
    path = sanitize_path(path);
    if (path != NULL) {
        if (setenv("PATH", path, /* overwrite = */1) != 0) {
            /* fatal error */
            exit(1);
        }
    }
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_ENV_VARIABLE`
**Impact:** Medium

# Version History

**Introduced in R2015b**

# Use of tainted pointer

Pointer from an unsecure source may be NULL or point to unknown memory

## Description

This defect occurs when:

- Tainted NULL pointer — the pointer obtained from an unsecure source is not validated against NULL.
- Tainted size pointer — the size of the memory zone that an unsecure pointer points to is not validated.

**Note** On a single pointer, your code can have instances of **Use of tainted pointer**, **Pointer dereference with tainted offset**, and **Tainted NULL or non-null-terminated string**. Bug Finder raises only the first tainted pointer defect that it finds.

### Risk

An attacker can give your program a pointer that points to unexpected memory locations. If the pointer is dereferenced to write, the attacker can:

- Modify the state variables of a critical program.
- Cause your program to crash.
- Execute unwanted code.

If the pointer is dereferenced to read, the attacker can:

- Read sensitive data.
- Cause your program to crash.
- Modify a program variable to an unexpected value.

### Fix

Avoid use of pointers from external sources.

Alternatively, if you trust the external source, sanitize the pointer before dereference. In a separate sanitization function:

- Check that the pointer is not NULL.
- Check the size of the memory location (if possible). This second check validates whether the size of the data the pointer points to matches the size your program expects.

The defect still appears in the body of the sanitization function. However, if you use a sanitization function, instead of several occurrences, the defect appears only once. You can justify the defect and hide it in later reviews by using code annotations. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Function That Dereferences an External Pointer

```
#include<stdlib.h>
void taintedptr(void) {
    char *p = getenv("ARG");
    char x = *(p+10);//Noncompliant
}
```

In this example, the pointer `*p` points to an string of unknown size. During the dereferencing operation, the pointer might be null or point to unknown memory, which can result in segmentation fault.

#### Correction — Check Pointer

One possible correction is to sanitize the pointer before using it. This example checks whether the pointer is `nullptr` before it is dereferenced.

```
#include<stdlib.h>
#include <string.h>
void taintedptr(void) {
    char *p = getenv("ARG");
    if(p!=NULL && strlen(p)>10)
    {
    char x = *(p+10);
    }
}
```

## Result Information

**Group:** Tainted Data
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `TAINTED_PTR`
**Impact:** Low

# Version History

**Introduced in R2015b**

# Concurrency Defects

# Asynchronously cancellable thread

Calling thread might be cancelled in an unsafe state

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when you use `pthread_setcanceltype` with argument `PTHREAD_CANCEL_ASYNCHRONOUS` to set the cancellability type of a calling thread to asynchronous (or immediate) . An asynchronously cancellable thread can be cancelled at any time, usually immediately upon receiving a cancellation request.

### Risk

The calling thread might be cancelled in an unsafe state that could result in a resources leak, a deadlock, a data race, data corruption, or unpredictable behavior.

### Fix

Remove the call to `pthread_setcanceltype` with argument `PTHREAD_CANCEL_ASYNCHRONOUS` to use the default cancellability type `PTHREAD_CANCEL_DEFERRED` instead. With the default cancellability type, the thread defers cancellation requests until it calls a function that is a cancellation point.

## Examples

### Cancellability Type of Thread Set to Asynchronous

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

static int fatal_error(void)
{
    exit(1);
}

volatile int a = 5;
volatile int b = 10;

pthread_mutex_t global_lock = PTHREAD_MUTEX_INITIALIZER;

void* swap_values_thread(void* dummy)
{
    int i;
    int c;
    int result;
    if ((result =
             pthread_setcanceltype(PTHREAD_CANCEL_ASYNCHRONOUS, &i)) != 0) {
        /* handle error */
        fatal_error();
    }
    while (1) {
        if ((result = pthread_mutex_lock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
        c = b;
        b = a;
        a = c;
        if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
    }
    return NULL;
}

int main(void)
{
    int result;
    pthread_t worker;

    if ((result = pthread_create(&worker, NULL, swap_values_thread, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }

    /* Additional code */

    if ((result = pthread_cancel(worker)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_join(worker, 0)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_mutex_lock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }
    printf("a: %i | b: %i", a, b);
    if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }

    return 0;
}
```

In this example, the cancellability type of the `worker` thread is set to asynchronous. The mutex `global_lock` helps ensure that the `worker` and `main` threads do not access variables `a` and `b` at the same time. However, the `worker` thread might be cancelled while holding `global_lock`, and the `main` thread will never acquire `global_lock`, which results in a deadlock.

#### Correction — Use the Default Cancellability Type

One possible correction is to remove the call to `pthread_setcanceltype`. By default, the cancellability type of a new thread is set to `PTHREAD_CANCEL_DEFERRED`. The `worker` thread defers cancellation requests until it calls a function that is a cancellation point.

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

static int fatal_error(void)
{
    exit(1);
}

volatile int a = 5;
volatile int b = 10;

pthread_mutex_t global_lock = PTHREAD_MUTEX_INITIALIZER;

void* swap_values_thread(void* dummy)
{
    int i;
    int c;
    int result;
    while (1) {
        if ((result = pthread_mutex_lock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
        c = b;
        b = a;
        a = c;
        if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
    }
    return NULL;
}

int main(void)
{
    int result;
    pthread_t worker;

    if ((result = pthread_create(&worker, NULL, swap_values_thread, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }

    /* Additional code */

    if ((result = pthread_cancel(worker)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_join(worker, 0)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_mutex_lock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }
    printf("a: %i | b: %i", a, b);
    if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }

    return 0;
}
```

# Atomic load and store sequence not atomic

Variable accessible between load and store operations

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

This defect occurs when you use these functions to load, and then store an atomic variable.

- C functions:
  - `atomic_load()`
  - `atomic_load_explicit()`
  - `atomic_store()`
  - `atomic_store_explicit()`
- C++ functions:
  - `std::atomic_load()`
  - `std::atomic_load_explicit()`
  - `std::atomic_store()`
  - `std::atomic_store_explicit()`
  - `std::atomic::load()`
  - `std::atomic::store()`

A thread cannot interrupt an atomic load or an atomic store operation on a variable, but a thread can interrupt a store, and then load sequence.

### Risk

A thread can modify a variable between the load and store operations, resulting in a data race condition.

### Fix

To read, modify, and store a variable atomically, use a compound assignment operator such as +=, `atomic_compare_exchange()` or `atomic_fetch_*`-family functions.

## Examples

### Loading Then Storing an Atomic Variable

```
#include <stdatomic.h>
#include <stdbool.h>
```

```
static atomic_bool flag = ATOMIC_VAR_INIT(false);

void init_flag(void)
{
    atomic_init(&flag, false);
}

void toggle_flag(void)
{
    bool temp_flag = atomic_load(&flag);
    temp_flag = !temp_flag;
    atomic_store(&flag, temp_flag);
}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

In this example, variable `flag` of type `atomic_bool` is referenced twice inside the `toggle_flag()` function. The function loads the variable, negates its value, then stores the new value back to the variable. If two threads call `toggle_flag()`, the second thread can access `flag` between the load and store operations of the first thread. `flag` can end up in an incorrect state.

#### Correction — Use Compound Assignment to Modify Variable

One possible correction is to use a compound assignment operator to toggle the value of `flag`. The C standard defines the operation by using ^= as atomic.

```
#include <stdatomic.h>
#include <stdbool.h>

static atomic_bool flag = ATOMIC_VAR_INIT(false);

void toggle_flag(void)
{
    flag ^= 1;
}

bool get_flag(void)
{
    return flag;
}
```

## Result Information

# Atomic variable accessed twice in an expression

Variable can be modified between accesses

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when C atomic types or C++ `std::atomic` class variables appear twice in an expression and there are:

- Two atomic read operations on the variable.
- An atomic read and a distinct atomic write operation on the variable.

The C standard defines certain operations on atomic variables that are thread safe and do not cause data race conditions. Unlike individual operations, a pair of operations on the same atomic variable in an expression is not thread safe.

### Risk

A thread can modify the atomic variable between the pair of atomic operations, which can result in a data race condition.

### Fix

Do not reference an atomic variable twice in the same expression.

## Examples

### Referencing Atomic Variable Twice in an Expression

```
#include <stdatomic.h>

atomic_int n = ATOMIC_VAR_INIT(0);

int compute_sum(void)
{
    return n * (n + 1) / 2;
}
```

In this example, the global variable `n` is referenced twice in the return statement of `compute_sum()`. The value of `n` can change between the two distinct read operations. `compute_sum()` can return an incorrect value.

#### Correction — Pass Variable as Function Argument

One possible correction is to pass the variable as a function argument `n`. The variable is copied to memory and the read operations on the copy guarantee that `compute_sum()` returns a correct result. If you pass a variable of type `int` instead of type `atomic_int`, the correction is still valid.

```
#include <stdatomic.h>

int compute_sum(atomic_int n)
{
    return n * (n + 1) / 2;
}
```

# Automatic or thread local variable escaping from a thread

Variable is passed from one thread to another without ensuring that variable stays alive through duration of latter thread

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when an automatic or thread local variable is passed by address from one thread to another thread without ensuring that the variable stays alive through the duration of the latter thread.

The defect checker applies to both C11 and POSIX threads.

### Risk

An automatic or thread local variable is allocated on the stack at the beginning of a thread and its lifetime extends till the end of the thread. The variable is not guaranteed to be alive when a different thread accesses it.

For instance, consider the start function of a C11 thread with these lines:

```
int start_thread(thrd_t *tid) {
   int aVar = 0;
   if(thrd_success != thrd_create(tid, start_thread_child, &aVar) {
     ...
   }
}
```

The `thrd_create` function creates a child thread with start function `start_thread_child` and passes the address of the automatic variable `aVar` to this function. When this child thread accesses `aVar`, the parent thread might have completed execution and `aVar` is no longer on the stack. The access might result in reading unpredictable values.

### Fix

When you pass a variable from one thread to another, make sure that the variable lifetime matches or exceeds the lifetime of both threads. You can achieve this synchronization in one of these ways:

- Declare the variable `static` so that it does not go out of stack when the current thread completes execution.
- Dynamically allocate the storage for the variable so that it is allocated on the heap instead of the stack and must be explicitly deallocated. Make sure that the deallocation happens after both threads complete execution.

These solutions require you to create a variable in nonlocal memory. Instead, you can use other solutions such as the `shared` keyword with OpenMP's threading interface that allows you to safely share local variables across threads.

## Examples

### Automatic or Thread-Local Variable Escaping Thread

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}

void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) {
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  int parentVal = 1;

  create_parent_thread(&tid, &parentVal);

  if (thrd_success != thrd_join(tid, NULL)) {
    /* Handle error */
  }
  return 0;
}
```

In this example, the value `parentVal` is local to the parent thread that starts in `main` and continues into the function `create_parent_thread`. However, in the body of `create_parent_thread`, the address of this local variable is passed to a child thread (the thread with start routine `create_child_thread`). The parent thread might have completed execution and the variable `parentVal` might have gone out of scope when the child thread accesses this variable.

The same issue appears if the variable is declared as thread-local, for instance with the C11 keyword `_Thread_local` (or `thread_local`):

```
_Thread_local int parentVal = 1;
```

#### Correction – Use Static Variables

One possible correction is to declare the variable `parentVal` as `static` so that the variable is on the stack for the entire duration of the program.

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}

void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) {
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  static int parentVal = 1;

  create_parent_thread(&tid, &parentVal);

  if (thrd_success != thrd_join(tid, NULL)) {
    /* Handle error */
  }
  return 0;
}
```

**Correction – Use Dynamic Memory Allocation**

Another possible correction is to dynamically allocate storage for variables to be shared across threads and explicitly free the storage after the threads complete execution.

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}

void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) {
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  int parentPtr = (int*) malloc(sizeof(int));

  if(parentPtr) {
      create_parent_thread(&tid, parentPtr);

      if (thrd_success != thrd_join(tid, NULL)) {
        /* Handle error */
      }
      free(parentPtr);
  }
  return 0;
}
```

## Result Information

# Blocking operation while holding lock

Task performs lengthy operation while holding a lock

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when a task (thread) performs a potentially lengthy operation while holding a lock.

The checker considers calls to these functions as potentially lengthy:

- Functions that access a network such as `recv`
- System call functions such as `fork`, `pipe` and `system`
- Functions for I/O operations such as `getchar` and `scanf`
- File handling functions such as `fopen`, `remove` and `lstat`
- Directory manipulation functions such as `mkdir` and `rmdir`

The checker automatically detects certain primitives that hold and release a lock, for instance, `pthread_mutex_lock` and `pthread_mutex_unlock`. For the full list of primitives that are automatically detected, see "Auto-Detection of Thread Creation and Critical Section in Polyspace".

### Risk

If a thread performs a lengthy operation when holding a lock, other threads that use the lock have to wait for the lock to be available. As a result, system performance can slow down or deadlocks can occur.

### Fix

Perform the blocking operation before holding the lock or after releasing the lock.

Some functions detected by this checker can be called in a way that does not make them potentially lengthy. For instance, the function `recv` can be called with the parameter `O_NONBLOCK` which causes the call to fail if no message is available. When called with this parameter, `recv` does not wait for a message to become available.

## Examples

### Network I/O Operations with `recv` While Holding Lock

```
#include <pthread.h>
#include <sys/socket.h>

pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) {
    /* Handle Error */
  }

  /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }

  return 0;
}
```

In this example, in each thread created with `pthread_create`, the function `thread_foo` performs a network I/O operation with `recv` after acquiring a lock with `pthread_mutex_lock`. Other threads using the same lock variable `mutex` have to wait for the operation to complete and the lock to become available.

#### Correction — Perform Blocking Operation Before Acquiring Lock

One possible correction is to call `recv` before acquiring the lock.

```
#include <pthread.h>
#include <sys/socket.h>

pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */
  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

    /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }

  return 0;
}
```

# Multiple threads waiting on same condition variable

Using `cnd_signal` to wake up one of the threads might result in indefinite blocking

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

This defect occurs when you use `cnd_signal` family functions to wake up one of at least two threads that are concurrently waiting on the same condition variable. For threads with the same priority level, `cnd_signal` family functions cause the thread scheduler to arbitrarily wake up on of the threads waiting on the condition variable that you signal with the `cnd_signal` family function.

The checkers flags the `cnd_signal` family function call. See the **Event** column in the **Results Details** pane to view the threads waiting on the same condition variable.

### Risk

The thread that is woken up with a `cnd_signal` family function usually tests for a condition predicate. While the condition predicate is false, the thread waits again on the condition variable until it is woken up by another thread that signals the condition variable. It is possible that the program ends up in a state where no thread is available to signal the condition variable, which results in indefinite blocking.

### Fix

Use `cnd_broadcast` family functions instead to wake all threads waiting on the condition variable, or use a different condition variable for each thread.

## Examples

### Use of `cnd_signal` to Wake Up One of Many Threads Waiting on Condition Variable

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <threads.h>

typedef int thrd_return_t;

static void fatal_error(void)
{
    exit(1);
}

enum { NTHREADS = 5 };

mtx_t mutex;
cnd_t cond;
```

```
thrd_return_t next_step(void* t)
{
    static size_t current_step = 0;
    size_t my_step = *(size_t*)t;

    if (thrd_success != mtx_lock(&mutex)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu has the lock\n", my_step);
    while (current_step != my_step) {
        printf("Thread %zu is sleeping...\n", my_step);
        if (thrd_success !=
            cnd_wait(&cond, &mutex)) {
            /* Handle error */
            fatal_error();
        }
        printf("Thread %zu woke up\n", my_step);
    }
    /* Do processing ... */
    printf("Thread %zu is processing...\n", my_step);
    current_step++;

    /* Signal a waiting task */
    if (thrd_success !=
        cnd_signal(&cond)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu is exiting...\n", my_step);

    if (thrd_success != mtx_unlock(&mutex)) {
        /* Handle error */
        fatal_error();
    }
    return (thrd_return_t)0;
}

int main(void)
{
    thrd_t threads[NTHREADS];
    size_t step[NTHREADS];

    if (thrd_success != mtx_init(&mutex, mtx_plain)) {
        /* Handle error */
        fatal_error();
    }
    if (thrd_success != cnd_init(&cond)) {
        /* Handle error */
        fatal_error();
    }
    /* Create threads */
    for (size_t i = 0; i < NTHREADS; ++i) {
        step[i] = i;
        if (thrd_success != thrd_create(&threads[i],
                                        next_step,
                                        &step[i])) {
            /* Handle error */
            fatal_error();
        }
    }
    /* Wait for all threads to complete */
    for (size_t i = NTHREADS; i != 0; --i) {
        if (thrd_success != thrd_join(threads[i - 1], NULL)) {
            /* Handle error */
            fatal_error();
        }
    }
    (void)mtx_destroy(&mutex);
    (void)cnd_destroy(&cond);
    return 0;
}
```

In this example, multiple threads are created and assigned step level. Each thread checks if its assigned step level matches the current step level (condition predicate). If the predicate is false, the thread goes back to waiting on the condition variable `cond`. The use of `cnd_signal` to signal the `cond` causes the thread scheduler to arbitrarily wake up one of the threads waiting on `cond`. This can result in indefinite blocking when the condition predicate of woken up thread is false and no other thread is available to signal `cond`.

**Correction — Use `cnd_broadcast` to Wake up All the Threads**

One possible correction is to use `cnd_broadcast` instead to signal `cond`. The function `cnd_signal` wakes up all the thread that are waiting on `cond`.

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <threads.h>

typedef int thrd_return_t;

static void fatal_error(void)
{
    exit(1);
}

enum { NTHREADS = 5 };

mtx_t mutex;
cnd_t cond;

thrd_return_t next_step(void* t)
{
    static size_t current_step = 0;
    size_t my_step = *(size_t*)t;

    if (thrd_success != mtx_lock(&mutex)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu has the lock\n", my_step);
    while (current_step != my_step) {
        printf("Thread %zu is sleeping...\n", my_step);
        if (thrd_success !=
            cnd_wait(&cond, &mutex)) {
            /* Handle error */
            fatal_error();
        }
        printf("Thread %zu woke up\n", my_step);
    }
    /* Do processing ... */
    printf("Thread %zu is processing...\n", my_step);
    current_step++;

    /* Signal a waiting task */
    if (thrd_success !=
        cnd_broadcast(&cond)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu is exiting...\n", my_step);

    if (thrd_success != mtx_unlock(&mutex)) {
        /* Handle error */
        fatal_error();
    }
    return (thrd_return_t)0;
}

int main_test_next_step(void)
{
    thrd_t threads[NTHREADS];
    size_t step[NTHREADS];

    if (thrd_success != mtx_init(&mutex, mtx_plain)) {
        /* Handle error */
        fatal_error();
    }
    if (thrd_success != cnd_init(&cond)) {
        /* Handle error */
        fatal_error();
    }
    /* Create threads */
    for (size_t i = 0; i < NTHREADS; ++i) {
        step[i] = i;
        if (thrd_success != thrd_create(&threads[i],
                                        next_step,
                                        &step[i])) {
            /* Handle error */
            fatal_error();
        }
    }
    /* Wait for all threads to complete */
    for (size_t i = NTHREADS; i != 0; --i) {
        if (thrd_success != thrd_join(threads[i - 1], NULL)) {
            /* Handle error */
            fatal_error();
        }
    }
    (void)mtx_destroy(&mutex);
    (void)cnd_destroy(&cond);
    return 0;
}
```

## Result Information

**Group:** Concurrency
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `SIGNALED_COND_VAR_NOT_UNIQUE`
**Impact:** Low

# Version History

**Introduced in R2020a**

# Data race

Multiple tasks perform unprotected nonatomic operations on shared variable

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when:

1. Multiple tasks perform unprotected operations on a shared variable.
2. At least one task performs a write operation.
3. At least one operation is nonatomic. To detect data race on both atomic and nonatomic operations, use the options `-detect-atomic-data-race`. See "Extend Data Race Checkers to Atomic Operations".

   See "Define Atomic Operations in Multitasking Code".

The defect checker reports one data race result for each shared variable with conflicting read-write or write-write operations.

If you activate this checker without specifying the multitasking options first, you see a warning in the log:To find this defect, specify the multitasking options before analysis.

To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see "Configuring Polyspace Multitasking Analysis Manually".

### Risk

Data race can result in unpredictable values of the shared variable because you do not control the order of the operations in different tasks.

Data races between two write operations are more serious than data races between a write and read operation. Two write operations can interfere with each other and result in indeterminate values. To identify write-write conflicts, use the filters on the **Detail** column of the **Results List** pane. For these conflicts, the **Detail** column shows the additional line:

```
 Variable value may be altered by write-write concurrent access.
```

See also "Filter and Group Results in Polyspace Desktop User Interface" or "Filter and Sort Results in Polyspace Access Web Interface".

### Fix

To fix this defect, protect the operations on the shared variable using critical sections, temporal exclusion or another means. See "Protections for Shared Variables in Multitasking Code".

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

### Extend Checker

Extend this checker to check for data races in operations that Bug Finder might not detect by default. For instance:

- You might be using multithreading functions that are not supported by Polyspace. Extend this checker by mapping the functions of your multithreading functions to their known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.
- Polyspace assumes that certain operations are atomic and excludes them from data race checks. See “Define Atomic Operations in Multitasking Code”. These assumptions might not apply to your environment. To extend the data race checkers to include these operations, use the option `-detect-atomic-data-race`. See “Extend Data Race Checkers to Atomic Operations”.

Note that the checker reports one data race result per shared variable. The event list for the result shows upto fifteen conflicting read-write and write-write conflicts. You cannot customize these limits.

## Examples

### Unprotected Operation on Global Variable from Multiple Tasks

```
int var;
void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
    var++;
}

void task1(void)  {
      increment();
}

void task2(void)  {
      increment();
}
