void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| `Configure multitasking manually` | ☑ | |
| `Tasks (-entry-points)` | `task1`<br>`task2`<br>`task3` | |
| `Critical section details (-critical-section-begin -critical-section-end)` | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2,task3
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

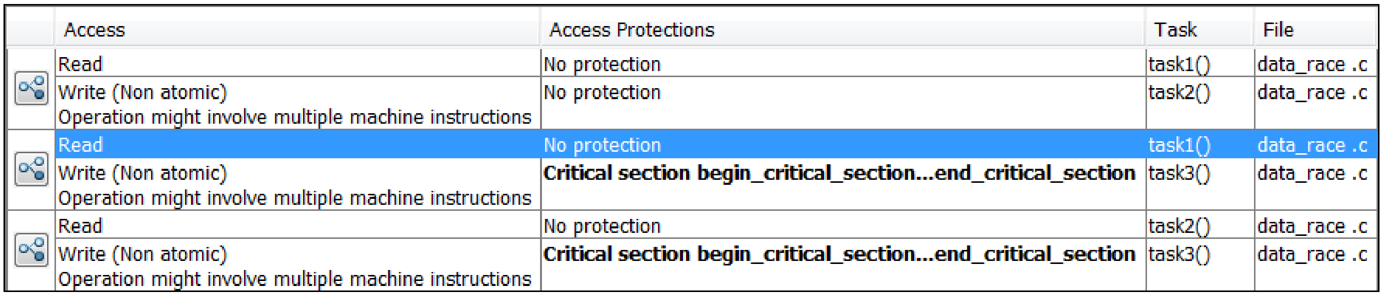
In this example, the tasks `task1`, `task2`, and `task3` call the function `increment`. `increment` contains the operation `var++` that can involve multiple machine instructions including:

- Reading `var`.
- Writing an increased value to `var`.

These machine instructions, when executed from `task1` and `task2`, can occur concurrently in an unpredictable sequence. For example, reading `var` from `task1` can occur either before or after writing to `var` from `task2`. Therefore the value of `var` can be unpredictable.

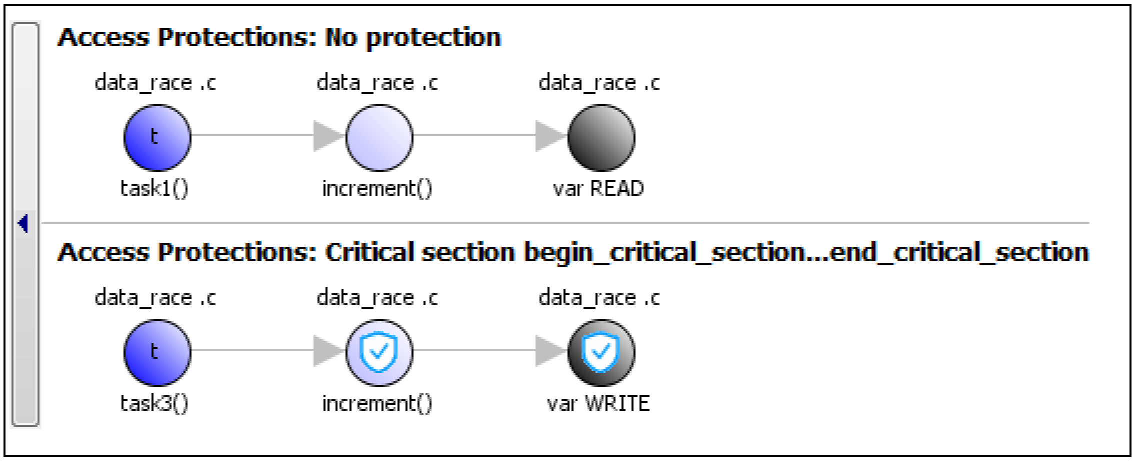
Though `task3` calls `increment` inside a critical section, other tasks do not use the same critical section. The operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

Therefore, the three tasks are operating on a shared variable without common protection. In your result details, you see each pair of conflicting function calls.



| | Access | Access Protections | Task | File |
|---|---|---|---|---|
| | Read | No protection | task1() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | No protection | task2() | data_race .c |
| | Read | No protection | task1() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | **Critical section begin_critical_section...end_critical_section** | task3() | data_race .c |
| | Read | No protection | task2() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | **Critical section begin_critical_section...end_critical_section** | task3() | data_race .c |

If you click the icon, you see the function call sequence starting from the entry point to the read or write operation. You also see that the operation starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



Access Protections: No protection

Access Protections: Critical section begin_critical_section...end_critical_section

**Correction — Place Operation in Critical Section**

One possible correction is to place the operation in critical section. You can implement the critical section in multiple ways. For instance:

- You can place `var++` in a critical section. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The operation `var++` from the three tasks cannot interfere with each other.

  To implement the critical section, in the function `increment`, place the operation `var++` between calls to `begin_critical_section` and `end_critical_section`.

  ```
  int var;

  void begin_critical_section(void);
  void end_critical_section(void);

  void increment(void) {
        begin_critical_section();
        var++;
        end_critical_section();
  }

  void task1(void)  {
        increment();
  }

  void task2(void)  {
        increment();
  }

  void task3(void)  {
        increment();
  }
  ```
- You can place the call to `increment` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `increment` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `increment` between calls to `begin_critical_section` and `end_critical_section`.

```
int var;

void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
      var++;
}

void task1(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task2(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| Temporally exclusive tasks (-temporal-exclusions-file) | task1 task2 task3 |

On the command-line, you can use the following:

```
 polyspace-bug-finder
     -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

### Unprotected Operation in Threads Created with `pthread_create`

```
#include <pthread.h>
```

```
pthread_mutex_t count_mutex;
long long count;

void* increment_count(void* args)
{
    count = count + 1;
    return NULL;
}

void* set_count(void *args)
{
    long long c;
    c = count;
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

In this example, Bug Finder detects the creation of separate threads with `pthread_create`. The **Data race** defect is raised because the operation `count = count + 1` in the thread with id `thread_increment` conflicts with the operation `c = count` in the thread with id `thread_get`. The variable `count` is accessed in multiple threads without a common protection.

The two conflicting operations are nonatomic. The operation `c = count` is nonatomic on 32-bit targets. See “Define Atomic Operations in Multitasking Code”.

#### Correction — Protect Operations with `pthread_mutex_lock` and `pthread_mutex_unlock` Pair

To prevent concurrent access on the variable `count`, protect operations on `count` with a critical section. Use the functions `pthread_mutex_lock` and `pthread_mutex_unlock` to implement the critical section.

```
#include <pthread.h>

pthread_mutex_t count_mutex;
long long count;

void* increment_count(void* args)
{
    pthread_mutex_lock(&count_mutex);
    count = count + 1;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}
```

```
void* set_count(void *args)
{
    long long c;
    pthread_mutex_lock(&count_mutex);
    c = count;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

### Result Information

“Extend Data Race Checkers to Atomic Operations”

# Data race on adjacent bit fields

Multiple threads perform unprotected operations on adjacent bit fields of a shared data structure

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when:

1. Multiple tasks perform unprotected operations on bit fields that are part of the same structure.

   For instance, a task operates on field `errorFlag1` and another task on field `errorFlag2` in a variable of this type:

   ```
   struct errorFlags {
      unsigned int errorFlag1 : 1;
      unsigned int errorFlag2 : 1;
      ...
   }
   ```

   Suppose that the operations are not atomic with respect to each other. In other words, you have not implemented protection mechanisms to ensure that one operation is completed before another operation begins.
2. At least one of the unprotected operations is a write operation.

To find this defect, before analysis, you must specify the multitasking options. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see "Configuring Polyspace Multitasking Analysis Manually".

### Risk

Adjacent bit fields that are part of the same structure might be stored in one byte in the same memory location. Read or write operations on all variables including bit fields occur one byte or word at a time. To modify only specific bits in a byte, steps similar to these steps occur in sequence:

1. The byte is loaded into RAM.
2. A mask is created so that only specific bits are modified to the intended value and the remaining bits remain unchanged.
3. A bitwise OR operation is performed between the copy of the byte in RAM and the mask.
4. The byte with specific bits modified is copied back from RAM.

When you access two different bit fields, these four steps have to be performed for each bit field. If the accesses are not protected, all four steps for one bit field might not be completed before the four steps for the other bit field begin. As a result, the modification of one bit field might undo the modification of an adjacent bit field. For instance, in the preceding example, the modification of `errorFlag1` and `errorFlag2` can occur in the following sequence. Steps 1,2 and 5 relate to modification of `errorFlag1` and while steps 3,4 and 6 relate to that of `errorFlag2`.

1. The byte with both `errorFlag1` and `errorFlag2` unmodified is copied into RAM, for purposes of modifying `errorFlag1`.

2 A mask that modifies only `errorFlag1` is bitwise OR-ed with this copy.

3 The byte containing both `errorFlag1` and `errorFlag2` unmodified is copied into RAM a second time, for purposes of modifying `errorFlag2`.

4 A mask that modifies only `errorFlag2` is bitwise OR-ed with this second copy.

5 The version with `errorFlag1` modified is copied back. This version has `errorFlag2` unmodified.

6 The version with `errorFlag2` modified is copied back. This version has `errorFlag1` unmodified and overwrites the previous modification.

#### Fix

To fix this defect, protect the operations on bit fields that are part of the same structure by using critical sections, temporal exclusion, or another means. See “Protections for Shared Variables in Multitasking Code”.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon.

## Examples

### Unprotected Operation on Global Variable from Multiple Tasks

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

In this example, `task1` and `task2` access different bit fields `IOFlag` and `SetupFlag`, which belong to the same structured variable `InterruptConfigbitsProc12`.

To emulate multitasking behavior, specify the options listed in this table.

| Option | Specification |
|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ |
| **Tasks** on page 2-121 | task1<br>task2 |

At the command-line, use:

```
polyspace-bug-finder
  -entry-points task1,task2
```

#### Correction – Use Critical Sections

One possible correction is to wrap the bit field access in a critical section. A critical section lies between a call to a lock function and an unlock function. In this correction, the critical section lies between the calls to functions `begin_critical_section` and `end_critical_section`.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void begin_critical_section(void);
void end_critical_section(void);

void task1 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.IOFlag = 0;
    end_critical_section();
}

void task2 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.SetupFlag = 0;
    end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify options listed in this table.

| Option | Specification |
|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ |

| Option | Specification | |
|---|---|---|
| **Tasks** on page 2-121 | `task1`<br>`task2` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

At the command-line, use:

```
polyspace-bug-finder
  -entry-points task1,task2
  -critical-section-begin begin_critical_section:cs1
  -critical-section-end end_critical_section:cs1
```

#### Correction – Avoid Bit Fields

If you do not have memory constraints, use the `char` data type instead of bit fields. The `char` variables in a structure occupy at least one byte and do not have the thread-safety issues that come from bit manipulations in a byte-sized operation. Data races do not result from unprotected operations on different `char` variables that are part of the same structure.

```
typedef struct
{
   unsigned char IOFlag;
   unsigned char InterruptFlag;
   unsigned char Register1Flag;
   unsigned char SignFlag;
   unsigned char SetupFlag;
   unsigned char Register2Flag;
   unsigned char ProcessorFlag;
   unsigned char GeneralFlag;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

Though the checker does not flag this correction, do not use this correction for C99 or earlier. Only from C11 and later does the C Standard mandate that distinct `char` variables cannot be accessed using the same word.

#### Correction – Insert Bit Field of Size 0

You can enter a non-bit field member or an unnamed bit field member of size 0 between two adjacent bit fields that might be accessed concurrently. A non-bit field member or size 0 bit field member ensures that the subsequent bit field starts from a new memory location. In this corrected example, the size 0 bit field member ensures that `IOFlag` and `SetupFlag` are stored in distinct memory locations.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int : 0;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

# Data race through standard library function call

Multiple tasks make unprotected calls to thread-unsafe standard library function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when:

1. Multiple tasks call the same standard library function.

   For instance, multiple tasks call the `strerror` function.
2. The calls are not protected using a common protection.

   For instance, the calls are not protected by the same critical section.

Functions flagged by this defect are not guaranteed to be reentrant. A function is reentrant if it can be interrupted and safely called again before its previous invocation completes execution. If a function is not reentrant, multiple tasks calling the function without protection can cause concurrency issues. For the list of functions that are flagged, see CON33-C: Avoid race conditions when using library functions.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see "Configuring Polyspace Multitasking Analysis Manually".

### Risk

The functions flagged by this defect are nonreentrant because their implementations can use global or static variables. When multiple tasks call the function without protection, the function call from one task can interfere with the call from another task. The two invocations of the function can concurrently access the global or static variables and cause unpredictable results.

The calls can also cause more serious security vulnerabilities, such as abnormal termination, denial-of-service attack, and data integrity violations.

### Fix

To fix this defect, do one of the following:

- Use a reentrant version of the standard library function if it exists.

  For instance, instead of `strerror()`, use `strerror_r()` or `strerror_s()`. For alternatives to functions flagged by this defect, see the documentation for CON33-C.
- Protect the function calls using common critical sections or temporal exclusion.

  See `Critical section details (-critical-section-begin -critical-section-end)` and `Temporally exclusive tasks (-temporal-exclusions-file)`.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

## Examples

### Unprotected Call to Standard Library Function from Multiple Tasks

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno);
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification |
|---|---|
| `Configure multitasking manually` | ☑ |

| Option | Specification | |
|---|---|---|
| Tasks (-entry-points) | task1<br>task2<br>task3 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

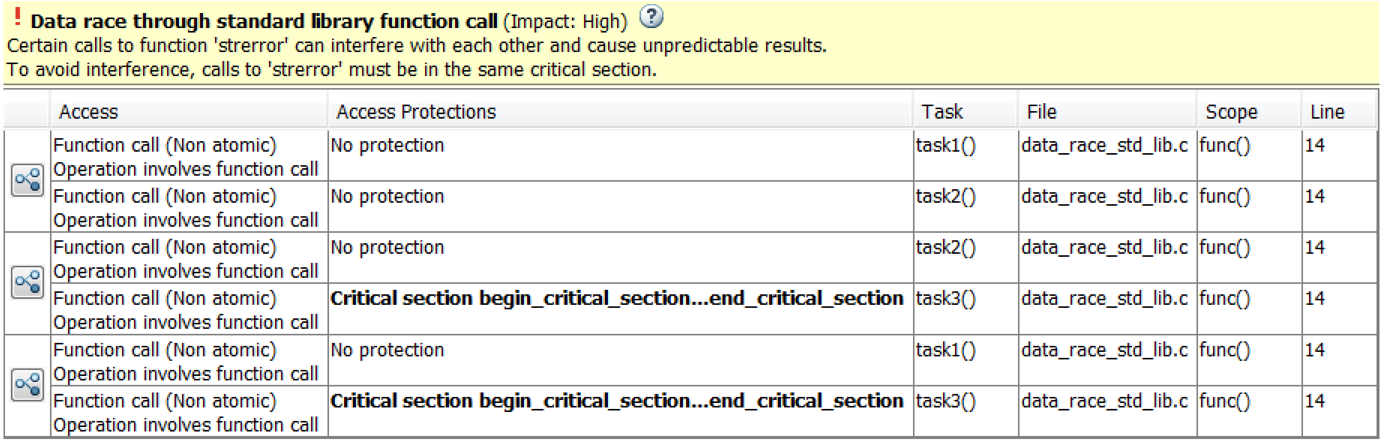
On the command-line, you can use the following:

```
polyspace-bug-finder
  -entry-points task1,task2,task3
  -critical-section-begin begin_critical_section:cs1
  -critical-section-end end_critical_section:cs1
```

In this example, the tasks, `task1`, `task2` and `task3`, call the function `func`. `func` calls the nonreentrant standard library function, `strerror`.

Though `task3` calls `func` inside a critical section, other tasks do not use the same critical section. Operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

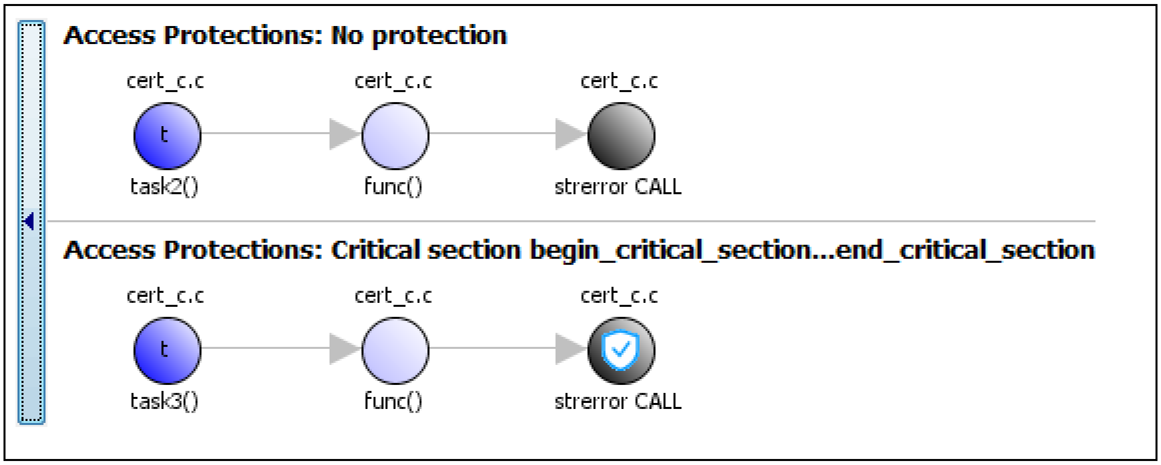
These three tasks are calling a nonreentrant standard library function without common protection. In your result details, you see each pair of conflicting function calls.



! **Data race through standard library function call** (Impact: High)
Certain calls to function 'strerror' can interfere with each other and cause unpredictable results.
To avoid interference, calls to 'strerror' must be in the same critical section.

| | Access | Access Protections | Task | File | Scope | Line |
|---|---|---|---|---|---|---|
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |

If you click the icon, you see the function call sequence starting from the entry point to the standard library function call. You also see that the call starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



Access Protections: No protection
cert_c.c
t
task2()
cert_c.c
func()
cert_c.c
strerror CALL
Access Protections: Critical section begin_critical_section...end_critical_section
cert_c.c
t
task3()
cert_c.c
func()
cert_c.c
strerror CALL

#### Correction — Use Reentrant Version of Standard Library Function

One possible correction is to use a reentrant version of the standard library function `strerror`. You can use the POSIX version `strerror_r` which has the same functionality but also guarantees thread-safety.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);
enum { BUFFERSIZE = 64 };

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char errmsg[BUFFERSIZE];
    if (strerror_r(errno, errmsg, BUFFERSIZE) != 0) {
      /* Handle error */
    }
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

**Correction — Place Function Call in Critical Section**

One possible correction is to place the call to `strerror` in critical section. You can implement the critical section in multiple ways.

For instance, you can place the call to the intermediate function `func` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `func` and therefore the calls to `strerror` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `func` between calls to `begin_critical_section` and `end_critical_section`.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno);
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    begin_critical_section();
    func(fptr1);
    end_critical_section();
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     begin_critical_section();
     func(fptr2);
     end_critical_section();
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| `Temporally exclusive tasks (-temporal-exclusions-file)` | `task1 task2 task3` |

On the command-line, you can use the following:

```
polyspace-bug-finder
    -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

# Deadlock

Call sequence to lock functions cause two tasks to block each other

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when multiple tasks are stuck in their critical sections (CS) because:

- Each CS waits for another CS to end.
- The critical sections (CS) form a closed cycle. For example:
  - CS #1 waits for CS #2 to end, and CS #2 waits for CS #1 to end.
  - CS #1 waits for CS #2 to end, CS #2 waits for CS #3 to end and CS #3 waits for CS #1 to end.

Polyspace expects critical sections of code to follow a specific format. A critical section lies between a call to a lock function and a call to an unlock function. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

### Risk

Each task waits for a critical section in another task to end and is unable to proceed. The program can freeze indefinitely.

### Fix

The fix depends on the root cause of the defect. You can try to break the cyclic order between the tasks in one of these ways:

- Write down all critical sections involved in the deadlock in a certain sequence. Whenever you call the lock functions of the critical sections within a task, respect the order in that sequence. See an example below.
- If one of the critical sections involved in a deadlock occurs in an interrupt, try to disable all interrupts during critical sections in all tasks. See `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Reviewing this defect is an opportunity to check if all operations in your critical section are really meant to be executed as an atomic block. It is a good practice to keep critical sections at a bare minimum.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.

- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Extend Checker

You might be using multithreading functions that are not supported by Polyspace. Extend this checker by mapping the functions of your multithreading functions to their known POSIX equivalent. See "Extend Concurrency Defect Checkers to Unsupported Multithreading Environments".

## Examples

### Deadlock with Two Tasks

```
void task1(void);
void task2(void);

int var;
void perform_task_cycle(void) {
 var++;
}

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_2();
    begin_critical_section_1();
    perform_task_cycle();
    end_critical_section_1();
    end_critical_section_2();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section_1 | end_critical_section_1 |
| | begin_critical_section_2 | end_critical_section_2 |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `begin_critical_section_1`.
2. `task2` calls `begin_critical_section_2`.
3. `task1` reaches the instruction `begin_critical_section_2();`. Since `task2` has already called `begin_critical_section_2`, `task1` waits for `task2` to call `end_critical_section_2`.
4. `task2` reaches the instruction `begin_critical_section_1();`. Since `task1` has already called `begin_critical_section_1`, `task2` waits for `task1` to call `end_critical_section_1`.

#### Correction-Follow Same Locking Sequence in Both Tasks

One possible correction is to follow the same sequence of calls to lock and unlock functions in both `task1` and `task2`.

```
void task1(void);
void task2(void);
void perform_task_cycle(void);

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}
```

### Deadlock with More Than Two Tasks

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2();
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock3();
    lock1();
    performTaskCycle();
    unlock1();
    unlock3();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | `task1`<br>`task2`<br>`task3` | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | `lock1` | `unlock1` |
| | `lock2` | `unlock2` |
| | `lock3` | `unlock3` |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `lock1`.
2. `task2` calls `lock2`.
3. `task3` calls `lock3`.
4. `task1` reaches the instruction `lock2();`. Since `task2` has already called `lock2`, `task1` waits for call to `unlock2`.
5. `task2` reaches the instruction `lock3();`. Since `task3` has already called `lock3`, `task2` waits for call to `unlock3`.
6. `task3` reaches the instruction `lock1();`. Since `task1` has already called `lock1`, `task3` waits for call to `unlock1`.

#### Correction — Break Cyclic Order

To break the cyclic order between critical sections, note every lock function in your code in a certain sequence, for example:

1. `lock1`
2. `lock2`
3. `lock3`

If you use more than one lock function in a task, use them in the order in which they appear in the sequence. For example, you can use `lock1` followed by `lock2` but not `lock2` followed by `lock1`.

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2();
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock1();
    lock3();
    performTaskCycle();
    unlock3();
    unlock1();
 }
}
```

# Destruction of locked mutex

Task tries to destroy a mutex in the locked state

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when a task destroys a mutex after it is locked (and before it is unlocked). The locking and destruction can happen in the same task or different tasks.

### Risk

A mutex is locked to protect shared variables from concurrent access. If a mutex is destroyed in the locked state, the protection does not apply.

### Fix

To fix this defect, destroy the mutex only after you unlock it. It is a good design practice to:

- Initialize a mutex *before* creating the threads where you use the mutex.
- Destroy a mutex *after* joining the threads that you created.

On the **Result Details** pane, you see two events, the locking and destruction of the mutex, and the tasks that initiated the events. To navigate to the corresponding line in your source code, click the event.

## Examples

### Locking and Destruction in Different Tasks

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
  pthread_mutex_unlock (&lock3);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_destroy (&lock3);
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

In this example, after task `t0` locks the mutex `lock3`, task `t1` can destroy it. The destruction occurs if the following events happen in sequence:

1. `t0` acquires `lock3`.
2. `t0` releases `lock2`.
3. `t0` releases `lock1`.
4. `t1` acquires the lock `lock1` released by `t0`.
5. `t1` acquires the lock `lock2` released by `t0`.
6. `t1` destroys `lock3`.

For simplicity, this example uses a mix of automatic and manual concurrency detection. The tasks `t0` and `t1` are manually specified as entry points by using the option `Tasks (-entry-points)`. The critical sections are implemented through primitives `pthread_mutex_lock` and `pthread_mutex_unlock` that the software detects automatically. In practice, for entry point specification (thread creation), you will use primitives such as `pthread_create`. The next example shows how the defect can appear when you use `pthread_create`.

**Correction — Place Lock-Unlock Pair Together in Same Critical Section as Destruction**

The locking and destruction of `lock3` occurs inside the critical section imposed by `lock1` and `lock2`, but the unlocking occurs outside. One possible correction is to place the lock-unlock pair in the same critical section as the destruction of the mutex. Use one of these critical sections:

- Critical section imposed by `lock1` alone.
- Critical section imposed by `lock1` and `lock2`.

In this corrected code, the lock-unlock pair and the destruction is placed in the critical section imposed by `lock1` and `lock2`. When `t0` acquires `lock1` and `lock2`, `t1` has to wait for their release before it executes the instruction `pthread_mutex_destroy (&lock3);`. Therefore, `t1` cannot destroy mutex `lock3` in the locked state.

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_destroy (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

#### Locking and Destruction in Start Routine of Thread

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_destroy(&lock);
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Thread that initializes mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use mutex for atomic operation*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   pthread_exit(NULL);
}
```

In this example, four threads are created. The threads are assigned different actions.

- The first thread `callThd[0]` initializes the mutex `lock`.
- The second and third threads, `callThd[1]` and `callThd[2]`, perform an atomic operation protected by the mutex `lock`.
- The fourth thread `callThd[3]` destroys the mutex `lock`.

The threads can interrupt each other. Therefore, immediately after the second or third thread locks the mutex, the fourth thread can destroy it.

#### Correction — Initialize and Destroy Mutex Outside Start Routine

One possible correction is to initialize and destroy the mutex in the `main` function outside the start routine of the threads. The threads perform only the atomic operation. You need two fewer threads because the mutex initialization and destruction threads are not required.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 2
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_work(void *arg) {
   pthread_mutex_lock (&lock);
   atomic_operation();
   pthread_mutex_unlock (&lock);
   pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);
   /* Initialize mutex */
   pthread_mutex_init(&lock, NULL);

   for(i=0; i<NUMTHREADS; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy mutex */
   pthread_mutex_destroy(&lock);

   pthread_exit(NULL);
}
```

#### Correction — Use A Second Mutex To Protect Lock-Unlock Pair and Destruction

Another possible correction is to use a second mutex and protect the lock-unlock pair from the destruction. This corrected code uses the mutex `lock2` to achieve this protection. The second mutex is initialized in the `main` function outside the start routine of the threads.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
pthread_mutex_t lock2;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_destroy(&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}
```

```
int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize second mutex */
   pthread_mutex_init(&lock2, NULL);

   /* Thread that initializes first mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use first mutex for atomic operation */
   /* The threads use second mutex to protect first from destruction in locked state*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys first mutex */
   /* The thread uses the second mutex to prevent destruction of locked mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy second mutex */
   pthread_mutex_destroy(&lock2);

   pthread_exit(NULL);
}
```

# Double lock

Lock function is called twice in a task without an intermediate call to unlock function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when:

- A task calls a lock function `my_lock`.
- The task calls `my_lock` again before calling the corresponding unlock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `task1` calls a lock function `lock`, other tasks calling `lock` must wait until `task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

### Risk

A call to a lock function begins a critical section so that other tasks have to wait to enter the same critical section. If the same lock function is called again within the critical section, the task blocks itself.

### Fix

The fix depends on the root cause of the defect. A double lock defect often indicates a coding error. Perhaps you omitted the call to an unlock function to end a previous critical section and started the next critical section. Perhaps you wanted to use a different lock function for the second critical section.

Identify each critical section of code, that is, the section that you want to be executed as an atomic block. Call a lock function at the beginning of the section. Within the critical section, make sure that you do not call the lock function again. At the end of the section, call the unlock function that corresponds to the lock function.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    ...
  }
  my_unlock();
}
```

```
void func2() {
  {
   my_lock();
   ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

You might be using locking functions that are not supported by Polyspace. Extend this checker by mapping your locking functions to its known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Double Lock

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    lock();
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Value | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | lock | unlock |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin lock:cs1
   -critical-section-end unlock:cs1
```

`task1` enters a critical section through the call `lock();`. `task1` calls `lock` again before it leaves the critical section through the call `unlock();`.

**Correction — Remove First Lock**

If you want the first `global_var+=1;` to be outside the critical section, one possible correction is to remove the first call to `lock`. However, if other tasks are using `global_var`, this code can produce a `Data race` error.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    global_var += 1;
    lock();
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

**Correction — Remove Second Lock**

If you want the first `global_var+=1;` to be inside the critical section, one possible correction is to remove the second call to `lock`.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

**Correction — Add Another Unlock**

If you want the second `global_var+=1;` to be inside a critical section, another possible correction is to add another call to `unlock`.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    unlock();
    lock();
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

### Double Lock with Function Call

```
int global_var;
```

```
void lock(void);
void unlock(void);

void performOperation(void) {
  lock();
  global_var++;
}

void task1(void)
{
    lock();
    global_var += 1;
    performOperation();
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | lock | unlock |

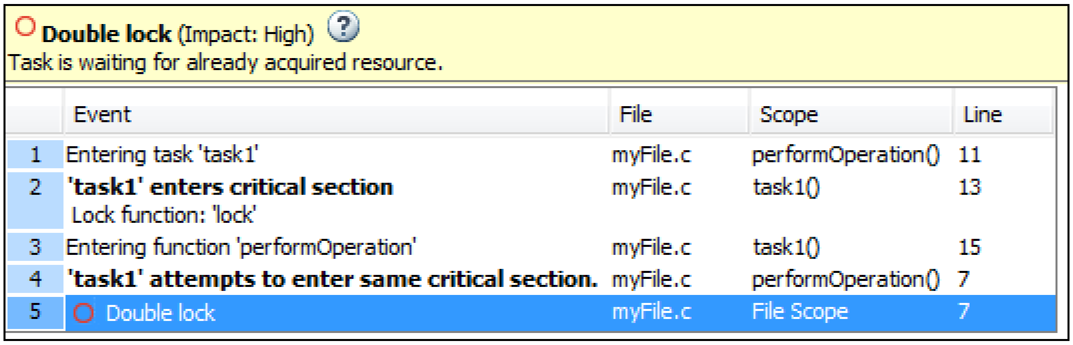
On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin lock:cs1
   -critical-section-end unlock:cs1
```

`task1` enters a critical section through the call `lock();`. `task1` calls the function `performOperation`. In `performOperation`, `lock` is called again even though `task1` has not left the critical section through the call `unlock();`.

In the result details for the defect, you see the sequence of instructions leading to the defect. For instance, you see that following the first entry into the critical section, the execution path:

- Enters function `performOperation`.
- Inside `performOperation`, attempts to enter the same critical section once again.



○ **Double lock** (Impact: High)

Task is waiting for already acquired resource.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Entering task 'task1' | myFile.c | performOperation() | 11 |
| 2 | **'task1' enters critical section**<br>Lock function: 'lock' | myFile.c | task1() | 13 |
| 3 | Entering function 'performOperation' | myFile.c | task1() | 15 |
| 4 | **'task1' attempts to enter same critical section.** | myFile.c | performOperation() | 7 |
| 5 | ○ Double lock | myFile.c | File Scope | 7 |

You can click each event to navigate to the corresponding line in the source code.

### Correction — Remove Second Lock

One possible correction is to remove the call to `lock` in `task1`.

```
int global_var;

void lock(void);
void unlock(void);

void performOperation(void) {
  global_var++;
}

void task1(void)
{
    lock();
    global_var += 1;
    performOperation();
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

## Result Information

# Double unlock

Unlock function is called twice in a task without an intermediate call to lock function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when:

- A task calls a lock function `my_lock`.
- The task calls the corresponding unlock function `my_unlock`.
- The task calls `my_unlock` again. The task does not call `my_lock` a second time between the two calls to `my_unlock`.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `task1` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `task1` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

### Risk

A double unlock defect can indicate a coding error. Perhaps you wanted to call a different unlock function to end a different critical section. Perhaps you called the unlock function prematurely the first time and only the second call indicates the end of the critical section.

### Fix

The fix depends on the root cause of the defect.

Identify each critical section of code, that is, the section that you want to be executed as an atomic block. Call a lock function at the beginning of the section. Only at the end of the section, call the unlock function that corresponds to the lock function. Remove any other redundant call to the unlock function.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    ...
  }
  my_unlock();
}
```

```
void func2() {
  {
   my_lock();
   ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

You might be using unlocking functions that are not supported by Polyspace. Extend this checker by mapping your unlocking functions to its known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Double Unlock

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Value | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | BEGIN_CRITICAL_SECTION | END_CRITICAL_SECTION |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin BEGIN_CRITICAL_SECTION:cs1
   -critical-section-end END_CRITICAL_SECTION:cs1
```

`task1` enters a critical section through the call `BEGIN_CRITICAL_SECTION();`. `task1` leaves the critical section through the call `END_CRITICAL_SECTION();`. `task1` calls `END_CRITICAL_SECTION` again without an intermediate call to `BEGIN_CRITICAL_SECTION`.

#### Correction — Remove Second Unlock

If you want the second `global_var+=1;` to be outside the critical section, one possible correction is to remove the second call to `END_CRITICAL_SECTION`. However, if other tasks are using `global_var`, this code can produce a `Data race` error.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    global_var += 1;
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

#### Correction — Remove First Unlock

If you want the second `global_var+=1;` to be inside the critical section, one possible correction is to remove the first call to `END_CRITICAL_SECTION`.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    global_var += 1;
    END_CRITICAL_SECTION();
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

#### Correction — Add Another Lock

If you want the second `global_var+=1;` to be inside a critical section, another possible correction is to add another call to `BEGIN_CRITICAL_SECTION`.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

## Result Information

# Function that can spuriously fail not wrapped in loop

Loop checks failure condition after possible spurious failure

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when the following atomic compare and exchange functions that can fail spuriously are called from outside a loop.

- C atomic functions:
  - `atomic_compare_exchange_weak()`
  - `atomic_compare_exchange_weak_explicit()`
- C++ atomic functions:
  - `std::atomic<T>::compare_exchange_weak(T* expected, T desired)`
  - `std::atomic<T>::compare_exchange_weak_explicit(T* expected, T desired, std::memory_order succ, std::memory_order fail)`
  - `std::atomic_compare_exchange_weak(std::atomic<T>* obj, T* expected, T desired)`
  - `std::atomic_compare_exchange_weak_explicit(volatile std::atomic<T>* obj, T* expected, T desired, std::memory_order succ, std::memory_order fail)`

The functions compare the memory contents of the object representations pointed to by `obj` and `expected`. The comparison can spuriously return false even if the memory contents are equal. This spurious failure makes the functions faster on some platforms.

### Risk

An atomic compare and exchange function that spuriously fails can cause unexpected results and unexpected control flow.

### Fix

Wrap atomic compare and exchange functions that can spuriously fail in a loop. The loop checks the failure condition after a possible spurious failure.

## Examples

### `atomic_compare_exchange_weak()` Not Wrapped in Loop

```
#include <stdatomic.h>

extern void reset_count(void);
atomic_int count = ATOMIC_VAR_INIT(0);
```

```
void increment_count(void)
{
    int old_count = atomic_load(&count);
    int new_count;
    new_count = old_count + 1;
    if (!atomic_compare_exchange_weak(&count, &old_count, new_count))
        reset_count();

}
```

In this example, `increment_count()` uses `atomic_compare_exchange_weak()` to compare `count` and `old_count`. If the counts are equal, `count` is incremented to `new_count`. If they are not equal, the count is reset. When `atomic_compare_exchange_weak()` fails spuriously, the count is reset unnecessarily.

#### Correction — Wrap `atomic_compare_exchange_weak()` in a `while` Loop

One possible correction is to wrap the call to `atomic_compare_exchange_weak()` in a `while` loop. The loop checks the failure condition after a possible spurious failure.

```
#include <stdatomic.h>

extern void reset_count(void);
atomic_int count = ATOMIC_VAR_INIT(0);

void increment_count(void)
{
    int old_count = atomic_load(&count);
    int new_count;
    new_count = old_count + 1;

    do {
        reset_count();

    } while (!atomic_compare_exchange_weak(&count, &old_count, new_count));

}
```

## Result Information

**Group:** Concurrency

# Function that can spuriously wake up not wrapped in loop

Loop checks wake-up condition after possible spurious wake-up

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

This defect occurs when the following wait-on-condition functions are called from outside a loop:

- C functions:
  - `cnd_wait()`
  - `cnd_timedwait()`
- POSIX functions:
  - `pthread_cond_wait()`
  - `pthread_cond_timedwait()`
- C++ `std::condition_variable` and `std::condition_variable_any` class member functions:
  - `wait()`
  - `wait_until()`
  - `wait_for()`

Wait-on-condition functions pause the execution of the calling thread when a specified condition is met. The thread wakes up and resumes once another thread notifies it with `cnd_broadcast()` or an equivalent function. The wake-up notification can be spurious or malicious.

### Risk

If a thread receives a spurious wake-up notification and the condition of the wait-on-condition function is not checked, the thread can wake up prematurely. The wake-up can cause unexpected control flow, indefinite blocking of other threads, or denial of service.

### Fix

Wrap wait-on-condition functions that can wake up spuriously in a loop. The loop checks the wake-up condition after a possible spurious wake-up notification.

## Examples

### `cnd_wait()` Not Wrapped in Loop

```
#include <stdio.h>
```

```
#include <stddef.h>
#include <threads.h>

#define THRESHOLD 100

static mtx_t lock;
static cnd_t cond;

void func(int input)
{
    if (thrd_success != mtx_lock(&lock)) {
        /* Handle error */
    }
    /* test condition to pause thread */
    if (input > THRESHOLD) {
        if (thrd_success != cnd_wait(&cond, &lock)) {
            /* Handle error */
        }
    }
    /* Proceed if condition to pause does not hold */

    if (thrd_success != mtx_unlock(&lock)) {
        /* Handle error */
    }
}
```

In this example, the thread uses `cnd_wait()` to pause execution when `input` is greater than `THRESHOLD`. The paused thread can resume if another thread uses `cnd_broadcast()`, which notifies all the threads. This notification causes the thread to wake up even if the pause condition is still true.

#### Correction — Wrap `cnd_wait()` in a `while` Loop

One possible correction is to wrap `cnd_wait()` in a `while` loop. The loop checks the pause condition after the thread receives a possible spurious wake-up notification.

```
#include <stdio.h>
#include <stddef.h>
#include <threads.h>

#define THRESHOLD 100

static mtx_t lock;
static cnd_t cond;

void func(int input)
{
    if (thrd_success != mtx_lock(&lock)) {
        /* Handle error */
    }
    /* test condition to pause thread */
    while (input > THRESHOLD) {
        if (thrd_success != cnd_wait(&cond, &lock)) {
            /* Handle error */
        }
    }
    /* Proceed if condition to pause does not hold */

    if (thrd_success != mtx_unlock(&lock)) {
        /* Handle error */
    }
}
```

### Result Information

**Group:** Concurrency
**Language:** C | C++

# Join or detach of a joined or detached thread

Thread that was previously joined or detached is joined or detached again

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when:

- You try to join a thread that was previously joined or detached.
- You try to detach a thread that was previously joined or detached.

The **Result Details** pane describes if the thread was previously joined or detached and also shows previous related events.

For instance, a thread joined with `thrd_join` is then detached with `thrd_detach`:

```
thrd_t id;
...
thrd_join(id, NULL);
thrd_detach(id);
```

Note that a thread is considered as joined only if a previous thread joining is successful. For instance, the thread is not considered as joined in the `if` branch here:

```
thrd_t t;
...
if (thrd_success != thrd_join(t, 0)) {
    /* Thread not considered joined */
}
```

The analysis cannot detect cases where a joined thread detaches itself using, for instance, the `thrd_current()` function.

### Risk

The C11 standard (clauses 7.26.5.3 and 7.26.5.6) states that a thread shall not be joined or detached once it was previously joined or detached. Violating these clauses of the standard results in undefined behavior.

### Fix

Avoid joining a thread that was already joined or detached previously. Avoid detaching a thread that was already joined or detached.

## Examples

### Joining a Thread Followed by Detaching the Thread

```
#include <stddef.h>
```

```
#include <threads.h>
#include <stdlib.h>

extern int thread_func(void *arg);

int main (void)
{
  thrd_t t;

  if (thrd_success != thrd_create (&t, thread_func, NULL)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_join (t, 0)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_detach (t)) {
    /* Handle error */
    return 0;
  }

  return 0;
}
```

In this example, the use of `thrd_detach` on a thread that was previously joined with `thrd_join` leads to undefined behavior.

To avoid compilation errors when running Bug Finder on this example, specify the C11 standard with the option `C standard version (-c-version)`.

#### Correction – Avoid Detaching a Joined Thread

Remove the prior `thrd_join` or the subsequent `thrd_detach` statement. In this corrected version, the `thrd_detach` statement is removed.

```
#include <stddef.h>
#include <threads.h>
#include <stdlib.h>

extern int thread_func(void *arg);

int main (void)
{
  thrd_t t;

  if (thrd_success != thrd_create (&t, thread_func, NULL)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_join (t, 0)) {
    /* Handle error */
    return 0;
  }

  return 0;
}
```

### Joining Thread Created in Detached State

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success != pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_DETACHED)) {
        return 0;
    }

    if(thread_success != pthread_create(&id, &attr, thread_func, NULL)) {
            return 0;
    }

    if(thread_success != pthread_join(id, NULL)) {
            return 0;
    }

    return 0;
}
```

In this example, the thread attribute is assigned the state `PTHREAD_CREATE_DETACHED`. A thread created using this attribute is then joined.

#### Correction – Create Threads as Joinable

One possible correction is to create a thread with thread attribute assigned to the state `PTHREAD_CREATE_JOINABLE` and then join the thread.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success != pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE)) {
        return 0;
    }

    if(thread_success != pthread_create(&id, &attr, thread_func, NULL)) {
            return 0;
    }

    if(thread_success != pthread_join(id, NULL)) {
            return 0;
    }

    return 0;
}
```

### Result Information

**Group:** Concurrency
**Language:** C
**Default:** Off
**Command-Line Syntax:** `DOUBLE_JOIN_OR_DETACH`
**Impact:** Medium

## Version History

**Introduced in R2019b**

# Missing lock

Unlock function without lock function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when a task calls an unlock function before calling the corresponding lock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait till `my_task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

### Risk

A call to an unlock function without a corresponding lock function can indicate a coding error. For instance, perhaps the unlock function does not correspond to the lock function that begins the critical section.

### Fix

The fix depends on the root cause of the defect. For instance, if the defect occurs because of a mismatch between lock and unlock function, check the lock-unlock function pair in your Polyspace analysis configuration and fix the mismatch.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
   ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

You might be using locking and unlocking functions that are not supported by Polyspace. Extend this checker by mapping these functions to their known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Missing lock

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
  begin_critical_section();
  global_var = 0;
  end_critical_section();
}

void my_task(void)
{
  global_var += 1;
  end_critical_section();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | my_task, reset | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, my_task and reset. my_task calls end_critical_section before calling begin_critical_section.

**Correction — Provide Lock**

One possible correction is to call the lock function begin_critical_section before the instructions in the critical section.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
  begin_critical_section();
  global_var = 0;
  end_critical_section();
}

void my_task(void)
{
    begin_critical_section();
    global_var += 1;
    end_critical_section();
}
```

### Lock in Condition

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      if(index%10==0) {
        begin_critical_section();
        global_var ++;
      }
      end_critical_section();
      index++;
    }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| `Configure multitasking manually` | ☑ | |
| `Tasks (-entry-points)` | `my_task`, `reset` | |
| `Critical section details (-critical-section-begin -critical-section-end)` | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`.

In the `while` loop, `my_task` leaves a critical section through the call `end_critical_section();`. In an iteration of the `while` loop:

- If `my_task` enters the `if` condition branch, the critical section begins through a call to `begin_critical_section`.
- If `my_task` does not enter the `if` condition branch and leaves the `while` loop, the critical section does not begin. Therefore, a **Missing lock** defect occurs.
- If `my_task` does not enter the `if` condition branch and continues to the next iteration of the `while` loop, the unlock function `end_critical_section` is called again. A **Double unlock** defect occurs.

Because `numCycles` is a `volatile` variable, it can take any value. Any of the cases above are possible. Therefore, a **Missing lock** defect and a **Double unlock** defect appear on the call `end_critical_section`.

# Missing or double initialization of thread attribute

Duplicated initialization of thread attributes or noninitialized thread attribute used in functions that expect initialized attributes

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs during one of these situations:

- You initialize a thread attribute twice with a function such as `pthread_attr_init` without an intermediate call to a function such as `pthread_attr_destroy`.

  The function `pthread_attr_destroy` destroys a thread attribute object and enables the system to reclaim resources associated with the object.
- You use a noninitialized thread attribute in a function such as `pthread_create`, which expects an initialized attribute. A thread attribute might be noninitialized because it was never initialized previously or destroyed with the `pthread_attr_destroy` function.

  Noninitialized thread attributes are detected for all functions in the POSIX standard.

The **Result Details** pane describes whether the attribute is doubly initialized or noninitialized and also shows previous related events.

Note that a thread attribute is considered initialized only if the call to `pthread_attr_init` is successful. For instance, the thread attribute is not initialized in the `if` branch here:

```
pthread_attr_t attr;
int thread_success;

thread_success = pthread_attr_init(&attr);
if(thread_success != 0) {
   /* Thread attribute considered noninitialized */
}
```

The issue is also flagged if you do not check the return value from a call to `pthread_attr_init`.

### Risk

Initializing a thread attribute without destroying the previously initialized attribute or using noninitialized thread attributes leads to undefined behavior.

### Fix

Before using a thread attribute, initialize the attribute by using the `pthread_attr_init` function.

```
pthread_attr_t attr;
int thread_success;

/* Initialize attribute */
thread_success = pthread_attr_init(&attr);
```

```
if(thread_success != 0) {
   /* Handle initialization error */
}
...
/* Use attribute */
thread_sucess = pthread_create(&thr, &attr, &thread_start, NULL);
```

After initialization, destroy a thread attribute by using `pthread_attr_destroy` before initializing again:

```
pthread_attr_t attr;
int thread_success;

/* Destroy attribute */
thread_success = pthread_attr_destroy(&attr);
if(thread_success != 0) {
   /* Handle destruction error */
}
...
/* Reinitialize attribute */
thread_success = pthread_attr_init(&attr);
```

## Examples

### Use of Noninitialized Thread Attribute

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success == pthread_create(&id, &attr, thread_func, NULL)) {
    }

    return 0;
}
```

In this example, the attribute `attr` is not initialized before its use in the `pthread_create` call.

#### Correction – Initialize Thread Attribute Before Use

Before using a thread attribute in the `pthread_create` function, initialize the attribute with the `pthread_attr_init` function.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success == pthread_create(&id, &attr, thread_func, NULL)) {
    }

    return 0;
}
```

### Return Value from Thread Attribute Initialization Not Checked

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    pthread_attr_init(&attr);

    if(thread_success == pthread_create(&id, &attr, thread_func, NULL)) {
    }

    return 0;
}
```

In this example, the return value of `pthread_attr_init` is not checked. If the thread attribute initialization fails, the error does not get handled. A possibly undefined thread attribute is later used in the `pthread_create` function.

#### Correction – Handle Errors from Thread Attribute Initialization

One possible correction is to use the thread attribute only if the return value from `pthread_attr_init` indicates successful initialization.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success == pthread_create(&id, &attr, thread_func, NULL)) {
    }
    return 0;
}
```

### Result Information

# Missing unlock

Lock function without unlock function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

This defect occurs when:

- A task calls a lock function.
- The task ends without a call to an unlock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task, `my_task`, calls a lock function, `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, before analysis, you must specify the multitasking options. On the **Configuration** pane, select **Multitasking**.

### Risk

An unlock function ends a critical section so that other waiting tasks can enter the critical section. A missing unlock function can result in tasks blocked for an unnecessary length of time.

### Fix

Identify the critical section of code, that is, the section that you want to be executed as an atomic block. At the end of this section, call the unlock function that corresponds to the lock function used at the beginning of the section.

There can be other reasons and corresponding fixes for the defect. Perhaps you called the incorrect unlock function. Check the lock-unlock function pair in your Polyspace analysis configuration and fix the mismatch.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
```

```
    ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Extend Checker

You might be using locking and unlocking functions that are not supported by Polyspace. Extend this checker by mapping these functions to their known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Missing Unlock

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset()
{
    begin_critical_section();
    global_var = 0;
    end_critical_section();
}

void my_task(void)
{
    begin_critical_section();
    global_var += 1;
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Value | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | my_task, reset | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`. `my_task` enters a critical section through the call `begin_critical_section();`. `my_task` ends without calling `end_critical_section`.

#### Correction — Provide Unlock

One possible correction is to call the unlock function `end_critical_section` after the instructions in the critical section.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
    begin_critical_section();
    global_var = 0;
    end_critical_section();
}

void my_task(void)
{
    begin_critical_section();
    global_var += 1;
    end_critical_section();
}
```

### Unlock in Condition

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;
    while(numCycles) {
      begin_critical_section();
      global_var ++;
      if(index%10==0) {
        global_var = 0;
        end_critical_section();
      }
      index++;
    }
}
```

In this example, to emulate multitasking behavior, specify the following options.

| Option | Specification | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | my_task, reset | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`.

In the `while` loop, `my_task` enters a critical section through the call `begin_critical_section();`. In an iteration of the `while` loop:

- If `my_task` enters the `if` condition branch, the critical section ends through a call to `end_critical_section`.
- If `my_task` does not enter the `if` condition branch and leaves the `while` loop, the critical section does not end. Therefore, a **Missing unlock** defect occurs.
- If `my_task` does not enter the `if` condition branch and continues to the next iteration of the `while` loop, the lock function `begin_critical_section` is called again. A **Double lock** defect occurs.

Because `numCycles` is a `volatile` variable, it can take any value. Any of the cases above is possible. Therefore, a **Missing unlock** defect and a **Double lock** defect appear on the call `begin_critical_section`.

#### Correction — Place Unlock Outside Condition

One possible correction is to call the unlock function `end_critical_section` outside the `if` condition.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      begin_critical_section();
      global_var ++;
      if(index%10==0) {
        global_var=0;
      }
      end_critical_section();
      index++;
    }
}
```

#### Correction — Place Unlock in Every Conditional Branch

Another possible correction is to call the unlock function `end_critical_section` in every branches of the `if` condition.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      begin_critical_section();
      global_var ++;
      if(index%10==0) {
        global_var=0;
        end_critical_section();
      }
      else
        end_critical_section();
      index++;
    }
}
```

# Multiple mutexes used with same condition variable

Threads using different mutexes when concurrently waiting on the same condition variable is undefined behavior

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when multiple threads use more than one mutex to concurrently wait on the same condition variable. A thread waits on a condition variable by calling the functions `pthread_cond_timedwait` or `pthread_cond_wait`. These functions take a condition variable and a locked mutex as arguments, and the condition variable is bound to that mutex when the thread waits on the condition variable.

The checkers flags the use of `pthread_cond_timedwait` or `pthread_cond_wait` in one of the threads. See the **Event** column in the **Results Details** pane to view the threads waiting on the same condition variable and using a different mutex.

### Risk

When a thread waits on a condition variable using a mutex, the condition variable is bound to that mutex. Any other thread using a different mutex to wait on the same condition variable is undefined behavior according to the POSIX standard.

### Fix

Use the same mutex argument for `pthread_cond_timedwait` or `pthread_cond_wait` when threads are concurrently waiting on the same condition variable, or use separate condition variables for each mutex.

## Examples

### Concurrent Waiting on Condition Variable with Multiple Mutexes

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <pthread.h>
#define Thrd_return_t                    void *

        }
        sleep(random() % DELAY);
        printf("count2 = %d\n", ++count2);
        if ((ret = pthread_mutex_unlock(&mutex2)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t signaler(void* arg)
{
    int ret;
    while ((count1 < COUNT_LIMIT) || (count2 < COUNT_LIMIT)) {
        sleep(1);
        printf("signaling\n");
        if ((ret = pthread_cond_broadcast(&cv)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter3(void* arg)
{
    int ret;
    while (count3 % COUNT_LIMIT != 0) {
        if ((ret = pthread_mutex_lock(&mutex3)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex3)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count3 = %d\n", ++count3);
        if ((ret = pthread_mutex_unlock(&mutex3)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

int main(void)
{
    int ret;
    pthread_t thread1, thread2, thread3;

    pthread_mutexattr_t attr;

    if ((ret = pthread_mutexattr_init(&attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutexattr_settype(&attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
        /* Handle error */
        fatal_error();
    }

    if ((ret = pthread_mutex_init(&mutex1, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex2, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex3, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_cond_init(&cv, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread1, NULL, &waiter1, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread2, NULL, &waiter2, NULL))) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread3, NULL, &signaler, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread1, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread2, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread3, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }

    while (1) { ; }

    return 0;
}
```

In this example, a different mutex is used to protect each `count` variable. Since all three `waiter` functions wait on the same condition variable `cv` with different mutexes, the call to `pthread_cond_wait` will succeed for one of the threads and the call will be undefined for the other two.

The checker raises a defect for function `waiter3` even though the function is not invoked directly or indirectly by a thread, entry-point, or interrupt. The analysis considers function `waiter3` called by the main program through its function address or an unidentified thread whose creation is the missing source code.

#### Correction — Use the Same Mutex for All Threads Waiting on Same Condition Variable

One possible correction is to pass the same mutex argument to all the call to `pthread_cond_wait` that are used to wait on the same condition variable.

```
 #include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <pthread.h>
#define Thrd_return_t                    void *
#define __USE_XOPEN2K8

#define COUNT_LIMIT 5

static void fatal_error(void)
{
    exit(1);
}

pthread_mutex_t mutex;

pthread_cond_t cv;

int count1 = 0, count2 = 0, count3 = 0;
#define DELAY 8

Thrd_return_t waiter1(void* arg)
{
    int ret;
    while (count1 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count1 = %d\n", ++count1);
        if ((ret = pthread_mutex_unlock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter2(void* arg)
{
    int ret;
    while (count2 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count2 = %d\n", ++count2);
        if ((ret = pthread_mutex_unlock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t signaler(void* arg)
```

```
{
    int ret;
    while ((count1 < COUNT_LIMIT) || (count2 < COUNT_LIMIT)) {
        sleep(1);
        printf("signaling\n");
        if ((ret = pthread_cond_broadcast(&cv)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }

# Signal call in multithreaded program

Program with multiple threads uses `signal` function

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when you use the `signal()` function in a program with multiple threads.

### Risk

According to the C11 standard (Section 7.14.1.1), use of the `signal()` function in a multithreaded program is undefined behavior.

### Fix

Depending on your intent, use other ways to perform an asynchronous action on a specific thread.

## Examples

### Use of `signal()` Function to Terminate Loop in Thread

```
#include <signal.h>
#include <stddef.h>
#include <threads.h>

volatile sig_atomic_t flag = 0;

void handler(int signum) {
  flag = 1;
}

/* Runs until user sends SIGUSR1 */
int func(void *data) {
  while (!flag) {
    /* ... */
  }
  return 0;
}

int main(void) {
  signal(SIGINT, handler); /* Undefined behavior */
  thrd_t tid;

  if (thrd_success != thrd_create(&tid, func, NULL)) {
    /* Handle error */
  }
  /* ... */
  return 0;
}
```

In this example, the `signal` function is used to terminate a `while` loop in the thread created with `thrd_create`.

**Correction — Use `atomic_bool` Variable to Terminate Loop**

One possible correction is to use an `atomic_bool` variable that multiple threads can access. In the corrected example, the child thread evaluates this variable before every loop iteration. After completing the program, you can modify this variable so that the child thread exits the loop.

```
#include <stdatomic.h>
#include <stdbool.h>
#include <stddef.h>
#include <threads.h>

atomic_bool flag = ATOMIC_VAR_INIT(false);

int func(void *data) {
  while (!flag) {
    /* ... */
  }
  return 0;
}

int main(void) {
  thrd_t tid;

  if (thrd_success != thrd_create(&tid, func, NULL)) {
    /* Handle error */
  }
  /* ... */
  /* Set flag when done */
  flag = true;

  return 0;
}
```

## Result Information

# Thread-specific memory leak

Dynamically allocated thread-specific memory not freed before end of thread

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

This defect occurs when you do not free thread-specific dynamically allocated memory before the end of a thread.

To create thread-specific storage, you generally do these steps:

1. You create a key for thread-specific storage.
2. You create the threads.
3. In each thread, you allocate storage dynamically and then associate the key with this storage.

   After the association, you can read the stored data later using the key.
4. Before the end of the thread, you free the thread-specific memory using the key.

The checker flags execution paths in the thread where the last step is missing.

The checker works on these families of functions:

- `tss_get` and `tss_set` (C11)
- `pthread_getspecific` and `pthread_setspecific` (POSIX)

### Risk

The data stored in the memory is available to other processes even after the threads end (memory leak). Besides security vulnerabilities, memory leaks can shrink the amount of available memory and reduce performance.

### Fix

Free dynamically allocated memory before the end of a thread.

You can explicitly free dynamically allocated memory with functions such as `free`.

Alternatively, when you create a key, you can associate a destructor function with the key. The destructor function is called with the key value as argument at the end of a thread. In the body of the destructor function, you can free any memory associated with the key. If you use this method, Bug Finder still flags a defect. Ignore this defect with appropriate comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

## Examples

### Memory Not Freed at End of Thread

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;

  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */
  }
  print_data();
  return 0;
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }

  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

In this example, the start function of each thread `func` calls two functions:

- `add_data`: This function allocates storage dynamically and associates the storage with a key using the `tss_set` function.
- `print_data`: This function reads the stored data using the `tss_get` function.

At the points where `func` returns, the dynamically allocated storage has not been freed.

**Correction — Free Dynamically Allocated Memory Explicitly**

One possible correction is to free dynamically allocated memory explicitly before leaving the start function of a thread. See the highlighted change in the corrected version.

In this corrected version, a defect still appears on the `return` statement in the error handling section of `func`. The defect cannot occur in practice because the error handling section is entered only if dynamic memory allocation fails. Ignore this remaining defect with appropriate comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;

  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */
  }
  print_data();
  free(tss_get(key));
  return 0;
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }

  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

# Use of signal to kill thread

Uncaught signal kills entire process instead of specific thread

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

This defect occurs when you use an uncaught signal to kill a thread. For instance, you use the POSIX function `pthread_kill` and send the signal `SIGTERM` to kill a thread.

### Risk

Sending a signal kills the entire process instead of just the thread that you intend to kill.

For instance, the `pthread_kill` specifications state that if the disposition of a signal is to terminate, this action affects the entire process.

### Fix

Use other mechanisms that are intended to kill specific threads.

For instance, use the POSIX function `pthread_cancel` to terminate a specific thread.

## Examples

### Use of `pthread_kill` to Terminate Threads

```
#include <signal.h>
#include <pthread.h>

void* func(void *foo) {
  /* Execution of thread */
}

int main(void) {
  int result;
  pthread_t thread;

  if ((result = pthread_create(&thread, NULL, func, 0)) != 0) {
  }
  if ((result = pthread_kill(thread, SIGTERM)) != 0) {
  }

  /* This point is not reached because the process terminates in pthread_kill() */

  return 0;
}
```

In this example, the `pthread_kill` function sends the signal `SIGTERM` to kill a thread. The signal kills the entire process instead of the thread previously created with `pthread_create`.

#### Correction — Use `pthread_cancel` to Terminate Threads

One possible correction is to use the `pthread_cancel` function. The `pthread_cancel` terminates a thread specified by its first argument at a specific cancellation point or immediately, depending on the thread's cancellation type.

```
#include <signal.h>
#include <pthread.h>

void* func(void *foo) {
  /* Execution of thread */
}

int main(void) {
  int result;
  pthread_t thread;

  if ((result = pthread_create(&thread, NULL, func, 0)) != 0) {
    /* Handle Error */
  }
  if ((result = pthread_cancel(thread)) != 0) {
    /* Handle Error */
  }

  /* Continue executing */

  return 0;
}
```

See also:

- `pthread_cancel` for more information on cancellation types.

# Use of undefined thread ID

Thread ID from failed thread creation used in subsequent thread functions

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

This defect occurs when a thread creation function such as `pthread_create` fails but you continue to use the ID from the thread creation.

For instance, `pthread_join` uses an undefined thread ID after the previous thread creation failed. The nonzero return value from `pthread_create` indicates the failed thread creation.

```
pthread_t id;
if(0! = pthread_create(&id, attr, start_func, NULL)) {
    ...
    phread_join(id, NULL);
    ...
}
```

The issue is also flagged if you do not check the return value from a call to `pthread_create`.

### Risk

According to the POSIX standard, if thread creation fails, the contents of the thread ID are undefined. The use of an undefined thread ID can lead to unpredictable results.

The issue often indicates a programming error. For instance, it is possible that you tested for nonzero values to determine successful thread creation:

```
if(0 != pthread_create(&id, attr, start_func, NULL))
```

instead of zero:

```
if(0 == pthread_create(&id, attr, start_func, NULL))
```

### Fix

If the use of an undefined thread ID comes from a programming error, fix the error. Otherwise, remove the thread functions that are using the undefined ID.

## Examples

### Threads Joined After Failed Thread Creation

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);
```

```
int main() {
    pthread_t id;
    if(thread_success != pthread_create(&id, NULL, thread_func, NULL)) {
         if(thread_success == pthread_join(id, NULL)) {
         }
    }

    return 0;
}
```

In this example, if `pthread_create` returns a nonzero value, thread creation has failed. The value of `*id` is undefined. The subsequent call to `pthread_join` uses this undefined value.

**Correction – Join Threads After Successful Thread Creation**

One possible correction is to call `pthread_join` with the thread ID as argument only if `pthread_create` returns zero.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    if(thread_success == pthread_create(&id, NULL, thread_func, NULL)) {
         if(thread_success == pthread_join(id, NULL)) {
         }
    }

    return 0;
}
```

### Return Value from Thread Creation Not Checked

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_create(&id, NULL, thread_func, NULL);
    if(thread_success == pthread_join(id, NULL)) {
    }

    return 0;
}
```

In this example, the return value of `pthread_create` is not checked. If thread creation fails, the error does not get handled. A possibly undefined thread ID is later used in the `pthread_join` function.

#### Correction – Handle Errors from Thread Creation

One possible correction is to use the ID from thread creation only if the return value from `pthread_create` indicates successful thread creation.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    if(thread_success == pthread_create(&id, NULL, thread_func, NULL)) {
         if(thread_success == pthread_join(id, NULL)) {
         }
    }

    return 0;
}
```

## Result Information

# Object Oriented Defects

# *this not returned in copy assignment operator

`operator=` method does not return a pointer to the current object

## Description

This defect occurs when assignment operators such as `operator=` and `operator+=` do not return a reference to `*this`, where `this` is a pointer to the current object. If the `operator=` method does not return `*this`, it means that `a=b` or `a.operator=(b)` is not returning the assignee `a` following the assignment.

For instance:

- The operator returns its parameter instead of a reference to the current object.

  That is, the operator has a form `MyClass & operator=(const MyClass & rhs) { ... return rhs; }` instead of `MyClass & operator=(const MyClass & rhs) { ... return *this; }`.
- The operator returns by value and not reference.

  That is, the operator has a form `MyClass operator=(const MyClass & rhs) { ... return *this; }` instead of `MyClass & operator=(const MyClass & rhs) { ... return *this; }`.

### Risk

Users typically expect object assignments to behave like assignments between built-in types and expect an assignment to return the assignee. For instance, a right-associative chained assignment `a=b=c` requires that `b=c` return the assignee `b` following the assignment. If your assignment operator behaves differently, users of your class can face unexpected consequences.

The unexpected consequences occur when the assignment is part of another statement. For instance:

- If the `operator=` returns its parameter instead of a reference to the current object, the assignment `a=b` returns `b` instead of `a`. If the `operator=` performs a partial assignment of data members, following an assignment `a=b`, the data members of `a` and `b` are different. If you or another user of your class read the data members of the return value and expect the data members of `a`, you might have unexpected results. For an example, see “Return Value of operator= Same as Argument” on page 17-3.
- If the `operator=` method returns `*this` by value and not reference, a copy of `*this` is returned. If you expect to modify the result of the assignment using a statement such as `(a=b).modifyValue()`, you modify a copy of `a` instead of `a` itself.

### Fix

Return `*this` from your assignment operators.

## Examples

### Return Value of operator= Same as Argument

```
class MyClass {
    public:
        MyClass(bool b, int i): m_b(b), m_i(i) {}
        const MyClass& operator=(const MyClass& obj) {
            if (&obj!=this) {
                /* Note: Only m_i is copied. m_b retains its original value. */
                m_i = obj.m_i;
            }
            return obj;
        }
        bool isOk() const { return m_b;}
        int getI() const { return m_i;}
    private:
        bool m_b;
        int m_i;
};

void main() {
        MyClass r0(true, 0), r1(false, 1);
        /* Object calling isOk is r0 and the if block executes. */
        if ( (r1 = r0).isOk()) {
            /* Do something */
        }
}
```

In this example, the operator operator= returns its current argument instead of a reference to *this.

Therefore, in main, the assignment r1 = r0 returns r0 and not r1. Because the operator= does not copy the data member m_b, the value of r0.m_b and r1.m_b are different. The following unexpected behavior occurs.

| What You Might Expect | What Actually Happens |
|---|---|
| • The statement (r1 = r0).isOk() returns r1.m_b which has value false<br>• The if block does not execute. | • The statement (r1 = r0).isOk() returns r0.m_b which has value true<br>• The if block executes. |

#### Correction — Return *this

One possible correction is to return *this from operator=.

```
class MyClass {
    public:
        MyClass(bool b, int i): m_b(b), m_i(i) {}
        const MyClass& operator=(const MyClass& obj) {
            if (&obj!=this) {
                /* Note: Only m_i is copied. m_b retains its original value. */
                m_i = obj.m_i;
            }
            return *this;
        }
        bool isOk() const { return m_b;}
        int getI() const { return m_i;}
    private:
        bool m_b;
        int m_i;
};

void main() {
        MyClass r0(true, 0), r1(false, 1);
        /* Object calling isOk is r0 and the if block executes. */
        if ( (r1 = r0).isOk()) {
            /* Do something */
        }
}
```

# Base class assignment operator not called

Copy assignment operator does not call copy assignment operators of base subobjects

## Description

This defect occurs when a derived class copy assignment operator does not call the copy assignment operator of its base class.

### Risk

If this defect occurs, unless you are initializing the base class data members explicitly in the derived class assignment operator, the operator initializes the members implicitly by using the default constructor of the base class. Therefore, it is possible that the base class data members do not get assigned the right values.

If users of your class expect your assignment operator to perform a complete assignment between two objects, they can face unintended consequences.

### Fix

Call the base class copy assignment operator from the derived class copy assignment operator.

Even if the base class data members are not `private`, and you explicitly initialize the base class data members in the derived class copy assignment operator, replace this explicit initialization with a call to the base class copy assignment operator. Otherwise, determine why you retain the explicit initialization.

## Examples

### Base Class Copy Assignment Operator Not Called

```
class Base0 {
public:
    Base0();
    virtual ~Base0();
    Base0& operator=(const Base0&);
private:
    int _i;
};

class Base1 {
public:
    Base1();
    virtual ~Base1();
    Base1& operator=(const Base1&);
private:
    int _i;
};

class Derived: public Base0, Base1 {
public:
    Derived();
    ~Derived();
    Derived& operator=(const Derived& d) {
        if (&d == this) return *this;
        Base0::operator=(d);
        _j = d._j;
        return *this;
    }
private:
    int _j;
};
```

In this example, the class `Derived` is derived from two classes `Base0` and `Base1`. In the copy assignment operator of `Derived`, only the copy assignment operator of `Base0` is called. The copy assignment operator of `Base1` is not called.

The defect appears on the copy assignment operator of the derived class. Following are some tips for navigating in the source code:

- To find the derived class definition, right-click the derived class name and select **Go To Definition**.
- To find the base class definition, first navigate to the derived class definition. In the derived class definition, right-click the base class name and select **Go To Definition**.
- To find the definition of the base class copy assignment operator, first navigate to the base class definition. In the base class definition, right-click the operator name and select **Go To Definition**.

#### Correction — Call Base Class Copy Assignment Operator

If you want your copy assignment operator to perform a complete assignment, one possible correction is to call the copy assignment operator of class `Base1`.

```
class Base0 {
public:
    Base0();
    virtual ~Base0();
    Base0& operator=(const Base0&);
private:
    int _i;
};

class Base1 {
public:
    Base1();
    virtual ~Base1();
    Base1& operator=(const Base1&);
private:
    int _i;
};

class Derived: public Base0, Base1 {
public:
    Derived();
    ~Derived();
    Derived& operator=(const Derived& d) {
        if (&d == this) return *this;
        Base0::operator=(d);
        Base1::operator=(d);
        _j = d._j;
        return *this;
    }
private:
    int _j;
};
```

## Result Information

**Group:** Object oriented
**Language:** C++
**Default:** On for handwritten code, off for generated code

# Base class destructor not virtual

Class cannot behave polymorphically for deletion of derived class objects

## Description

This defect occurs when a class has virtual functions but not a virtual destructor.

### Risk

The presence of virtual functions indicates that the class is intended for use as a base class. However, if the class does not have a virtual destructor, it cannot behave polymorphically for deletion of derived class objects.

If a pointer to this class refers to a derived class object, and you use the pointer to delete the object, only the base class destructor is called. Additional resources allocated in the derived class are not released and can cause a resource leak.

### Fix

One possible fix is to always use a virtual destructor in a class that contains virtual functions.

## Examples

### Base Class Destructor Not Virtual

```
class Base {
        public:
                Base(): _b(0) {};
                virtual void update() {_b += 1;};
        private:
                int _b;
};

class Derived: public Base {
        public:
                Derived(): _d(0) {};
                ~Derived() {_d = 0;};
                virtual void update() {_d += 1;};
        private:
                int _d;
};
```

In this example, the class Base does not have a virtual destructor. Therefore, if a Base* pointer points to a Derived object that is allocated memory dynamically, and the delete operation is performed on that Base* pointer, the Base destructor is called. The memory allocated for the additional member _d is not released.

The defect appears on the base class definition. Following are some tips for navigating in the source code:

- To find classes derived from the base class, right-click the base class name and select **Search For All References**. Browse through each search result to find derived class definitions.
- To find if you are using a pointer or reference to a base class to point to a derived class object, right-click the base class name and select **Search For All References**. Browse through search results that start with `Base*` or `Base&` to locate pointers or references to the base class. You can then see if you are using a pointer or reference to point to a derived class object.

#### Correction — Make Base Class Destructor Virtual

One possible correction is to declare a `virtual` destructor for the class `Base`.

```
class Base {
        public:
                Base(): _b(0) {};
                virtual ~Base() {_b = 0;};
                virtual void update() {_b += 1;};
        private:
                int _b;
};

class Derived: public Base {
        public:
                Derived(): _d(0) {};
                ~Derived() {_d = 0;};
                virtual void update() {_d += 1;};
        private:
                int _d;
};
```

### Result Information

**Group:** Object oriented
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `DTOR_NOT_VIRTUAL`
**Impact:** Medium

# Bytewise operations on nontrivial class object

Value representations may be improperly initialized or compared

## Description

This defect occurs when you use C Standard library functions to perform bytewise operation on non-trivial or non-standard layout class type objects. For definitions of trivial and standard layout classes, see the C++ Standard (ISO/IEC 14882:2017), [class], paragraphs 6 and 7 respectively.

The checker raises a defect when:

- You initialize or copy non-trivial class type objects using these functions:

  - `std::memset`
  - `std::memcpy`
  - `std::strcpy`
  - `std::memmove`

  To check whether a class type is trivial, use the type-traits library function `std::is_trivial`, for instance:

  ```
  #include <iostream>
  #include <type_traits>

  class trivialClass {};

  void checkTrivial(){
      static_assert(std::is_trivial<trivialClass>::value,
                    "Class is not trivial");
  }
  ```

  It is not sufficient to check that the object type is trivially copyable (`std::is_trivially_copyable<>:value`). A trivially copyable object does not guarantee the class invariants hold when you use the object later in your program.
- You compare non-standard layout class type objects using these functions:

  - `std::memcmp`
  - `std::strcmp`

Note that an incomplete class can be potentially nontrivial.

The checker does not raise a defect if the bytewise operation is performed through an alias. For example no defect is raised in the bytewise comparison and copy operations in this code. The bytewise operations use `dptr` and `sptr`, the aliases of non-trivial or non-standard layout class objects `d` and `s`.

```
void func(NonTrivialNonStdLayout *d, const NonTrivialNonStdLayout *s)
{
   void* dptr = (void*)d;
   const void* sptr = (void*)s;
   // ...
   // ...
   // ...
   if (!std::memcmp(dptr, sptr, sizeof(NonTrivialNonStdLayout))) {
     (void)std::memcpy(dptr, sptr, sizeof(NonTrivialNonStdLayout));
      // ...
   }
}
```

### Risk

Performing bytewise comparison operations by using C Standard library functions on non-trivial or non-standard layout class type object might result in unexpected values due to implementation details. The object representation depends on the implementation details, such as the order of private and public members, or the use of virtual function pointer tables to represent the object.

Performing bytewise setting operations by using C Standard library functions on non-trivial or non-standard layout class type object can change the implementation details. The operation might result in abnormal program behavior or a code execution vulnerability. For instance, if the address of a member function is overwritten, the call to this function invokes an unexpected function.

### Fix

To perform bytewise operations non-trivial or non-standard layout class type object, use these C++ special member functions instead of C Standard library functions.

| C Standard Library Functions | C++ Member Functions |
|---|---|
| `std::memset` | Class constructor |
| `std::memcpy`<br>`std::strcpy`<br>`std::memmove` | Class copy constructor<br>Class move constructor<br>Copy assignment operator<br>Move assignment operator |
| `std::memcmp`<br>`std::strcmp` | `operator<()`<br>`operator>()`<br>`operator==()`<br>`operator!=()` |

## Examples

### Using `memset` with non-trivial class object

```
#include <cstring>
#include <iostream>
#include <utility>

class nonTrivialClass
{
    int scalingFactor;
    int otherData;
public:
    nonTrivialClass() : scalingFactor(1) {}
    void set_other_data(int i);
    int f(int i)
    {
        return i / scalingFactor;
    }
    // ...
};

void func()
{
    nonTrivialClass c;
    // ... Code that mutates c ...
    std::memset(&c, 0, sizeof(nonTrivialClass));
    std::cout << c.f(100) << std::endl;
}
```

In this example, `func()` uses `std::memset` to reinitialize non-trivial class object `c` after it is first initialized with its default constructor. This bytewise operation might not properly initialize the value representation of `c`.

**Correction — Define Function Template That Uses `std::swap`**

One possible correction is to define a function template `clear()` that uses `std::swap` to perform a swap operation. The call to `clear()`properly reinitializes object `c` by swapping the contents of `c` and default initialized object `empty`.

```
 #include <cstring>
#include <iostream>
#include <utility>

class nonTrivialClass
{
    int scalingFactor;
    int otherData;
public:
    nonTrivialClass() : scalingFactor(1) {}
    void set_other_data(int i);
    int f(int i)
    {
        return i / scalingFactor;
    }
    // ...
};

template <typename T>
T& clear(T& o)
{
    using std::swap;
    T empty;
    swap(o, empty);
    return o;
}

void func()
{
    nonTrivialClass c;
    // ... Code that mutates c ...

    clear(c);
    std::cout << c.f(100) << std::endl;
}
```

## Result Information

# Conversion or deletion of incomplete class pointer

You delete or cast to a pointer to an incomplete class

## Description

This defect occurs when you delete or cast to a pointer to an incomplete class. An incomplete class is one whose definition is not visible at the point where the class is used.

For instance, the definition of class `Body` is not visible when the `delete` operator is called on a pointer to `Body`:

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; }
  // ...
};
```

### Risk

When you delete a pointer to an incomplete class, it is not possible to call any nontrivial destructor that the class might have. If the destructor performs cleanup activities such as memory deallocation, these activities do not happen.

A similar problem happens, for instance, when you downcast to a pointer to an incomplete class (downcasting is casting from a pointer to a base class to a pointer to a derived class). At the point of downcasting, the relationship between the base and derived class is not known. In particular, if the derived class inherits from multiple classes, at the point of downcasting, this information is not available. The downcasting cannot make the necessary adjustments for multiple inheritance and the resulting pointer cannot be dereferenced.

A similar statement can be made for upcasting (casting from a pointer to derived class to a pointer to a base class).

### Fix

When you delete or downcast to a pointer to a class, make sure that the class definition is visible.

Alternatively, you can perform one of these actions:

- Instead of a regular pointer, use the `std::shared_ptr` type to point to the incomplete class.
- When downcasting, make sure that the result is valid. Write error-handling code for invalid results.

## Examples

### Deletion of Pointer to Incomplete Class

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; }
  // ...
};
```

In this example, the definition of class `Body` is not visible when the pointer to `Body` is deleted.

#### Correction — Define Class Before Deletion

One possible correction is to make sure that the class definition is visible when a pointer to the class is deleted.

```
class Handle {
  class Body *impl;
public:
  ~Handle();
  // ...
};

// Elsewhere
class Body { /* ... */ };

Handle::~Handle() {
  delete impl;
}
```

#### Correction — Use `std::shared_ptr`

Another possible correction is to use the `std::shared_ptr` type instead of a regular pointer.

```
#include <memory>

class Handle {
  std::shared_ptr<class Body> impl;
  public:
    Handle();
    ~Handle() {}
    // ...
};
```

### Downcasting to Pointer to Incomplete Class

`File1.h`:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

`File2.h`:

```
void funcprint(class Derived *);
class Base *get_derived();
```

`File1.cpp`:

```
#include "File1.h"
#include "File2.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(reinterpret_cast<class Derived *>(v));
}
```

File2.cpp:

```
#include "File2.h"
#include "File1.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;
public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
 };

void funcprint(Derived *d) {
  d->do_something();
}

Base *get_derived() {
  return new Derived;
}
```

In this example, the definition of class Derived is not visible in File1.cpp when a Base* pointer to downcast to a Derived* pointer.

In File2.cpp, class Derived derives from two classes, Base and Base2. This information about multiple inheritance is not available at the point of downcasting in File1.cpp. The result of downcasting is passed to the function funcprint and dereferenced in the body of funcprint. Because the downcasting was done with incomplete information, the dereference can be invalid.

**Correction — Define Class Before Downcasting**

One possible correction is to define the class Derived before downcasting a Base* pointer to a Derived* pointer.

In this corrected example, the downcasting is done in File2.cpp in the body of funcprint at a point where the definition of class Derived is visible. The downcasting is not done in File1.cpp where the definition of Derived is not visible. The changes from the previous incorrect example are highlighted.

File1_corr.h:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

File2_corr.h:

```
void funcprint(class Base *);
class Base *get_derived();
```

File1.cpp:

```
#include "File1_corr.h"
#include "File2_corr.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(v);
}
```

File2.cpp:

```
#include "File2_corr.h"
#include "File1_corr.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;

public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
};

void funcprint(Base *d) {
  Derived *temp = dynamic_cast<Derived*>(d);
  if(temp)  {
     d->do_something();
  }
  else {
      //Handle error
  }
}

Base *get_derived() {
  return new Derived;
}
```

## Result Information

# Copy constructor not called in initialization list

Copy constructor does not call copy constructors of some members or base classes

## Description

This defect occurs when the copy constructor of a class does not call the *copy constructor* of the following in its initialization list:

- One or more of its members.
- Its base classes when applicable.

  The defect occurs even when a base class constructor is called instead of the base class copy constructor.

### Risk

The calls to the copy constructors can be done only from the initialization list. If the calls are missing, it is possible that an object is only partially copied.

- If the copy constructor of a member is not called, it is possible that the member is not copied.
- If the copy constructor of a base class is not called, it is possible that the base class members are not copied.

### Fix

If you want your copy constructor to perform a complete copy, call the copy constructor of all members and all base classes in its initialization list.

## Examples

### Base Class Copy Constructor Not Called

```
class Base {
public:
    Base();
    Base(int);
    Base(const Base&);
    virtual ~Base();
private:
    int ib;
};

class Derived:public Base {
public:
    Derived();
    ~Derived();
    Derived(const Derived& d): Base(), i(d.i) { }
private:
    int i;
};
```

In this example, the copy constructor of class `Derived` calls the default constructor, but not the copy constructor of class `Base`.

The defect appears on the `:` symbol in the copy constructor definition. Following are some tips for navigating in the source code:

- To navigate to the class definition, right-click a member that is initialized in the constructor. Select **Go To Definition**. In the class definition, you see the class members, including those members whose copy constructors are not called.
- To navigate to a base class definition, first navigate to the derived class definition. In the derived class definition, where the derived class inherits from a base class, right-click the base class name and select **Go To Definition**.

#### Correction — Call Base Class Copy Constructor

One possible correction is to call the copy constructor of class `Base` from the initialization list of the `Derived` class copy constructor.

```
class Base {
public:
    Base();
    Base(int);
    Base(const Base&);
    virtual ~Base();
private:
    int ib;
};

class Derived:public Base {
public:
    Derived();
    ~Derived();
    Derived(const Derived& d): Base(d), i(d.i) { }
private:
    int i;
};
```

## Result Information

**Group:** Object oriented
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `MISSING_COPY_CTOR_CALL`
**Impact:** High

# Version History

**Introduced in R2015b**

# Copy operation modifying source operand

Copy operation modifies data member of source object

## Description

This defect occurs when a copy constructor or copy assignment operator modifies a mutable data member of its source operand.

For instance, this copy constructor `A` modifies the data member `m` of its source operand `other`:

```
class A {
  mutable int m;

public:
 ...
  A(const A &other) : m(other.m) {
    other.m = 0; //Modification of source
  }
}
```

### Risk

A copy operation with a copy constructor (or copy assignment operator):

```
className new_object = old_object; //Calls copy constructor of className
```

copies its source operand `old_object` to its destination operand `new_object`. After the operation, you expect the destination operand to be a copy of the unmodified source operand. If the source operand is modified during copy, this assumption is violated.

### Fix

Do not modify the source operand in the copy operation.

If you are modifying the source operand in a copy constructor to implement a move operation, use a move constructor instead. Move constructors are defined in the C++11 standard and later.

## Examples

### Copy Constructor Modifying Source

```
#include <algorithm>
#include <vector>

class A {
  mutable int m;

public:
  A() : m(0) {}
  explicit A(int m) : m(m) {}
  A(const A &other) : m(other.m) {
    other.m = 0;
  }

  A& operator=(const A &other) {
    if (&other != this) {
      m = other.m;
      other.m = 0;
    }
    return *this;
  }

  int get_m() const { return m; }
};

void f() {
  std::vector<A> v{10};
  A obj(12);
  std::fill(v.begin(), v.end(), obj);
}
```

In this example, a vector of ten objects of type A is created. The std::fill function copies an object of type A, which has a data member with value 12, to each of the ten objects. After this operation, you might expect that all ten objects in the vector have a data member with value 12.

However, the first copy modifies the data member of the source to the value 0. The remaining nine copies copy this value. After the std::fill call, the first object in the vector has a data member with value 12 and the remaining objects have data members with value 0.

#### Correction — Use Move Constructor for Modifying Source

Do not modify data members of the source operand in a copy constructor or copy assignment operator. If you want your class to have a move operation, use a move constructor instead of a copy constructor.

In this corrected example, the copy constructor and copy assignment operator of class A do not modify the data member m. A separate move constructor modifies the source operand.

```
#include <algorithm>
#include <vector>

class A {
  int m;

public:
  A() : m(0) {}
  explicit A(int m) : m(m) {}

  A(const A &other) : m(other.m) {}
  A(A &&other) : m(other.m) { other.m = 0; }

  A& operator=(const A &other) {
    if (&other != this) {
      m = other.m;
    }
    return *this;
  }
  //Move constructor
  A& operator=(A &&other) {
    m = other.m;
    other.m = 0;
    return *this;
  }

  int get_m() const { return m; }
};

void f() {
  std::vector<A> v{10};
  A obj(12);
  std::fill(v.begin(), v.end(), obj);
}
```

Move constructors (C++11 and beyond)

# Incompatible types prevent overriding

Derived class method hides a `virtual` base class method instead of overriding it

## Description

This defect occurs when a derived class method has the same name and number of parameters as a `virtual` base class method but:

- The parameter lists differ in at least one parameter type.
- The parameter lists differ in the presence or absence of qualifiers such as `const`.

The derived class method hides the `virtual` base class method instead of overriding it.

### Risk

- You might inadvertently hide the base class method instead of overriding it with the derived class method.
- If the base class method is hidden and you use a derived class object to call the method with the base class parameters, the derived class method is called instead. For the parameters whose types do not match the arguments that you pass, a cast takes place if possible. Otherwise, a compilation failure occurs.

### Fix

To override a base class virtual method with a derived class method, declare the methods by using identical parameter lists. For instance, change the parameter type or add a `const` qualifier if required.

In C++11 and later, you can declare intended overriding methods in the derived class by using the specifier `override`. When you declare the derived class methods by using the specifier `override`, the compilation fails if the parameter lists of the base class method and the derived class method are different. The derived class methods cannot hide base class methods inadvertently and overriding of the base class virtual methods is ensured.

Otherwise, add the line `using` *`Base_class_name`*`::`*`method_name`* to the derived class declaration. You can then access the base class method using an object of the derived class.

## Examples

### `typedef` Causing Virtual Function Hiding in Derived Class

```
class Base {
public:
    Base();
    virtual ~Base();
    virtual void func(float i);
    virtual void funcp(float* i);
    virtual void funcr(float& i);
};

typedef double Float;

class Derived: public Base {
public:
    Derived();
    ~Derived();
    void func(Float i);
    void funcp(Float* i);
    void funcr(Float& i);
};
```

In this example, because of the statement `typedef double Float;`, the `Derived` class methods `func`, `funcp`, and `funcr` have `double` arguments while the `Base` class methods with the same name have `float` arguments. Therefore, you cannot access the `Base` class methods using a `Derived` class object.

The defect appears on the method that hides a base class method. To find which base class method is hidden:

1. Navigate to the base class definition. On the **Source** pane, right-click the base class name and select **Go To Definition**.
2. In the base class definition, identify the `virtual` method that has the same name as the derived class method name.

**Correction — Unhide Base Class Method**

One possible correction is to use the same argument type for the base and derived class methods to enable overriding. Otherwise, if you want to call the `Base` class methods with the `float` arguments using a `Derived` class object, add the line `using Base::`*`method_name`* to the `Derived` class declaration.

```
class Base {
public:
    Base();
    virtual ~Base();
    virtual void func(float i);
    virtual void funcp(float* i);
    virtual void funcr(float& i);
};

typedef double Float;

class Derived: public Base {
public:
    Derived();
    ~Derived();
    using Base::func;
    using Base::funcp;
    using Base::funcr;
    void func(Float i);
    void funcp(Float* i);
    void funcr(Float& i);
};
```

#### Correction — Specify Derived Class Method by using override

Another correction is to explicitly specify the derived class methods as overriding methods by using the specifier `override`. This way, it is clear that you intend to override the base class methods in the derived class. If the overriding methods have different parameter lists than their base class counterparts, the code does not compile. As a result, the derived class methods cannot hide the base class methods.

```
class Base {
public:
    Base();
    virtual ~Base();
    virtual void func(float i);
    virtual void funcp(float* i);
    virtual void funcr(float& i);
};

typedef double Float;

class Derived: public Base {
public:
    Derived();
    ~Derived();
//    Compilation error
//  void func(Float i) override;
//  void funcp(Float* i) override;
//  void funcr(Float& i) override;

    void func(float i) override;
    void funcp(float* i) override;
    void funcr(float& i) override;
};
```

The commented out method definitions have different parameter lists compared to their base class counterparts. Because the derived class methods are declared by using the specifier `override`, the differing parameter lists do not hide the base class methods. Instead, the code fails to compile. Using the `override` specifier enforces the rule that virtual methods in base and derived classes must have identical parameter lists.

### const Qualifier Missing in Derived Class Method

```
namespace Missing_Const {
class Base {
public:
    virtual void func(int) const ;
    virtual ~Base() ;
} ;

class Derived : public Base {
public:
    virtual void func(int) ;

} ;
}
```

In this example, `Derived::func` does not have a `const` qualifier but `Base::func` does. Therefore, `Derived::func` does not override `Base::func`.

#### Correction — Add const Qualifier to Derived Class Method

To enable overriding, add the `const` qualifier to the derived class method declaration.

```
namespace Missing_Const {
class Base {
public:
    virtual void func(int) const ;
    virtual ~Base() ;
} ;

class Derived : public Base {
public:
    virtual void func(int) const;

} ;
}
```

To avoid hiding base class methods or turning virtual methods into nonvirtual methods unintentionally:

- Declare virtual methods in the base class by using the specifier `virtual`.
- Declare virtual methods in a nonfinal derived base class by using the specifier `override`.
- Declare virtual methods in the final class by using the specifier `final`.

### Value Instead of Reference in Derived Class Method

```
namespace Missing_Ref {

class Obj {
    int data;
};

class Base {
public:
    virtual void func(Obj& o);
    virtual ~Base() ;
} ;

class Derived : public Base {
public:
    virtual void func(Obj o) ;

} ;
}
```

In this example, `Derived::func` accepts an `Obj` parameter by value but `Base::func` accepts an `Obj` parameter by reference. Therefore, `Derived::func` does not override `Base::func`.

#### Correction — Use Reference for Parameter of Derived Class Method

To enable overriding, pass the derived class method parameter by reference.

```
namespace Missing_Ref {

class Obj {
    int data;
};
class Base {
public:
    virtual void func(Obj& o);
    virtual ~Base() ;
} ;

class Derived : public Base {
public:
    virtual void func(Obj& o) ;

} ;
}
```

To avoid hiding base class methods or turning virtual methods into nonvirtual methods unintentionally:

- Declare virtual methods in the base class by using the specifier `virtual`.
- Declare virtual methods in a nonfinal derived base class by using the specifier `override`.
- Declare virtual methods in the final class by using the specifier `final`.

### Result Information

# Lambda used as typeid operand

typeid is used on lambda expression

## Description

This defect occurs when you use typeid on a lambda expression.

### Risk

According to the C++ Standard, the type of a lambda expression is a unique, unnamed class type. Because the type is unique, another variable or expression cannot have the same type. Use of typeid on a lambda expression indicates that you expect a second variable or expression to have the same type as the operand lambda expression. Using the type of a lambda expression in this way can lead to unexpected results.

typeid returns the data type of its operand. Typically the operator is used to compare the types of two variables. For instance:

```
(typeid(var1) == typeid(var2))
```

compares the types of var1 and var2. This use does not apply to a lambda expression, which has a unique type.

### Fix

Avoid using the typeid operator on lambda expressions.

## Examples

### Use of typeid on Lambda Expressions

```
#include <cstdint>
#include <typeinfo>

 void func()
 {
 auto lambdaFirst = []() -> std::int8_t { return 1; };
 auto lambdaSecond = []() -> std::int8_t { return 1; };

 if (typeid(lambdaFirst) == typeid(lambdaSecond))
     {
     // ...
     }
 }
```

The use of typeid on lambda expressions can lead to unexpected results. The comparison above is false even though lambdaFirst and lambdaSecond appear to have the same body.

#### Correction – Assign Lambda Expression to Function Object Before Using `typeid`

One possible correction is to assign the lambda expression to a function object and then use the `typeid` operator on the function objects for comparison.

```
#include <cstdint>
#include <functional>
#include <typeinfo>

 void func()
 {
 std::function<std::int8_t()> functionFirst = []() { return 1; };
 std::function<std::int8_t()> functionSecond = []() { return 1; };

 if (typeid(functionFirst) == typeid(functionSecond))
     {
     // ...
     }
 }
```

## Result Information

**Group:** Object Oriented
**Language:** C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `LAMBDA_TYPE_MISUSE`
**Impact:** Low

# Member not initialized in constructor

Constructor does not initialize some members of a class

## Description

This defect occurs when a class constructor has at least one execution path on which it does not initialize some data members of the class.

The defect does not appear in the following cases:

- Empty constructors.
- The non-initialized member is not used in the code.

### Risk

The members that the constructor does not initialize can have unintended values when you read them later.

Initializing all members in the constructor makes it easier to use your class. If you call a separate method to initialize your members and then read them, you can avoid uninitialized values. However, someone else using your class can read a class member *before* calling your initialization method. Because a constructor is called when you create an object of the class, if you initialize all members in the constructor, they cannot have uninitialized values later on.

### Fix

The best practice is to initialize all members in your constructor, preferably in an initialization list.

## Examples

### Non-Initialized Member

```
class MyClass {
public:
    explicit MyClass(int);
private:
    int _i;
    char _c;
};

MyClass::MyClass(int flag) {
    if(flag == 0) {
        _i = 0;
        _c = 'a';
    }
    else {
        _i = 1;
    }
}
```

In this example, if `flag` is not 0, the member `_c` is not initialized.

The defect appears on the closing brace of the constructor. Following are some tips for navigating in the source code:

- On the **Result Details** pane, see which members are not initialized.
- To navigate to the class definition, right-click a member that is initialized in the constructor. Select **Go To Definition**. In the class definition, you can see all the members, including those members that are not initialized in the constructor.

#### Correction — Initialize All Members on All Execution Paths

One possible correction is to initialize all members of the class `MyClass` for all values of `flag`.

```
class MyClass {
public:
    explicit MyClass(int);
private:
    int _i;
    char _c;
};

MyClass::MyClass(int flag) {
    if(flag == 0) {
        _i = 0;
        _c = 'a';
    }
    else {
        _i = 1;
        _c = 'b';
    }
}
```

## Result Information

**Group:** Object oriented
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `NON_INIT_MEMBER`
**Impact:** Medium

# Missing explicit keyword

Constructor or user-defined conversion operator missing the `explicit` specifier

## Description

This defect occurs when the declaration or in-class definition of a constructor or user-defined conversion operator does not use the `explicit` specifier. The `explicit` specifier prevents implicit conversion from a variable of another type to the current class type.

The defect applies to:

- One-parameter constructors.
- Constructors where all but one parameters have default values.

  For instance, `MyClass::MyClass(float f, bool b=true){}`.
- User-defined conversation operators.

  For instance, `operator int() {}` converts a variable of the current class type to an `int` variable.

### Risk

If you do not declare a constructor or conversion operator `explicit`, compilers can perform implicit and often unintended type conversions to or from the class type with possibly unexpected results.

The implicit conversion using a constructor can occur, for instance, when a function accepts a parameter of the class type but you call the function with an argument of a different type. The call to `func` here causes an implicit conversion from type `int` to `myClass`:

```
class myClass {}{
  ...
  myClass(int) {...}
};
void func(myClass);
func(0);
```

The reverse implicit conversion can occur when using a user-defined conversion operator. For instance, you pass the class type as argument but the function has a parameter of a different type. The call to `func` here causes an implicit conversion from type `myClass` to `int`:

```
class myClass {} {
  ...
  operator int() {...}
};
myClass myClassObject;

void func(int) {...}
func(myClassObject);
```

#### Fix

For better readability of your code and to prevent implicit conversions, in the declaration or in-class definition of the constructor or conversion operator, place the `explicit` keyword before the constructor or operator name. You can then detect all implicit conversions as compilation errors and convert them to explicit conversions.

## Examples

### Missing `explicit` Keyword on Constructor

```
class MyClass {
public:
    MyClass(int val);
private:
    int val;
};

void func(MyClass);

void main() {
    MyClass MyClassObject(0);

    func(MyClassObject);   // No conversion
    func(MyClass(0));      // Explicit conversion
    func(0);               // Implicit conversion
}
```

In this example, the constructor of `MyClass` is not declared `explicit`. Therefore, the call `func(0)` can perform an implicit conversion from `int` to `MyClass`.

#### Correction — Use explicit Keyword

One possible correction is to declare the constructor of `MyClass` as `explicit`. If an operation in your code performs an implicit conversion, the compiler generates an error. Therefore, using the `explicit` keyword, you detect unintended type conversions in the compilation stage.

For instance, in function `main` below, if you add the statement `func(0);` that performs implicit conversion, the code does not compile.

```
class MyClass {
public:
    explicit MyClass(int val);
private:
    int val;
};

void func(MyClass);

void main() {
    MyClass MyClassObject(0);

    func(MyClassObject);   // No conversion
    func(MyClass(0));      // Explicit conversion
}
```

### Incorrect Argument Order Preventable Through `explicit` Keyword

```
class Month {
    int val;
public:
    Month(int m): val(m) {}
    ~Month() {}
};

class Day {
    int val;
public:
    Day(int d): val(d) {}
    ~Day() {}
};

class Year {
    int val;
public:
    Year(int y): val(y) {}
    ~Year() {}
};

class Date {
    Month mm;
    Day dd;
    Year yyyy;
public:
    Date(const Month & m, const Day & d, const Year & y):mm(m), dd(d), yyyy(y) {}
};

void main() {
    Date(20,1,2000); //Implicit conversion, wrong argument order undetected
}
```

In this example, the constructors for classes `Month`, `Day` and `Year` do not have an `explicit` keyword. They allow implicit conversion from `int` variables to `Month`, `Day` and `Year` variables.

When you create a `Date` variable and use an incorrect argument order for the `Date` constructor, because of the implicit conversion, your code compiles. You might not detect that you have switched the month value and the day value.

#### Correction — Use explicit Keyword

If you use the `explicit` keyword for the constructors of classes `Month`, `Day` and `Year`, you cannot call the `Date` constructor with an incorrect argument order.

- If you call the `Date` constructor with `int` variables, your code does not compile because the `explicit` keyword prevents implicit conversion from `int` variables.
- If you call the `Date` constructor with the arguments explicitly converted to `Month`, `Day` and `Year`, and have the wrong argument order, your code does not compile because of the argument type mismatch.

```
class Month {
    int val;
public:
    explicit Month(int m): val(m) {}
    ~Month() {}
};

class Day {
    int val;
public:
    explicit Day(int d): val(d) {}
    ~Day() {}
};

class Year {
    int val;
public:
    explicit Year(int y): val(y) {}
    ~Year() {}
};

class Date {
    Month mm;
    Day dd;
    Year yyyy;
public:
    Date(const Month & m, const Day & d, const Year & y):mm(m), dd(d), yyyy(y) {}
};

void main() {
    Date(Month(1),Day(20),Year(2000));
    // Date(20,1,2000); - Does not compile
    // Date(Day(20), Month(1), Year(2000)); - Does not compile
}
```

### Missing `explicit` Keyword on Conversion Operator

```
#include <cstdint>

class MyClass {
public:
    explicit MyClass(int32_t arg): val(arg) {};
    operator int32_t() const { return val; }
    explicit operator bool() const {
        if (val>0) {
          return true;
        }
        return false;
     }
private:
    int32_t val;
};

void useIntVal(int32_t);
void useBoolVal(bool);

void func() {
    MyClass MyClassObject{0};
    useIntVal(MyClassObject);
    useBoolVal(static_cast<bool>(MyClassObject));
}
```

In this example, the conversion operator `operator int32_t()` is not defined with the `explicit` specifier and allows implicit conversions. The conversion operator `operator bool()` is defined explicit.

When converting to a `bool` variable, for instance, in the call to `useBoolVal`, the `explicit` keyword in the conversion operator ensures that you have to perform an explicit conversion from the type `MyClass` to `bool`. There is no such requirement when converting to an `int32_t` variable. In the call to `useIntVal`, an implicit conversion is performed.

# Missing virtual inheritance

A base class is inherited virtually and nonvirtually in the same hierarchy

## Description

This defect occurs when:

- A class is derived from multiple base classes, and some of those base classes are themselves derived from a common base class.

  For instance, a class `Final` is derived from two classes, `Intermediate_left` and `Intermediate_right`. Both `Intermediate_left` and `Intermediate_right` are derived from a common class, `Base`.
- At least one of the inheritances from the common base class is `virtual` and at least one is not `virtual`.

  For instance, the inheritance of `Intermediate_right` from `Base` is `virtual`. The inheritance of `Intermediate_left` from `Base` is not `virtual`.

### Risk

If this defect appears, multiple copies of the base class data members appear in the final derived class object. To access the correct copy of the base class data member, you have to qualify the member and method name appropriately in the final derived class. The development is error-prone.

For instance, when the defect occurs, two copies of the base class data members appear in an object of class `Final`. If you do not qualify method names appropriately in the class `Final`, you can assign a value to a `Base` data member but not retrieve the same value.

- You assign the value using a `Base` method accessed through `Intermediate_left`. Therefore, you assign the value to one copy of the `Base` member.
- You retrieve the value using a `Base` method accessed through `Intermediate_right`. Therefore, you retrieve a different copy of the `Base` member.

### Fix

Declare all the intermediate inheritances as `virtual` when a class is derived from multiple base classes that are themselves derived from a common base class.

If you indeed want multiple copies of the `Base` data members as represented in the intermediate derived classes, use aggregation instead of inheritance. For instance, declare two objects of class `Intermediate_left` and `Intermediate_right` in the `Final` class.

## Examples

### Missing Virtual Inheritance

```
#include <stdio.h>
class Base {
```

```
public:
    explicit Base(int i): m_b(i) {};
    virtual ~Base() {};
    virtual int get() const {
        return m_b;
    }
    virtual void set(int b) {
        m_b = b;
    }
private:
    int m_b;
};

class Intermediate_left: virtual public Base {
public:
    Intermediate_left():Base(0), m_d1(0) {};
private:
    int m_d1;
};

class Intermediate_right: public Base {
public:
    Intermediate_right():Base(0), m_d2(0) {};
private:
    int m_d2;
};

class Final: public Intermediate_left, Intermediate_right {
public:
    Final(): Base(0), Intermediate_left(), Intermediate_right() {};
    int get() const {
        return Intermediate_left::get();
    }
    void set(int b) {
        Intermediate_right::set(b);
    }
    int get2() const {
        return Intermediate_right::get();
    }
};

int main(int argc, char* argv[]) {
    Final d;
    int val = 12;
    d.set(val);
    int res = d.get();
    printf("d.get=%d\n",res);            // Result: d.get=0
    printf("d.get2=%d\n",d.get2());      // Result: d.get2=12
    return res;
}
```

In this example, `Final` is derived from both `Intermediate_left` and `Intermediate_right`. `Intermediate_left` is derived from `Base` in a non-`virtual` manner and `Intermediate_right` is derived from `Base` in a `virtual` manner. Therefore, two copies of the base class and the data member `m_b` are present in the final derived class, Both derived classes Intermediate_left and Intermediate_right do not override the Base class methods get and set. However, Final overrides both methods. In the overridden get method, it calls Base::get through Intermediate_left. In the overridden set method, it calls Base::set through Intermediate_right.

Following the statement d.set(val), Intermediate_right's copy of m_b is set to 12. However, Intermediate_left's copy of m_b is still zero. Therefore, when you call d.get(), you obtain a value zero.

Using the printf statements, you can see that you retrieve a value that is different from the value that you set.

The defect appears in the final derived class definition and on the name of the class that are derived virtually from the common base class. Following are some tips for navigating in the source code:

- To find the definition of a class, on the **Source** pane, right-click the class name and select **Go To Definition**.
- To navigate up the class hierarchy, first navigate to the intermediate class definition. In the intermediate class definition, right-click a base class name and select **Go To Definition**.

#### Correction — Make Both Inheritances Virtual

One possible correction is to declare both the inheritances from Base as virtual.

Even though the overridden get and set methods in Final still call Base::get and Base::set through different classes, only one copy of m_b exists in Final.

```
#include <stdio.h>
class Base {
public:
    explicit Base(int i): m_b(i) {};
    virtual ~Base() {};
    virtual int get() const {
        return m_b;
    }
    virtual void set(int b) {
        m_b = b;
    }
private:
    int m_b;
};

class Intermediate_left: virtual public Base {
public:
    Intermediate_left():Base(0), m_d1(0) {};
private:
    int m_d1;
};

class Intermediate_right: virtual public Base {
public:
    Intermediate_right():Base(0), m_d2(0) {};
private:
    int m_d2;
};

class Final: public Intermediate_left, Intermediate_right {
```

```
public:
    Final(): Base(0), Intermediate_left(), Intermediate_right() {};
    int get() const {
        return Intermediate_left::get();
    }
    void set(int b) {
        Intermediate_right::set(b);
    }
    int get2() const {
        return Intermediate_right::get();
    }
};

int main(int argc, char* argv[]) {
    Final d;
    int val = 12;
    d.set(val);
    int res = d.get();
    printf("d.get=%d\n",res);             // Result: d.get=12
    printf("d.get2=%d\n",d.get2());       // Result: d.get2=12
    return res;
}
```

## Result Information

**Group:** Object oriented
**Language:** C++
**Default:** Off
**Command-Line Syntax:** MISSING_VIRTUAL_INHERITANCE
**Impact:** Medium

# Version History

# Object slicing

Derived class object passed by value to function with base class parameter

## Description

This defect occurs when you pass a derived class object by value to a function, but the function expects a base class object as parameter.

### Risk

If you pass a derived class object *by value* to a function, you expect the derived class copy constructor to be called. If the function expects a base class object as parameter:

1. The base class copy constructor is called.
2. In the function body, the parameter is considered as a base class object.

In C++, `virtual` methods of a class are resolved at run time according to the actual type of the object. Because of object slicing, an incorrect implementation of a `virtual` method can be called. For instance, the base class contains a `virtual` method and the derived class contains an implementation of that method. When you call the `virtual` method from the function body, the base class method is called, even though you pass a derived class object to the function.

### Fix

One possible fix is to pass the object by reference or pointer. Passing by reference or pointer does not cause invocation of copy constructors. If you do not want the object to be modified, use a `const` qualifier with your function parameter.

Another possible fix is to overload the function with another function that accepts the derived class object as parameter.

## Examples

### Function Call Causing Object Slicing

```
#include <iostream>

class Base {
public:
    explicit Base(int b) {
        _b = b;
    }
    virtual ~Base() {}
    virtual int update() const;
protected:
    int _b;
};

class Derived: public Base {
```

```
public:
    explicit Derived(int b):Base(b) {}
    int update() const;
};

//Class methods definition

int Base::update() const {
    return (_b + 1);
}

int Derived::update() const {
    return (_b -1);
}

//Other function definitions
void funcPassByValue(const Base bObj) {
    std::cout << "Updated _b=" << bObj.update() << std::endl;
}

int main() {
    Derived dObj(0);
    funcPassByValue(dObj);       //Function call slices object
    return 0;
 }
```

In this example, the call `funcPassByValue(dObj)` results in the output `Updated _b=1` instead of the expected `Updated _b=-1`. Because `funcPassByValue` expects a `Base` object parameter, it calls the `Base` class copy constructor.

Therefore, even though you pass the `Derived` object `dObj`, the function `funcPassByValue` treats its parameter `b` as a `Base` object. It calls `Base::update()` instead of `Derived::update()`.

**Correction — Pass Object by Reference or Pointer**

One possible correction is to pass the `Derived` object `dObj` by reference or by pointer. In the following, corrected example, `funcPassByReference` and `funcPassByPointer` have the same objective as `funcPassByValue` in the preceding example. However, `funcPassByReference` expects a reference to a `Base` object and `funcPassByPointer` expects a pointer to a `Base` object.

Passing the `Derived` object `d` by a pointer or by reference does not slice the object. The calls `funcPassByReference(dObj)` and `funcPassByPointer(&dObj)` produce the expected result `Updated _b=-1`.

```
#include <iostream>

class Base {
public:
    explicit Base(int b) {
        _b = b;
    }
    virtual ~Base() {}
    virtual int update() const;
protected:
    int _b;
};
```

```
class Derived: public Base {
public:
    explicit Derived(int b):Base(b) {}
    int update() const;
};

//Class methods definition

int Base::update() const {
    return (_b + 1);
}

int Derived::update() const {
    return (_b -1);
}

//Other function definitions
void funcPassByReference(const Base& bRef) {
    std::cout << "Updated _b=" << bRef.update() << std::endl;
}

void funcPassByPointer(const Base* bPtr) {
    std::cout << "Updated _b=" << bPtr->update() << std::endl;
}

int main() {
    Derived dObj(0);
    funcPassByReference(dObj);       //Function call does not slice object
    funcPassByPointer(&dObj);       //Function call does not slice object
    return 0;
 }
```

**Note** If you pass by value, because a copy of the object is made, the original object is not modified. Passing by reference or by pointer makes the object vulnerable to modification. If you are concerned about your original object being modified, add a `const` qualifier to your function parameter, as in the preceding example.

# Operator new not overloaded for possibly over-aligned class

Allocated storage might be smaller than object alignment requirement

## Description

This defect occurs when you do not adequately overload operator `new/new[]` and you use this operator to create an object with an alignment requirement specified with `alignas`. The checker raises a defect for these versions of throwing and non-throwing operator `new/new[]`.

- `void* operator new(std::size_t size)`
- `void* operator new(std::size_t size, const std::nothrow_t&)`
- `void* operator new[](std::size_t size)`
- `void* operator new[](std::size_t size, const std::nothrow_t&)`

The use of `alignas` indicates that you do not expect the default operator `new/new[]` to satisfy the alignment requirement or the object, and that the object is possibly over aligned. A type is over aligned if you use `alignas` to make the alignment requirement of the type larger than `std::max_align_t`. For instance, `foo` is over aligned in this code snippet because its alignment requirement is 32 bytes, but `std::max_align_t` has an alignment of 16 bytes in most implementations.

```
struct alignas(32) foo {
  char elems[32];
}
```

**Operator new not overloaded for possibly overaligned class** raises no defect if you do not overload the operator `new/new[]` and you use version C++17 or later of the Standard. The default operator `new/new[]` in C++17 or later supports over alignment by passing the alignment requirement as an argument of type `std::align_val_t`, for instance `void* operator new(std::size_t size, std::align_val_t alignment)`.

### Risk

The default operator `new/new[]` allocates storage with the alignment requirement of `std::align_val_t` at most. If you do not overload the operator when you create an object with over aligned type, the resulting object may be misaligned. Accessing this object might cause illegal access errors or abnormal program terminations.

### Fix

If you use version C++14 or earlier of the Standard, pass the alignment requirement of over aligned types to the operator `new/new[]` by overloading the operator.

## Examples

### Allocated Memory Is Smaller Than Alignment Requirement of Type foo

```
#include <new>
#include <cstdlib>
#include <iostream>

struct alignas(64) foo {
    char elems[32];
};

foo*  func()
{
    foo*  bar = 0x0;
    try {
        bar =  new  foo ;
    } catch (...) { return nullptr; }
    delete bar;
}
```

In this example, structure `foo` is declared with an alignment requirement of 32 bytes. When you use the default operator `new` to create object `bar`, the allocated memory for `bar` is smaller than the alignment requirement of type `foo` and `bar` might be misaligned.

#### Correction — Define Overloaded Operator new to Handle Alignment Requirement of Type foo

One possible correction, if you use C11 `stdlib.h` or POSIX-C `malloc.h`, is to define an overloaded operator `new` that uses `aligned_alloc()` or `posix_memalign()` or to obtain storage with the correct alignment.

```
#include <new>
#include <cstdlib>
#include <iostream>

struct alignas(64) foo {
    char elems[32];
    static void* operator new (size_t nbytes)
    {
        if (void* p =
                ::aligned_alloc(alignof(foo), nbytes)) {
            return p;
        }
        throw std::bad_alloc();
    }
    static void operator delete(void *p) {
        free(p);
    }
};

foo*  func()
{
    foo*  bar = 0x0;
    try {
        bar =  new  foo ;
    } catch (...) { return nullptr; }
    delete bar;
}
```

# Partial override of overloaded virtual functions

Class overrides fraction of inherited virtual functions with a given name

## Description

This defect occurs when:

- A base class has multiple `virtual` methods with the same name but different signatures (overloading).
- A class derived from the base class overrides at least one of those `virtual` methods, but not all of them.

### Risk

The `virtual` methods that the derived class does not override are hidden. You cannot call those methods using an object of the derived class.

### Fix

See if the overloads in the base class are required. If they are needed, possible solutions include:

- In your derived class, if you override one `virtual` method, override all `virtual` methods from the base class with the same name as that method.
- Otherwise, add the line `using` *`Base_class_name`*`::`*`method_name`* to the derived class declaration. In this way, you can call the base class methods using an object of the derived class.

## Examples

### Partial Override

```
class Base {
public:
    explicit Base(int b);
    virtual ~Base() {};
    virtual void set()           {
        _b = (int)0;
    };
    virtual void set(short i)    {
        _b = (int)i;
    };
    virtual void set(int i)      {
        _b = (int)i;
    };
    virtual void set(long i)     {
        _b = (int)i;
    };
    virtual void set(float i)    {
        _b = (int)i;
    };
    virtual void set(double i)   {
        _b = (int)i;
    };
private:
    int _b;
};

class Derived: public Base {
        public:
                Derived(int b, int d): Base(b), _d(d) {};
                void set(int i)    { Base::set(i); _d = (int)i; };
        private:
                int _d;
};
```

In this example, the class `Derived` overrides the function `set` that takes an `int` argument. It does not override other functions that have the same name `set` but take arguments of other types.

The defect appears on the derived class name in the derived class definition. To find which base class method is overridden:

1 Navigate to the base class definition. On the **Source** pane, right-click the base class name and select **Go To Definition**.
2 In the base class definition, identify the method that has the same name and signature as a derived class method name.

**Correction — Unhide Base Class Method**

One possible correction is add the line `using Base::set` to the `Derived` class declaration.

```
class Base {
public:
    explicit Base(int b);
    virtual ~Base() {};
    virtual void set()           {
        _b = (int)0;
    };
    virtual void set(short i)    {
        _b = (int)i;
    };
    virtual void set(int i)      {
        _b = (int)i;
    };
    virtual void set(long i)     {
        _b = (int)i;
    };
    virtual void set(float i)    {
        _b = (int)i;
    };
    virtual void set(double i)   {
        _b = (int)i;
    };
private:
    int _b;
};

class Derived: public Base {
        public:
                Derived(int b, int d): Base(b), _d(d) {};
                using Base::set;
                void set(int i)    { Base::set(i); _d = (int)i; };
        private:
                int _d;
};
```

# Return of non-const handle to encapsulated data member

Method returns pointer or reference to internal member of object

## Description

This defect occurs when:

- A class method returns a handle to a data member. Handles include pointers and references.
- The method is more accessible than the data member. For instance, the method has access specifier `public`, but the data member is `private` or `protected`.

### Risk

The access specifier determines the accessibility of a class member. For instance, a class member declared with the `private` access specifier cannot be accessed outside a class. Therefore, nonmember, nonfriend functions cannot modify the member.

When a class method returns a handle to a less accessible data member, the member accessibility changes. For instance, if a `public` method returns a pointer to a `private` data member, the data member is effectively not `private` anymore. A nonmember, nonfriend function calling the `public` method can use the returned pointer to view and modify the data member.

Also, if you assign the pointer to a data member of an object to another pointer, when you delete the object, the second pointer can be left dangling. The second pointer points to the part of an object that does not exist anymore.

### Fix

One possible fix is to avoid returning a handle to a data member from a class method. Return a data member by value so that a copy of the member is returned. Modifying the copy does not change the data member.

If you must return a handle, use a `const` qualifier with the method return type so that the handle allows viewing, but not modifying, the data member.

## Examples

### Return of Pointer to `private` Data Member

```
#include <string>
#define NUM_RECORDS 100

struct Date {
    int dd;
    int mm;
    int yyyy;
};
```

```
struct Period {
    Date startDate;
    Date endDate;
};

class DataBaseEntry {
private:
    std::string employeeName;
    Period employmentPeriod;
public:
    Period* getPeriod(void);
};

Period* DataBaseEntry::getPeriod(void) {
    return &employmentPeriod;
}

void use(Period*);
void reset(Period*);

int main() {
    DataBaseEntry dataBase[NUM_RECORDS];
    Period* tempPeriod;
    for(int i=0;i < NUM_RECORDS;i++) {
        tempPeriod = dataBase[i].getPeriod();
        use(tempPeriod);
        reset(tempPeriod);
    }
    return 0;
}

void reset(Period* aPeriod) {
       aPeriod->startDate.dd = 1;
       aPeriod->startDate.mm = 1;
       aPeriod->startDate.yyyy = 2000;
}
```

In this example, `employmentPeriod` is `private` to the class `DataBaseEntry`. It is therefore immune from modification by nonmember, nonfriend functions. However, returning a pointer to `employmentPeriod` breaks this encapsulation. For instance, the nonmember function `reset` modifies the member `startDate` of `employmentPeriod`.

**Correction: Return Member by Value**

One possible correction is to return the data member `employmentPeriod` by value instead of pointer. Modifying the return value does not change the data member because the return value is a copy of the data member.

```
#include <string>
#define NUM_RECORDS 100

struct Date {
    int dd;
    int mm;
    int yyyy;
};
```

```
struct Period {
    Date startDate;
    Date endDate;
};

class DataBaseEntry {
private:
    std::string employeeName;
    Period employmentPeriod;
public:
    Period getPeriod(void);
};

Period DataBaseEntry::getPeriod(void) {
    return employmentPeriod;
}

void use(Period*);
void reset(Period*);

int main() {
    DataBaseEntry dataBase[NUM_RECORDS];
    Period tempPeriodVal;
    Period* tempPeriod;
    for(int i=0;i < NUM_RECORDS;i++) {
        tempPeriodVal = dataBase[i].getPeriod();
        tempPeriod = &tempPeriodVal;
        use(tempPeriod);
        reset(tempPeriod);
    }
    return 0;
}

void reset(Period* aPeriod) {
       aPeriod->startDate.dd = 1;
       aPeriod->startDate.mm = 1;
       aPeriod->startDate.yyyy = 2000;
}
```

# Self assignment not tested in operator

Copy assignment operator does not test for self-assignment

## Description

This defect occurs when you do not test if the argument to the copy assignment operator of an object is the object itself. Polyspace does not raise this defect when you implement the copy operator by using the copy and swap idiom.

### Risk

Self-assignment causes unnecessary copying. Though it is unlikely that you assign an object to itself, because of aliasing, you or users of your class cannot always detect a self-assignment.

Self-assignment can cause subtle errors if a data member is a pointer and you allocate memory dynamically to the pointer. In your copy assignment operator, you typically perform these steps:

1. Deallocate the memory originally associated with the pointer.

   ```
   delete ptr;
   ```
2. Allocate new memory to the pointer. Initialize the new memory location with contents obtained from the operator argument.

   ```
    ptr = new ptrType(*(opArgument.ptr));
   ```

If the argument to the operator, `opArgument`, is the object itself, after your first step, the pointer data member in the operator argument, `opArgument.ptr`, is not associated with a memory location. `*opArgument.ptr` contains unpredictable values. Therefore, in the second step, you initialize the new memory location with unpredictable values.

### Fix

Test for self-assignment in the copy assignment operator of your class. Only after the test, perform the assignments in the copy assignment operator.

## Examples

### Missing Test for Self-Assignment

```
#include <algorithm>

class MyClass1 { };
class MyClass2 {
public:
    MyClass2() : p_(new MyClass1()) { }
    MyClass2(const MyClass2& f) : p_(new MyClass1(*f.p_)) { }
    ~MyClass2() {
        delete p_;
    }
    MyClass2& operator= (const MyClass2& f)
```

```
    {
        delete p_;
        p_ = new MyClass1(*f.p_);
        return *this;
    }
private:
    MyClass1* p_;
};

class MyClass3 {
public:
    MyClass3& operator=( MyClass3& other) {
        MyClass3 tmp(other);
        swap(tmp);
        return *this;
    }

    void swap(MyClass3& other) noexcept{
        std::swap(obj_, other.obj_);
    }

private:

    MyClass1* obj_;
};
```

In this example, the copy assignment operator in `MyClass2` does not test for self-assignment. If the parameter `f` is the current object, after the statement `delete p_`, the memory allocated to pointer `f.p_` is also deallocated. The statement `p_ = new MyClass1(*f.p_)` might initializes the memory location that `p_` points to with unpredictable values. Polyspace flags the copy assignment operator.

The class `MyClass3` implements the copy assignment operator by using the copy-and-swap idiom. When the parameter `other` is the current object, the operator creates a temporary copy of the current object by using the copy constructor. Then, the objects `tmp.obj_` and `this.obj_` is swapped before returning the `this` pointer. By creating a temporary object, this copy assignment operator avoids the unexpected behavior in `MyClass2::operator=`. Polyspace does not flag this copy assignment operator.

**Correction — Test for Self-Assignment**

One possible correction is to test for self-assignment in the copy assignment operator.

```
class MyClass1 { };
class MyClass2 {
public:
    MyClass2() : p_(new MyClass1()) { }
    MyClass2(const MyClass2& f) : p_(new MyClass1(*f.p_)) { }
    ~MyClass2() {
        delete p_;
    }
    MyClass2& operator= (const MyClass2& f)
    {
        if(&f != this) {
           delete p_;
           p_ = new MyClass1(*f.p_);
        }
        return *this;
    }
private:
    MyClass1* p_;
};
```

## Result Information

# Performance Defects

# A move operation may throw

Throwing move operations might result in STL containers using the corresponding copy operations

## Description

This defect occurs when a class explicitly declares a move constructor that is missing a `noexcept` specifier or has a `noexcept` specifier whose argument evaluates to `false`. The defect also occurs if an explicitly declared move constructor has the `throw(`*`type`*`)` exception specification (deprecated in C++11 and removed in C++17).

The checker does not raise a flag if the move constructor is implicitly declared or explicitly declared as `=default`.

### Risk

If a move operation can throw exceptions, some STL containers will use the copy operations instead and not get the performance benefits of a move operation. For instance, the implementation of the `std::vector::resize` method uses `std::move_if_noexcept` and performs a move operation for resizing a vector only if the move operation is declared `noexcept`.

### Fix

Add a `noexcept` specifier to the declaration of the move constructor.

If the move constructor contains expressions that might throw, fix those expressions. To detect violations of the `noexcept` exception specification, use the checker `Noexcept function exits with exception`.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Move Constructors Without `noexcept` Specifier

```
#include <string>

class Database {
  private:
      std::string* initEntry;
      int size;
  public:
      //Copy constructor
      Database (const Database& other);
      //Move constructor
      Database (Database&& other): initEntry{other.initEntry}, size{other.size} {
      other.initEntry = nullptr;
      other.size = 0;
    }
};
```

In this example, the `Database` move constructor does not have a `noexcept` specification.

### Correction – Add `noexcept` Specifier

Add the `noexcept` specifier to the move constructor.

```
#include <string>

class Database {
   private:
       std::string* initEntry;
       int size;
   public:
       //Copy constructor
       Database (const Database& other);
       //Move constructor
       Database (Database&& other) noexcept: initEntry{other.initEntry}, size{other.size} {
       other.initEntry = nullptr;
       other.size = 0;
       }
};
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `MOVE_OPERATION_MAY_THROW`
**Impact:** Low

# Const parameter values may cause unnecessary data copies

Const parameter values may prevent a move operation resulting in a more performance-intensive copy operation

## Description

This defect occurs when `const` objects as function parameters may prevent a move operation resulting in a more performance-intensive copy operation.

The checker does not check if a move operation is possible in a given function call. The checker simply highlights `const` function parameters that have class types with a nontrivial copy operation and a move operation. You can determine for yourself if the parameter can be moved to the called function.

### Risk

If the function argument is an rvalue, the resources associated with the argument are no longer required and can be *moved* to parameters in the called function. Compilers ensure that the move operation is used in this situation since they are generally less expensive than copy operations. If you use a `const` object as function parameter, you explicitly prevent this compiler optimization.

### Fix

If you think that the parameter can be moved to the called function, remove the `const` qualifier from the flagged function parameter.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### `const` Parameter Value Preventing Move Operation

```
#include <string>

std::string getStringFromUser() {
    //Get a string of arbitrary length
}

void countWordsInString(const std::string str) {
    //Count number of words in string
}

void main() {
    std::string aString = getStringFromUser();
    std::string anotherString = getStringFromUser();

    std::string joinedString = aString + anotherString;
    countWordsInString(joinedString);
    countWordsInString(aString + anotherString);
}
```

In this example, the checker flags the `const str::string` parameter `str`. In situations where a move operation is possible, for example in the call:

```
countWordsInString(aString + anotherString);
```

the `const` parameter forces a copy operation, which can be significantly more expensive.

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `CONST_PARAMETER_VALUE`
**Impact:** Low

# Version History

# Const return values may cause unnecessary data copies

Const return values may prevent a move operation resulting in a more performance-intensive copy operation

## Description

This defect occurs when `const` objects as return values may prevent a move operation resulting in a more performance-intensive copy operation.

The checker does not check if a move operation is possible for any calling function. The checker simply highlights `const` function return values that have class types with a nontrivial copy operation and a move operation.

### Risk

The resources associated with the function return value are no longer required and can be moved to objects in the calling function. Compilers ensure that the move operation is used in this situation since they are generally less expensive than copy operations. If you use a `const` object as return value, you explicitly prevent this compiler optimization.

In addition, the calling function can store the return value in a non-`const` object. The `const`-ness of the return value does not prevent any operation on the non-`const` object.

### Fix

Remove `const` qualifiers from function return values.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### `const` Return Value Preventing Move Operation

```
#include <string>

class stringPair {
    std::string str1;
    std::string str2;

    public:
    stringPair& operator=(const stringPair & aPair){
        if(&aPair != this) {
            str1 = aPair.str1;
            str2 = aPair.str2;
        }
        return *this;
    }
    const std::string getJoinedString(void) {
        return (str1 + str2);
    }
};
```

In this example, the `const` specifier on the return value of `getJoinedString` forces a copy operation instead of move operations.

# Const rvalue reference parameter may cause unnecessary data copies

The `const`-ness of an rvalue reference prevents intended move operation

## Description

This defect occurs when a function takes a `const` rvalue reference as parameter. For instance, this move constructor takes a `const` rvalue reference:

```
class aClass {
   public:
     aClass (const aClass&& anotherClass);
}
```

### Risk

The `const` nature of the rvalue reference parameter prevents the expected move operation.

For instance, this issue can happen when you write a move constructor by copy-paste from a copy constructor with a `const` parameter, for instance:

```
aClass (const aClass& anotherClass);
```

After the copy-paste, you might modify the & to && but forget to omit the `const` in the reference or the copy operations in the constructor body. In this case, the move constructor with the `const` rvalue reference compiles without errors but leads to an inefficient move constructor that actually copies the data.

### Fix

Remove the `const` qualifier from the rvalue reference parameter.

For instance, the move constructor in the preceding section can be rewritten as:

```
class aClass {
   public:
     aClass (aClass&& anotherClass);
}
```

You might also want to check the move constructor body and make sure that you are actually moving the data and not copying.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Move Constructors with `const` Rvalue Reference Parameters

```
#include <string>
```

```
#include <utility>

class Task {
    public:
       Task( const Task& ) = delete;
       Task( const Task&& other ) noexcept;
    private:
       std::string m_name;
       bool m_is_pending = false;
};
```

In this example, the move constructor has a `const` rvalue reference, which causes the defect.

The defect could have been introduced because the move constructor was created by copy-paste from the copy constructor that is deleted here.

#### Correction – Remove `const` from Parameter

Remove the `const` qualifier from the move constructor parameter to allow mutation of the parameter within the constructor body.

```
#include <string>
#include <utility>

class Task {
    public:
       Task( const Task& ) = delete;
       Task( Task&& other ) noexcept;
    private:
       std::string m_name;
       bool m_is_pending = false;
};
```

## Result Information

# Const `std::move` input may cause a more expensive object copy

Const `std::move` input cannot be moved and results in more expensive copy operation

## Description

This defect occurs when you use `std::move` on a `const` object, resulting in a more expensive copy operation.

The checker raises a violation only for class types with a nontrivial copy operation and a move operation.

### Risk

A `const` object cannot be modified and therefore cannot be moved. An `std::move` on a `const` object silently falls back to a copy operation without compilation errors. Your code might suffer from poorer performance without you noticing the issue.

### Fix

Remove the `const` qualifier from the object being moved.

If you want a copy operation instead, remove the redundant `std::move` call.

Note that this issue also triggers the checker `Move operation on const object`, which applies to all move operations on `const` objects irrespective of whether the class type has a move operation and a nontrivial copy operation. If you decide to justify the issue, you can use the same justification for both results.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### `std::move` on `const` Object

```
#include <string>

#include <string>

class MyClass {
public:
    void setName( const std::string& name ) {
        m_name = std::move( name );
    }
private:
    std::string m_name;
};
```

In this example, `std::move` is called on a `const` objects, `name`. Instead of a move assignment, a possibly more expensive copy assignment takes place.

#### Remove `const` Qualifiers

If you want move operations, remove the `const` qualifier from the definitions of the objects being moved.

```
#include <string>

#include <string>

class MyClass {
public:
    void setName( std::string& name ) {
        m_name = std::move ( name );
    }
private:
    std::string m_name;
};
```

### Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_STD_MOVE_CONST_OBJECT`
**Impact:** Medium

# Empty destructors may cause unnecessary data copies

User-declared empty destructors prevent autogeneration of move constructors and move assignment operators

## Description

This defect occurs when a class definition contains a user-defined destructor that has an empty or `=default` implementation and does not declare both a move constructor and move assignment operator. For instance:

```
class aClass
{
public:
    ~aClass() noexcept
     {} // Empty body
};
class bClass
{
public:
    ~bClass() = default;
};
```

The destructors above are exactly the same as the compiler provided version, but they prevent automatic generation of the move operators. As a result, the class type is not movable.

An empty destructor is not flagged if:

- The destructor is private or protected.
- The destructor is declared final.
- The destructor is declared virtual and does not override a base class destructor.
- The destructor overrides a base class pure virtual destructor.
- The class has a trivial copy constructor (and therefore a copy operation is not more expensive than a move operation).

### Risk

Instances of this class might be unnecessarily copied in situations where a move operation would have been possible. Copy operations are more expensive than move operations and might impact performance.

### Fix

Try one of these solutions:

- Remove the empty destructor if possible. If a class does not have a destructor, the compiler generates a destructor, which is essentially the empty destructor that you explicitly declared.

  See also Rule of Zero.

- If you cannot remove the destructor, add an explicit move constructor and move assignment operator to the class definition. Use the `=default` syntax to clarify that the compiler definitions of move constructors and move assignment operators are used.

  ```
  class aClass
  {
  public:
       ~aClass() noexcept = default;
       aClass(aClass&& ) = default;
       aClass& operator=(aClass&& ) = default;
  };
  ```

  See also Rule of Five.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

### Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EMPTY_DESTRUCTOR_DEFINED`
**Impact:** Low

# Expensive allocation in loop

Fixed sized memory is allocated or deallocated in a loop

## Description

This defect occurs when these conditions are met:

- The functions `malloc()`, `calloc()`, or `aligned_alloc()` is called inside a loop.
- The input for the memory allocating function is a fixed size.
- The function `free()` is then called to deallocate that same memory inside the loop.

### Risk

If the size of the memory is constant, allocating and deallocating memory in a loop is unnecessary and inefficient. Allocating the necessary memory once and deallocating the memory once at the end of all relevant operations is more efficient. Repeated allocation and deallocation of memory is inefficient and might lead to memory fragmentation and reduced performance.

### Fix

Perform the memory allocation and deallocation outside of a loop when the memory size is constant. For instance, before entering the loop, allocate the required memory. Use the memory inside the loop. After the relevant operations are completed, deallocate the memory after the loop.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Allocating Constant-Size Memory in a Loop

```
#include <stdbool.h>
#include <stdlib.h>

bool keep_working(void);
void use_buffer(void*);

void Loop() {
    while(keep_working())
    {
        void* buffer = malloc(10); // Defect
        use_buffer(buffer);
        free(buffer);
    }
}
```

In this example, a `buffer` that has a constant size `10` bytes is allocated, used, and deallocated in a `while` loop. The size of the object `buffer` does not change in the loop. Moving the memory management out of the loop might make the code more efficient. Polyspace flags the call to `malloc()`.

#### Correction — Allocate and Deallocate Constant-Size Memory Out of the Loop

To fix this defect, move the `malloc` statement above the loop and the `free` statement below the loop.

```
#include <stdbool.h>
#include <stdlib.h>

bool keep_working( void );
void use_buffer( void* );

void Loop() {
    void* buffer = malloc(10); // No Defect
    while(keep_working())
    {
        use_buffer(buffer);
    }
    free(buffer);
}
```

### Avoid Using `calloc()` with Constant Arguments in a Loop

```
#include <stdbool.h>
#include <stdlib.h>

bool keep_working(void);
void use_buffer(void*);

void Loop() {

    while(keep_working())
    {
        void* buffer = calloc(10,4); // Defect
        use_buffer(buffer);
        free(buffer);
    }
}
```

In this example, a `buffer` containing `10` elements of four bytes each is allocated, used, and deallocated in a `while` loop. The size of `buffer` does not change in the loop. Moving the memory management out of the loop might make the code more efficient. Polyspace flags the call to `calloc()`.

#### Correction — Allocate and Deallocate Constant Sized Memory Out of the Loop

To fix this defect, move the `calloc` statement above the loop and the `free` statement below the loop. Because `calloc()` allocates the memory, and then initiates all bytes to zero, the function `use_buffer()` expects a cleared buffer. To avoid incorrect behavior, reset the memory to zero at the beginning of the loop.

```
#include <stdbool.h>
#include <stdlib.h>

bool keep_working(void);
void use_buffer(void*);
void Loop() {
    void* buffer = calloc(10,5); // No Defect
    while(keep_working())
    {
        memset(buffer,0,50);//reset the memory to zero
        use_buffer(buffer);
        free(buffer);
    }
}
```

## Result Information

# Expensive construction of std::string or std::regex from constant string

A constant `std::string` or `std::regex` object is constructed from constant data, resulting in inefficient code

## Description

Polyspace reports this defect when both of these conditions are true:

- You construct an `std::string` or `std::regex` object from constant data, such as a string literal or the output of a `constexpr` function.
- The `std::string` or `std::regex` object remains constant or unmodified after the construction.

This defect checker does not flag class member variables, and string literals that are function arguments.

### Risk

Consider a code block that constructs an `std::string` or `std::regex` object from constant data that remains unmodified after construction. Every time this code block executes, a new object is constructed without the same constant data. Repeated construction of such an object with no modification to the content is inefficient and difficult for you detect. Consider this code:

```
#include <string>
constexpr char* getStrPtr() {
    return "abcd";
}
void foo(){
    std::string s1 = "abcd";
    std::regex reg1{"(\\w+)"};
    std::string s2 = getStrPtr();
}
int main(){
    //...
    for(int i = 0; i<10000; ++i)
    foo();
}
```

In this code, `main()` invokes the function `foo` `10000` times in a loop. Each time, the function `foo` constructs the objects `reg1`, `s1`, `s2` from the same constant string literal, resulting in inefficient code. Because such inefficient code compiles and functions correctly, you might not notice the inefficient construction of these objects from constant data.

### Fix

The fix for this defect depends on how you intend to use the constant data.

- If you do not need to reuse the constant data, use is directly as temporary literals
- If you need to reuse the constant data and you need the functionalities of `std::string` or `std::regex` class, store the constant data in a `static` string object.

- If you need to reuse the constant data and you do not need the functionalities of or `std::regex` class, store the constant data by using a `const` character array or an `std::string_view` object. Use of `std::string_view` is supported by C++17 and later.

Consider this code:

```
constexpr char* getStrPtr() {
    return "abcd";
}
void foo(){
    static const std::string s1 = getStrPtr();
    static const std::regex reg1{"(\\w+)"};
    std::string_view s1a{s1};

}
int main(){
    //...
    for(int i = 0; i<10000; ++i)
    foo();
}
```

In this code, you declare the objects `reg1` and `s1` as `static const`. Because these are `static`, they are constructed only once even if `foo` is called `10000` times. The `std::string_view` object `s1a` shows the content of `s1` and avoids the construction of an `std::string` object. By using `std::string_view` and `static const` objects, you avoid unnecessary construction of constant objects. This method also clarifies that the objects `s1` and `s1a` represent the same data.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Reconstructing Constant std::string and std::regex Objects

In this example, you declare several `std::string` and `std::regex` objects that are not modified after their construction.

- Because `foo()` constructs the objects `reg1`, `s1`, `s2`, `s5`, and `s6` from string literals and these objects remains unmodified after construction, Polyspace flags these objects.
- Because `foo()` constructs `s4` and `s3` from compile-time constants and these objects remains unmodified after construction, Polyspace flags these objects. The object `s3a` is not flagged because the output of `getCount` is not a constant.
- Polyspace does not flag these objects when they are constructed from constant data:
  - An object that is not an `std::string`, such as `*p`.
  - Temporary objects that are constructed as a function argument, such as the object containing the string literal `message` in the argument of `CallFunc`.

```
#include <string>
#include <regex>
constexpr char* getStrPtr() {
    return "abcd";
}
constexpr size_t FOUR(){
    return 4;
}
size_t getCount();
void CallFunc(std::string s);
void foo(){
    std::regex reg1{"(\\w+)"};
    std::string s1 = "abcd";
    std::string s2{"abcd"};
    std::string s3 = getStrPtr();
    std::string s4("abcd", FOUR());
    std::string s5("abcd"), s6("abcd");
}

void bar(){
    std::string s3a("abcd", getCount());
    char *p = "abcd";
    std::string s_p = p;
    CallFunc("message");
}
```

**Correction**

You can fix this defect using several enhancements:

- Declare the objects `s1`, `reg1` and `s4` as `static const`. When an object is `static`, the compiler does not reconstruct it in different scopes. When you need the functionalities of an `std::string` or `std::regex` class, this declaration is a good fix.
- Declare `s3` by using a constant character pointer `p`.
- Declare the constant strings `s2`, `s5` and `s6` as `std::string_view` objects. These objects do not contain copies of the constant strings, which makes these objects efficient.

```
#include <string>
#include <string_view>
#include<regex>
constexpr char* getStrPtr() {
    return "abcd";
}
constexpr size_t FOUR(){
    return 4;
}

void foo(){
    static const std::string s1 = "abcd";
    static const std::regex reg1{"(\\w+)"};
    std::string_view s2{s1};
    const char *p = getStrPtr();
    std::string s3 = p;
    static std::string s4("abcd", FOUR());
    std::string_view s5{s1}, s6{s4};
}
```

# Expensive copy in a range-based for loop iteration

The loop variable of a range-based `for` loop is copied from the range elements instead of being referenced resulting in inefficient code

## Description

This defect occurs when the loop variable of a range-based `for` loop is copied from the range elements instead of reading the range elements by reference. Copy the range elements only when its necessary because copying them might result in inefficient code. This defect is raised when the loop variable is unmodified and any of these conditions are true:

- The copied loop variable is a large trivially copyable type variable. Copying a trivially copyable object is more expensive than referencing it when the object is large.
- The copied loop variable is a nontrivially copyable type. Copying such an object might require an external function call, which is more expensive than referencing it. To check whether an object is nontrivially copyable, use the function `std::is_trivially_copyable`. For more details about this function, see `std::is_trivially_copyable` in the C++ reference.

### Risk

Range-based `for` loops can become inefficient when an expensive copy of the loop variable is made in each iteration of the loop. Consider this code:

```
void foo( std::map<std::string, std::string> const& property_map )
{
    for( std::pair< const std::string, std::string > const property: property_map)
    {}
}
```

The loop variable `property` is declared as a `const` instead of `const&`. In each iteration of the `for` loop, an `std::pair` object is copied from the map `property_maps` to the loop variable `property`. Because of the missing & in the declaration of `propert`, an expensive copy operation is done in each iteration instead of a referencing operation, resulting in inefficient code. Because this code compiles and functions correctly, the inefficient `for` loops might not be noticed. For similar source of inefficiencies, see `Expensive pass by value` and `Expensive return by value`.

### Fix

To fix this defect, declare the loop variable of a range-based `for` loop as a `const&`. Consider this code:

```
void foo( std::map<std::string, std::string> const& property_map )
{
    for( std::pair< const std::string, std::string > const& property: property_map)
    {}
}
```

Because the loop variable `property` is declared as a `const&`, the variable references a different element of the map `property_map` in each loop iteration, without copying any resource. By preventing an expensive copy in each iteration, the code becomes more efficient.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Expensive Copy in Loop Iterations

```
#include <initializer_list>
#include <unordered_map>
#include <vector>
struct Small_Trivial_Type
{
    unsigned char values[ sizeof( void* ) ];
};

struct Large_Trivial_Type
{
    unsigned char values[ 4u * sizeof( void* ) ];
};

class Nontrivial_Type
{
    Nontrivial_Type() noexcept;
    Nontrivial_Type( Nontrivial_Type const& );
    Nontrivial_Type& operator=( Nontrivial_Type const& );
    ~Nontrivial_Type() noexcept;
    int read() const;
    void modify( int );
};
extern std::vector< Nontrivial_Type > getNtts();

void foo( std::vector< Nontrivial_Type > const& ntts )
{
    for( Nontrivial_Type ntt: ntts )
    {}
}

void foo_auto( std::vector< Nontrivial_Type > const& ntts )
{
    for( auto ntt: ntts )
    {}
}
void foo_c_array( Nontrivial_Type const ( & ntts )[ 10 ] )
{
    for( Nontrivial_Type ntt: ntts )
    {}
}
void foo_large( std::vector< Large_Trivial_Type > const& ltts )
{
    for( Large_Trivial_Type ltt: ltts )
    {}
}
void foo_small( std::vector< Small_Trivial_Type > const& stts )
{
    for( Small_Trivial_Type const stt: stts )
    {}
}
```

```
void modify_elem( std::vector< Nontrivial_Type > const& ntts )
{
    for( Nontrivial_Type ntt: ntts )
    {
        ntt.modify( 42 );//Modification
    }
}
```

In this example, range-based `for` loops that have different types of loop variables are shown.

- Polyspace flags the nontrivially copyable loop variable `ntt` in `foo()` due to an expensive copy operation that is unnecessary because the loop variable is not modified. For the same reason, the loop variables in `foo_auto()` and `foo_c_array()` are flagged.
- Polyspace flags the large loop variable `ltt` in `foo_large()` because it is more expensive to copy the elements of `ltts` into `ltt` than to reference elements of `ltts`, even though `ltt` is a trivially copyable type.
- Polyspace does not flag the loop variable `stt` in `foo_small()` because copying the elements of `stts` into `stt` is not more expensive than referencing the elements of `stts`.
- Polyspace does not flag the loop variable `ntt` in `modify_elem()` because the loop variable is modified in the loop.

**Correction**

To fix this issue, use constant references (`const&`) as loop variables in range-based `for` loops. Using `const&` loop variables prevents expensive copying and produces efficient code.

```
#include <initializer_list>
#include <unordered_map>
#include <vector>
struct Small_Trivial_Type
{
    unsigned char values[ sizeof( void* ) ];
};

struct Large_Trivial_Type
{
    unsigned char values[ 4u * sizeof( void* ) ];
};

class Nontrivial_Type
{
    Nontrivial_Type() noexcept;
    Nontrivial_Type( Nontrivial_Type const& );
    Nontrivial_Type& operator=( Nontrivial_Type const& );
    ~Nontrivial_Type() noexcept;
    int read() const;
    void modify( int );
};
extern std::vector< Nontrivial_Type > getNtts();
// Test iterating over a const vector.
void foo( std::vector< Nontrivial_Type > const& ntts )
{
    for( Nontrivial_Type const& ntt: ntts ) // NC2C
    {}
}
```

```
void foo_auto( std::vector< Nontrivial_Type > const& ntts )
{
    for( auto const& ntt: ntts ) //NC2C
    {}
}
void foo_c_array( Nontrivial_Type const ( & ntts )[ 10 ] )
{
    for( Nontrivial_Type const& ntt: ntts ) // NC2C
    {}
}
void foo_large( std::vector< Large_Trivial_Type > const& ltts )
{
    for( Large_Trivial_Type const& ltt: ltts )
    {}
}
```

# Expensive dynamic_cast

Expensive `dynamic_cast` is used instead of more efficient `static_cast` or `const_cast`

## Description

This defect is raised when `dynamic_cast` is used on a pointer, which is then immediately dereferenced. For instance:

```
std::iostream* iostream_ptr;
//...
std::string str = dynamic_cast< std::stringstream* >( iostream_ptr )->str();
```

The `iostream` pointer `iosreeam_ptr` is cast into a `stringstream` pointer, and then immediately dereferenced. Such use implies that the casting always succeeds. When you know that a casting operation succeeds, `static_cast` or `const_cast` are a more efficient choice.

### Risk

When casting one class to another in a polymorphic hierarchy, you might want to use `dynamic_cast` when run-time type of the most derived class in the hierarchy is unknown. The `dynamic_cast` is more powerful because it checks the type of the argument at run time and reports error if the check fails. These functionalities make `dynamic_cast` a more expensive operation than either of `static_cast` or `const_cast`. Because `dynamic_cast` can achieve many different goals, its use might hide the developers intent when casting. Using `dynamic_cast` when cheaper or more explicit casting operations might be more appropriate results in code that is inefficient and more difficult to maintain. Because such code compiles and runs correctly, the inefficiency might remain undetected.

### Fix

To fix this defect, replace the `dynamic_cast` with a more appropriate cheaper option. For instance:

- When calling virtual functions in a polymorphic base class, remove any casting operation.
- When downcasting from a base class to derived class, use `static_cast` if the casting operation succeeds in all conditions.
- When sidecasting from one base class to another base class, use `static_cast` if the casting operation succeeds in all conditions.
- When upcasting from a derived class to a base class, use `static_cast`.
- To modify the `const` or `volatile` qualifiers of an object, use `const_cast`.
- Refactor your code to remove inappropriate casting such as casting between unrelated classes.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Casting a Base Class into a Derived Class

```
#include <cstddef>
```

```
#include <sstream>
#include <string>
// downcast using `dynamic_cast` with pointer,
// and unconditionally call member function
void Downcast_NC( std::iostream* iostream_ptr )
{
    // ...
    std::string str = dynamic_cast< std::stringstream* >( iostream_ptr )->str();
    // ...
}
```

In this example, an `std::iostream*` object is cast into a `std::stringstream*` object by calling `dynamic_cast`. After the casting, the cast pointer is immediately dereferenced. Polyspace flags the `dynamic_cast`.

#### Correction

To fix this defect, replace `dynamic_cast` by using `static_cast`. Because `static_cast` does not check whether a casting operation might fail, consider adding an `assert` statement to check if the conversion fails. After completing the development and debugging, you might remove the `assert` statement.

```
#include <cstddef>
#include <sstream>
#include <string>
void Downcast_C( std::iostream* iostream_ptr )
// if `dynamic_cast` may fail
{
    // ...
    assert( dynamic_cast< std::stringstream* >( iostream_ptr ) != NULL );//Only for debugging
    std::string str = static_cast< std::stringstream* >( iostream_ptr )->str();
}
```

### Sidecasting and Upcasting Classes in a Polymorphic Hierarchy

```
class A{
    //...
public:
    virtual void func_A() ;
};
class B{
    //...
public:
    virtual void func_B() ;
};
class C: public A, public B{/**/};
void foo(A& a){

    dynamic_cast<B*> (&a)->func_B();//Noncompliant
}
void bar(C& c){

    dynamic_cast<B*> (&c)->func_B();//Noncompliant
}
```

In this example, the class C is derived from A and B. The function foo casts the A& object a into a B* type to access the member function B::func_B. The casting operation calls dynamic_cast, which is inefficient. Polyspace flags this conversion.

The casting from the C& object to its base class, as shown in the function bar, always succeeds. Using dynamic_cast for this operation is unnecessary and Polyspace flags the conversion.

**Correction**

Sidecasting through an unknown most derived class is a unique capability of dynamic_cast. If your code cannot function properly without a sidecast, use dynamic_cast and justify the defect. See "Annotate Code and Hide Known or Acceptable Results".

In some cases, it might be more efficient to replace a sidecast with a downcast. For instance, the function foo uses sidecasting for the explicit purpose of accessing the members of another branch in a class hierarchy. In such cases, it might be more efficient to perform the casting through the most derived class. Instead of using dynamic_cast to cast a into a B* object, you might use static_cast to cast a into a C* object. Such a downcast enables access to B::func_B while making the code more efficient. To check if the static conversion succeeds in all conditions, use assert statements during development and debugging.

Upcasting from a derived class to a base class, as shown in the function bar, always succeeds. Use static_cast for such conversions. In the preceding code, because func_B is a public virtual function, invoke the function directly by using the pointer to the class C. Casting is not necessary in this case.

```
class A{
    //...
public:
    virtual void func_A() ;
};
class B{
    //...
public:
    virtual void func_B() ;
};
class C: public A, public B{/**/};
void foo(A& a){

    static_cast<C*> (&a)->func_B();//Compliant
}
void bar(C& c){

    c.func_B();//Compliant
}
```

## Result Information

# Expensive local variable copy

Local variable is created by copy from a `const` reference and not modified later

## Description

This defect occurs when a local variable is created by copy from a `const` reference but not modified later.

For instance, the variable `name` is created by copy from a `const` reference returned from the `get_name` function:

```
const std::string& get_name();
...
void func {
    std::string name = get_name();
}
```

The defect is raised only if the local variable has a non-trivially copyable type or a trivially copyable type with size greater than `2 * sizeof(void *)`.

### Risk

If a variable is created from a `const` reference and not modified later, the variable itself can be defined as a `const` reference. Creating a `const` reference avoids a potentially expensive copy operation.

### Fix

Avoid creating a new local variable by copy from a `const` reference if you do not intend to modify the variable later. Create a `const` reference instead.

For instance, in the preceding section, you can redefine the variable `name` as:

```
const std::string& get_name();
...
void func {
    const std::string& name = get_name();
}
```

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Expensive String Created from `const` Reference

```
#include <string>

class Task
{
public:
    // ...
    const std::string& get_name() const;
    // ...
private:
    // ...
};

void inspect( const Task& task )
{
    // ...
    const std::string name = task.get_name();
    // ...
}
```

In this example, the variable `name` is created by copy from a `const` reference but not modified later.

**Correction – Use `const` Reference**

To avoid a potentially expensive copy operation, avoid creating a new local variable if you do not intend to modify the variable later. Instead, assign the `const`-reference return value to another `const` reference.

```
#include <string>

class Task
{
public:
    // ...
    const std::string& get_name() const;
    // ...
private:
    // ...
};

void inspect( const Task& task )
{
    // ...
    const std::string& name = task.get_name();
    // ...
}
```

## Result Information

# Expensive logical operation

A logical operation requires the evaluation of both operands because of their order, resulting in inefficient code

## Description

This defect occurs when all of these conditions are true:

- Left and right operands have no side effects.
- The right operand does not contain any calls to `const` member functions.
- The left operand contains one or more calls to `const` member functions.

When assessing possible side effects of an operand:

- Polyspace assumes that `const` member functions of a class do not have side effects. Nonmember functions are assumed to have side effects.
- Polyspace treats floating-point operations in accordance to the C++ standard. In C++03 or earlier, floating-point operations have no side effects. In C++11 or later, floating-point operations might have side effects, such as modifying the floating-point status flags to indicate abnormal results or auxiliary information. See Floating-point environment.
- Polyspace treats the `bool` conversion operator and logical `NOT` operators of a `struct` or a class as built-in operators. These operations are not treated as member function calls. The standard template library contains many classes that define such a `bool` conversion operator or a logical `NOT` operator.

### Risk

When evaluating logical operation, the compiler evaluates the left argument first, and then evaluates the right argument only when necessary. In a logical operation, it is inefficient to put function calls as the left argument while putting constant and variables as the right argument. Consider this code:

```
if(Object.attribute()|| var1){
//...
}
```

In the logical expression inside the `if` statement, the compiler always evaluates the function call `Object.attribute()`. Evaluating the function is not always necessary. For instance, if `var1` evaluates to `true`, then the logical expression always evaluates to true. Because `var1` is the right operand, not the left operand, the compiler unnecessarily evaluates a function call, which is inefficient. Because the inefficient code compiles and behaves correctly, this defect might go unnoticed.

### Fix

To fix this defect, flip the order of the operands in a logical expression if the left operand does not perform an operation that must be performed *before* the right operand in order to evaluate the right operand safely and correctly.

If this condition is not true, then the code relies on the exact order in which the compiler evaluates the flagged logical expression. The best practice is not to rely on the evaluation order of an expression. Consider refactoring your code so that the order of evaluation has no impact. If refactoring the code is not possible, justify the defect by using annotation or review information. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Member Function Call as Left Operand

```
#include <string>
bool updateNewProperty( const std::string& name );
void updateNewMetaProperty( const std::string& name );
volatile char externalFlag;

void updateProperty( const std::string& name )
{
    bool is_new_property = updateNewProperty( name );

    if( name.compare( "meta" ) == 0 && is_new_property )
    {
        updateNewMetaProperty( name );
    }
    if( name.compare( "meta" ) == 0 && externalFlag )
    {
        updateNewMetaProperty( name );
    }

}
```

In the first `if` statement, the variable `is_new_property` is the right operand of a logical operand. The member function `std::string::compare` is called as the left argument. The compiler evaluates the function call regardless of the value of `is_new_property`, which is inefficient. Polyspace flags the logical operation.

In the second `if` statement, the `volatile` variable `externalFlag` is the right operand. Because the variable is `volatile`, Polyspace assumes it might cause a side effect. Because the `volatile` variable might have a side effect, Polyspace does not flag the logical operation.

#### Correction

Determine if the order of the operands needs to be maintained to evaluate the expression safely and correctly. In this case, the two operands `is_new_property` and `name.compare( "meta" ) == 0` are independent and changing their order does not change the value of the logical expression. To fix this defect, use `is_new_property` as the left operand.

```
#include <string>
bool updateNewProperty( const std::string& name );
void updateNewMetaProperty( const std::string& name );
```

```
volatile char externalFlag;

void updateProperty( const std::string& name )
{
    bool is_new_property = updateNewProperty( name );
    if(is_new_property && name.compare( "meta" ) == 0 )
    {
        updateNewMetaProperty( name );
    }
    if( name.compare( "meta" ) == 0 && externalFlag )
    {
        updateNewMetaProperty( name );
    }
}
```

The compiler evaluates the call to `std::string::compare` in the first `if` statement only when `is_new_property` is `true`.

### Floating-Point Operation in Logical Expression

When you use floating-point operations in a logical expression, Polyspace estimates the side effects of the operands differently based on the version of C++ that you use. In C++03 or earlier versions, floating-point operations do not have any side effects by themselves. In C++11 or later, floating-point operations themselves might have side effects.

```
class A{
    //...
    float makeFloat() const{
        //..
    }
    void testfloat(){
        if( makeFloat() == 0.1f && fp==0.2f)
        {
            //...
        }
    }

private:
    float fp;
};
```

In this code, if you use C++03, neither of the operands has side effects. Because the left operand invokes a member function call, Polyspace flags the expression.

If you use C++11 or later, the floating-point operations might have side effects. In this case, Polyspace does not flag the logical expression.

#### Correction

Determine if the order of the operands needs to be maintained to evaluate the expression safely and correctly. In this case, the two operands `fp==0.2f` and `makeFloat() == 0.1f` are independent and changing their order does not change the value of the logical expression. To fix this defect, use `fp==0.2f` as the left operand.

```
class A{
    //...
    float makeFloat() const{
        //..
    }
    void testfloat(){
        if( fp==0.2f && makeFloat() == 0.1f)
        {
            //...
        }
    }

private:
    float fp;
};
```

The compiler evaluates the call to `makeFloat()` only when `fp==0.2f` evaluates to `true`.

### Logical Expression that Requires Specific Evaluation Order

```
#include<cstdlib>
class A{
    //...
    bool isLoaded() const { return p != NULL; }
    int get() {
        if(isLoaded() && *p > 0) {
            return *p;
        }
    }

private:
    int* p;
};
```

In the expression `(isLoaded() && *p > 0)`, the dereferencing of `*p` in the right argument is safe only when the left argument is `true`. Polyspace does not check when logical expression require such specific evaluation order. Because neither operands have side effects and the member function call is the left operand, Polyspace flags the operation.

#### Correction

In this case, the order if the operands in the logical expression needs to be maintained to evaluate the expression safely and correctly. To fix this defect, refactor your code. The best practice is not to rely on the order of evaluation of an expression.

```
#include<cstdlib>
class A{
    //...
    bool isLoaded() const { return p != NULL; }
    int get() {
        if(isLoaded()== true) {
            if(*p > 0){
                return *p;
            }

        }
    }

private:
    int* p;
};
```

This code checks the two conditions separately and does not rely on the order of evaluation. If such refactoring is not feasible, justify the defect by using annotations or review information.

# Expensive pass by value

Parameter might be expensive to copy

## Description

This defect occurs when you pass a parameter by value instead of by reference or pointer, but the parameter is unmodified and either:

- The parameter is a non-trivially copyable type. For more on non-trivially copyable types, see *is_trivially_copyable*.
- The parameter is a trivially copyable type that is above a certain size. For example, an object greater than `2 * sizeof(void *)` is more expensive to pass by value than by reference or pointer.

Polyspace flags unmodified parameters that meet the preceding conditions even if the parameters are not declared `const`.

Polyspace raises no defect if:

- The passed by value parameter is a move-only type. For instance, `std::unique_ptr` can be moved-from but cannot be copied.
- The passed by value parameter is modified.
- The parameter is passed by value to a `virtual` overriding method in a derived class.

  In this instance, fixing the defect might require modifying the signature of the base class method which might not be possible for the owner of the derived class.
- The parameter is passed by value to a `virtual` method in a base class and the parameter is non-`const`.

  In this instance, if there are overriding methods in derived classes that modify their parameter, it might not be possible to properly update those methods if a fix is applied to the base class method.

  Note that if the parameter is `const`, overriding methods in derived classes do not modify their parameters and applying a fix in the base class is safe. In this case, Polyspace reports an expensive pass by value defect.

For example, in the following code, Polyspace does not report a defect in these functions and methods:

- The function `offset()` because its parameter is modified.
- The function `moveOnly()` because its parameter is a move-only type.
- Methods `D::parse_M` and `D::print_M` because they are `virtual` overriding methods in a derived class.
- The method `Base::print_M` because it is a `virtual` method in a base class with a non-`const` parameter.

Polyspace does report a defect for `Base::parse_M` because its parameter is `const` and non-trivially copyable.

```
#include <string>
#include <memory>
#include <iostream>

typedef struct Buffer
{
    unsigned char bytes[20];
    int index;
} Buffer;

void offset(Buffer modifiedBuffer)
{
    ++modifiedBuffer.index;
}

void moveOnly(std::unique_ptr<Buffer> move_only_param);

// virtual methods example

class Base
{
public:
    virtual void parse_M(const std::string msg);
    virtual void print_M(std::string msg)
    {
        std::cout << "Base message: " << msg << "\n";
    }
};

class D : public Base
{
public:
    void parse_M(const std::string msg) override;
    void print_M(std::string msg) override
    {
        std::cout << "Derived message: " << msg << "\n";
    }
};
```

### Risk

Passing a parameter by value creates a copy of the parameter which is inefficient if the parameter is expensive to copy. Even if your intent is to pass by reference or pointer, you might forget the `const&` or `const*` in your function signature and inadvertently run an inefficient version of the function.

### Fix

Convert the parameter to a `const` pointer (`const*`) for C code, or to a `const` reference (`const&`) for C++ code.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Expensive Pass by Value in C++ Setter Function

```
#include<string>

class Player
{
public:
    void setName(std::string const str)
    {
        name = str;
    }
    void setRank(size_t r)
    {
        rank = r;
    }
    // getter functions implementation
private:
    std::string name;
    size_t rank;

};
```

In this example, Polyspace flags the parameter of setter function `setName` which is passed by value and results in an expensive copy. The type `std::string` is not trivially copyable. The passed by value parameter of `setRank` is not flagged because `size_t` is a small trivially copyable type.

#### Correction — Pass `std::string` Parameter by `const` Reference

To avoid an inefficient copy operation, use a `const&` to pass the parameter.

```
#include<string>

class Player
{
public:
    void set_name(std::string const& s)
    {
        name = s;
    }
    void set_rank(size_t r)
    {
        rank = r;
    }
    // getter functions implementation
private:
    std::string name;
    size_t rank;

};
```

### Expensive Pass by Value in C Function

```
#include<stdio.h>
#include<string.h>

typedef struct _Player {
    char name[50];
    size_t rank;
} Player;

void printPlayer(Player const player)
{

    printf("Player name: %s\n", player.name);
    printf("Player rank: %zu\n", player.rank);
}
```

In this example, Polyspace flags the parameter of `printPlayer` which is passed by value and results in an expensive copy.

#### Correction — Pass Large Struct by `const` Pointer

To avoid an inefficient copy operation, use a `const*` to pass the parameter, then use the appropriate notation to read the structure elements.

```
#include<stdio.h>
#include<string.h>

typedef struct _Player {
    char name[50];
    size_t rank;
} Player;

void printPlayer(Player const* player)
{

    printf("Player name: %s\n", player->name);
    printf("Player rank: %zu\n", player->rank);
}
```

## Result Information

# Expensive post-increment operation

Object is post-incremented when pre-incrementing is faster

## Description

This defect is raised when you use the post-increment or post-decrement operation instead of a more efficient pre-increment or pre-decrement operation. The pre-increment operation is equally or more efficient when all of these conditions are true:

- Pre and post increment or decrement operations are defined for the object.
- The return type of post-increment or decrement operation is expensive to copy.
- The returned value is unused.
- The return type of pre-increment or decrement operation is not expensive to copy, such as a reference.

The efficiencies of pre-increment and pre-decrement operations depends on the version and implementation of the C++ standard that you use. If you switch C++ version or the library implementation, you might see a change in the number of violation of this check.

### Risk

Post-increment or decrement operations create a copy of the object, increment or decrement the original, and then return the copied object. When the object is expensive to copy and you do not use the returned copy of the object, the post-increment or post-decrement operation is inefficient. Use a pre-increment or pre-decrement operation, which does not copy the object and typically returns a reference to the incremented or decrement object. Inadvertently using post-increment instead of pre-increment with a large object might make the code inefficient. Code that uses inefficient post-increment or post-decrement operations compiles and behaves correctly. The inefficient operations might remain undetected.

### Fix

When you do not use the returned object from a decrement or increment operation, use a pre-increment operation.

When iterating over each element of a container, you might want to use loops that do not require increment or decrement operations, such as `std::for_each` or the range-based `for` loop. These loops are optimized for such iterations. They do not require manual increment or decrement operations.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Using Post-Increment Operation Instead of Pre-Increment Operation

```
// Using C++ 03
```

```
#include <complex>
#include <iterator> // istream_iterator
#include <sstream> // istringstream
#include <string>
#include <vector>

std::vector< std::complex< double > > deserialize( const std::string& s )
{
    std::vector< std::complex< double > > v;
    std::stringstream iss( s );
    for( std::istream_iterator< std::complex< double > > it( iss );
         it != std::istream_iterator< std::complex< double > >(); it++ )
    { v.push_back( *it ); }
    return v;
}
```

In this example, post-increment operations are performed on expensive iterators. Polyspace assumes that the C++ version is C++03. Use the analysis option `-cpp-version` by using the value `cpp03`.

In the function `deserialize`, the `for` loops iterate over a `std::istream_iterator< std::complex< double > >` iterator `it`. Because these iterators are expensive to copy, the post-increment operation is more expensive than the pre-increment operation. The expensive post-increment is unnecessary and inefficient because the incremented iterator is not used. Polyspace flags the post-increment operations.

#### Correction

You can fix these defects in several ways. For instance, replace the post-increment operations by pre-increment operations. If C++11 is available, you might want to use range-based for loops when you iterate over each element of a container.

```
#include <complex>
#include <iterator> // istream_iterator
#include <sstream> // istringstream
#include <string>
#include <vector>

std::vector< std::complex< double > > deserialize( const std::string& s )
{
    std::vector< std::complex< double > > v;
    std::stringstream iss( s );
    for( std::istream_iterator< std::complex< double > > it( iss );
         it != std::istream_iterator< std::complex< double > >(); ++it )
    { v.push_back( *it ); }
    return v;
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_POST_INCREMENT`
**Impact:** Low

# Expensive return by value

Functions return large output by value instead of by reference or pointer

## Description

This defect occurs when functions return large output objects by value instead of the object being returned by reference or pointer.

This checker is raised if both of these conditions are true:

- The address of the returned object remains valid after the `return` statement.
- The returned object is any of these:
  - A nontrivially copyable object. Returning such an object by value might require an external function call, which is more expensive than returning it by reference. To check whether an object is nontrivially copyable, use the function `std::is_trivially_copyable`. For more details about this function, see `std::is_trivially_copyable` in the C++ reference.
  - A large trivially copyable object. Returning a trivially copyable object by value is more expensive when the object is large.

This defect is not raised if the returned object is:

- Inexpensive to copy.
- A temporary object or a nonstatic local object.

### Risk

It is inefficient to return a large object by value when you can return the object by reference or pointer. Functions might inadvertently return a large object by value because of a missing & or *. Such inefficient return statements might not be noticed. Consider this code:

```
#include<string>
class Buffer{
public:
    //..
    const std::string getName() {
        return m_names;
    }
    //...
private:
    std::string m_names;
};
```

The class `Buffer` contains a large private object `m_names`. It is common to have a public getter function for such a private object, such as `getName`, which returns the large object `m_names`. Because the return type of `getNames` is set as `const std::string` instead of `const std::string&`, the function returns the large object by value instead of by reference. The expensive return by copy might not be noticed because this code compiles and functions correctly despite the missing &. For similar sources of inefficiency, see `Expensive pass by value` and `Expensive copy in a range-based for loop iteration`.

### Fix

To fix this defect, return objects by using references. When using C code, use pointers to avoid returning objects by value.

- To return objects from a C++ function by reference, set the return type of the function as a reference. For instance:

  ```
  #include<string>
  class Buffer{
  public:
      //..
      const std::string& getName() {
          return m_name;
      }
      //...
  private:
      std::string m_name;
  };
  ```

  The function `getName()` returns the large object `m_names` by reference because the return type of the function is `const std::string&`, which is a reference.
- Alternatively, use pointers to avoid returning objects by value. For instance, set the return type of `getName()` to `const std::string*`, and then return the address of `m_names` as `&m_names`.

  ```
  #include<string>
  class Buffer{
  public:
      //..
      const std::string* getName() {
          return &m_name;
      }
      //...
  private:
      std::string m_name;
  };
  ```

  By using a pointer, the function `getName()` avoids returning `m_names` by value. This method is useful in C code where references are not available.

  Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Expensive Return by Value in C++ Code

```
#include<string>
#include<memory>
#include<array>
#include<cstdint>
class Buffer{
private:
    static const size_t SIZE = 10;
    std::string m_name; //Nontrivially copyable type
    std::array<uint8_t,SIZE> m_byteArray; // Large trivially copyable type
```

```
    size_t m_currentSize; // Small trivially copyable
public:
    //...
    const std::string getName(){
        return m_name;
    }
    const std::array<uint8_t,SIZE> getByteArray(){
        return m_byteArray;
    }
    size_t getCurrentSize(){
        return m_currentSize;
    }
};
```

In this example, various private objects in the class `Buffer` are accessed by their getter functions.

- The large object `m_name` is returned by the getter functions `getName` by value. Returning this nontrivially copyable object by value is inefficient when it can be returned by reference instead. Polyspace flags the unction.
- The object `m_byteArray` is returned by the getter function `getByteArray` by value. Returning this large object by value is inefficient when it can be returned by reference instead. Polyspace flags the function.
- The function `getCurrentSize` returns the integer `m_currentSize` by value. Copying this small object is not inefficient. Polyspace does not flag the function.

**Correction**

To fix these defects, return large objects by using references as return types of the getter functions. For instance, set the return type of `getName` to `const std::string&` instead of `const std::string`.

```
#include<string>
#include<memory>
#include<array>
#include<cstdint>
class Buffer{
private:
    static const size_t SIZE = 10;
    std::string m_name; //Nontrivially copyable type
    std::array<uint8_t,SIZE> m_byteArray; // Large trivially copyable type
    size_t m_currentSize; // Small trivially copyable
public:
    //...
    const std::string& getName(){
        return m_name;
    }
    const std::array<uint8_t,SIZE>& getByteArray(){
        return m_byteArray;
    }
    size_t getCurrentSize(){
        return m_currentSize;
    }
};
```

### Expensive Return by Value in C Code

```
typedef struct _Circle{
    double Origin_abscissa;
    double Origin_ordinate;
    double Radius;
    char name[10];
}Circle;

const Circle getCircle(){
    static Circle SpecificCircle;
    //...
    return SpecificCircle;
}
```

In this example, the function `getCircle` returns the large `static` object `SpecificCircle` by value. Polyspace flags the function.

#### Correction

To fix this issue, return the object `SpecificCircle` by using a pointer. Declare the return type of the function `getCircle` as `const Circle*` instead of `const Circle`, and then return the address of the object, that is, &`SpecificCircle`.

```
typedef struct _Circle{
    double O_abscissa;
    double O_ordinate;
    double Radius;
    char name[10];
}Circle;

const Circle* getCircle(){
    static Circle SpecificCircle;
    //...
    return &SpecificCircle;
}
```

# Expensive return of a const object

The return statement of a function copies an objects instead of moving it because the returned object is declared as a const

## Description

This defect occurs when these conditions are true:

- A function returns a const object, forcing a copy construction of the returned object from a const object.
- The returned object implements an available move constructor.

For instance, consider this code:

```
std::string foo(const std::string& str){
    const std::string cstr{str};
    //...
    return cstr;
}
```

The string cstr is constructed from a const string. Because cstr is a const, the return statement copies it instead of moving it. Polyspace flags the declaration of cstr.

### Risk

When returning objects, compilers implicitly attempt moving the returned object instead of copying it when the object supports move semantics. When you declare an object as a const, this implicit move is suppressed and the compiler copies the object. When the return statement copies the constructed return object instead of moving it, the code becomes less efficient. Because the inefficient code compiles and behaves correctly, the inefficiency might be difficult to diagnose.

### Fix

To fix this defect, make the returned object into a nonconst.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Returning const Objects

```
#include <string>

class Task
{
public:
    std::string exchangeName( const std::string& name )
    {
        const std::string old_name = m_name;
        m_name = name;
        return old_name;
    }
     //...
private:
    std::string m_name;
};
```

In this example, the function `exchangeName` returns the string `old_name`, which is a `const` object. The compiler cannot move `old_name`. The return statement of the function `exchangeName` is forced to copy the constructed return object, which is inefficient. Polyspace flags the declaration of `old_name`.

**Correction — Return Nonconst Objects**

To facilitate implicit move operation when returning an object, declare the returned objects as nonconst.

```
#include <string>

class Task
{
public:
    std::string exchangeName( const std::string& name )
    {
        std::string old_name = m_name;
        m_name = name;
        return old_name;
    }
     //...
private:
    std::string m_name;
};
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_RETURN_CONST_OBJECT`
**Impact:** Low

# Expensive use of a standard algorithm when a more efficient method exists

Functions from the `algorithm` library are misused with inappropriate inputs, resulting in inefficient code

## Description

Polyspace reports a defect when you misuse functions in the `algorithm` library with a container, which results in inefficient code. You might be recalculating known or constant information about the container or using a function that is inappropriate for the container. The scenarios that trigger this defect include:

- Running a search by calling functions such as `std::find`, `std::equal_range`, `std::upper_bound`, `std::binary_search`, and `std::lower_bound` with associative containers such as `std::set`, `std::map`, `std::multiset`, and `std::mutimap`.
- Checking for the presence of a certain key in a container by calling `std::count`. That is, you convert the output of `std::count` to a `bool` or compare the output to either `0` or `1`.
- Checking for a sorted associative container by calling `std::is_sorted`.
- Calculating the size of an associative container by calling `std::distance`.
- Searching for consecutive equal elements in unique-value containers such as `std::set` or `std::map` by calling `std::adjacent_find`.
- Passing expensive functors by value to standard functions.

### Risk

Misusing the functions from the `algorithm` library might result in inefficient code or unexpected behavior.

- Searching associative containers by using linear search functions, such as `std::find` and `std::binary_search`, is inefficient.
- When checking for a certain key in a container, performing an exhaustive search for every instance of the key by calling `std::count` is unnecessary and inefficient.
- If an associative container is already sorted, calling `std::is_sorted` is unnecessary. If the associative container is not sorted, the output of `std::is_sorted` might be indeterminate, resulting in unexpected behavior.
- Calculating the size of an associative container by calling its `size` method is more efficient than using the `std::distance` function.
- Calling `std::adjacent_find` with unique-value containers such as `std::set` or `std::map` always results in `end()`. Because the output is constant, the call is unnecessary.
- If you pass a functor to a standard algorithm function, it is always copied. If the functor is expensive, this copy operation makes your code expensive and inefficient.

### Fix

To fix this defect, refactor your code to use the standard `algorithm` functions more efficiently.

- When searching in associative containers, avoid using `std` functions. If possible, use the search method of the container, such as `std::set::find`.
- When checking for the presence of a certain key, call the `find` or `contains` (C++20) method of the container. For containers that do not implement these methods, use `std::find` instead of `std::count`.
- Avoid using `std::is_sorted` or `std::adjacent_find` with associative containers.
- To check the size of an associative container, use the `size` method of the container. Avoid using `std::distance` to calculate size.
- Avoid passing expensive-to-copy functors to `std` functions. Instead, create a wrapper functor that contains a reference to the original functor and pass the wrapper to standard algorithm functions.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Use of `std` Functions with Associative Containers

In this example, Polyspace flags the use of `std` functions, such as `std::find` or `std::count`, with associative containers when the containers have equivalent `find` or `count` methods. Using these `std` functions with containers that do not have equivalent methods is not reported as a defect. For instance,

- Polyspace flags the use of `std::find` with a `set` because `std::set::find` is more efficient.
- Polyspace does not flag the use of `std::find` with a `vector` because the class `vector` has no `find` method.

```
#include <unordered_set>
#include <unordered_map>
#include <forward_list>
#include <array>
#include <set>
#include <map>
#include <vector>
#include <deque>
#include <list>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void lookup()
{
    std::string key;
    std::pair<const K, V> kv;

    std::set<V> s;
    std::multiset<V> ms;
    std::map<K, V> m;
    std::multimap<K, V> mm;
    std::vector<V> v;
    std::list<V> l;
    std::deque<V> d;
    std::string str;
    std::unordered_map<K, V> um;

    std::find(s.begin(), s.end(), key);
    std::equal_range(m.begin(), m.end(), kv);
    std::lower_bound(mm.begin(), mm.end(), kv);
    std::upper_bound(ms.begin(), ms.end(), key);
    std::count(um.begin(), um.end(), kv);
    if(std::binary_search(s.begin(), s.end(), key)==0){
          //....
      }

    std::find(v.begin(),v.end(), key); //Compliant
    std::equal_range(l.begin(),l.end(), key); //Compliant
    std::lower_bound(d.begin(),d.end(), key); //Compliant

}
```

**Correction — Use the Methods of Containers**

To fix this defect, use the methods of a container instead of the `std` functions. For instance, when using a `set`, use `std::set::find` instead of `std::binary_search`. It might be necessary to refactor your code to use the lookup methods of the container.

```
#include <unordered_set>
#include <unordered_map>
#include <forward_list>
#include <array>
#include <set>
#include <map>
#include <vector>
#include <deque>
#include <list>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void lookup()
{
    std::string key;
    std::pair<const K, V> kv;

    std::unordered_map<K, V> um;
    std::set<V> s;
    std::multiset<V> ms;
    std::map<K, V> m;
    std::multimap<K, V> mm;
    std::vector<V> v;
    std::list<V> l;
    std::deque<V> d;
    std::string str;

    s.find(key);
    m.equal_range(key);
    mm.lower_bound(key);
    ms.upper_bound(key);
      if(s.find(key)==s.end()){
          //....
      }
      um.count(key);//Compliant

}
```

### Use of `std::count` to Check Containment

In this example, Polyspace flags the use of `std::count` to check if a container contains a particular member. Using the `find` method of the container or the `std::find` function is more efficient when checking containment.

Using `std::count` to count instances of a member does not cause a defect if the container does not have an equivalent member. For instance, Polyspace does not report a defect when you use `std::count` to check if `v` contains two instances of the string `key`.

```
#include <unordered_set>
#include <unordered_map>
#include <forward_list>
#include <array>
#include <set>
#include <map>
#include <vector>
#include <deque>
#include <list>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void contains()
{
    std::string key;
    std::pair<const K, V> kv;

    std::set<V> s;
    std::multiset<V> ms;
    std::vector<V> v;
    std::unordered_map<K, V> um;

    //Check containment
    bool b_v = std::count(v.begin(), v.end(), key);
    bool b_um = std::count(um.begin(), um.end(), kv);
    bool b_s = std::count(s.begin(), s.end(), key);
    bool b_ms = std::count(ms.begin(), ms.end(), key);
    if(std::count(v.begin(), v.end(), key)==2){ //Compliant
        //...
    }

}
```

#### Correction — Use `find` to Check Containment

To fix these defects, use the `find` method of a container, such as `std::set::find`, to check for containment. When checking containment in a container that does not have a `find` method, use `std::find`.

```
#include <unordered_set>
#include <unordered_map>
#include <forward_list>
#include <array>
#include <set>
#include <map>
#include <vector>
#include <deque>
#include <list>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void contains()
{
    std::string key;
    std::pair<const K, V> kv;

    std::set<V> s;
    std::multiset<V> ms;
    std::vector<V> v;
    std::unordered_map<K, V> um;

    //Check containment
    bool b_v = (std::find(v.begin(), v.end(), key)!=v.end());
    bool b_um = (um.find(key)!=um.end());
    bool b_s = (s.find(key)!=s.end());
    bool b_ms = (ms.find(key)!=ms.end());

}
```

#### Inappropriate Use of `std` Functions with Containers

In this example, Polyspace flags inappropriate uses of `algorithm` functions with container.

- The function `std::is_sorted` returns a known constant when you call the function with a `std::set` object. The function returns an indeterminate value when you call it with an `std::unoerderd_set` object. Because the function call either returns a constant or an indeterminate value, calling `std::is_sorted` on `std::set` or `std::unoerderd_set` is unnecessary. Polyspace flags these usages.

- An `std::set` or `std::map` object cannot contain duplicate elements by definition. Calling `std::adjacent_find` on these types of containers is unnecessary because the call always returns `end()`. Polyspace flags such usage.
- Associative containers have their own `size` methods. Polyspace flags the use of `std::distance` to measure the size of an associative container.

```
#include <unordered_set>
#include <unordered_map>
#include <forward_list>
#include <array>
#include <set>
#include <map>
#include <vector>
#include <deque>
#include <list>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void contains()
{
    std::string key;
    std::pair<const K, V> kv;
    std::map<K, V> m;
    std::set<V> s;
    std::multiset<V> ms;
    std::vector<V> v;
    std::unordered_set< V> us;

    // Expression always returns same value
    bool b1 = std::is_sorted(s.begin(), s.end());

    // Result might be indeterminate
    bool b2 = std::is_sorted(us.begin(), us.end());

    // std::set never has duplicates
    std::adjacent_find(s.begin(), s.end());

    // std::map never has duplicates
    std::adjacent_find(m.begin(), m.end());

    //Inefficient use
    std::distance(s.begin(), s.end());
}
```

### Passing Expensive Functors to `std` Functions

In this example, you pass the functor `ExpensiveLess` to `std::stable_sort`. This function copies the expensive functor, resulting in inefficient code. Polyspace reports a defect.

```
#include <string>
#include <vector>
#include <algorithm>
#include <functional>
```

```
class ExpensiveLess {
public:
    ExpensiveLess() {}

    bool operator()(const std::string &s1, const std::string &s2) const
    {
        return s1 < s2;
    }

    std::vector<std::string> m_list;
};

void foo()
{
    ExpensiveLess f;
    std::vector<std::string> v, v1;

    std::stable_sort(v.begin(), v.end(), f); //Defect
}
```

**Correction — Use `std::reference_wrapper` Object**

To fix this defect, create a `std::reference_wrapper` object `wrapper`. This object contains a reference to an `ExpensiveLess` object. Passing this inexpensive wrapper might improve the efficiency of your code.

```
#include <string>
#include <vector>
#include <algorithm>
#include <functional>

class ExpensiveLess {
public:
    ExpensiveLess() {}

    bool operator()(const std::string &s1, const std::string &s2) const
    {
        return s1 < s2;
    }

    std::vector<std::string> m_list;
};

void foo()
{
    ExpensiveLess f;
    std::reference_wrapper<ExpensiveLess> wrapper(f);
    std::vector<std::string> v, v1;
    std::stable_sort(v.begin(), v.end(), wrapper); //No Defect
}
```

## Result Information

# Expensive use of container's count method

The function member `count()` of a container is used for checking if a key is present, leading to inefficient code

## Description

This defect is raised when the function member `count()` of these containers is called for checking if a key is present:

- `std::multimap`
- `std::multiset`
- `std::unordered_multiset`
- `std::unordered_multimap`

When checking containment, you convert the output of the container's `count()` method to a `bool`, or compare it to either `0` or `1`.

### Risk

The `count` function of the preceding containers performs a linear search and finds all the instances of a key in the container. When checking if a key is present in a container, performing an exhaustive search for every instance of the key is unnecessary and inefficient.

### Fix

To fix this defect, call the member `find` or `contains` function of a container when checking for containment. These functions stop searching for a key as soon as one instance of the key is found. These functions check containment more efficiently compared to the `count` function.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Inefficient Containment Check

```
#include <unordered_set>
#include <unordered_map>
#include <set>
#include <map>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void conatins()
{
    std::string key;
    std::pair<const K, V> kv;

    std::multiset<V> ms;
    std::multimap<K, V> mm;
    std::unordered_multimap<K, V> umm;
    std::unordered_multiset<K> ums;

    //Check containment

    bool b_ms = (ms.count(key)==0);
    bool b_mm = (mm.count(key)==0);
    bool b_ums = (ums.count(key)==0);
    bool b_umm = (umm.count(key)==0);

}
```

In this example, Polyspace flags the use of the member count function to check containment in various containers. These count functions are inefficient because they continue searching for `key` even after the first instance is found.

**Correction**

To fix this defect, use the member find function to check for containment. For instance, use `std::multimap::find` instead of `std::multimap::count`. The find functions are more efficient because they stop searching as soon as the first instance of `key` is found.

```
#include <unordered_set>
#include <unordered_map>
#include <set>
#include <map>
#include <algorithm>
#include <string>

typedef std::string V;
typedef std::string K;

void conatins()
{
    std::string key;
    std::pair<const K, V> kv;

    std::multiset<V> ms;
    std::multimap<K, V> mm;
    std::unordered_multimap<K, V> umm;
    std::unordered_multiset<K> ums;

    //Check containment

    bool b_ms = (ms.find(key)== ms.end());
    bool b_mm = (mm.find(key)== mm.end());
    bool b_ums = (ums.find(key)==ums.end());
    bool b_umm = (umm.find(key)==umm.end());

}
```

## Result Information

# Expensive use of container's insertion method

One of the insertion methods of a container is used to insert a temporary object

## Description

This defect occurs when you use a container's insertion method to insert a temporary object into a container. For instance:

```
std::vector<std::string> v;
v.push_back("foo");//Defect
```

This checker flags use of these methods to insert a temporary object:

- `insert()`
- `push()`
- `push_front()`
- `push_back()`

Most containers from the C++ standard template library implements these insertion methods and are supported by this checker.

### Risk

When you insert a temporary object by using a container's insertion method, the compiler constructs a temporary object, and then moves or copies the object into the container. Because this insertion method requires a move or copy operation in addition to a construction, it is less efficient. Using this method results in inefficient code.

### Fix

Avoid the unnecessary move or copy operation by constructing the object-to-be-inserted in place in the container by using the container's `emplace` methods. Such methods might include `emplace()`, `emplace_front()`, or `emplace_back()`. Because these methods require no copy or move operations, they are more efficient.

When using `emplace` methods, avoid supplying constructor functions manually. It is more efficient to allow the `emplace` methods to construct the object. For instance:

```
std::vector<std::string> v;
v.emplace_back(std::string("foo"));//Compliant but less efficient
v.emplace_back("foo");// Efficient fix
 std::map<int, std::string> m;
m.emplace(std::make_pair(5, "foo"));//Compliant but less efficient
m.emplace(5, "foo");// Efficient fix
```

Using `v.emplace_back(std::string("foo"))` or `m.emplace(std::make_pair(5, "foo"))` does not raise a violation of this checker. But it is more efficient to use `emplace` methods without specifying constructor functions, such as `m.emplace(5, "foo")`.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Inserting Temporary Objects By Using Container's Insertion Method

```
#include <vector>
#include <string>

void addNameToList(std::vector<std::string> &names, const char *pszName)
{
    names.push_back(pszName); //Defect
}
```

In this example, the method `push_back` is used to insert a temporary string into a vector. Using the `push_back` method necessitates constructing a string object, and then moving the object into the vector. The move operation results in inefficient code. Polyspace flags the method `push_back`.

#### Correction — Construct Object In Place

To resolve this defect, construct the object to be inserted in place by using `emplace_back`. This method avoids the unnecessary move operation, resulting in more efficient code.

```
#include <vector>
#include <string>

void addNameToList(std::vector<std::string> &names, const char *pszName)
{
    names.emplace_back(pszName);
}
```

## Result Information

# Expensive use of non-member `std::string operator+()` instead of a simple append

The non-member `std::string operator+()` function is called when the append (or +=) method would have been more efficient

## Description

This defect occurs when you append to a string using the non-member function `std::string operator+()`, for instance:

```
std::string s1;
s1 = s1 + "Other";
```

### Risk

The operation:

```
s1 = s1 + "Other";
```

invokes the non-member function `std::string operator+()` for the string concatenation on the right-hand side of the assignment. The function returns a temporary string, which is then assigned to `s1`.

Directly calling the member function `operator+=()` avoids the creation of this temporary string and is more efficient.

### Fix

To append to a string, use the member function `operator+=()`, for instance:

```
std::string s1;
s1 += "Other";
```

or the member function `append`, for instance:

```
std::string s1;
s1.append("Other");
```

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Appending to String Using `std::string operator+()`

```
#include <string>

void addJunior(std::string &name) {
    name = name + ", Jr.";
}
```

```
void addSenior(std::string &name) {
    name += ", Sr.";
}

void addDoctor(std::string &name) {
    name.append(", MD");
}
```

In this example, the checker flags the string append in the `addJunior` function, but not the ones in the other two functions. If the function `addJunior` is called several times in a loop, creation of a temporary string each time can be a significant performance issue.

### Result Information

# Expensive use of `std::string` method instead of more efficient overload

An `std::string` method is called with a string literal of known length, instead of a single quoted character

## Description

This defect occurs when you invoke certain `std::string` methods with a string literal of known length instead of a single quoted character. When certain `std::string` methods are called with a string literal, the method must compute the length of the literal even though the information is known at compile time. Polyspace flags such calls as inefficient. For instance, Polyspace flags the first two calls to `std::string::find`:

```
std::string str;
//...
str.find("A");//Inefficient
//...
str.find("ABC",offset,1);//Inefficient
str.find('A');//Efficient
```

In the first two calls, the compiler computes the length of the string literal "A" when it is already known before runtime. In the third call, the compiler does not compute the length of the input, making the call more efficient than the first two. Polyspace raises this defect when these `std::string` methods are invoked by using a string literal of known length instead of a single quoted character:

- `find`
- `rfind`
- `find_first_of`
- `find_last_of`
- `find_first_not_of`
- `find_last_not_of`
- `replace`
- `operator=`
- `operator+=`
- `starts_with` (C++20)
- `ends_with` (C++20)

### Risk

In some cases, you can call `std::string` methods with either a string literal or a single quoted character. In these cases, it is inefficient to call the `std::string` methods with string literal because such calls force the compiler to compute the lengths of the string literals, which is already known before runtime. Because `std::string` methods are frequently used, inefficient calls to these methods might result in expensive and inefficient code.

#### Fix

To fix this issue, call the `std::string` methods by using single quoted characters instead of a string literal when appropriate. For instance, you might use a single quoted character as an input instead of a string literal consisting of a single character or a repetition of a single character. You might need to use a different overload of the method that accepts a single quoted character.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Use Single Quoted Characters to Invoke `std::string` Methods

```
#include <string>
#include <set>
constexpr size_t ONE(){ return 1; }
void foo(std::string& str){
    int pos, count;
    str += "A";
    str += "\0";
    str.find("AA", 0, ONE());
    str.find("A");
    str.find_first_of("A");
    str.find_last_of("A");
    str.find_first_not_of("A");
    str.find_last_not_of("A");
    str.replace(0, 1, "A");
    str.rfind("AA", 0,1);
    str.replace(0, count, "AAAAA");
    str.replace(pos, count, "AB", 1);
}
```

In this example, several methods and operators of the `std::string` class are invoked to perform string operations. For these calls, you already know the length of the string literals before program runtime. Because the input is passed as a string object, the compiler performs a linear search to find its length, which is redundant. Polyspace flags such inefficient invocation of string operations.

#### Correction – Use Overloads that Accepts `char` as Input

To fix this issue, use a single quoted character instead of a string literal. For methods such as `replace`, rewrite the function call and use the overload that accepts `char` type variables when the input is a single character.

```
#include <string>
#include <set>
constexpr size_t ONE(){ return 1; }
void foo(std::string& str){
    int pos, count;
    str += 'A';
    str += '\0';
    str.find('A');
    str.find_first_of('A');
    str.find_last_of('A');
    str.find_first_not_of('A');
    str.find_last_not_of('A');
    str.replace(0, 1, 1,'A');//Rewritten call that accepts a single char
    str.rfind('A');
    str.replace(0, count, 5,'A');//Rewritten call that accepts a single char
    str.replace(pos, count, 1,'A');
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** EXPENSIVE_USE_OF_STD_STRING_METHODS
**Impact:** Low

# Expensive use of `std::string` with empty string literal

Use of `std::string` with empty string literal can be replaced by less expensive calls to `std::basic_string` member functions

## Description

In your C/C++ code, the checker flags these operations:

- Constructing an instance of `std::string` by using an empty string literal
- Assigning an empty string literal to an instance of `std::string`
- Comparing an instance of `std::string` to an empty string literal

Usage notes and limitations:

- The checker does not track the origin of `const char` pointer variables that are empty and are eventually used with `std::string`.
- This checker is partially obsolete when you use current compilers. Compilers such as GCC 5.1 and Visual Studio 2015 optimize out construction from an empty string literal and treat it as identical to the default construction.

### Risk

The preceding operations can be replaced by calls to the default constructor and the `empty` and `clear` member functions of the `std::basic_string` class template. Certain compilers might generate additional instructions for the explicit operations compared to the use of the built-in member functions. The use of these operations might reduce the performance of the compiled code.

### Fix

Replace explicit operations involving empty string literals by these calls to the default constructor and member functions of `std::basic_string`.

| Do not Use | Use |
|---|---|
| `std::string s("");` | `std::string s;` |
| `std::string s = "";` | `std::string s;` |
| `s = "";` | `s.clear();` |
| `if (s == "")` | `if (s.empty())` |
| `return "";` | `return {};` |
| `void foo(const std::string& s = "");` | `void foo(const std::string& s = {});`(C++11) or `foo(const std::string &str2 = std::string())` |
| `foo("");` | `foo({})` (C++11) or `foo(std::string())` |
| `Class::Class() : str("") {//...}` | `Class::Class() : str() {//...}` |

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Comparison With Empty String Literal

```
#include <iostream>
#include <string>

void compareString(const std::string &str1, const std::string &str2="")//Noncompliant
{
    if (str1 == "")//Noncompliant
    {
        std::cout << "The string is empty" << std::endl;
    }
    else
    {
        if (str1.compare(str2) != 0)
        std::cout << str1 << " is not " << str2 << '\n';
    }
}

void bar(){
    compareString("String1");
    compareString("String1","");//Noncompliant
}
```

In this example, three string operations are performed by using empty string literals. Polyspace flags these operations as inefficient.

#### Correction — Use Member Functions of `std::string`

To fix the flagged issues, replace string operations with empty string literals with calls to member functions of `std::string`. For instance:

- Replace `const std::string &str2=""` with `const std::string &str2={}`
- Replace `if(str1 == "")` with `if(str1.empty())`
- Replace `compareString("String1","")` with `compareString("String1",{})`

```
#include <iostream>
#include <string>

void compareString(const std::string &str1, const std::string &str2 = {})//Compliant
{
    if (str1.empty())//Cmpliant
    {
        std::cout << "The string is empty" << std::endl;
    }
    else
    {
        if (str1.compare(str2) != 0)
        std::cout << str1 << " is not " << str2 << '\n';
    }
}

void bar(){
    compareString("String1");
    compareString("String1",{});//Compliant
}
```

## Result Information

# Expensive use of string functions from the C standard library

String functions from the C standard library are used inefficiently

## Description

This defect occurs when any of these conditions are true:

- You use `strcmp()` or `strlen()` to check if a C-string is empty.
- You use `strcpy()` to clear an existing C- string.

### Risk

When determining if a C-string is empty, it is not efficient to compare its length to zero by using `strlen()` or compare the C-string to an empty string (`""`) by using `strcmp()`. The function `strlen()` checks the entire C-string until it finds a null, which is inefficient when checking if a C-string is empty. Invoking these functions to check for empty C-strings is inefficient and might result in unnecessary function call overhead.

Similarly, using `strcpy()` to clear a C-string is unnecessary.

### Fix

To fix this defect:

- When checking if a C-string is empty, avoid using `strcmp()` or `strlen()`. Instead, compare the first character of the C-string to `'\0'`.
- When clearing a C-string, avoid using `strcpy()`. Instead, assign the `'\0'` character to the C-string.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Using `strcmp()` or `strlen()` to Check for Empty C-String

```
#include <cstring>

int isEmpty(const char* pszName)
{
   return strcmp(pszName, "") == 0; //Defect
}

int isEmpty2(const char* pszName)
{
   return strlen(pszName) == 0;  //Defect
}
```

In this example, Polyspace flags the use of string functions `strcmp()` and `strlen()` to check for empty C- strings. Checking for empty C-strings is not the intended use of these functions. Such use of these functions results in inefficient and unnecessarily complex code.

#### Correction — Check for Empty C-String by Comparing First Character to `'\0'`

Instead of using the string functions, it is more efficient to check for empty C-strings by comparing the first character of the string to null or `'\0'`. This method reduces the function overhead and makes the code more efficient.

```
#include <cstring>

int isEmpty(const char* pszName)
{
   return *pszName == 0;
}
```

### Avoid Clearing C-Strings by Using `strcpy()`

```
#include <string.h>

void foo(void){
    char* str;
    //...
    strcpy(str,"");
    //...
}
```

In this example, a C-string is cleared by copying an empty string into it. Calling `strcpy` to clear a C-string is unnecessary and makes the code inefficient.

#### Correction

To clear a C-string, assign null or `'\0'` to the string.

```
#include <string.h>

void foo(void){
    char* str;
    //...
    *str = '\0';
    //...
}
```

## Result Information

**Group:** Performance  
**Language:**C | C++  
**Default:** Off  
**Command-Line Syntax:** `EXPENSIVE_USE_OF_C_STRING_API`  
**Impact:** Low

# Version History

# Expensive use of substr() to shorten a std::string

The method std::string::substr() is called to shorten an std::string object

## Description

This defect occurs when you call std::string::substr() to shorten an std::string up to the n^th character:

```
std::string str;
str = str.substr(0, n); ;//Defect
```

### Risk

When you call std::string::substr() to shorten or truncate a string, the compiler first constructs a temporary string containing the smaller substring, and then assigns the temporary string object to the original string. Shortening a string by calling std::string::substr() requires constructing a temporary string, which is unnecessary. This method results in inefficient code.

### Fix

Instead of calling std::string::substr(), use std::string::resize() to shorten a string. When you shorten strings by using the method std::string::resize(), the end of the string is moved to the location that you want without requiring any additional construction. The method std::string::resize() is more efficient than std::string::substr() for shortening strings.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Using std::string::substr() to Shorten Strings

```
#include<string>
void shortenString(std::string& str, size_t pos){
    str = str.substr(0, pos);//Defect
}
```

In this example, the substr() method is called to shorten the string str. This method creates a temporary string object containing the first pos characters of str, and then overwrites str with the temporary string. This method of shortening a string object is inefficient and Polyspace flags it.

#### Correction — Use std::string::resize()

To resolve this defect, use the resize() method to shorten the string. This method does not create any new string objects and is more efficient.

```
#include<string>
void shortenString(std::string& str, size_t pos)
{
    if (pos < str.size()) {
        str.resize(pos);
    }
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_STD_STRING_RESIZE`
**Impact:** Low

# Version History

# Inefficient string length computation

String length calculated by using string length functions on return from `std::basic_string::c_str()` instead of using `std::basic_string::length()`

## Description

This defect occurs when the length of a `std::basic_string` string is calculated by using string length functions on the pointer returned from `std::basic_string::c_str()` instead of using the method `std::basic_string::length()`.

The checker flags string length functions such as `strlen`, `wcslen` and `char_traits::length`.

### Risk

`std::basic_string::c_str()` returns a pointer to a null-terminated character array that stores the same data as the data stored in the string. Using a string length function such as `strlen` on this character array is expected to return the string length. This approach might seem superficially equivalent to using the `std::basic_string::length()` method for the string length.

However, the function `strlen(str)` is of linear complexity O(N) where N is the length of string `str`. If `str` is of type `std::basic_string`, this complexity is unnecessary since calling the `std::basic_string::length()` method returns the length more efficiently (with complexity O(1)).

### Fix

If a string is of type `std::basic_string`, to get the string length, instead of using string length functions such as `strlen`, for instance:

```
std::string s;
auto len = strlen(s.ctr());
```

use the `std::basic_string::length()` method, for instance:

```
std::string s;
auto len = s.length();
```

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Result Information

**Group:** Performance<br>
**Language:** C++<br>
**Default:** Off<br>
**Command-Line Syntax:** `INEFFICIENT_BASIC_STRING_LENGTH`<br>
**Impact:** Medium

# Inefficient use of for loop

Range-based for loop can perform equivalent iteration more efficiently

## Description

This defect occurs when you use `for` loops that loop through all elements of a container or a C-style array and both of these conditions are true:

- The `for` loop has only one loop counter variable. For instance, Polyspace does not flag this `for` loop:

  ```
  for(int i=0, j=0; i < 10; ++i, ++j){
  //...
  }
  ```
- The `for` loop uses the loop counter variable to access only the elements of the container or the C-style array. For instance, in this code snippet, Polyspace flags the first loop but not the second one.

  ```
  #include <iostream>

  int myArray[10]

  void cArray()
  {
      //First loop: Loop counter used only to access elements of myArray
      for (int i = 0; i < 10; ++i) {
          myArray[i] = 0;
      }

      //Second loop: Loop counter assigned to elements of myArray
      for (int i = 0; i < 10; ++i) {
          myArray[i] = i;
      }

  }
  ```

Polyspace does not raise an **Inefficient use of for loop** defect in these scenarios:

- You iterate through a user-defined container. For instance, this `for` loop is compliant.

  ```
  template<typename T>
  class customContainer {
    typedef T* iterator;
    public:
      iterator begin();
      iterator end();
  };

  void func() {
    customContainer<int> myContainer;

    for(auto it = myContainer.begin(); it != myContainer.end(); it++) {
      std::cout << *it;
  ```

```
  }
}
```

Polyspace raises a defect only for C-style arrays and Standard Template Library containers.

- You use reverse iterators to loop through the elements of the C-style array or container. For instance, in this code snippet, there is no defect because you cannot use a range-based `for` loop to perform an equivalent operation.

```
#include <iostream>
#include <vector>
#include <cstdint>

std::vector<std::uint32_t> myVector(10);

void myContainer()
{
    //loop uses reverse iteration
    for (auto it = myVector.rbegin(); it != myVector.rend(); ++it) {

        std::cout << *it;
    }
}
```

- If you loop through arrays:

  - You loop through the elements of multiple arrays or you loop through the elements of a multidimensional array.
  - The array size is unknown.

For instance, Polyspace does not flag these `for` loops:

```
int myArray[10];
int myOtherArray[10];
int multiArray[10][10];

void cArray()
{
    //loop through multiple array
    for (int i = 0; i < 10; ++i) {
        myArray[i] = 0;
        myOtherArray[i] = 0;
    }
    //loop through 2-dimensional array
    for (int i = 0; i < 10; ++i) {
        multiArray[i][i] = 0;
    }

}

void unknownSize(int someArray[])
{
    //loop through array of unknown size
    for (int i = 0; i < 10; ++i) {
        someArray[i] = 0;
    }
}
```

#### Risk

If you loop through all the elements of a container or a C-style array and you use the loop counter variable to access only the value of the elements, a `for` loop is slower, less readable, and more difficult to maintain than an equivalent range-based `for` loop.

#### Fix

Replace the `for` loop with a range-based `for` loop, which makes your code run more efficiently, more readable, and easier to maintain.

## Examples

### Inefficient Use of a `for` Loop

```
#include <iostream>
#include <vector>
#include <cstdint>

std::vector<std::uint32_t> myVector(10);

void myContainer()
{
    for (auto it = myVector.begin(); it != myVector.end(); ++it) {
        std::cout << *it;
    }
}
```

In this example, Polyspace flags the `for` loop, which iterates through all the elements of vector `myVector` and uses the loop counter `it` to only print the value of each element. To run this example, specify C++ version as `cpp11`.

#### Correction — Use a Range-Based `for` Loop Instead

One possible correction is to use a range-based `for` loop to perform an equivalent operation. The range-based `for` loop uses less code and makes your code run more efficiently, more readable, and easier to maintain

```
#include <iostream>
#include <vector>
#include <cstdint>

std::vector<std::uint32_t> myVector(10);

void myContainer()
{
    for (auto it : myVector) {
        std::cout << it;
    }
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `PREFER_RANGE_BASED_FOR_LOOPS`
**Impact:** Low

`Find defects (-checkers)`

# Inefficient use of sprintf

The function sprintf, snprintf, or swprintf copies strings instead of the more efficient strcpy, strncopy, or wcsncpy

## Description

This checker is triggered when you use sprintf, snprintf, or swprintf to copy strings.

### Risk

The functions sprintf, snprintf, or swprintf are complex function with a variable argument list. Before executing these functions, the compiler parses the argument list to determine the argument types, which adds overhead to the code. Handling the different input formats that these functions support makes the function difficult to optimize. For instance, even if you want to copy only strings by using sprintf, the function must still support copying integers. Using these functions for copying strings make your code inefficient.

### Fix

To fix this defect, refactor your code and use dedicated functions such as strcpy, strcat, strncopy, wcsncpy or their variants to copy strings.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Inefficient Copying of C-Style Strings

```
#include <string.h>
#include <stdio.h>
#include <stddef.h>

void foo(char* p1, const char* p2, const char* p3, size_t N){
    //...
    sprintf(p1, "%s", p2); //Defect
    sprintf(p1, "%s", "String");//Defect
    sprintf(p1, "NoFormatting"); //Defect
    sprintf(p1, ""); //Defect
    sprintf(p1, "%s%s", p2, p3);//Defect
    snprintf(p1, N, "%s", p2); //Defect
    snprintf(p1, N, p2);//Defect
}

void foo_w(wchar_t* w1, const wchar_t* w2, size_t N){
    swprintf(w1, N, L"%s", w2); //Defect
    swprintf(w1, N, w2);  //Defect
}
```

```
void bar(char* p1, const char* p2, const char* p3){
    sprintf(p1, "%d", 5);//No Defect
    sprintf(p1, "%s%d", "String", 123);//No Defect
    int n = sprintf(p1, "%s", p2);//No Defect
}
```

In this example, the C strings `p2` and `p3` are copied into `p1` by calling `sprintf` and `snprintf`. Polyspace flags these inefficient copying. In the function, `foo_w`, the wide string `w2` is copied into `w1` by calling `swprintf`. Polyspace flags the inefficient copying. In the function `bar`, `sprintf` is called for formatting strings. When you use `sprintf` for formatting strings or use the return value of the function, Polyspace does not flag the call as inefficient.

#### Correction

To fix this defect, use dedicated string copying functions such as `strcpy`, `strncopy`, or `wcsncpy`.

```
#include <string.h>
#include <stdio.h>
#include <stddef.h>

void foo(char* p1, const char* p2, const char* p3, size_t N){
    //...
    strcpy(p1, p2); //Compliant
    strcpy(p1, "String");//Compliant
    strcpy(p1, "NoFormatting"); //Compliant
    *p1 = '\0';//Compliant
    strcpy(p1, p2); //Compliant
    strcat(p1, p3);//Compliant
    strncpy(p1, p2, N);//Compliant

}

void foo_w(wchar_t* w1, const wchar_t* w2, size_t N){
    wcsncpy(w1, w2, N);//Compliant
}
```

# Missing constexpr specifier

constexpr specifier can be used on variable or function for compile-time evaluation

## Description

This defect identifies potential constexpr variables and functions. For instance, the defect occurs if:

- You omit the constexpr specifier when a variable is initialized by using an expression that can be evaluated at compile time.

  The defect checker flags a local variable definition without the constexpr specifier if the variable is initialized with one of the following and not modified subsequently in the code:

  - An expression involving compile-time constants only.
  - Calls to a function with compile-time constants as parameters, provided the function is itself constexpr or the function contains only a return statement involving its parameters.
  - A constructor call with a compile-time constant, provided all member functions of the class including the constructor are themselves constexpr.

  The checker does not flag local, static variables.
- You omit the constexpr specifier from functions with a single return statement that could potentially be evaluated at compile time (given compile-time constants as arguments).

### Risk

If a variable value is computed from an expression that involves compile-time constants only, using constexpr before the variable definition, like this:

```
constexpr double eValSquared = 2.718*2.718;
```

ensures that the expression is evaluated at compile time. The compile-time evaluation saves on run-time overheads. Sometimes, the performance gains at run time can be significant.

If the expression cannot be evaluated at compile time, the constexpr keyword ensures that you get a compilation error. You can then fix the underlying issue if possible.

Note that the const keyword does not guarantee compile-time evaluation. The const keyword simply forbids direct modification of the variable value after initialization. Depending on how the variable is initialized, the initialization can happen at compile time or run time.

### Fix

Add the constexpr specifier to the variable or function definition.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Potential constexpr Variables and Functions

```
double squareIfPositive(double val) {
    return val > 0? (val * val): 0;
}

void initialize(void) {
    double eVal = 2.718;
    double eValSquare = squareIfPositive(2.718);
}
```

In this example, the checker flags the definition of squareIfPositive because the function contains a single return statement involving only its parameter val. Therefore, if val is a compile-time constant, the function can be evaluated at compile-time and can be a constexpr function.

The checker also flags the definition of eValSquare because it is initialized with a potentially constexpr function that takes a compile-time constant as argument.

#### Correction – Add constexpr Specifier

Add constexpr specifiers to the variable and function definitions.

```
constexpr double squareIfPositive(double val) {
    return val > 0? (val * val): 0;
}

void initialize(void) {
    constexpr double eVal = 2.718;
    constexpr double eValSquare = squareIfPositive(2.718);
}
```

## Result Information

# Move operation uses copy

A move constructor or move assignment operator uses copy operations on base classes or data members

## Description

This defect is raised if all of these conditions are true:

- A move constructor or a move assignment operator of a class copies a base class or data member.
- Move operations for the base class or data members are available.
- The base class or data members are more expensive to copy than to move.

For instance, in this code the move constructor copies the data member `data`. Polyspace flags the copy operation.

```
class wrapper{
    //...
    wrapper(wrapper&& rhs): data(rhs.data){
        //...
    }

    private:
    std::string data;
}
```

### Risk

Developers often assume that move operations are cheaper than copy operations. They use move operations when dealing with large resources that are expensive to copy. Inadvertently omitting calls to `std::move` might cause a move constructor or a move assignment operator to copy data members and base classes, making the code inefficient. Because such unexpected move operations compile and run correctly, the inefficiency inducing omission of `std::move` might be difficult to detect.

### Fix

To fix this defect, use `std::move` to move base classes and data members of a class. As a best practice, use the default implicit move constructor and move assignment operator by setting them as `=default`. Instead of managing raw resources, use smart containers to enable the default move operations to move the resources correctly.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Copying Base Classes and Data Members in Move Operations

```
#include <memory>
#include <string>
```

```
#include <utility>

class ManagerInterface;
// ...
class UtilInterface
{
public:
    // ...
    UtilInterface( UtilInterface&& other )
      : m_name( other.m_name ),
        m_manager( other.m_manager )
    {/**/}
    UtilInterface& operator=( UtilInterface&& other )
    {
        m_name = other.m_name;
        m_manager = other.m_manager;
        return *this;
    }
    // ...
private:
    // ...
    std::string m_name;
    std::shared_ptr< ManagerInterface > m_manager;
    // ...
};
```

In this example, the move operations of the class `UtilInterface` copy the data member instead of moving them by using `std::move`. Polyspace flags the unexpected copy operations.

**Correction**

To fix the defect, use `std::move` to move the data members.

```
#include <memory>
#include <string>
#include <utility>

class ManagerInterface;
// ...
class UtilInterface
{
public:
    // ...
    UtilInterface( UtilInterface&& other )
      : m_name( std::move(other.m_name) ),
        m_manager( std::move(other.m_manager) )
    {}
    UtilInterface& operator=( UtilInterface&& other )
    {
        m_name = std::move(other.m_name);
        m_manager = std::move(other.m_manager);
        return *this;
    }
    // ...
private:
    // ...
    std::string m_name;
    std::shared_ptr< ManagerInterface > m_manager;
    // ...
};
```

#### Correction

Another method of fixing this defect is to declare the move assignment operator and the move constructor as `=default`.

```
#include <memory>
#include <string>
#include <utility>

class ManagerInterface;
// ...
class UtilInterface
{
public:
    // ...
    UtilInterface( UtilInterface&& other ) = default;//Compliant
    UtilInterface& operator=( UtilInterface&& other ) = default;//Compliant
    // ...
private:
    // ...
    std::string m_name;
    std::shared_ptr< ManagerInterface > m_manager;
    // ...
};
```

## Result Information

# `std::endl` may cause an unnecessary flush

`std::endl` is used instead of the more efficient `\n`

## Description

This defect flags uses of `std::endl` in I/O operations and allows you to use the more efficient alternative, `\n`.

### Risk

`std::endl` inserts a newline (`\n`) followed by a flush operation. For instance:

```
std::cout << "Some content" << std::endl;
```

is equivalent to:

```
std::cout << "Some content" << '\n' << std::flush;
```

The implicit flush operation might not be necessary or intended. If your program has many I/O operations that use `std::endl`, the implicit flush operation can significantly reduce program performance. Since the flush operation is implicit, in case of a performance issue, it will be difficult to track the root cause of the issue.

### Fix

Use `\n` to enter a newline wherever possible.

If you require a flush operation, instead of `std::endl`, use `\n` followed by an explicit flush operation, for instance:

```
std::cout << "Some content" << '\n' << std::flush;
```

In this case, the analysis considers your use of a flush operation as deliberate and does not flag the use.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Possible Performance Impact from `std::endl` Use

```
#include <fstream>
using namespace std;

int main()
{
  ofstream aFile("file.txt");
  for ( int i = 0; i < 100000; i++) {
    aFile << "Hello World " << std::endl ;
  }
  aFile.close();
  return 0;
}
```

In this example, an `std::endl` is used in a loop during a write operation on a file. Since the loop has 100000 iterations, the slight delay from each implicit flush operation can add up to a significant reduction of performance.

#### Use \n and Avoid Flush

In a loop with several iterations, avoid the performance reduction in I/O operations by using `\n` instead of `std::endl`.

```
#include <fstream>
using namespace std;

int main()
{
  ofstream aFile("file.txt");
  for ( int i = 0; i < 100000; i++) {
    aFile << "Hello World \n" ;
  }
  aFile.close();
  return 0;
}
```

### Result Information

**Group:** Performance

# std::move called on an unmovable type

std::move used on a class type with no move constructor or move assignment operator

## Description

This defect occurs when you use std::move to move an object of a class type that does not have a move constructor or move assignment operator.

### Risk

The use of std::move in statements such as:

```
Obj objTo {std::move(objFrom)};
objTo = std::move(objFrom);
```

indicates that you want to benefit from the performance gains of a move operation. However, because of the missing move constructor or move assignment operator, a copy operation happens instead.

If the class is expensive to copy, the unintended copy operation can cause a loss of performance.

### Fix

To make an object of type T movable, add a move constructor:

```
T (T&&);
```

and move assignment operator:

```
T& operator=(T&&);
```

to the class T. If the class does not have to directly manage a resource, you can use compiler-generated move operators using the =default syntax, for instance:

```
T (T&&) = default;
```

Otherwise, if a move operation is not required, remove the std::move call and directly copy the object.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### std::move Used with Unmovable Types

```
#include <utility>
#include <string>

class stringPair {
    std::string str1;
    std::string str2;
    public:
        stringPair(const stringPair & aPair); //Copy constructor
        stringPair& operator=(const stringPair & aPair);  //Copy assignment operator
};

void exchangePairs (stringPair& first, stringPair& second) {
    stringPair tempPair {std::move(first)};
    first = std::move(second);
    second = std::move(tempPair);
}
```

In this example, the type `stringPair` does not have a move constructor or move assignment operator. Uses of `std::move` on objects of this type result in copy operations instead.

**Correction – Add Move Constructor and Move Assignment Operator**

Make the type `stringPair` movable by adding a move constructor or move assignment operator.

```
#include <utility>
#include <string>

class stringPair {
    std::string str1;
    std::string str2;

    public:
        stringPair(const stringPair & aPair); //Copy constructor
        stringPair(stringPair && aPair) noexcept; //Move constructor
        stringPair& operator=(const stringPair & aPair);  //Copy assignment operator
        stringPair& operator=(stringPair && aPair) noexcept; //Move assignment operator
};

void exchangePairs (stringPair& first, stringPair& second) {
    stringPair tempPair {std::move(first)};
    first = std::move(second);
    second = std::move(tempPair);
}
```

**Correction -- Remove `std::move` call**

If you do not want to make the type `stringPair` movable, omit the `std::move` calls.

```
#include <utility>
#include <string>

class stringPair {
    std::string str1;
    std::string str2;

    public:
        stringPair(const stringPair & aPair); //Copy constructor
        stringPair& operator=(const stringPair & aPair);  //Copy assignment operator
};

void exchangePairs (stringPair& first, stringPair& second) {
    stringPair tempPair {first};
    first = second;
    second = tempPair;
}
```

### Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `STD_MOVE_UNMOVABLE_TYPE`
**Impact:** Medium

# Unnecessary padding

Members of a `struct` are padded to fulfill alignment requirement when rearranging the members to fulfill this requirement saves memory

## Description

This checker flags a `struct` object where the arrangement of its members necessitates additional padding to fulfill alignment requirement. Rearranging the members of such a `struct` object might fulfill the alignment requirement without requiring any additional padding. Because the padding is unnecessary for alignment purposes, eliminating the padding saves memory. Consider this `struct` in a 64bit system:

```
struct A {
     uint32_t m1;// 4 bytes
     uint64_t m2;// 8 bytes
     uint32_t m3;// 4 bytes
 };
```

To maximize speed, C/C++ requires that a variable be read in one cycle if possible. In this system, 8 bytes can be read during one cycle. If `m1` and `m2` are placed consecutively, the machine requires two cycles to read `m2`. Instead, the variable `m1` is placed in a 8 byte slot by itself after padding it by 4 bytes. Then `m2` is placed in its own 8 byte slot. The variable `m3` is also padded to fulfill alignment requirement for the `struct A`. Because of the padding, the size of `A` is 24 bytes even though the combined size of `m1`, `m2`, and `m3` is 16.

Polyspace raises this defect when alignment requirement can be fulfilled by rearranging the members of a `struct`. For instance, rearranging the members of `A` can eliminate padding:

```
struct A {
     uint64_t m2;// 8 bytes
     uint32_t m1;// 4 bytes
     uint32_t m3;// 4 bytes
 };
```

Here, `m2` is placed first in a 8 byte slot. Then `m1` and `m3` are placed together in another 8 byte slot. This rearrangement eliminates the padding.

### Risk

Unnecessary padding wastes memory, which can have several adverse impacts:

- Using more memory than necessary might exhaust the available memory, resulting in paging fault.
- Functions such as `memcpy` and `memcmp` might take longer.

### Fix

To fix this defect, rearrange the members of the `struct` to eliminate the unnecessary padding. Declare the largest `struct` members first, and then keep the declarations of same-sized members together. You might also use `pragma` directives to eliminate padding.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Unnecessary Padding in C-Style `struct`

```
#include <stdint.h>
struct GlobalStructA {
    uint32_t m1;
    uint64_t m2;
    uint32_t m3;
};

// Using pragma pack to eliminate padding
//
#pragma pack(push, 1)
struct GlobalStructPragmaPack {
    uint8_t  m1;
    uint64_t m2;
    uint8_t  m3;
};
#pragma pack(pop)
struct Array
{
    uint8_t  m1[5];
    uint64_t m2;
    uint8_t  m3[3];
};
struct StructWithBitField
{
    uint8_t  m1 : 1;
    uint8_t     : 1;
    uint8_t     : 1;
    uint8_t  m2 : 1;

    uint64_t m3;

    uint8_t  m4 : 1;
    uint8_t     : 1;
    uint8_t     : 1;
    uint8_t  m5 : 1;
};
```

In this example, Polyspace flags C style `struct` objects that contain unnecessary padding. Polyspace assumes that the processor has a 32-bit word length by default. Use the option `-target x86_64` to run this example.

- Because the 32-bit variable `m1` is declared first in the `GlobalStructA` object, it is padded to 64 bit. Polyspace flags the object because the padding can be eliminated by declaring `m1` after `m2`.
- The object `GlobalStructPragmaPack` has a similar issue with the order of its member declaration, but the padding is eliminated by a `pragma` directive. Polyspace does not flag this object.

- In the object Array, because m1[5] is declared before m2, the 40-bit array is padded to 64 bit. The 24-bit array m3 is padded to 64 bit. These paddings can be eliminated by declaring m2 first. Because Array contains unnecessary padding, Polyspace flags the object.
- In the object StructWithBitField, there are two bit-fields, each consisting of 4 bits. Because m3 is declared between these two bitfields, they are padded. Polyspace flags the object.

#### Correction

To fix this defect, change the order of the declaration to eliminate padding. For instance:

```
#include <stdint.h>
struct GlobalStructA {
    uint64_t m2;
    uint32_t m1;
    uint32_t m3;
};

// Using pragma pack to eliminate padding
//
#pragma pack(push, 1)
struct GlobalStructPragmaPack {
    uint64_t m2;
    uint8_t  m1;
    uint8_t  m3;
};
#pragma pack(pop)
struct Array
{
    uint64_t m2;
    uint8_t  m1[5];
    uint8_t  m3[3];
};
struct StructWithBitField
{
    uint64_t m3;

    uint8_t  m1 : 1;
    uint8_t     : 1;
    uint8_t     : 1;
    uint8_t  m2 : 1;

    uint8_t  m4 : 1;
    uint8_t     : 1;
    uint8_t     : 1;
    uint8_t  m5 : 1;
};
```

### Unnecessary Padding in class

```
#include <string>
#include<stdint.h>
class GlobalClassWithString {
    uint32_t    m1;
    std::string m2;
    uint32_t    m3;
};
class GlobalClassC {
  public:
    uint32_t m1;
  protected:
    uint64_t m2;
  private:
    uint32_t m3;
};
```

Polyspace assumes that the processor has a 32-bit word length by default. Use the option `-target x86_64` to run this example. Because of the order in which the members of the preceding classes are declared, the classes contain unnecessary padding. Polyspace flags these classes. The `public`, `private`, or `protected` labels of the members do not impact how they are organized in the memory.

#### Correction

To fix this defect, change the order of the declaration to eliminate padding. For instance:

```
#include <string>
#include<stdint.h>
class GlobalClassWithString{
    std::string m2;
    uint32_t    m1;
    uint32_t    m3;
};
class GlobalClassC {
  protected:
    uint64_t m2;
  public:
    uint32_t m1;
  private:
    uint32_t m3;
};
```

### Unnecessary Padding in 16-Bit Processor

```
#include <stdint.h>
struct SmallPadding {     //Defect in 16-bit, no defect in 32-bit
    uint8_t m1;
    uint8_t m2;
    uint8_t m3;
    uint8_t m4;
    uint8_t m5;
    uint8_t m6;
    uint8_t m7;
    uint32_t m8;
    uint8_t m9;
    uint8_t m10;
    uint8_t m11;
    uint8_t m12;
    uint8_t m13;
    uint8_t m14;
    uint8_t m15;
};
```

This example shows the sensitivity of this checker to the processor word length. In the object `SmallPadding`, there are 16 bits of padding, which is small compared to the total size of the `struct`. When the processor word length is large, the small padding is unlikely to cause inefficiency. For instance, reading `SmallPadding` requires three cycles regardless of the padding if the processor has a 64-bit alignment. Polyspace does not flag the object in this case. When the processor word length is smaller, the padding can lead to inefficiency. For instance, if the processor alignment is 16 bit, the added padding might cause inefficiency in reading the object. Polyspace flags `SmallPadding` in this case. To set the alignment of processor to 16 bit in a Polyspace analysis, use the options `-target mcpu -align 16`. See Generic target options on page 2-45.

# Unnecessary use of std::string::c_str() or equivalent string methods

Instead of a std::string object, a string operation uses the C-string obtained from std::string functions including std::string::c_str, std::string::data(), std::string::at(), or std::string::operator[], resulting in inefficient code

## Description

This defect occurs when a string operation is performed by using a C-string pointer obtained from string functions such as std::string::c_str, std::string::data(), std::string::at(), and std::string::operator[]. For instance, this checker is raised when:

- A new std::string or std::wstring is implicitly or explicitly constructed from the C-string obtained from a string function. This situation arises when a function expecting a const reference to the string encounters a const char* instead.
- A new copy of a string object is created explicitly from the C-string obtained from a string function. Using the copy constructor is the more efficient way of copying the string object.
- Certain std::string member functions are invoked by using the C-string obtained from a string function. Flagged functions include replace, append, assign, compare, and find. Using an std::string object directly to invoke std::string member functions is more efficient.
- A user-defined function that is overloaded to accept either of the const char* or const std::string arguments is invoked by using a C-string pointer. It is more efficient to invoke the std::string overload of such a function. When a function is overloaded in this way, calling the const char* overload from the body of the const std::string overload by using the C-string pointer does not raise the defect.

### Risk

It is expensive and inefficient to use the C-string output of a std::string function when you can use an std::string object instead. An std::string object contains the length of the string. When you use a C-string instead of an std::string object, the constructor determines the length of the C-string by a linear search, resulting in inefficient code. Using the C-string is also often unnecessary. Consider this code:

```
void set_prop1(const char* str);
void set_prop2(const std::string& str);
void foo( std::string& str){
    //...
    set_prop1(str.c_str()); // Necessary
    //...
    set_prop2(str.c_str()); // Inefficient
}
```

The function foo calls two different functions. Because the function set_prop1 requires a C-string as the input, using the str.c_str function is necessary to form the input to set_prop1. The function set_prop2 takes an std::string as an input. Instead of directly using str as an input to set_prop2, str.c_str is used, perhaps as a copy-paste mistake. The compiler implicitly constructs a new std::string object, which is identical to str, by using the output of str.c_str. Constructing a new std::string object in this case is unnecessary and inefficient. Because this code compiles and functions correctly, this inefficient code might not be noticed.

### Fix

To fix this defect, eliminate calls to std::string functions that produce a C-sting. Use std::string instead. Choose appropriate function overloads when you use a string object instead of a C-string. Consider this code:

```
void set_prop1(const char* str);
void set_prop2(const std::string& str);
void foo( std::string& input){
    //...
    set_prop1(str.c_str()); // Necessary
    //...
    set_prop2(str); // Efficient
}
```

Using str instead of str.c_str as input to set_prop2 makes the code more efficient and fixes the defect.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Implicit Construction of std::string Objects by Using C-String

```
#include <string>
#include <utility>

class A
{
public:
    A( char const* );
    char const* c_str() const;
};
void CppLibFuncA(const std::string&);
void CppLibFuncB(std::string &&);
void bar( A const& );
std::string make_string();
bool contains( std::string const& str1, std::string const& str2 )
{
    return str1.find( str2.data() ) == std::string::npos;
}

void foo(const std::string& s, std::string&& rs, A& other){
    CppLibFuncA( s.data() );
    CppLibFuncB( std::move( rs ).c_str() );
    CppLibFuncA( make_string().data() );
    bar( other.c_str() );
    if(contains(s,make_string())){
        //...
    }

}
```

In this example, Polyspace flags the implicit construction of a `string` object by using a C-string that is obtained from a `string` function.

- The function `CppLibFuncA` takes a `const std::string&` as input. When the function `CppLibFunc` is called by using `s.data()`, the compiler cannot pass a reference to the object `s` to the function. Instead, the compiler implicitly constructs a new `std::string` object from the C-string pointer and passes the new object to the function,which is inefficient. Polyspace flags the call to `std::string::data`.
- Because calling `CppLibFuncB` by using the output of `std::string::c_str` also implicitly constructs a new `str::string` object, Polyspace flags the call to `std::string::c_str`.
- A call to the function `bar` is not flagged because a `const char*` is not implicitly converted to a new `std::string` object.
- In the function `contain`, Polyspace flags the call to `std::string::find()`, where the output of `std::string::data` is used instead of an `std::string` object.

#### Correction

To fix this issue, avoid implicit construction of new `std::string` objects from the outputs of the `std::string::c_str` or `std::string::data` functions. Use the existing `std::string` objects instead.

```
#include <string>
#include <utility>
void CppLibFuncA(std::string const &);
void CppLibFuncB(std::string &&);
std::string make_string();
bool contains( std::string const& str1, std::string const& str2 )
{
    return str1.find( str2 ) == std::string::npos;
}
void foo(std::string const & s, std::string&& rs){
    CppLibFuncA( s );
    CppLibFuncB( std::move( rs ) );
    CppLibFuncA( make_string());
    if(contains(s,make_string())){
        //...
    }
}
```

Fix calls to the functions `CppLibFunc`, `CppLibFuncB`, and `CppLibFuncC` by using the existing `std::string` objects as input.

### Explicit Construction of `std::string` Objects by Using C-String

```
#include <string>
#include <utility>
std::string make_string(void);
void bar(const std::string& s){
    std::string s1 = s.c_str(); // Inefficient
    std::string s2 = make_string();
    s2.append(s1.data());
}
```

In this example, Polyspace flags the explicit use of a C-string when:

- The std::string object s is copied to s1 by calling s.c_str().
- The std::string object s1 is appended calling s1.data().

.

#### Correction

To fix this issue, avoid using a C-string when you can use an std::string object.

```
#include <string>
#include <string>
#include <utility>
std::string make_string(void);
void bar(const std::string& s){
    std::string s1 = s; // Efficient
    std::string s2 = make_string();
    s2.append(s1);
}
```

### Invoking std::string Member Functions by Using C-String

```
#include <string>
#include <utility>
std::string make_string(void);
void bar2( std::string& s1){
    std::string s2 = make_string();
    s1.replace(1, 1, &s2[0]);
    s1.replace(s1.begin(), s1.end(), &s2.at(0));
    s1.append(s2.c_str());
    s1.assign(s2.data());
    s1.compare(s2.data());
    const char* p = s2.c_str();
    s1.find(p);
}
```

In this example, Polyspace flags the explicit use of a C-string to invoke member functions of the std::string class.

#### Correction

To fix this issue, avoid using C-strings when you can use an std::string object instead.

```
#include <string>
#include <string>
#include <utility>
std::string make_string(void);
void bar( std::string& s1){
    std::string s2 = make_string();
    s1.replace(1, 1, s2);
    s1.replace(s1.begin(), s1.end(), s2);
    s1.append(s2);
    s1.assign(s2);
    s1.compare(s2);
    s1.find(s2);
}
```

#### Invoking User-Defined Functions by Using C-String

```
#include <string>
#include <utility>
void userDefined(const char* p){
    //...
}
void userDefined(const std::string& s){
    //...
    userDefined(s.c_str());//Compliant
    //userDefined(s);//Infinite recursion
}
void bar( const std::string& s){
    const char* p = s.data();
    userDefined(p);
    userDefined(s.c_str());
}
```

In this example, the user-defined function `userDefined` is overloaded to accept either a `const char*` or a `const std::string` parameter. Polyspace flags the use of a C-string instead of an `std::string` object to call the function. Polyspace does not flag calls to `std::string::c_str` or `std::string::data` when they are used for calling the `const char*` overload of `userDefined` from the body of the `std::string` overload of `userDefined`. In this case, using `std::string` instead of a C-string results in an unintended infinite recursion.

##### Correction

To fix this issue, avoid using C-strings when you can use an `std::string` object instead.

```
#include <string>
#include <string>
#include <utility>
extern void userDefined(const char *);
extern void userDefined(const std::string &);
void bar( const std::string& s){
    userDefined(s);
}
```

## Result Information

# Use of new or make_unique instead of more efficient make_shared

Using new or make_unique to initialize or reset shared_ptr results in additional memory allocation

## Description

This defect occurs when you use:

- new or make_unique to initialize a shared_ptr instance. For example:

  ```
  std::shared_ptr<T> p1(new T());
  std::shared_ptr<T> p2(make_unique<T>());
  ```
- new to reset a shared_ptr instance. For example:

  ```
  std::shared_ptr<T> p1;
  //...
  p1.reset(new T);
  ```

You use shared_ptr instances when you want multiple smart pointers to own and manage the same object. The instances also share a control block that holds a count of the number of instances that own the managed object.

Polyspace does not flag the use of new to initialize a shared_ptr instance in private or protected constructors. For example, no defect is raised on the use of new in this code snippet:

```
class PrivateCTor
{
public:
    static std::shared_ptr<PrivateCTor> makeOne()
    {
        return std::shared_ptr<PrivateCTor>(new PrivateCTor);
    }
private:
    PrivateCTor();
};
```

### Risk

When you use new or make_unique to initialize a shared_ptr instance, an additional allocation operation creates storage for the control block. The address of the additional allocation might be in a different memory page or outside the data-cache compared to the address of the managed object.

### Fix

Use std::make_shared to initialize a shared_ptr instance. The function performs a single allocation operation with enough memory to store the managed object and the control block.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Use of `new` to Initialize a `shared_ptr`

```
#include <memory>
#include <string>

struct Profile {
    virtual ~Profile() = default;
};

struct Player : public Profile {
    std::string name;
    std::int8_t rank;

    Player();
    Player(const std::string& name_, const std::int8_t& rank_) :
        name{ name_ }, rank{ rank_ } {}
};

void func()
{

    std::shared_ptr<Player> player1(new Player("Serena Williams", 1));
    std::shared_ptr<Player> top_rank(player1);

}
```

In this example, Polyspace flags the use of `new` to initialize `player1`. The program performs an additional allocation operation for the control block that holds the counter of all instances of `shared_ptr` that own the managed `Player` object.

#### Correction — Use `std::make_shared` to Initialize `shared_ptr`

One possible correction is to use `std::make_shared` to initialize `player1`.

```
#include <memory>
#include <string>

struct Profile {
    virtual ~Profile() = default;
};

struct Player : public Profile {
    std::string name;
    std::int8_t rank;

    Player();
    Player(const std::string& name_, const std::int8_t& rank_) :
        name{ name_ }, rank{ rank_ } {}
};

void func()
{

    auto player1 = std::make_shared<Player>("Serena Williams", 1);
    std::shared_ptr<Player> top_rank(player1);

}
```

## Result Information

**Group:** Performance

**Language:** C++
**Default:** Off
**Command-Line Syntax:** `MISSING_MAKE_SHARED`
**Impact:** Low

# Expensive use of container's size method

A container's `size()` method is used for checking emptiness instead of its `empty()` method, which is more efficient

## Description

This defect occurs when you call a container's `size()` method to check if the container is empty. For instance:

```
std::list l;
//...
if(l.size()==0)// Inefficient
//..
```

when you use the method to check whether the container is empty, Polyspace flags `l.size()` .

### Risk

A container's `size()` method might be expensive if you use C++ version predating C++11. Using such a method to check for emptiness of a container is unnecessarily expensive and might result in inefficient code.

### Fix

To check a container's emptiness, use its `empty()` method instead. For instance:

```
std::list l;
//...
if(l.empty())// Efficient
//..
```

In C++ version predating C++11, the `empty()` methods of STL containers are `O(1)` but the `size()` method is `O(N)`. When checking for emptiness, the `empty()` method is the more efficient solution.

If you are using C++11 or later, the `size()` method of an STL container is as efficient as the `empty()` method. Because the `empty()` method clearly communicates the developers intent, it is a good practice to use it when checking if a container is empty.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Do Not Use Container's `size()` for Emptiness Check

```
#include <list>
#include <algorithm>
#include <string>

// is_container_empty
bool is_container_empty(const std::list<std::string> &mylist)
```

```
{
   return mylist.size() != 0;
}
```

In this example, the function `is_container_empty()` checks whether the list `mylist` is empty by comparing the output of `mylist.size()` to zero. This method of checking empliness of a container is inefficient. Polyspace flags the call to `mylist.size()`.

#### Correction — Use the Containers `empty()` Method

To resolve this defect, use the `empty()` method of the container when checking for emptiness.

```
#include <list>
#include <algorithm>
#include <string>

// is_container_empty
bool is_container_empty(const std::list<std::string> &mylist)
{
   return mylist.empty();
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_CONTAINER_EMPTINESS_CHECK`
**Impact:** Low

# Version History

**Introduced in R2022b**

# Expensive use of map's bracket operator to insert or assign a value

The bracket operator of std::map or std::unordered_map is used for inserting or assigning a value in the container instead of the insert_or_assign() method, which is more efficient

## Description

This defect occurs when you use the [] operators to insert or assign a value to a key in a std::map or std::unordered_map instead of using the insert_or_assign() method. For instance:

```
std::map<int, std::string> Data;
Data[55] = "Fifty five"; //defect
```

Polyspace flags the use of the [] operator to insert a key value pair in the map data. This checker applies to code that uses C++17 or later.

### Risk

When you insert or assign a value in a std::map or std::unordered_map by using the [] operator, the compiler calls the default constructor of pair to constructs a key-value pair. The method insert_or_assign() inserts or assigns a value without calling the constructor, which makes it more efficient. Using the less efficient [] operator makes your code inefficient.

### Fix

When inserting or assigning a value in maps, use their insert_or_assign() method. For instance:

```
std::map<int, std::string> Data;
Data.insert_or_assign(55,"Fifty five");
```

The insert_or_assign() method inserts the key-value pair without having to construct a pair first, making it more efficient.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Avoid Using [] When Inserting a Value in a Map

```
#include <map>
#include <string>

void foo(std::map<std::string, std::string> &m, std::string name, std::string address)
{
    m[name] = address;
}
```

In this example, the value address is inserted against the key name in the map m. During this insertion a pair (name,address) is formed by calling the default constructor. This method of insertion into a map is inefficient and Polyspace flags it.

#### Correction — Use the Method `insert_or_assign()` Instead of `[]`

To fix this defect, use `insert_or_assign()` instead of `[]`.

```
#include <map>
#include <string>

void foo(std::map<std::string, std::string> &m, std::string name, std::string address)
{
    m.insert_or_assign(name,address);
}
```

### Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `EXPENSIVE_MAP_INSERT_OR_ASSIGN`
**Impact:** Low

## Version History

**Introduced in R2022b**

# Expensive return caused by unnecessary std::move

An unnecessary call to `std::move` in the return statement hinders return value optimization, resulting in inefficient code

## Description

This defect occurs when you use `std::move` to force the compiler to return a local variable from a function by using move semantics. Polyspace reports a defect if the returned local variable satisfies all of these requirements:

- It is not a `volatile` object.
- It is not an input parameter of the function or a `catch` block.
- It has the same type as the return type of the function.
- It is returned by using `std::move`.

In this code, a local object is returned by using `std::move`. Polyspace flags the return statement.

```
class A{};
A func(A a){
A local_obj;
return std::move(local_obj);
}
```

The C++ standards define the necessary conditions when compilers are permitted to perform return value optimization. For more information, see copy elision.

### Risk

In C++, compilers can optimize return values by omitting the call to a copy or move constructor when returning objects. Using `std::move` to return certain local objects might stop the compiler from attempting this optimization, which results in inefficient code. This inefficiency might be difficult to diagnose because the code compiles and behaves correctly.

### Fix

Remove the call to `std::move` in return statements.

Performance improvements can vary based on your compiler, library implementation, and environment.

## Examples

### Avoid Calling `std::move` in Return Statements

```
#include<vector>
template<typename T>
std::vector<T> vectorFactory(size_t size)
```

```
{
    std::vector<T> bigdata;
    //...
    return std::move(bigdata);
}

class data{
    char* name;
    char* address;
    public:
    data():name(nullptr), address(nullptr){}
    //...
};
void foo(){
    std::vector<data> database = vectorFactory<data>(5);
}
```

In this example, the function template `vectorFactory` returns a `vector` of objects. Calling `std::move` in the return statement might hinder return value optimization, which results in inefficient code. Polyspace reports a defect.

#### Correction — Allow Return Value Optimization

To facilitate return value optimization by the compiler, avoid using `std:move` in the return statement.

```
#include<vector>
template<typename T>
std::vector<T> vectorFactory(size_t size)
{
    std::vector<T> bigdata;
    //...
    return bigdata;
}

class data{
    char* name;
    char* address;
    public:
    data():name(nullptr), address(nullptr){}
    //...
};
void foo(){
    std::vector<data> database = vectorFactory<data>(5);
}
```

## Result Information

# Missing call to container's reserve method

A fixed number of items are added to a container without calling the `reserve()` method of the container beforehand, resulting in inefficient code

## Description

This defect occurs when you add a fixed number of items to a container without preallocating the necessary memory by calling the `reserve()` method of the container.

This code inserts three items into the vector `v` but does not preallocate the required memory by calling `v.reserve()`.

```
//...
std::vector< int > v;
    v.push_back( 0 );
    v.push_back( 1 );
    v.push_back( 2 );
```

Polyspace reports a defect.

### Risk

If you do not preallocate sufficient memory by calling the `reserve()` method of a container, insertion operations might allocate progressively larger chunks of memory, resulting in inefficient code. Allocating sufficient memory before the insertion operations allows for efficient use of memory and might allow for faster execution.

### Fix

Call the `reserve()` method of the container to preallocate memory. If you are able to use C++11, use `std::initializer_lists` to insert a known number of elements.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Insert Elements Without Preallocating Memory

```
#include <vector>

void fill_3() {
    std::vector< int > v;
    v.push_back( 0 ); /* Defect */
    v.push_back( 1 );
    v.push_back( 2 );
}
```

In this example, the function `fill_3` pushes three elements into a vector. Because the number of elements to be inserted is known, reserving memory for them beforehand might make the code more efficient. Polyspace reports a defect on the inefficient code.

#### Correction — Preallocate Necessary Memory

Call the `reserve()` method of the container to preallocate the necessary memory before the insertion operations.

```
#include <vector>

void fill_3() {
    std::vector< int > v;
    v.reserve( 3 );
    v.push_back( 0 ); /* Defect */
    v.push_back( 1 );
    v.push_back( 2 );
}
```

#### Correction — Use `std::Initializer_list`

If the number of elements to be inserted and their values are known, use an `initializer_list` to initiate the container. This solution applies to C++11 and later.

```
#include <vector>

void fill_3() {
    std::vector< int > v{0,1,2};
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `MISSING_CONTAINER_RESERVE`
**Impact:** Medium

# Version History

**Introduced in R2022b**

# Unnecessary construction before reassignment

Instead of directly constructing objects with value, you construct objects and then immediately assign values to objects

## Description

Polyspace reports this defect if you construct a local object and then you immediately assign a value to the object in the same scope. For example:

```
class obj{/*...*/};
void foo(obj a){
    obj b;
    b = a; //Defect
}
```

This code is inefficient because you construct the object b and reassign a to b without using b. This is inefficient and Polyspace reports a defect. Polyspace flags the unnecessary construction of both trivial and nontrivial objects.

### Risk

Construction and immediate reassignment of an object requires two calls:

1. Call to the constructor of the object.
2. Call to the assignment operator.

When the assignment operator reconstructs the object, the code immediately discards the previously constructed value. The immediate reassignment makes the constructor call unnecessary. Because the code compiles and behaves correctly, you might not detect the unnecessary construction, making the code inefficient.

### Fix

To resolve this defect, directly construct the object with the value by using the copy or move constructor. For instance:

```
class obj{/*...*/};
void foo(obj a){
    obj b{a};

}
```

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Inefficient Construction of Expensive Object

In this example, the functions `func1()` and `func2` construct an object and then immediately reassign the value. Using two statements for construction and reassignment is inefficient. Polyspace reports defects on the reassignment statements.

```
#include <string>
#include <unordered_set>
#include <vector>

typedef std::unordered_set<std::string> Type1;
typedef std::vector<std::string> Type2;

template< typename T >
T factory();

void func1(){
    Type1 obj;
    obj = factory< Type1 >(); // Defect
}

void func2(){
    Type2 obj;
    obj = factory< Type2 >(); // Defect
}
```

#### Correction — Construct Objects by Using Value

To fix this defect, combine the constructor and assignment statements into one statement:

```
#include <string>
#include <unordered_set>
#include <vector>

typedef std::unordered_set<std::string> Type1;
typedef std::vector<std::string> Type2;

template< typename T >
T factory();

void func1(){
    Type1 obj = factory< Type1 >(); //No defect
}

void func2(){
    Type2 obj = factory< Type2 >(); //No defect
}
```

## Result Information

**Group:** Performance
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `UNNECESSARY_CONSTRUCTION_BEFORE_ASSIGNMENT`
**Impact:** Low

## Version History

**Introduced in R2023a**

# Unnecessary implementation of a special member function

Implementing special member functions hinders code optimization when implicit versions are equivalent

## Description

Polyspace reports this defect if you implement a special member function in your class with the same functionalities as the implicit version of the function. The implicit special member functions typically have these properties:

- The implicit default constructor has an empty body, an empty parameter list, and an empty initializer list.
- The implicit destructor has an empty body.
- The implicit copy constructor copies the base classes and nonstatic data members by using an initializer list. The implicit move constructor moves the base classes and nonstatic data members using an initializer list. The implicit copy and move constructors do not create deep copies and do not move the data associated with a raw pointer.
- The implicit copy and move assignment operators use base and member-wise assignments.

For details about how implicitly defined special member functions behave, see:

- Default constructor
- Destructor
- Copy constructor
- Copy assignment operator
- Move constructor
- Move assignment operator

### Risk

Compilers optimize your code by turning implicit special member functions into trivial functions, which are faster to execute. This optimization does not take place if you implement a special member function in your code. Implementing a special member function that you can omit or declare as `=default` results in slower code.

Unnecessary implementation of a special member function makes your code more complex, hinders optimization, and makes the code harder to read and maintain.

### Fix

To fix this defect, take one of these actions:

- Omit the implementation of the flagged special member function.
- Declare the special member function as `=default`.

Performance improvements might vary based on the compiler, library implementation, and environment that you are using.

## Examples

### Unnecessary Copy and Move Constructors

In this example, you define the class A. In this class:

- Because the user-defined copy and move constructors of A do not manage any resources and they can be defined as =default or left undefined, Polyspace reports defects for these functions. Leaving these functions undeclared or declaring them as =default allows the compiler to turn these operations into trivial operations, resulting in more efficient code.
- The user-defined default constructor has a nonempty initializer list. Because this default constructor initializes two data members, an implicit default constructor cannot replicate its functionalities. Similarly, an implicit constructor cannot replace the nondefault constructor. Polyspace does not report defects for these constructors.

```
#include <cstdint>
#include <utility> //for std::move
class A
{
public:
    A() : x(0), y(0) {}                                   // Not a defect
    A(std::int32_t first, std::int32_t second)            // Not a defect
    : x(first), y(second) {}
    A(const A& oth) : x(oth.x),y(oth.y){}                 // Defect
    A(A&& oth): x(std::move(oth.x)),y(std::move(oth.y)){} // Defect
    ~A(){}                                                // Defect

private:
    std::int32_t x;
    std::int32_t y;
};
```

#### Correction — Avoid Implementing Unnecessary Special Member Functions

To resolve the defects, declare the flagged special member functions a =default.

```
#include <cstdint>
#include <utility>
class A
{
public:
    A() : x(0), y(0) {}                                   // Not a defect
    A(std::int32_t first, std::int32_t second)            // Not a defect
    : x(first), y(second) {}
    A(const A& oth)   =default;                           // Resolved
    A(A&& oth)=default;                                   // Resolved
    ~A()=default;                                         // Resolved

private:
    std::int32_t x;
    std::int32_t y;
};
```

### Necessary Implementation of Special Member Function

When your class manages resources such as a raw pointer or a POSIX file descriptor, the implicit special member functions are typically insufficient. In such cases, to avoid unexpected behavior, the best practice is to implement all the special member functions. In this example, the class A manages a raw pointer *p. To avoid unexpected behavior, implement special member functions that perform memory operations. For instance, the copy constructor in this code performs a deep copy and the move constructor invokes std::move(). Because these member functions perform actions that the implicit member functions do not perform, Polyspace does not report a defect.

```
#include <iostream>
#include<utility>
class A{
    private:
    int* p;
    public:
    A(){
        p = new int;
    }
    A(int in){
        p = new int;
        *p = in;
    }
    ~A(){
        delete p;
    }
    A(const A& oth){
        p = new int;
        *p = *(oth.p);
    }
    A(A&& oth){
        p = new int;
        *p = std::move(*oth.p);
    }
};
```

### Default Construction of const Instances

In this example, the function foo() constructs a const instance of myclass. Because the code does not initialize myclass::x in the class, the implicit default constructor cannot correctly construct a const instance myclass. When you use compilers such as gcc or clang, declaring myclass()=default; results in a compile fail.

Providing a user-defined constructor that is identical to the implicit constructor to resolve this issue is inefficient. In this code, the constructor myclass::myclass() is identical to an implicit constructor. This constructor resolves the compilation issue, but this solution is inefficient and Polyspace reports a defect.

```
class myclass{
    public:
    //myclass()=default;// Compile fail
    myclass(){}         //Defect
    int x;
};

void foo(){
```

```
const myclass obj;
}
```

#### Correction — Refactor myclass to Use Implicit Constructor

To allow implicit default construction of `const` instances of `myclass`, initialize `myclass::x` in the class definitions.

```
class myclass{
    public:
    myclass()=default;// Resolved
    int x=0;
};

void foo(){
const myclass obj;
}
```

### Result Information

**Group:** Performance
**Language:** C++ (C++11 or later)
**Default:** Off
**Command-Line Syntax:** `UNNECESSARY_IMPL_OF_SPECIAL_MEMBER_FUNCTION`
**Impact:** Low

# Resource Management Defects

# Closing previously closed resource

Function closes a previously closed stream

## Description

This defect occurs when a function attempts to close a stream that was closed earlier in your code and not reopened later.

### Risk

The standard states that the value of a `FILE*` pointer is indeterminate after you close the stream associated with it. Performing the close operation on the `FILE*` pointer again can cause unwanted behavior.

### Fix

Remove the redundant close operation.

## Examples

### Closing Previously Closed Resource

```
#include <stdio.h>

void func(char* data) {
    FILE* fp = fopen("file.txt", "w");
    if(fp!=NULL) {
        if(data)
            fputc(*data,fp);
        else
            fclose(fp);
    }
    fclose(fp);
}
```

In this example, if `fp` is not `NULL` and `data` is `NULL`, the `fclose` operation occurs on `fp` twice in succession.

#### Correction — Remove Close Operation

One possible correction is to remove the last `fclose` operation. To avoid a resource leak, you must also place an `fclose` operation in the `if(data)` block.

```
#include <stdio.h>

void func(char* data) {
    FILE* fp = fopen("file.txt", "w");
    if(fp!=NULL) {
        if(data) {
            fputc(*data,fp);
            fclose(fp);
        }
        else
            fclose(fp);
    }
}
```

### Result Information

**Group:** Resource management
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `DOUBLE_RESOURCE_CLOSE`
**Impact:** High

## Version History

**Introduced in R2015b**

# Opening previously opened resource

Opening an already opened file

## Description

This defect occurs when a file handling function such as `fopen` opens a file that was previously opened and not closed subsequently.

### Risk

If you open a resource multiple times, you can encounter:

- A race condition when accessing the file.
- Undefined or unexpected behavior for that file.
- Portability issues when you run your program on different targets.

### Fix

Once a resource is open, close the resource before reopening.

## Examples

### File Reopened With New Permissions

```
#include <stdio.h>
const char* logfile = "my_file.log";

void doubleresourceopen()
{
    FILE* fpa = fopen(logfile, "w");
    if (fpa == NULL) {
        return;
    }
    (void)fprintf(fpa, "Writing");
    FILE* fpb = fopen(logfile, "r");
    (void)fclose(fpa);
    (void)fclose(fpb);
}
```

In this example, a `logfile` is opened in the first line of this function with write privileges. Halfway through the function, the `logfile` is opened again with read privileges.

#### Correction — Close Before Reopening

One possible correction is to close the file before reopening the file with different privileges.

```
#include <stdio.h>
const char* logfile = "my_file.log";

void doubleresourceopen()
```

```
{
    FILE* fpa = fopen(logfile, "w");
    if (fpa == NULL) {
        return;
    }
    (void)fprintf(fpa, "Writing");
    (void)fclose(fpa);
    FILE* fpb = fopen(logfile, "r");
    (void)fclose(fpb);
}
```

## Result Information

**Group:** Resource management
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `DOUBLE_RESOURCE_OPEN`
**Impact:** Medium

# Resource leak

File stream not closed before FILE pointer scope ends or pointer is reassigned

## Description

This defect occurs when you open a file stream by using a FILE pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

### Fix

Close a FILE pointer before the end of its scope, or before you assign the pointer to another stream.

## Examples

### FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer fp1 is pointing to a file data1.txt. Before fp1 is explicitly dissociated from the file stream of data1.txt, it is used to access another file data2.txt.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate fp1 from the file stream of data1.txt.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

## Result Information

**Group:** Resource management
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** RESOURCE_LEAK
**Impact:** High

# Use of previously closed resource

Function operates on a previously closed stream

## Description

This defect occurs when a function operates on a stream that you closed earlier in your code.

### Risk

The standard states that the value of a `FILE*` pointer is indeterminate after you close the stream associated with it. Operations using the `FILE*` pointer can produce unintended results.

### Fix

One possible fix is to close the stream only at the end of operations. Another fix is to reopen the stream before using it again.

## Examples

### Use of FILE* Pointer After Closing Stream

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fclose(fp);
        fprintf(fp,"text");
    }
}
```

In this example, `fclose` closes the stream associated with `fp`. When you use `fprintf` on `fp` after `fclose`, the **Use of previously closed resource** defect appears.

#### Correction — Close Stream After All Operations

One possible correction is to reverse the order of the `fprintf` and `fclose` operations.

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fprintf(fp,"text");
        fclose(fp);
    }
}
```

## Result Information

**Group:** Resource management
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `CLOSED_RESOURCE_USE`
**Impact:** High

# Writing to read-only resource

File initially opened as read only is modified

## Description

This defect occurs when you attempt to write to a file that you have opened earlier in read-only mode.

For instance, you open a file using `fopen` with the access mode argument `r`. You write to that file with a function in the `fprintf` family.

### Risk

Writing to a read-only file causes undefined behavior.

### Fix

If you want to write to the file, open the file in a mode that is suitable for writing.

## Examples

### Writing to Read-Only File

```
#include <stdio.h>

void func(void) {
    FILE* fp ;

    fp = fopen("file.txt", "r");
    fprintf(fp, "Some data");
    fclose(fp);
}
```

In this example, the file `file.txt` is opened in read-only mode. When the `FILE` pointer associated with `file.txt` is used as an argument of `fprintf`, a **Writing to read-only resource** defect occurs.

#### Correction — Open File as Writable

One possible correction is to use the access specifier `"a"` instead of `"r"`. `file.txt` is now open for output at the end of the file.

```
#include <stdio.h>

void func(void) {
    FILE* fp ;

    fp = fopen("file.txt", "a");
    fprintf(fp, "Some data");
    fclose(fp);
}
```

## Result Information

**Group:** Resource management
**Language:** C | C++
**Default:** On for handwritten code, off for generated code
**Command-Line Syntax:** `READ_ONLY_RESOURCE_WRITE`
**Impact:** High

# Good Practice Defects

# Ambiguous declaration syntax

Declaration syntax can be interpreted as object declaration or part of function declaration

## Description

This defect occurs when it is not clear from a declaration whether an object declaration or function/ parameter declaration is intended. The ambiguity is often referred to as most vexing parse.

For instance, these declarations are ambiguous:

- `ResourceType aResource();`

  It is not immediately clear if `aResource` is a function returning a variable of type `ResourceType` or an object of type `ResourceType`.
- `TimeKeeper aTimeKeeper(Timer());`

  It is not immediately clear if `aTimeKeeper` is an object constructed with an unnamed object of type `Timer` or a function with an unnamed function pointer type as parameter. The function pointer refers to a function with no argument and return type `Timer`.

The checker does not flag ambiguous declarations with global scope. For instance, the analysis does not flag declarations with global scope using the format *`Type`* `a()` where *`Type`* is a class type with a default constructor. The analysis interprets `a` as a function returning the type *`Type`*.

### Risk

In case of an ambiguous declaration, the C++ Standard chooses a specific interpretation of the syntax. For instance:

- `ResourceType aResource();`

  is interpreted as a declaration of a function `aResource`.
- `TimeKeeper aTimeKeeper(Timer());`

  is interpreted as a declaration of a function `aTimeKeeper` with an unnamed parameter of function pointer type.

If you or another developer or code reviewer expects a different interpretation, the results can be unexpected.

For instance, later you might face a compilation error that is difficult to understand. Since the default interpretation indicates a function declaration, if you use the function as an object, compilers might report a compilation error. The compilation error indicates that a conversion from a function to an object is being attempted without a suitable constructor.

### Fix

Make the declaration unambiguous. For instance, fix these ambiguous declarations as follows:

- `ResourceType aResource();`

*Object declaration*:

If the declaration refers to an object initialized with the default constructor, rewrite it as:

```
ResourceType aResource;
```

prior to C++11, or as:

```
ResourceType aResource{};
```

after C++11.

*Function declaration*:

If the declaration refers to a function, use a typedef for the function.

```
typedef ResourceType(*resourceFunctionType)();
resourceFunctionType aResource;
```

- `TimeKeeper aTimeKeeper(Timer());`

  *Object declaration*:

  If the declaration refers to an object `aTimeKeeper` initialized with an unnamed object of class `Timer`, add an extra pair of parenthesis:

  ```
  TimeKeeper aTimeKeeper( (Timer()) );
  ```

  prior to C++11, or use braces:

  ```
  TimeKeeper aTimeKeeper{Timer{}};
  ```

  after C++11.

  *Function declaration*:

  If the declaration refers to a function `aTimeKeeper` with a unnamed parameter of function pointer type, use a named parameter instead.

  ```
  typedef Timer(*timerType)();
  TimeKeeper aTimeKeeper(timerType aTimer);
  ```

## Examples

### Function or Object Declaration

```
class ResourceType {
      int aMember;
    public:
      int getMember();
};

void getResource() {
    ResourceType aResource();
}
```

In this example, `aResource` might be used as an object but the declaration syntax indicates a function declaration.

#### Correction — Use {} for Object Declaration

One possible correction (after C++11) is to use braces for object declaration.

```
class ResourceType {
      int aMember;
    public:
      int getMember();
};

void getResource() {
    ResourceType aResource{};
}
```

### Unnamed Object or Unnamed Function Parameter Declaration

```
class MemberType {};

class ResourceType {
      MemberType aMember;
    public:
      ResourceType(MemberType m) {aMember = m;}
      int getMember();
};

void getResource() {
    ResourceType aResource(MemberType());
}
```

In this example, `aResource` might be used as an object initialized with an unnamed object of type `MemberType` but the declaration syntax indicates a function with an unnamed parameter of function pointer type. The function pointer points to a function with no arguments and type `MemberType`.

#### Correction — Use {} for Object Declaration

One possible correction (after C++11) is to use braces for object declaration.

```
class MemberType {};

class ResourceType {
      MemberType aMember;
    public:
      ResourceType(MemberType m) {aMember = m;}
      int getMember();
};

void getResource() {
    ResourceType aResource{MemberType()};
}
```

### Unnamed Object or Named Function Parameter Declaration

```
class Integer {
    int aMember;
public:
    Integer(int d) {aMember = d;}
    int getMember();
};

int aInt = 0;
void foo(){
    Integer aInteger(Integer(aInt));
}
```

In this example, `aInteger` might be an object constructed with an unnamed object `Integer(aInt)` (an object of class `Integer` which itself is constructed using the variable `aInt`). However, the declaration syntax indicates that `aInteger` is a function with a named parameter `aInt` of type `Integer` (the superfluous parenthesis is ignored).

**Correction — Use of {} for Object Declaration**

One possible correction (after C++11) is to use {} for object declaration.

```
class Integer {
    int aMember;
public:
    Integer(int d) {aMember = d;}
    int getMember();
};

int aInt = 0;
void foo(){
    Integer aInteger(Integer{aInt});
}
```

**Correction — Remove Superfluous Parenthesis for Named Parameter Declaration**

If `aInteger` is a function with a named parameter `aInt`, remove the superfluous () around `aInt`.

```
class Integer {
    int aMember;
public:
    Integer(int d) {aMember = d;}
    int getMember();
};

int aInt = 0;
void foo(){
    Integer aInteger(Integer aInt);
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `MOST_VEXING_PARSE`
**Impact:** Low

## Version History

**Introduced in R2019a**

# Bitwise and arithmetic operations on the same data

Statement with mixed bitwise and arithmetic operations

## Description

This defect occurs when bitwise and arithmetic operations are performed in the same expression.

### Risk

Mixed bitwise and arithmetic operations *do* compile. However, the size of integer types affects the result of these mixed operations. For instance, the arithmetic equivalent of a left shift (<<) by a certain number of bits depends on the number of bits in the variable being shifted and therefore on the internal representation of its data type. With a mix of bitwise and arithmetic operations, the same expression can produce different results on different targets.

Mixed operations also reduce readability and maintainability.

### Fix

Separate bitwise and arithmetic operations, or use only one type of operation per statement.

## Examples

### Shift and Addition

```
unsigned int bitwisearithmix()
{
    unsigned int var = 50;
    var += (var << 2) + 1;
    return var;
}
```

This example shows bitwise and arithmetic operations on the variable `var`. `var` is shifted by two (bitwise), then increased by 1 and added to itself (arithmetic).

#### Correction — Arithmetic Operations Only

You can reduce this expression to arithmetic-only operations: `var + (var << 2)` is equivalent to `var * 5`.

```
unsigned int bitwisearithmix()
{
    unsigned int var = 50;
    var = var * 5 +1;
    return var;
}
```

## Result Information

**Group:** Good Practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `BITWISE_ARITH_MIX`
**Impact:** Low

# Version History

**Introduced in R2016b**

# C++ reference to const-qualified type with subsequent modification

Reference to `const`-qualified type is subsequently modified

## Description

This defect occurs when a variable that refers to a `const`-qualified type is modified after declaration.

For instance, in this example, `refVal` has a type `const int &`, but its value is modified in a subsequent statement.

```
using constIntRefType = const int &;
void func(constIntRefType refVal, int val){
   ...
   refVal = val; //refVal is modified
   ...
}
```

### Risk

The `const` qualifier on a reference type implies that a variable of the type is initialized at declaration and will not be subsequently modified.

Compilers can detect modification of references to `const`-qualified types as a compilation error. If the compiler does not detect the error, the behavior is undefined.

### Fix

Avoid modification of `const`-qualified reference types. If the modification is required, remove the `const` qualifier from the reference type declaration.

## Examples

### Modification of `const`-qualified Reference Types

```
typedef const int cint;
typedef cint& ref_to_cint;

void func(ref_to_cint refVal, int initVal){
   refVal = initVal;
}
```

In this example, `ref_to_cint` is a reference to a `const`-qualified type. The variable `refVal` of type `ref_to_cint` is supposed to be initialized when `func` is called and not modified subsequently. The modification violates the contract implied by the `const` qualifier.

#### Correction — Avoid Modification of `const`-qualified Reference Types

One possible correction is to avoid the `const` in the declaration of the reference type.

```
typedef int& ref_to_int;
```

```
void func(ref_to_int refVal, int initVal){
   refVal = initVal;
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `WRITE_REFERENCE_TO_CONST_TYPE`
**Impact:** Low

# Version History

**Introduced in R2019a**

# C++ reference type qualified with const or volatile

Reference type declared with a redundant `const` or `volatile` qualifier

## Description

This defect occurs when a variable with reference type is declared with the `const` or `volatile` qualifier, for instance:

```
char &const c;
```

### Risk

The C++14 Standard states that `const` or `volatile` qualified references are ill formed (unless they are introduced through a `typedef`, in which case they are ignored). For instance, a reference to one variable cannot be made to refer to another variable. Therefore, using the `const` qualifier is not required for a variable with a reference type.

Often the use of these qualifiers indicate a coding error. For instance, you meant to declare a reference to a `const`-qualified type:

```
char const &c;
```

but instead declared a `const`-qualified reference:

```
char &const c;
```

If your compiler does not detect the error, you can see unexpected results. For instance, you might expect `c` to be immutable but see a different value of `c` compared to its value at declaration.

### Fix

See if the `const` or `volatile` qualifier is incorrectly placed. For instance, see if you wanted to refer to a `const`-qualified type and entered:

```
char &const c;
```

instead of:

```
char const &c;
```

If the qualifier is incorrectly placed, fix the error. Place the `const` or `volatile`qualifier before the & operator. Otherwise, remove the redundant qualifier.

## Examples

### `const`-Qualified Reference Type

```
int func (int &const iRef) {
    iRef++;
    return iRef%2;
}
```

In this example, `iRef` is a `const`-qualified reference type. Since `iRef` cannot refer to another variable, the `const` qualifier is redundant.

#### Correction — Remove `const` Qualifier

Remove the redundant `const` qualifier. Since `iRef` is modified in `func`, it is not meant to refer to a `const`-qualified variable. Moving the `const` qualifier before & will cause a compilation error.

```
int func (int &iRef) {
    iRef++;
    return iRef%2;
}
```

#### Correction — Fix Placement of `const` Qualifier

If you do not identify to modify `iRef` in `func`, declare `iRef` as a reference to a `const`-qualified variable. Place the `const` qualifier before the & operator. Make sure you do not modify `iRef` in `func`.

```
int func (int const &iRef) {
    return (iRef+1)%2;
}
```

### Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `CV_QUALIFIED_REFERENCE_TYPE`
**Impact:** Low

## Version History

**Introduced in R2019a**

# Delete of void pointer

`delete` operates on a `void*` pointer pointing to an object

## Description

This defect occurs when the `delete` operator operates on a `void*` pointer.

### Risk

Deleting a `void*` pointer is undefined according to the C++ Standard.

If the object is of type `MyClass` and the `delete` operator operates on a `void*` pointer pointing to the object, the `MyClass` destructor is not called.

If the destructor contains cleanup operations such as release of resources or decreasing a counter value, the operations do not take place.

### Fix

Cast the `void*` pointer to the appropriate type. Perform the `delete` operation on the result of the cast.

For instance, if the `void*` pointer points to a `MyClass` object, cast the pointer to `MyClass*`.

## Examples

### Delete of void* Pointer

```
#include <iostream>

class MyClass {
public:
    explicit MyClass(int i):m_i(i) {}
    ~MyClass() {
        std::cout << "Delete MyClass(" << m_i << ")" << std::endl;
    }
private:
    int m_i;
};

void my_delete(void* ptr) {
    delete ptr;
}

int main() {
    MyClass* pt = new MyClass(0);
    my_delete(pt);
    return 0;
}
```

In this example, the function my_delete is designed to perform the delete operation on any type. However, in the function body, the delete operation acts on a void* pointer, ptr. Therefore, when you call my_delete with an argument of type MyClass, the MyClass destructor is not called.

#### Correction — Cast void* Pointer to MyClass*

One possible solution is to use a function template instead of a function for my_delete.

```
#include <iostream>

class MyClass {
public:
    explicit MyClass(int i):m_i(i) {}
    ~MyClass() {
        std::cout << "Delete MyClass(" << m_i << ")" << std::endl;
    }
private:
    int m_i;
};

template<typename T> void safe_delete(T*& ptr) {
    delete ptr;
    ptr = NULL;
}

int main() {
    MyClass* pt = new MyClass(0);
    safe_delete(pt);
    return 0;
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** DELETE_OF_VOID_PTR
**Impact:** Low

# Hard-coded buffer size

Size of memory buffer is a numerical value instead of symbolic constant

## Description

This defect occurs when you use a numerical value instead of a symbolic constant when declaring a memory buffer such as an array.

### Risk

Hard-coded buffer size causes the following issues:

- Hard-coded buffer size increases the likelihood of mistakes and therefore maintenance costs. If a policy change requires developers to change the buffer size, they must change every occurrence of the buffer size in the code.
- Hard-constant constants can be exposed to attack if the code is disclosed.

### Fix

Use a symbolic name instead of a hard-coded constant for buffer size. Symbolic names include `const`-qualified variables, `enum` constants, or macros.

`enum` constants are recommended.

- Macros are replaced by their constant values after preprocessing. Therefore, they can expose the loop boundary.
- `enum` constants are known at compilation time. Therefore, compilers can optimize the loops more efficiently.

  `const`-qualified variables are usually known at run time.

## Examples

### Hard-Coded Buffer Size

```
int table[100];

void read(int);

void func(void) {
    for (int i=0; i<100; i++)
        read(table[i]);
}
```

In this example, the size of the array `table` is hard-coded.

#### Correction — Use Symbolic Name

One possible correction is to replace the hard-coded size with a symbolic name.

```
const int MAX_1 = 100;
#define MAX_2 100
enum { MAX_3 = 100 };

int table_1[MAX_1];
int table_2[MAX_2];
int table_3[MAX_3];

void read(int);

void func(void) {
    for (int i=0; i < MAX_1; i++)
        read(table_1[i]);
    for (int i=0; i < MAX_2; i++)
        read(table_2[i]);
    for (int i=0; i < MAX_3; i++)
        read(table_3[i]);
}
```

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `HARD_CODED_BUFFER_SIZE`
**Impact:** Low

# Hard-coded loop boundary

Loop boundary is a numerical value instead of symbolic constant

## Description

This defect occurs when you use a numerical value instead of symbolic constant for the boundary of a `for`, `while` or `do-while` loop.

### Risk

Hard-coded loop boundary causes the following issues:

- Hard-coded loop boundary makes the code vulnerable to denial of service attacks when the loop involves time-consuming computation or resource allocation.
- Hard-coded loop boundary increases the likelihood of mistakes and maintenance costs. If a policy change requires developers to change the loop boundary, they must change every occurrence of the boundary in the code.

  For instance, the loop boundary is 10000 and represents the maximum number of client connections supported in a network server application. If the server supports more clients, you must change all instances of the loop boundary in your code. Even if the loop boundary occurs once, you have to search for a numerical value of `10000` in your code. The numerical value can occur in places other than the loop boundary. You must browse through those places before you find the loop boundary.

### Fix

Use a symbolic name instead of a hard-coded constant for loop boundary. Symbolic names include `const`-qualified variables, `enum` constants or macros.`enum` constants are recommended because:

- Macros are replaced by their constant values after preprocessing. Therefore, they can expose the buffer size.
- `enum` constants are known at compilation time. Therefore, compilers can allocate storage for them more efficiently.

  `const`-qualified variables are usually known at run time.

## Examples

### Hard-Coded Loop Boundary

```
void performOperation(int);

void func(void) {
    for (int i=0; i<100; i++)
        performOperation(i);
}
```

In this example, the boundary of the `for` loop is hard-coded.

#### Correction — Use Symbolic Name

One possible correction is to replace the hard-coded loop boundary with a symbolic name.

```
const int MAX_1 = 100;
#define MAX_2 100
enum { MAX_3 = 100 };

void performOperation_1(int);
void performOperation_2(int);
void performOperation_3(int);

void func(void) {
    for (int i=0; i<MAX_1; i++)
        performOperation_1(i);
    for (int i=0; i<MAX_2; i++)
        performOperation_2(i);
    for (int i=0; i<MAX_3; i++)
        performOperation_3(i);
}
```

## Result Information

# Hard-coded object size used to manipulate memory

Memory manipulation with hard-coded size instead of `sizeof`

## Description

This defect occurs when you use hard-coded constants as memory size arguments for these memory functions:

- Dynamic memory allocation function such as `malloc` or `calloc`.
- Memory manipulation functions such as `memcpy`, `memmove`, `memcmp`, or `memset`.

When performing memory operations with a string literal, Polyspace does not report a defect if you hard code the memory size.

### Risk

If you hard code object size, your code is not portable to architectures with different type sizes. If the constant value is not the same as the object size, the buffer might or might not overflow.

### Fix

For the size argument of memory functions, use `sizeof(`*`object`*`)`.

## Examples

### Assume 4-Byte Integer Pointers

```
#include <stddef.h>
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};
extern void fill_ints(int **matrix, size_t nb, size_t s);

void bug_hardcodedmemsize()
{
    size_t i, s;

    s = 4;
    int **matrix = (int **)calloc(SIZE20, s);
    if (matrix == NULL) {
        return; /* Indicate calloc() failure */
    }
    fill_ints(matrix, SIZE20, s);
    free(matrix);
}
```

In this example, the memory allocation function `calloc` is called with a memory size of 4. The memory is allocated for an integer pointer, which can be a more or less than 4 bytes depending on your target. If the integer pointer is not 4 bytes, your program can fail.

#### Correction — Use `sizeof(int *)`

When calling `calloc`, replace the hard-coded size with a call to `sizeof`. This change makes your code more portable.

```
#include <stddef.h>
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};
extern void fill_ints(int **matrix, size_t nb, size_t s);

void corrected_hardcodedmemsize()
{
    size_t i, s;

    s = sizeof(int *);
    int **matrix = (int **)calloc(SIZE20, s);
    if (matrix == NULL) {
        return; /* Indicate calloc() failure */
    }
    fill_ints(matrix, SIZE20, s);
    free(matrix);
}
```

### Hard Coded Size in `memset`

In this example, the function `clean_sensitive_memory` clears sensitive information from the memory. Here, the memory size argument of `memset` is hardcoded to be 64 bytes. If `s->data` cannot accommodate `64` bytes, the program fails and the sensitive information might remain in memory. Polyspace reports defects on the memory operation.

```
#include<string.h>

struct sensitiveInfo
{
    unsigned char data[64];
    int length;
};

char key[64];

void clean_sensitive_memory (struct sensitiveInfo *s)
{
    memset (s->data, 0, 64);          //Defect
    memset ((void *) key, 0, 64);  //Defect
}
```

#### Correction — Use `sizeof()` for Size Argument

To fix this defect, replace the hardcoded memory sizes by calls to `sizeof()`.

```
#include<string.h>

struct sensitiveInfo
{
    unsigned char data[64];
    int length;
};

char key[64];

void clean_sensitive_memory (struct sensitiveInfo *s)
{
  memset (s->data, 0, sizeof (s->data));    //Fixed
  memset ((void *) key, 0, sizeof(key)); //Fixed
}
```

## Result Information

# Incorrect syntax of flexible array member size

Flexible array member defined with size zero or one

## Description

This defect occurs when you do not use the standard C syntax to define a structure with a flexible array member.

Since C99, you can define a flexible array member with an unspecified size. For instance, `desc` is a flexible array member in this example:

```
struct record {
    size_t len;
    double desc[];
};
```

Prior to C99, you might have used compiler-specific methods to define flexible arrays. For instance, you used arrays of size one or zero:

```
struct record {
    size_t len;
    double desc[0];
};
```

This usage is not compliant with the C standards following C99.

### Risk

If you define flexible array members by using size zero or one, your implementation is compiler-dependent. For compilers that do not recognize the syntax, an `int` array of size one has buffer for one `int` variable. If you try to write beyond this buffer, you can run into issues stemming from array access out of bounds.

If you use the standard C syntax to define a flexible array member, your implementation is portable across all compilers conforming with the standard.

### Fix

To implement a flexible array member in a structure, define an array of unspecified size. The structure must have one member besides the array and the array must be the last member of the structure.

## Examples

### Flexible Array Member Defined with Size One

```
#include <stdlib.h>

struct flexArrayStruct {
  int num;
  int data[1];
};

unsigned int max_size = 100;

void func(unsigned int array_size) {
  if(array_size<= 0 || array_size > max_size)
      exit(1);
  /* Space is allocated for the struct */
  struct flexArrayStruct *structP
    = (struct flexArrayStruct *)
     malloc(sizeof(struct flexArrayStruct)
          + sizeof(int) * (array_size - 1));
  if (structP == NULL) {
    /* Handle malloc failure */
    exit(2);
  }

  structP->num = array_size;

  /*
   * Access data[] as if it had been allocated
   * as data[array_size].
   */
  for (unsigned int i = 0; i < array_size; ++i) {
    structP->data[i] = 1;
  }

  free(structP);
}
```

In this example, the flexible array member `data` is defined with a size value of one. Compilers that do not recognize this syntax treat `data` as a size-one array. The statement `structP->data[i] = 1;` can write to `data` beyond the first array member and cause out of bounds array issues.

#### Correction — Use Standard C Syntax to Define Flexible Array

Define flexible array members with unspecified size.

```
#include <stdlib.h>

struct flexArrayStruct{
  int num;
  int data[];
};

unsigned int max_size = 100;

void func(unsigned int array_size) {
  if(array_size<=0 || array_size > max_size)
      exit(1);

  /* Allocate space for structure */
  struct flexArrayStruct *structP
    = (struct flexArrayStruct *)
    malloc(sizeof(struct flexArrayStruct)
         + sizeof(int) * array_size);

  if (structP == NULL) {
    /* Handle malloc failure */
    exit(2);
  }

  structP->num = array_size;

  /*
   * Access data[] as if it had been allocated
   * as data[array_size].
   */
  for (unsigned int i = 0; i < array_size; ++i) {
    structP->data[i] = 1;
  }

  free(structP);
}
```

## Result Information

**Group:** Good Practice
**Language:**C (checker disabled if the analysis runs on C90 code indicated by the option `-c-version c90`)
**Default:** Off
**Command-Line Syntax:** `FLEXIBLE_ARRAY_MEMBER_INCORRECT_SIZE`
**Impact:** Low

# Incorrectly indented statement

Statement indentation incorrectly makes it appear as part of a block

## Description

This defect occurs when the indentation of a statement makes it appear as part of an `if`, `else` or another block but the arrangement or lack of braces actually keeps the statement outside the block.

### Risk

A developer or reviewer might incorrectly associate the statement with a block based on its indentation, leading to an incorrect assumption about the program logic.

For instance, in this example:

```
if(credentialsOK())
   login=1;
   setCookies();
```

the line `setCookies();` is not part of the `if` block, but the indentation suggests otherwise.

### Fix

If you want a statement to be part of a block, make sure that the statement is within the braces associated with the block. To identify the extent of a block, on the **Source** pane, click the opening brace.

If an `if`, `else` or `while` statement has no braces following the condition, only the next line on an execution path up to a semicolon is considered part of the `if`, `else` or `while` block. If you want subsequent lines to be included in the block, wrap the lines in braces.

For instance, in the preceding example, to include both statements in the `if` block, use:

```
if(credentialsOK()) {
   login=1;
   setCookies();
}
```

## Examples

### `else` Statement Incorrectly Indented

```
int switch1, switch2;

void doSomething(void);
void doSomethingElse(void);

void func() {
    if(switch1)
        if(switch2)
            doSomething();
    else
```

```
        doSomethingElse();
}
```

In this example, the `else` is indented as if it is associated with the first `if`. However, the `else` is actually associated with the second `if`. The indentation does not match the actual association and might lead to incorrect assumptions about the program logic.

#### Correction – Use Braces Appropriately

If you want the `else` to be associated with the first `if`, use braces to mark the boundaries of the first `if` block.

```
int switch1, switch2;

void doSomething(void);
void doSomethingElse(void);

void func() {
    if(switch1) {
        if(switch2)
            doSomething();
    }
    else
        doSomethingElse();
}
```

### Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INCORRECT_INDENTATION`
**Impact:** Low

# Invalid scientific notation format

the use of an invalid format makes the code less readable

## Description

This issue occurs when you express a floating-point literal in exponential form but you do not use the standard scientific notation format of one nonzero digit before the decimal.

Polyspace does not flag the use of zero before the decimal to represent literal `0.0` in exponential form, for instance `0.00E+0`.

### Risk

The use of non-standard scientific notations to represent literals makes your code less readable and more error-prone.

### Fix

Use the standard format of one nonzero digit before the decimal to express floating-point literals in scientific notation.

## Examples

### Literals Represented with Invalid Scientific Format

```
#include <stdio.h>

void printUsingEFormat()
{
    float literalVals[] = {
        1154.12e+5L, //more than one digit before decimal
        .1E4F,       //no digit before decimal
        58.L,
        0.1E4F,     //zero digit before decimal
        1.34e+4,
        13.4e+3,    //more than one digit before decimal
        0.0000E+0,
        0xa.bp10l,
        0x15.0p5};
    for (int i = 0;
         i < sizeof(literalVals) / sizeof(literalVals[0]);
         ++i)
    {
        printf("%.6e\n", literalVals[i]);
    }
}
```

In this example, function `printUsingEFormat()` cycles through the elements of array `literalVals` and prints each element in scientific notation format.

Polyspace flags every literal that does not use a standard scientific notation format. The other array elements use the correct format or are not represented using scientific notation.

## Result Information

**Group:** Good Practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `INVALID_NOTATION_ON_E_CONSTANT`
**Impact:** Low

# Version History

**Introduced in R2022b**

## See Also

`Find defects (-checkers)`

# Macro terminated with a semicolon

Macro definition ends with a semicolon

## Description

This defect occurs when a macro that is invoked at least once has a definition ending with a semicolon.

### Risk

If a macro definition ends with a semicolon, the macro expansion can lead to unintended program logic in certain contexts, such as within an expression.

For instance, consider the macro:

```
#define INC_BY_ONE(x) ++x;
```

If used in the expression:

```
res = INC_BY_ONE(x)%2;
```

the expression resolves to:

```
res = ++x; %2;
```

The value of `x+1` is assigned to `res`, which is probably unintended. The leftover standalone statement `%2;` is valid C code and can only be detected by enabling strict compiler warnings.

### Fix

Do not end macro definitions with a semicolon. Leave it up to users of the macro to add a semicolon after the macro when needed.

Alternatively, use inline functions in preference to function-like macros that involve statements ending with semicolon.

## Examples

### Spurious Semicolon in Macro Definition

```
#define WHILE_LOOP(n) while(n>0);

void performAction(int timeStep);

void main() {
    int loopIter = 100;
    WHILE_LOOP(loopIter) {
        performAction(loopIter);
        loopIter--;
    }
}
```

In this example, the defect occurs because the definition of the macro `WHILE_LOOP(n)` ends with a semicolon. As a result of the semicolon, the `while` loop has an empty body and the subsequent statements in the block run only once. It was probably intended that the loop must iterate 100 times.

#### Correction – Remove Semicolon from Macro Definition

Remove the trailing semicolon from the macro definition. Users of the macro can add a semicolon after the macro when needed. In this example, a semicolon is not required.

```
#define WHILE_LOOP(n) while(n>0)

void performAction(int timeStep);

void main() {
    int loopIter = 100;
    WHILE_LOOP(loopIter) {
        performAction(loopIter);
        loopIter--;
    }
}
```

### Result Information

# Line with more than one statement

Multiple statements on a line

## Description

This defect occurs when, before preprocessing starts, the analysis detects additional text after the semicolon (`;`) on a line. A defect is not raised for comments, `for`-loop definitions, braces, or backslashes.

### Risk

Use of one statement per line improves readability of the code. Since most statements in your code appear on a new line, use of multiple statements per line in a few cases within this arrangement can make code review difficult.

### Fix

Write one statement per line.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

## Examples

### Single-Line Initialization

```
int multi_init(void){
int abc = 4; int efg = 0; //defect

    return abc*efg;
}
```

In this example, `abc` and `efg` are initialized on the second line of the function as separate statements.

#### Correction — Comma-Separated Initialization

One possible correction is to use a comma instead of a semicolon to declare multiple variables on the same line.

```
int multi_init(void){
    int a = 4, b = 0;

    return a*b;
}
```

#### Correction — New Line for Each Initialization

One possible correction is to separate each initialization. By putting the initialization of b on the next line, the code longer raises a defect.

```
int multi_init(void){
    int a = 4;
    int b = 0;

    return a*b;
}
```

### Single-Line Loops

```
int multi_loop(void){
    int a, b = 0;
    int index = 1;
    int tab[9] = {1,1,2,3,5,8,13,21};

    for(a=0; a < 3; a++) {b+=a;} // no defect

for(b=0; b < 3; b++) {a+=b; index=b;} //defect

while (index < 7) {index++; tab[index] = index * index;} //defect
    return a*b;
}
```

In this example, there are three loops coded on single lines, each with multiple semicolons.

- The first for loop has multiple semicolons. Polyspace does not raise a defect for multiple statements within a for loop declaration.
- Polyspace does raise a defect on the second for loop because there are multiple statements after the for loop declaration.
- The while loop also has multiple statements after the loop declaration. Polyspace raises a defect on this line.

#### Correction — New Line for Each Loop Statement

One possible correction is to use a new line for each statement after the loop declaration.

```
int multi_loop(void){
    int a, b = 0;
    int index = 1;
    int tab[9] = {1,1,2,3,5,8,13,21};

    for(a=0; a < 3; a++) {b+=a;}

    for(b=0; b < 3; b++){
      a+=b;
      index=b;
    }

    while (index < 7){
      index++;
      tab[index] = index * index;
    }
    return a*b;
}
```

#### Single-line Conditionals

```
int multi_if(void){

    int a, b = 1;
    if(a == 0) { a++;} // no defect
else if(b == 1) {b++; a *= b;} //defect
}
```

In this example, there are two conditional statements an: `if` and an `else if`. The `if` line does not raise a defect because only one statement follows the condition. The `else if` statement does raise a defect because two statements follow the condition.

##### Correction — New Lines for Multi-Statement Conditionals

One possible correction is to use a new line for conditions with multiple statements.

```
int multi_if(void){
    int a, b = 1;

    if(a == 0) a++;
    else if(b == 1){
      b++;
      a *= b;
    }
}
```

# Missing break of switch case

case block of switch statement does not end in a break, [[fallthrough]] or explanatory comment

## Description

This defect occurs when a case block of switch statement does not end in a break, a [[fallthrough]], or a code comment.

If the last entry in the case block is a code comment, for instance:

```
switch (wt)
    {
      case WE_W:
        do_something_for_WE_W();
        do_something_else_for_WE_W();
        /* fall through to WE_X*/
      case WE_X:
        ...
    }
```

Polyspace assumes that the missing break is intentional and does not raise a defect.

### Risk

Switch cases without break statements fall through to the next switch case. If this fall-through is not intended, the switch case can unintentionally execute code and end the switch with unexpected results.

### Fix

If you forgot the break statement, add it before the end of the switch case.

If you do not want a break for the highlighted switch case, add a comment to your code to document why this case falls through to the next case. This comment removes the defect from your results and makes your code more maintainable.

In some cases, such as in template functions, the defect checker might ignore the comment at the end of a case statement. A cleaner way to indicate a deliberate fall through to the next case is to use one of these fallthrough attributes if possible:

- [[fallthrough]]: Available since C++17.
- [[gnu::fallthrough]] and [[clang::fallthrough]]: Available with GCC and Clang compilers.
- __attribute__((fallthrough)): Available with GCC compilers.

## Examples

### Switch Without Break Statements

```
enum WidgetEnum { WE_W, WE_X, WE_Y, WE_Z } widget_type;
```

```
extern void demo_do_something_for_WE_W(void);
extern void demo_do_something_for_WE_X(void);
extern void demo_report_error(void);

void bug_missingswitchbreak(enum WidgetEnum wt)
{
    /*
      In this non-compliant code example, the case where widget_type is WE_W lacks a
      break statement. Consequently, statements that should be executed only when
      widget_type is WE_X are executed even when widget_type is WE_W.
    */
    switch (wt)
    {
      case WE_W:
        demo_do_something_for_WE_W();
      case WE_X:
        demo_do_something_for_WE_X();
      default:
        /* Handle error condition */
        demo_report_error();
    }
}
```

In this example, there are two cases without `break` statements. When `wt` is `WE_W`, the statements for `WE_W`, `WE_X`, and the `default` case execute because the program falls through the two cases without a break. No defect is raised on the `default` case or last case because it does not need a break statement.

#### Correction — Add a Comment or break

To fix this example, either add a comment after the last statement in the case block and before the next case block to mark and document the acceptable fall-through or add a break statement to avoid fall-through. In this example, case `WE_W` is supposed to fall through, so a comment is added to explicitly state this action. For the second case, a break statement is added to avoid falling through to the `default` case.

```
enum WidgetEnum { WE_W, WE_X, WE_Y, WE_Z } widget_type;

extern void demo_do_something_for_WE_W(void);
extern void demo_do_something_for_WE_X(void);
extern void demo_report_error(void);

void corrected_missingswitchbreak(enum WidgetEnum wt)
{
    switch (wt)
    {
      case WE_W:
        demo_do_something_for_WE_W();
        /* fall through to WE_X*/
      case WE_X:
        demo_do_something_for_WE_X();
        break;
      default:
        /* Handle error condition */
        demo_report_error();
    }
}
```

## Result Information

# Missing overload of allocation or deallocation function

Only one function in an allocation-deallocation function pair is overloaded

## Description

This defect occurs when you overload `operator new` but do not overload the corresponding `operator delete`, or vice versa.

### Risk

You typically overload `operator new` to perform some bookkeeping in addition to allocating memory on the free store. Unless you overload the corresponding `operator delete`, it is likely that you omitted some corresponding bookkeeping when deallocating the memory.

The defect can also indicate a coding error. For instance, you overloaded the placement form of `operator new[]`:

```
void *operator new[](std::size_t count, void *ptr);
```

but the non-placement form of `operator delete[]`:

```
void operator delete[](void *ptr);
```

instead of the placement form:

```
void operator delete[](void *ptr, void *p );
```

### Fix

When overloading `operator new`, make sure that you overload the corresponding `operator delete` in the same scope, and vice versa.

For instance, in a class, if you overload the placement form of `operator new`:

```
class MyClass {
   void* operator new  ( std::size_t count, void* ptr ){
   ...
   }
};
```

Make sure that you also overload the placement form of `operator delete`:

```
class MyClass {
   void operator delete  ( void* ptr, void* place ){
   ...
   }
};
```

To find the `operator delete` corresponding to an `operator new`, see the reference pages for `operator new` and `operator delete`.

## Examples

### Mismatch Between Overloaded operator new and operator delete

```
#include <new>
#include <cstdlib>

int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
      global_store++;
   else
      global_store--;
}

void *operator new(std::size_t size, const std::nothrow_t& tag);
void *operator new(std::size_t size, const std::nothrow_t& tag) {
    void *ptr = (void*)malloc(size);
    if (ptr != nullptr)
        update_bookkeeping(ptr, true);
    return ptr;
}

void operator delete[](void *ptr, const std::nothrow_t& tag);
void operator delete[](void* ptr, const std::nothrow_t& tag) {
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

In this example, the operators `operator new` and `operator delete[]` are overloaded but there are no overloads of the corresponding `operator delete` and `operator new[]` operators.

The overload of `operator new` calls a function `update_bookkeeping` to change the value of a global variable `global_store`. If the default `operator delete` is called, this global variable is unaffected, which might defy developer's expectations.

#### Correction — Overload the Correct Form of operator delete

If you want to overload `operator new`, overload the corresponding form of `operator delete` in the same scope.

```
#include <new>
#include <cstdlib>

int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
      global_store++;
   else
      global_store--;
}
```

```
void *operator new(std::size_t size, const std::nothrow_t& tag);
void *operator new(std::size_t size, const std::nothrow_t& tag) {
    void *ptr = (void*)malloc(size);
    if (ptr != nullptr)
        update_bookkeeping(ptr, true);
    return ptr;
}

void operator delete(void *ptr, const std::nothrow_t& tag);
void operator delete(void* ptr, const std::nothrow_t& tag) {
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

### Result Information

# Missing reset of freed pointer

Pointer `free` not followed by a reset statement to clear leftover data

## Description

This defect occurs when a pointer is freed and not reassigned another value. After freeing a pointer, the memory data is still accessible. To clear this data, the pointer must also be set to NULL or another value.

### Risk

Not resetting pointers can cause dangling pointers. Dangling pointers can cause:

- Freeing already freed memory.
- Reading from or writing to already freed memory.
- Hackers executing code stored in freed pointers or with vulnerable permissions.

### Fix

After freeing a pointer, if it is not immediately assigned to another valid address, set the pointer to NULL.

## Examples

### Free Without Reset

```
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};

void allocateAndFreeMemory()
{
    static char *str = NULL;

    if (str == NULL)
        str = (char *)malloc(SIZE20);

    if (str != NULL)
        free(str);
}
```

In this example, the pointer `str` is freed at the end of the program. The next call to `allocateAndFreeMemory` can fail because `str` is not NULL and the initialization to NULL can be invalid.

#### Correction — Redefine `free` to Free and Reset

One possible correction is to customize `free` so that when you free a pointer, it is automatically reset.

```
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};

static void sanitize_free(void **p)
{
    if ((p != NULL) && (*p != NULL))
    {
        free(*p);
        *p = NULL;
    }
}

#define free(X) sanitize_free((void **)&X)

void allocateAndFreeMemory()
{
    static char *str = NULL;

    if (str == NULL)
        str = (char *)malloc(SIZE20);

    if (str != ((void *)0))
    {
        free(str);
    }
}
```

### Result Information

**Group:** Good Practice
**Language:** C | C++

# Macro with multiple statements

Macro consists of multiple semicolon-terminated statements, enclosed in braces or not

## Description

This defect occurs when a macro contains multiple semicolon-terminated statements, irrespective of whether the statements are enclosed in braces.

### Risk

The macro expansion, in certain contexts such as an `if` condition or a loop, can lead to unintended program logic.

For instance, consider the macro:

```
#define RESET(x,y) \
   x=0; \
   y=0;
```

In an `if` statement such as:

```
if(checkSomeCondition)
   RESET(x,y);
```

the macro expands to:

```
if(checkSomething)
   x=0;
y=0;
```

which might be unexpected if you want both statements to be executed in an `if` block.

### Fix

In a macro definition, wrap multiple statements in a `do...while(0)` loop.

For instance, in the preceding example, use the definition:

```
#define RESET(x,y) \
   do { \
     x=0; \
     y=0; \
   } while(0)
```

This macro is appropriate to expand in all contexts. The `while(0)` ensures that the statements are executed only once.

Alternatively, use inline functions in preference to function-like macros that involve multiple statements.

Note that the loop is required for the correct solution and wrapping the statements in braces alone does not fix the issue. The macro expansion can still lead to unintended code.

## Examples

### Macro with Multiple Statements

```
#define RESET(x,y) \
   x=0; \
   y=0;

void func(int *x, int *y, int resetFlag){
    if(resetFlag)
        RESET(x,y);
}
```

In this example, the defect occurs because the macro RESET consists of multiple statements.

#### Correction – Wrap Multiple Statements of Macro in do-while Loop

Wrap the statements of the macro in a do..while(0) loop in the macro definition.

```
#define RESET(x,y) \
   do { \
     x=0; \
     y=0; \
   } while(0)

void func(int *x, int *y, int resetFlag){
    if(resetFlag)
        RESET(x,y);
}
```

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** MULTI_STMT_MACRO
**Impact:** Low

# Version History

**Introduced in R2020a**

# Possibly inappropriate data type for switch expression

switch expression has a data type other than char, short, int or enum

## Description

This defect occurs when a switch expression has a data type other than char, short, int or enum.

The checker flags other integer data types such as boolean types, bit fields, or long.

### Risk

It is preferred to use char, short, int or enum in switch expressions instead of:

- Boolean types, because a switch expression with a boolean type can be replaced with an if condition that evaluates the same expression. A switch expression is too heavy for a simple control flow based on a boolean condition.
- Bit field types, because bit field types imply memory restrictions. If you just want to specify a variable with a finite number of values, enumerations are preferred since they enable a more readable code.
- Types with size greater than int because a switch expression that requires a type with size greater than int implies too many case labels and can be possibly redesigned.

Non-integer types are not supported in switch expressions.

### Fix

Use variables of char, short, int or enum data types in switch expressions.

## Examples

### Use of Inappropriate Types in switch Expressions

```
#ifndef __cplusplus
#include <stdbool.h>
#endif

void func(bool s) {
    switch(s) {
        case 0: //Perform some operation
        break;
        case 1: //Perform another operation
        break;
    }
}
```

In this C++ example, the checker flags the use of a bool variable in a switch expression.

#### Correction – Use `if` Condition Instead of `switch`

If the `switch` expression indeed requires two values, use an `if` statement instead.

```
#ifndef __cplusplus
#include <stdbool.h>
#endif

void func(bool s) {
    if(s) {
        //Perform some operation
        }
    else {
        //Perform another operation
        }
}
```

#### Correction – Use Different Data Type

If you anticipate adding more labels to the `switch` expression later, use a data type that can accommodate larger values.

```
void func(char s) {
    switch(s) {
        case 0: //Perform some operation
        break;
        case 1: //Perform another operation
        break;
        default: //Default behavior
    }
}
```

## Result Information

# Semicolon on the same line as an if, for or while statement

Semicolon on same line results in empty body of `if`, `for` or `while` statement

## Description

This defect occurs when a semicolon on the same line as the last token of an `if`, `for` or `while` statement results in an empty body.

The checker makes an exception for the case where the `if` statement is immediately followed by an `else` statement:

```
if(condition);
else {
  ...
}
```

### Risk

The semicolon following the if, for or while statement often indicates a programming error. The spurious semicolon changes the execution flow and leads to unintended results.

### Fix

If you want an empty body for the `if`, `for` or `while` statement, wrap the semicolon in a block and place the block on a new line to explicitly indicate your intent:

```
if(condition)
   {;}
```

Otherwise, remove the spurious semicolon.

## Examples

### Spurious Semicolon

```
int credentialsOK(void);

void login () {
    int loggedIn = 0;
    if(credentialsOK());
      loggedIn = 1;
}
```

In this example, the spurious semicolon results in an empty `if` body. The assignment `loggedIn=1` is always performed. However, the assignment was probably to be performed only under a condition.

#### Correction – Remove Spurious Semicolon

If the semicolon was unintended, remove the semicolon.

```
int credentialsOK(void);

void login () {
    int loggedIn = 0;
    if(credentialsOK())
      loggedIn = 1;
}
```

## Result Information

# Unmodified variable not const-qualified

Variable not `const`-qualified but variable value not modified during lifetime

## Description

This defect occurs when a local variable is not `const`-qualified and one of the following statements is true during the variable lifetime:

- You do not perform write operations on the variable after initialization.
- When you perform write operations, you reassign the same constant value to the variable.

The checker considers a variable as modified if its address is assigned to a pointer or reference (unless it is a pointer or reference to a `const` variable), passed to another function, or otherwise used. In these situations, the checker does not suggest adding a `const` qualifier.

The checker flags arrays as candidates for `const`-qualification only if you do not perform write operations on the array elements at all after initialization.

### Risk

`const`-qualifying a variable avoids unintended modification of the variable during later code maintenance. The `const` qualifier also indicates to a developer that the variable retains its initial value in the remainder of the code.

### Fix

If you do not expect to modify a variable value during its lifetime, add the `const` qualifier to the variable declaration and initialize the variable at declaration.

If you expect the variable to be modified, see if the absence of a modification indicates a programming omission and fix the issue.

## Examples

### Missing `const` Qualification on Pointer

```
#include <string.h>

char returnNthCharacter (int n) {
    char* pwd = "aXeWdf10fg" ;
    char nthCharacter;

    for(int i=0; i < strlen(pwd); i++) {
        if(i==n)
            nthCharacter = pwd[i];
    }
    return nthCharacter;
}
```

In this example, the pointer pwd is not `const`-qualified. However, beyond initialization with a constant, it is not reassigned anywhere in the `returnNthCharacter` function.

#### Correction – Add const at Variable Declaration

If the variable is not intended to be modified, add the const qualifier at declaration. In this example, both the pointer and the pointed variable are not modified. Add a const qualifier to both the pointer and the pointed variable. Later modifications cannot reassign the pointer pwd to point at a different variable nor modify the value at the pointed location.

```
#include <string.h>

char returnNthCharacter (int n) {
    const char* const pwd = "aXeWdf10fg" ;
    char nthCharacter;

    for(int i=0; i < strlen(pwd); i++) {
        if(i==n)
            nthCharacter = pwd[i];
    }
    return nthCharacter;
}
```

Note that the checker only flags the missing const from the pointer declaration. The checker does not determine if the pointed location also merits a const qualifier.

### Reassignment of Variable to Initial Value

```
void resetBuffer(int aCondition) {
    int addr = 0xff;
    if(aCondition){
        addr = 0xff;
    }
    else {
        addr = 0xff;
    }
}
```

In this example, the variable addr is initialized to a value and reassigned the same value twice. In larger code examples, such issues can easily arise from copy-paste errors.

#### Correction – Fix Programming Error

The reassignment in this example indicates a possible programming error. One possible correction is to fix the programming error and thereby avoid reassigning the same value.

```
void resetBuffer(int aCondition) {
    int addr = 0xff;
    if(aCondition){
        addr = 0x00;
    }
}
```

## Result Information

# Unused parameter

Function prototype has parameters not read or written in function body

## Description

This defect occurs when a function parameter is neither read nor written in the function body. The checker does not flag unused parameters in functions with empty bodies.

### Risk

Unused parameters can indicate that the code is possibly incomplete. The parameter is possibly intended for an operation that you forgot to code.

If the copied objects are large, redundant copies can slow down performance.

### Fix

Determine if you intend to use the parameters. Otherwise, remove parameters that you do not use in the function body.

You can intentionally have unused parameters. For instance, you have parameters that you intend to use later when you add enhancements to the function. Add a code comment indicating your intention for later use. The code comment helps you or a code reviewer understand why your function has unused parameters.

Alternatively, add a statement such as `(void)var;` in the function body. `var` is the unused parameter. You can define a macro that expands to this statement and add the macro to the function body.

## Examples

### Unused Parameter

```
void func(int* xptr, int* yptr, int flag) {
    if(flag==1) {
        *xptr=0;
    }
    else {
        *xptr=1;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

In this example, the parameter `yptr` is not used in the body of `func`.

### Correction — Use Parameter

One possible correction is to check if you intended to use the parameter. Fix your code if you intended to use the parameter.

```
void func(int* xptr, int* yptr, int flag) {
    if(flag==1) {
        *xptr=0;
        *yptr=1;
    }
    else {
        *xptr=1;
        *yptr=0;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

### Correction — Explicitly Indicate Unused Parameter

Another possible correction is to explicitly indicate that you are aware of the unused parameter.

```
#define UNUSED(x) (void)x

void func(int* xptr, int* yptr, int flag) {
    UNUSED(yptr);
    if(flag==1) {
        *xptr=0;
    }
    else {
        *xptr=1;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `UNUSED_PARAMETER`
**Impact:** Low

# Useless include

An include directive is present but not used

## Description

This defect occurs when you do not use an included header.

For instance, when you do not:

- Invoke macros defined in the included file or the included file's includes.
- Use data types defined in the included file or the included file's includes.
- Call or use references to an object or function defined in the included file or the included file's includes.
- Use an externally visible object provided by the included file outside of the file.

### Risk

Unnecessary file dependencies slow the build speed of the project. To improve build speed, remove include directives that are not used.

### Fix

Remove the unused include directive.

## Examples

### Unused Include Directive

This example does not use the `<cmath>` and `<stdexcedpt>` header files or their include directives.

```
#include <iostream>     //Compliant
#include <cmath>        //Noncompliant
#include <stdexcept>    //Noncompliant
#include <vector>       //Compliant

int age = 0;
std::vector<int> allAges;

void saveAge()
{
    std::cout << "Enter age: ";
    std::cin >> age;

    allAges.push_back(age);
}

int main() {
    while (age <= 40)
    {
        saveAge();
    }

    for (int x : allAges)
    {
        std::cout << x << std::endl;
    }

    return 0;
}
```

**Correction — Remove Unused Include Directives**

One correction is to delete the unused include directives from the file.

```
#include <iostream>
#include <vector>

int age = 0;
std::vector<int> allAges;

void saveAge()
{
    std::cout << "Enter age: ";
    std::cin >> age;

    allAges.push_back(age);
}

int main() {
    while (age <= 40)
    {
        saveAge();
    }

    for (int x : allAges)
    {
        std::cout << x << std::endl;
    }

    return 0;
}
```

## Result Information

# Use of a forbidden function

Use of function that appears in a blocklist of forbidden functions

## Description

This defect occurs when you use a function that appears in a blocklist of forbidden functions. To create the blocklist:

- List functions in an XML file in a specific syntax.

  Copy the template file `code-behavior-specifications-template.xml` from the folder *`polyspaceroot`*`\polyspace\verifier\cxx` to a writable location and modify the file. Enter each function in the file using the following syntax after existing similar entries:

  ```
  <function name="funcname">
     <behavior name="FORBIDDEN_FUNC"/>
  </function>
  ```

  where *`funcname`* is the name of the function you want to block.
- Specify this XML file as argument for the option `-code-behavior-specifications`. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

### Risk

A function might be blocked for one of these reasons:

- The function can lead to many situations where the behavior is undefined leading to security vulnerabilities, and a more secure function exists.

  You can forbid functions that are not explicitly checked by existing checkers such as `Use of dangerous standard function` or `Use of obsolete standard function`.
- The function is being deprecated as part of a migration, for instance, from C++98 to C++11.

  As part of a migration, you can make a list of functions that need to be replaced and use this checker to identify their use.

### Fix

Replace the blocked function with an allowed function.

When rolling out this checker to a group, project or organization, create a list of blocked functions and their replacements so that results reviewers can consult the list and make appropriate replacements.

### Extend Checker

This defect checker requires a blocklist of functions to be specified. Even if you specify the checker using the option `Find defects (-checkers)`, it is not enabled unless you also specify the blocklist. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

## Examples

### Use of Forbidden Function `std::signal`

```
#include <csignal>
#include <iostream>

namespace
{
  volatile std::sig_atomic_t gSignalStatus;
}

void signal_handler(int signal)
{
  gSignalStatus = signal;
}

int main()
{
  // Install a signal handler
  std::signal(SIGINT, signal_handler);

  std::cout << "SignalValue: " << gSignalStatus << '\n';
  std::cout << "Sending signal " << SIGINT << '\n';
  std::raise(SIGINT);
  std::cout << "SignalValue: " << gSignalStatus << '\n';
}
```

Suppose you want to deprecate the `std::signal` function. Add the following to the template XML file after similar existing entries:

```
<?xml version="1.0" encoding="UTF-8"?>
<specifications xmlns="http://www.mathworks.com/PolyspaceCodeBehaviorSpecifications">
  <functions>
     <function name="std::signal">
        <behavior name="FORBIDDEN_FUNC"/>
     </function>
   </functions>
</specifications>
```

and specify the XML file with the option `-code-behavior-specifications`.

In the analysis results, all uses of the `std::signal` function are flagged by this checker.

### Blocking C++ Overloaded Operators

```
class orderedPair {
        int var1;
        int var2;
    public:
        orderedPair() {
            var1 = 0;
            var2 = 0;
        }
        orderedPair(int arg1, int arg2) {
            var1 = arg1;
            var2 = arg2;
        }
        orderedPair& operator=(const orderedPair& rhs) {
            var1 = rhs.var1;
            var2 = rhs.var2;
            return *this;
        }
        orderedPair& operator+(orderedPair& rhs) {
            var1 += rhs.var1;
            var2 += rhs.var2;
            return *this;
        }
};

void main() {
    int one=1, zero=0, sum;
    orderedPair firstOrderedPair(one, one);
    orderedPair secondOrderedPair(zero, one);
    orderedPair sumPair;

    sum = zero + one;
    sumPair = firstOrderedPair + secondOrderedPair;
}
```

Suppose you want to identify all the locations where operator overloads in the `orderedPair` class are used. Add the overloaded operators to the template XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<specifications xmlns="http://www.mathworks.com/PolyspaceCodeBehaviorSpecifications">
  <functions>
     <function name="orderedPair::operator=">
        <behavior name="FORBIDDEN_FUNC"/>
     </function>
     <function name="orderedPair::operator+">
        <behavior name="FORBIDDEN_FUNC"/>
     </function>
   </functions>
</specifications>
```

and specify the XML file with the option `-code-behavior-specifications`.

The analysis identifies all calls to the overloaded operators and flags their use. Using this method, you can distinguish specific overloads of an operator instead of searching for and browsing through all instances of the operator.

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `FORBIDDEN_FUNC`
**Impact:** Low

# Version History

**Introduced in R2020a**

# Use of a forbidden C/C++ keyword

Use of keyword that appears in a blocklist of forbidden keywords

## Description

This defect occurs when you use a keyword that appears in a blocklist of forbidden keywords. To create the blocklist:

- List keywords in an XML file in a specific syntax.

  Copy the template file `code-behavior-specifications-template.xml` from the folder *`polyspaceroot`*`\polyspace\verifier\cxx` to a writable location and modify the file. Enter each keyword in the file using the following syntax after existing similar entries:

  ```
  <token name="keywordname" kind="keyword">
        <behavior name="FORBIDDEN_KEYWORD"/>
  </token>
  ```

  where *`keywordname`* is the name of the keyword you want to block.
- Specify this XML file as argument for the option `-code-behavior-specifications`. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

The checker can be used to forbid keywords with whitespaces such as `for each` or `enum class`.

### Risk

A keyword might be blocked for one of these reasons:

- The keyword is prone to misuse or makes the code difficult to maintain.
- The keyword is being deprecated as part of a migration, for instance, from C++98 to C++11.

  As part of a migration, you can make a list of keywords that need to be replaced and use this checker to identify their use.

### Fix

Replace the blocked keyword with an allowed keyword.

When rolling out this checker to a group, project or organization, create a list of blocked keywords and their replacements so that results reviewers can consult the list and make appropriate replacements.

### Extend Checker

This defect checker requires a blocklist of keywords to be specified. Even if you specify the checker using the option `Find defects (-checkers)`, it is not enabled unless you also specify the blocklist. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

## Examples

### Use of Forbidden Keyword `final`

```
class Base {
public:
    virtual bool isThisFinal() const {
        return false;
    }
};
class final : public Base {
    virtual bool isThisFinal() const
    override
    final {
        return true;
    }
};
```

Suppose you want to deprecate the `final` keyword. Add the following to the template XML file after similar existing entries:

```
<?xml version="1.0" encoding="UTF-8"?>
<specifications xmlns="http://www.mathworks.com/PolyspaceCodeBehaviorSpecifications">
  <tokens>
    <token name="final" kind="keyword">
       <behavior name="FORBIDDEN_KEYWORD"/>
    </token>
  </tokens>
</specifications>
```

and specify the XML file with the option `-code-behavior-specifications`.

In the analysis results, all uses of the `final` keyword are flagged by this checker. Note that the checker flags only the keyword `final` and not the class name `final`.

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `FORBIDDEN_KEYWORD`
**Impact:** Low

# Version History

**Introduced in R2022a**

# Use of a forbidden macro

Use of macro that appears in a blocklist of forbidden macros

## Description

This defect occurs when you use a macro that appears in a blocklist of forbidden macros. To create the blocklist:

- List macros in an XML file in a specific syntax.

  Copy the template file `code-behavior-specifications-template.xml` from the folder *`polyspaceroot`*`\polyspace\verifier\cxx` to a writable location and modify the file. Enter each macro in the file using the following syntax after existing similar entries:

  ```
  <token name="macroname" kind="macro">
        <behavior name="FORBIDDEN_MACRO"/>
  </token>
  ```

  where *`macroname`* is the name of the macro you want to block.
- Specify this XML file as argument for the option `-code-behavior-specifications`. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

### Risk

A macro might be blocked for one of these reasons:

- The macro is prone to misuse or makes the code difficult to maintain.
- The macro is being deprecated as part of a migration. For instance, you might want to allow the boolean macros `TRUE` and `FALSE` only in their all-caps form, and forbid other forms such as `true` and `false`.

  As part of a migration, you can make a list of macros that need to be replaced and use this checker to identify their use.

### Fix

Replace the blocked macro with an allowed macro.

When rolling out this checker to a group, project or organization, create a list of blocked macros and their replacements so that results reviewers can consult the list and make appropriate replacements.

### Extend Checker

This defect checker requires a blocklist of macros to be specified. Even if you specify the checker using the option `Find defects (-checkers)`, it is not enabled unless you also specify the blocklist. See “Flag Deprecated or Unsafe Functions, Keywords, or Macros Using Bug Finder Checkers”.

## Examples

### Use of Forbidden Macros `true` and `false`

```
#define TRUE 1u
#define FALSE 0u
#define true 1u
#define false 0u

unsigned char isPositive(int num){
    if(num > 0)
        return TRUE;
    else
        return FALSE;
}

unsigned char isEven(int num){
    if(num%2 == 0)
        return true;
    else
        return false;
}
```

Suppose you want to allow the boolean macros `TRUE` and `FALSE` only in their all-caps form, and forbid other forms such as `true` and `false`. Add the following to the template XML file after similar existing entries:

```
<?xml version="1.0" encoding="UTF-8"?>
<specifications xmlns="http://www.mathworks.com/PolyspaceCodeBehaviorSpecifications">
  <tokens>
    <token name="true" kind="macro">
       <behavior name="FORBIDDEN_MACRO"/>
    </token>
    <token name="false" kind="macro">
       <behavior name="FORBIDDEN_MACRO"/>
    </token>
  </tokens>
</specifications>
```

and specify the XML file with the option `-code-behavior-specifications`.

In the analysis results, all uses of the `true` and `false` macros are flagged by this checker.

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `FORBIDDEN_MACRO`
**Impact:** Low

# Use of setjmp/longjmp

`setjmp` and `longjmp` cause deviation from normal control flow

## Description

This defect occurs when you use a combination of `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` to deviate from normal control flow and perform non-local jumps in your code.

### Risk

Using `setjmp` and `longjmp`, or `sigsetjmp` and `siglongjmp` has the following risks:

- Nonlocal jumps are vulnerable to attacks that exploit common errors such as buffer overflows. Attackers can redirect the control flow and potentially execute arbitrary code.
- Resources such as dynamically allocated memory and open files might not be closed, causing resource leaks.
- If you use `setjmp` and `longjmp` in combination with a signal handler, unexpected control flow can occur. POSIX does not specify whether `setjmp` saves the signal mask.
- Using `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` makes your program difficult to understand and maintain.

### Fix

Perform nonlocal jumps in your code using `setjmp/longjmp` or `sigsetjmp/siglongjmp` only in contexts where such jumps can be performed securely. Alternatively, use POSIX threads if possible.

In C++, to simulate throwing and catching exceptions, use standard idioms such as `throw` expressions and `catch` statements.

## Examples

### Use of `setjmp` and `longjmp`

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

static jmp_buf env;
void sighandler(int signum) {
    longjmp(env, signum);
}
void func_main(int i) {
    signal(SIGINT, sighandler);
    if (setjmp(env)==0) {
        while(1) {
            /* Main loop of program, iterates until SIGINT signal catch */
            i = update(i);
        }
    } else {
        /* Managing longjmp return */
        i = -update(i);
    }

    print_int(i);
    return;
}
```

In this example, the initial return value of `setjmp` is 0. The `update` function is called in an infinite `while` loop until the user interrupts it through a signal.

In the signal handling function, the `longjmp` statement causes a jump back to `main` and the return value of `setjmp` is now 1. Therefore, the `else` branch is executed.

**Correction — Use Alternative to `setjmp` and `longjmp`**

To emulate the same behavior more securely, use a `volatile` global variable instead of a combination of `setjmp` and `longjmp`.

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

volatile sig_atomic_t eflag = 0;

void sighandler(int signum) {
     eflag = signum;                   /* Fix: using global variable */
}

void func_main(int i) {
      /* Fix: Better design to avoid use of setjmp/longjmp */
    signal(SIGINT, sighandler);
    while(!eflag) {                   /* Fix: using global variable */
        /* Main loop of program, iterates until eflag is changed */
        i = update(i);
    }

    print_int(i);
    return;
}
```

## Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `SETJMP_LONGJMP_USE`
**Impact:** Low

# Redundant expression in sizeof operand

`sizeof` operand contains expression that is not evaluated

## Description

This defect occurs when a `sizeof` operand contains expressions whose evaluation does not affect the `sizeof` result. In place of the current expression in the `sizeof` operand, a data type, a variable or a simpler expression could have been used without any loss of functionality.

### Risk

In situations flagged by this defect, the expression in the `sizeof` operand is needlessly complicated, reduces the code readability and adds to maintainability costs. The expression might also give a false impression about the result of the `sizeof` operand.

For instance, consider the expression:

```
sizeof(void (*[n])(int arr[U+V]))
```

The operand of `sizeof` is an array of `n` function pointers, each of type `void () (int*)`. The additional `U+V`, which is not evaluated, makes the full expression needlessly complicated. The expression also gives the false impression that the function pointer argument being an array of size `U+V` matters for the `sizeof` result.

### Fix

The first event in the defect traceback shows where the redundant subexpression of the `sizeof` operand begins.

Simplify or completely remove the redundant expression. When possible, use a data type as the `sizeof` operand. For instance, in the preceding example, a simpler equivalent `sizeof` operation is:

```
sizeof(void (*[n])(int*))
```

If you want the expression to be evaluated, perform the evaluation in a separate statement.

## Examples

### Unnecessarily Complex Expression in `sizeof` Operand

```
void func() {
    int size1, size2, size3;
    char x = 0;
    short y = 0;
    int z = 0, w = 0;

    size1 = sizeof(x + y);
    size2 = sizeof(x + z);
    size3 = sizeof(z + w);
}
```

In this example, the defect checker flags the second and third `sizeof` operation because the expressions in the `sizeof` operand can be simplified without changing the `sizeof` result.

The checker does not flag the first operation because the expression in the `sizeof` operand cannot be simplified further without affecting the `sizeof` result.

#### Correction – Simplify Expression in `sizeof` Operand

Simplify the expression in the `sizeof` operand. In the following corrections, the `sizeof` results are the same as with the preceding expressions.

```
void func() {
    int size1, size2, size3;
    char x = 0;
    short y = 0;
    int z = 0, w = 0;

    size1 = sizeof(x + y);
    size2 = sizeof(z);
    size3 = sizeof(z);
}
```

### Result Information

**Group:** Good practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `SIZEOF_USELESS_OP`
**Impact:** Low

## Version History

**Introduced in R2020a**

# File does not compile

File has a compilation error

## Description

This defect occurs when Polyspace cannot analyze a file because of compilation errors. The defect is located on the first line and column of the file, and indicates that the file has one or more compilation errors.

To find the actual compilation errors, see the analysis log. For information on how to investigate further in:

- Polyspace Bug Finder or Polyspace Bug Finder Server, see "View Error Information When Analysis Stops".
- Polyspace as You Code, see how to follow the progress of analysis in your IDE. See steps in Visual Studio, Visual Studio Code or Eclipse.

Use this checker to find out at a glance whether you have files with compilation issues in an integration analysis (Polyspace Bug Finder or Polyspace Bug Finder Server) or whether the current file being analyzed does not compile yet (Polyspace as You Code). Using this checker saves you from opening the analysis log each time to find out if there are compilation issues. You can determine from your analysis results if a file did not compile.

### Risk

Typically, your compiler can also find the issues that this defect checker finds.

If your file compiles with your compiler but the compilation phase of a Polyspace analysis fails, it means that your analysis configuration does not emulate your compiler accurately. For instance, if the analysis fails because a standard library function appears to be undefined, you might have to explicitly specify the folders containing your compiler headers, use the `polyspace-configure` command to extract the paths, or otherwise improve your configuration.

### Fix

Identify all compilation errors from the analysis log and fix them.

## Examples

### Undefined Identifier

```
int nthFib (int n) {
    int i=0, sum=1;
    for (int iter = 0; iter < n; iter++) {
      int t = i;
      i = sum;
      sum += t;
    }
    return iter;
}
```

In this example, the variable `iter` is defined only in the `for` loop. But the `return` statement outside the loop refers to the variable, causing an undefined identifier error. (The compilation error here also indicates a logical error since the intent was to return the variable `sum`.)

**(C++ Only) Missing Header**

```
#include <cstdio>
#include <cstdlib>

void func() {
   char* message = (char*)malloc (strlen ("Hello, World\n")+1);
   strcpy (message, "Hello, World\n");
   printf ("%s", message);
   free (message);
}
```

In this example, the string functions `strlen` and `strcpy` are used but the header file `cstring` is not included. This leads to the functions appearing as undefined.

## Result Information

**Group:** Good Practice
**Language:** C | C++
**Default:** Off
**Command-Line Syntax:** `FILE_DOES_NOT_COMPILE`
**Impact:** Low

# Declaration of catch for generic exception

A `catch` block handles a generic exception that might have many different subtypes

## Description

This defect occurs when you design `catch` blocks to handle generic high level exceptions. Polyspace checks the exception specifications of a function and raises a violation if a catch block handles:

- All exceptions by using a catch-all block.
- Exception of the class `std::exception`. Because `std::exception` is the base class for all standard C++ exceptions, a catch block that handles `std::exception` type matches all derived exceptions.

### Risk

Using generic catch blocks hides the emergence of unexpected new exceptions and hinders their proper handling. Such generic catch blocks makes the code vulnerable to security issues. For instance:

```
void foo(void){
    try{
        //..
    }catch(std::exception& e){
        //Log error
    }
}
```

Because the `catch` block handles the generic `std::exception` class, this code hides unexpected exceptions or those that need to be handled differently. For instance, If an unexpected `std::invalid_argument` exception is raised in `foo()`, it might remain undetected by the developer because it is matched with the catch block. Because the catch block is not programmed to handle `std::invalid_argument` properly, the poorly handled exception becomes a vulnerability for the code.

### Fix

To fix this defect, avoid catching high-level generic exceptions. Write catch blocks that handle specific exceptions to enable handling different exceptions in different ways. Unexpected or new exceptions are also easily detected when catch blocks are specific.

## Examples

### Avoid Generic Catch Blocks

```
#include<string>
#include<exception>
#include<stdexcept>

extern void logger(std::string s, std::exception& e);
void foo(void){
    try{
        //..
    }catch(std::exception& e){
         logger("foo failed", e);
    }
}
```

In this example, Polyspace flags the use of the generic `catch` block.

**Correction — Use Specific Catch Blocks**

To resolve this defect, use specific catch blocks. When you use specific catch blocks, new and unexpected exceptions become unhandled exceptions that are easily detected.

```
#include<string>
#include<exception>
extern void logger(std::string s, std::exception& e);
void foo(void){
    try{
        //..
    }catch(std::domain_error& e){
         logger("Domain Error in foo", e);
    }catch(std::invalid_argument& e){
        logger("Invalid Argument in foo", e);
    }
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `CATCH_FOR_GENERIC_EXCEPTION`

# Declaration of throw for generic exception

A function throws a generic exception, which might have many subtypes

## Description

This defect occurs when a function throws a generic exception. Polyspace checks the throw statements, dynamic exception specifications, or the documentation of a function and raises this defect if any of these conditions is true:

- The function contains `throw` statements that raise generic exceptions.
- The dynamic exception specification contains generic exceptions.
- The function is documented with a `@throw` comment that contains generic exceptions.

Polyspace considers exceptions of the class `std::exception` as generic.These are base exception classes that have many derived exception classes.

### Risk

Raising generic exceptions hinders proper error handling and error recovery. For instance:

```
void foo(void) throw(std::exception){
    //...
}

void caller(void){
    try{
        //...
        foo();
    }catch(std::exception& e){
        // Need to figure out what the error is.
    }
}
```

When handling the exceptions raised by `foo()`, determining what errors might happen in `foo()` is handled by `caller()`. Because the exception specification of `foo()` is broad, the emergence of new or unexpected exceptions might not be detected. Handling and recovering from errors in `foo()` becomes more complicated for `caller()`.

### Fix

To resolve this defect, use specific exceptions when documenting the exception in a function. Caller functions are then able to address specific exceptions by using specific error-handling code. Unexpected exceptions are easily detected.

## Examples

### Avoid Generic Exception Specification

```
#include<exception>
#include<stdexcept>
```

```
#include<iostream>

void foo(void) throw(std::exception){
    //...
}
// @throw std::exception
void bar() {  //Noncompliant
    //...
    throw std::exception();
}

void foo1(){
    //...
    throw std::exception();
}
int main(void){
    try{
        //...
        foo();
    }catch(std::exception& e){
        // Need to figure out what the error is.

    }
    try{
        //...
        bar();
    }catch(std::exception& e){
        // Need to figure out what the error is.

    }
    try{
        //...
        foo1();
    }catch(std::exception& e){
        // Need to figure out what the error is.

    }
}
```

In this example, Polyspace flags the generic `throw` specifications. For instance:

- Polyspace flags the dynamic exception specification of `foo()` because it uses `std::exception`.
- Polyspace flags the function `bar()` because it is documented to raise the generic exception `std::exception`. Polyspace also flags the generic `throw` statement in this function.
- Polyspace flags the generic `throw` statement in `foo1()`.

Because these functions raise generic exceptions, identifying the exceptions is handled by the caller function `main()`. Because the caller does not know which specific exception are expected, it might fail to detect unexpected exceptions.

#### Correction — Use Specific Exceptions

To fix this issue, document specific exceptions that might arise from a function. This specific documentation enables the caller function to address specific exceptions. Unexpected exceptions become unhandled exceptions and are easily detected.

```
#include<exception>
#include<stdexcept>
```

```
#include<iostream>

void foo(void) throw(std::overflow_error){
    //...
}
// @throw std::invalid_argument
void bar() {
    //...
}

void foo1(){
    //...
    throw std::range_error("MSG");
}
int main(void){
    try{
        //...
        foo();
    }catch(std::overflow_error& e){
        // Expecting an overflow.

    }
    try{
        //...
        bar();
    }catch(std::invalid_argument& e){
        // Expecting an invalid argument.

    }
    try{
        //...
        foo1();
    }catch(std::range_error& e){
        // Expecting a range error.

    }
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `THROW_FOR_GENERIC_EXCEPTION`
**Impact:** Low

# Public static field not `const`

A `static` and `public` field of a `struct` or `class` is not marked as a `const`

## Description

This defect occurs when all of these conditions are true:

- A class contains a data member that is both `static` and `public`
- The `static` and `public` data member is not `const`

### Risk

The `public` `static` data members of a class can be modified by any of class in the program. Unless `public` `static` data members are specified as `const`, they might be modified in unexpected ways and result in bugs that are difficult to diagnose.

### Fix

To resolve this defect, specify the `public static` data members as `const` or `constexpr`.

## Examples

### Avoid Nonconst `public static` Data Members

```
#include<string>
class SomeAppClass {

private:
    static std::string appPropertiesConfigFilep2;

protected:
    static std::string appPropertiesConfigFilepr2;

public:
    static std::string appPropertiesConfigFile2; //Defect

    static void foo() {}
    int bar() {
        static int v = 3;
        return v;
    }
};
```

In this example, the data member `appPropertiesConfigFile2` is `static` and `public`, but not `const`. Polyspace flags the member. The `static` data members that are `private` and `protected` are not flagged. This rule does not apply to `static` objects that are in the scope of `public` member functions of a class.

#### Correction — Declare `public static` Data Members as `const`

To resolve this defect, declare the `public static` data members of a class as `const`.

```
#include<string>
class SomeAppClass {

private:
    static std::string appPropertiesConfigFilep2;

protected:
    static std::string appPropertiesConfigFilepr2;

public:
    static const std::string appPropertiesConfigFile2; //No Defect

    static void foo() {}
    int bar() {
        static int v = 3;
        return v;
    }
};
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `PUBLIC_STATIC_FIELD_NOT_CONST`
**Impact:** Low

# Version History

**Introduced in R2022a**

# Method not `const`

A method that can be made `const` is not marked `const`

## Description

This defect occurs when a method that meets these criteria is not marked as a `const`:

- The method is not `virtual`.
- The method does not return pointers or references to nonconst data.
- The method does not modify any variables, does not call global functions, and does not call any nonconst member functions.

### Risk

If a method in your code satisfies the requirements of being a `const` method, then declaring the method as a `const` has these advantages:

- Objects that are `const` are not allowed to invoke nonconst methods. When you declare a method as `const`, some additional references and objects in your code might be declared as `const`, increasing the `const` correctness of your code.
- The C++11 standard assumes that `const` methods are free of data races. Using such methods in multiple threads does not require external synchronization, for instance, by using `mutex` objects. Using `const` method makes concurrent programming convenient.

Not declaring eligible methods a `const` makes maintaining the `const` correctness of your code more difficult. Code that is not const-correct remains vulnerable to unexpected mutation of variables, unexpected assignments, and inefficient compiler optimization.

### Fix

To fix this defect, declare eligible methods as `const`. If a `const` overload of the function already exists, consider removing the nonconst overload.

## Examples

### Declare Methods as `const` if Applicable

```
 class LossyPolymer{
    double n;
    double k;
    public:
    LossyPolymer(double n_in, double k_in):n(n_in), k(k_in){}
    double getN() {
        return n;
    }
    double getk() {
        return k;
    }

};
```

```
void foo(){
    LossyPolymer PMMA = LossyPolymer(1.5,0.001);
    const LossyPolymer PVK = LossyPolymer(1.6,0.01);
    int k_PMMA = PMMA.getk();
    //int k_PVK = PVK.getk(); Compile error
}
```

In this example, a class `LossyPolymer` is implemented that represents the optical properties of polymer materials. The optical properties of a `LossyPolymer` is represented by the private variables `n` and `k`. The class has getter methods for these variables that return a copy of the private variables. The getter methods of `LossyPolymer` do not modify any variable, but they are not declared `const`, perhaps inadvertently.

The class `LossyPolymer` represents a physical material. A physical material has constant optical properties. Objects of the class `LossyPolymer` are expected to be `const` objects, such as `PVK`. Because `getk()` is nonconst, the `const` object `PVK` cannot call its `getK()` method. To use the getter, you must declare instances of `LossyPolymer` as nonconst objects, which is not the best practice. The incorrect constness of the getter function prevents const-correct behavior in the code. Polyspace flags them.

#### Correction — Declare Eligible Methods as `const`

To fix this defect, declare the getter methods as `const`. Doing so allows you to declare `PVK` and `PMMA` as `const` objects and call the getter functions.

```
 class LossyPolymer{
    double n;
    double k;
    public:
    LossyPolymer(double n_in, double k_in):n(n_in), k(k_in){}
    const double getN() const{
        return n;
    }
    const double getk() const{
        return k;
    }

};

void foo(){
    LossyPolymer PMMA = LossyPolymer(1.5,0.001);
    const LossyPolymer PVK = LossyPolymer(1.6,0.01);
    int k_PMMA = PMMA.getk();
    int k_PVK = PVK.getk();
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `METHOD_NOT_CONST`
**Impact:** Low

# Reference to un-named temporary

Local reference is declared by using unnamed temporary variable that is returned by value

## Description

This defect occurs when:

1. A function returns an unnamed temporary object by value.
2. You declare a local reference by using the returned temporary object.

Consider this code:

```
std::string get();
const std::string &s = get();
```

The function `get()` returns a string by value. The local reference `s` is declared by using the unnamed temporary string. Polyspace reports a defect.

### Risk

Returning an object by copy and then declaring a local reference by using the returned copy can lead to unexpected behavior. For instance, If you later update the code to return the temporary object by reference, perhaps to improve performance, the local reference then resolves to a nonlocal object instead of a local copy. Modifying the nonlocal object causes unexpected results. See “Local Reference Declared by Using Unnamed Returned-by-Value Temporary Object” on page 20-85.

This defect can lead to inefficiencies in cases where it is possible to use the unnamed temporary object directly instead of using a reference to the temporary objeect. See “Local Reference Used for Passing Object to Function” on page 20-87.

### Fix

To fix this defect, capture the returned unnamed temporary object by using a variable instead of a reference. When possible, use the unnamed temporary object directly.

## Examples

### Local Reference Declared by Using Unnamed Returned-by-Value Temporary Object

In this example, the function `f.getname()` returns an unnamed temporary `std::string` object by value. The function `func` declares the local reference `s` by using this temporary string object. Polyspace reports a defect.

```
#include<string>
class myString
{
    public:
        myString(const std::string &s): m_name(s) {}

        std::string getName() const { return m_name; }
        void setName(const std::string &s) { m_name = s; }
    private:
        std::string m_name;
};

void func()
{
    myString f("Brian");

    const std::string &s = f.getName();

    f.setName("Bob");
    assert(s == "Brian"); //Succeeds
}
```

Suppose that to improve efficiency, you update the function `myString::getname` to return an `std::string` object by reference. Then, the reference `s` resolves to the string `myString::m_name` instead of a copy of the string. If your code relies on the fact that `s` is a copy of `myString::m_name`, then the code might produce unexpected results after the change to `myString::getname`. For instance, in the preceding code, `s` contains `Brian`, but in the following code, `s` contains `Bob`, which causes the `assert()` statement to fail.

```
#include<string>
class myString
{
    public:
        myString(const std::string &s): m_name(s) {}

        //Updated getname() for improved performance

        const std::string &getName() const { return m_name; }
        void setName(const std::string &s) { m_name = s; }

    private:
        std::string m_name;
};
void func()
{
    myString f("Brian");

    const std::string &s = f.getName();

    f.setName("Bob");
    assert(s == "Brian");//Fails!
}
```

**Correction — Avoid Using Local References to Store Returned-by-Value Objects**

To fix this defect, capture the returned-by-value temporary string in a variable instead of a reference.

```
#include<string>
class myString
{
    public:
        myString(const std::string &s): m_name(s) {}

        std::string getName() const { return m_name; }
        void setName(const std::string &s) { m_name = s; }
    private:
        std::string m_name;
};

void func()
{
    myString f("Brian");

    const std::string s = f.getName(); //No defect

    f.setName("Bob");
    assert(s == "Brian"); //Succeeds
}
```

The `assert` statement succeeds if `myString::getname` is later changed to return an `std::string` by reference.

#### Local Reference Used for Passing Object to Function

In some cases, it is more efficient to use the unnamed temporary object directly instead of capturing the object in a reference. For instance, in this code, Polyspace reports a defect.

```
#include<string>
extern       std::string  getSByValue();
extern void useString(std::string s);

void func()
{
    const std::string &s = getSByValue();
    useString(s);
}
```

##### Correction — Use Unnamed Temporary Directly

To fix this issue, use the unnamed temporary object directly when calling `useString()`. In this case, capturing the temporary object is unnecessary.

```
#include<string>
extern       std::string  getSByValue();
extern void useString(std::string s);

void func()
{
    useString(getSByValue());
}
```

## Result Information

**Group:** Good practice
**Language:** C++
**Default:** Off
**Command-Line Syntax:** `LOCAL_REF_TO_UNNAMED_TEMPORARY`
**Impact:** Low

# Polyspace Results: Coding Standards

21

# MISRA C 2012

# MISRA C:2012 Dir 1.1

Any implementation-defined behavior on which the output of the program depends shall be documented and understood

## Description

### Directive Definition

*Any implementation-defined behavior on which the output of the program depends shall be documented and understood.*

### Rationale

A code construct has implementation-defined behavior if the C standard allows compilers to choose their own specifications for the construct. The full list of implementation-defined behavior is available in Annex J.3 of the standard ISO/IEC 9899:1999 (C99) and in Annex G.3 of the standard ISO/IEC 9899:1990 (C90).

If you understand and document all implementation-defined behavior, you can be assured that all output of your program is intentional and not produced by chance.

### Polyspace Implementation

The analysis detects the following possibilities of implementation-defined behavior in C99 and their counterparts in C90. If you know the behavior of your compiler implementation, justify the analysis result with appropriate comments. To justify a result, assign one of these statuses: `Justified`, `No action planned`, or `Not a defect`.

**Tip** To mass-justify all results that indicate the same implementation-defined behavior, use the **Detail** column on the **Results List** pane. Click the column header so that all results with the same entry are grouped together. Select the first result and then select the last result while holding the `Shift` key. Assign a status to one of the results. If you do not see the **Detail** column, right-click any other column header and enable this column.

| C99 Standard Annex Ref | Behavior to Be Documented | How Polyspace Helps |
|---|---|---|
| J.3.2: Environment | An alternative manner in which `main` function may be defined. | The analysis flags `main` with arguments and return types other than:<br>`int main(void) { ... }`<br>or<br>`int main(int argc, char *argv[]) { ... }`<br>See section 5.1.2.2.1 of the C99 Standard. |

| C99 Standard Annex Ref | Behavior to Be Documented | How Polyspace Helps |
|---|---|---|
| J.3.2: Environment | The set of environment names and the method for altering the environment list used by the `getenv` function. | The analysis flags uses of the `getenv` function. For this function, you need to know the list of environment variables and how the list is modified.<br>See section 7.20.4.5 of the C99 Standard. |
| J.3.6: Floating Point | The rounding behaviors characterized by non-standard values of `FLT_ROUNDS`. | The analysis flags the include of `float.h` if values of `FLT_ROUNDS` are outside the set, {-1, 0, 1, 2, 3}. Only the values in this set lead to well-defined rounding behavior.<br>See section 5.2.4.2.2 of the C99 Standard. |
| J.3.6: Floating Point | The evaluation methods characterized by non-standard negative values of `FLT_EVAL_METHOD`. | The analysis flags the include of `float.h` if values of `FLT_EVAL_METHOD` are outside the set, {-1, 0, 1, 2}. Only the values in this set lead to well-defined behavior for floating-point operations.<br>See section 5.2.4.2.2 of the C99 Standard. |
| J.3.6: Floating Point | The direction of rounding when an integer is converted to a floating-point number that cannot exactly represent the original value. | The analysis flags conversions from integer to floating-point data types of smaller size (for example, 64-bit `int` to 32-bit `float`).<br>See section 6.3.1.4 of the C99 Standard. |
| J.3.6: Floating Point | The direction of rounding when a floating-point number is converted to a narrower floating-point number. | The analysis flags these conversions:<br>• `double` to `float`<br>• `long double` to `double` or `float`<br>See section 6.3.1.5 of the C99 Standard. |
| J.3.6: Floating Point | The default state for the `FENV_ACCESS` pragma. | The analysis flags use of the pragma other than:<br>`#pragma STDC FENV_ACCESS ON`<br>or<br>`#pragma STDC FENV_ACCESS OFF`<br>See section 7.6.1 of the C99 Standard. |

| C99 Standard Annex Ref | Behavior to Be Documented | How Polyspace Helps |
|---|---|---|
| J.3.6: Floating Point | The default state for the `FP_CONTRACT` pragma. | The analysis flags use of the pragma other than:<br>`#pragma STDC FP_CONTRACT ON`<br>or<br>`#pragma STDC FP_CONTRACT OFF`<br>See section 7.12.2 of the C99 Standard. |
| J.3.11: Preprocessing Directives | The behavior on each recognized non-STDC #pragma directive. | The analysis flags the pragma usage:<br>`#pragma` *`pp-tokens`*<br>where the processing token `STDC` does not immediately follow`pragma`. For instance:<br>`#pragma FENV_ACCESS ON`<br>See section 6.10.6 of the C99 Standard. |
| J.3.12: Library Functions | Whether the `feraiseexcept` function raises the ‘‘inexact’’ floating-point exception in addition to the ‘‘overflow’’ or ‘‘underflow’’ floating-point exception. | The analysis flags calls to the `feraiseexcept` function.<br>See section 7.6.2.3 of the C99 Standard. |
| J.3.12: Library Functions | Strings other than `"C"` and `""` that may be passed as the second argument to the `setlocale` function. | The analysis flags calls to the `setlocale` function when its second argument is not `"C"` or `""`.<br>See section 7.11.1.1 of the C99 Standard. |
| J.3.12: Library Functions | The types defined for `float_t` and `double_t` when the value of the `FLT_EVAL_METHOD` macro is less than 0 or greater than 2. | The analysis flags the include of `math.h` if `FLT_EVAL_METHOD` has values outside the set {0,1,2}.<br>See section 7.12 of the C99 Standard. |

| C99 Standard Annex Ref | Behavior to Be Documented | How Polyspace Helps |
|---|---|---|
| J.3.12: Library Functions | The base-2 logarithm of the modulus used by the `remquo` functions in reducing the quotient. | The analysis flags calls to the `remquo`, `remquof` and `remquol` function.<br>See section 7.12.10.3 of the C99 Standard. |
| J.3.12: Library Functions | The termination status returned to the host environment by the `abort`, `exit`, or `_Exit` function. | The analysis flags calls to the `abort`, `exit`, or `_Exit` function.<br>See sections 7.20.4.1, 7.20.4.3 or 7.20.4.4 of the C99 Standard. |

### Troubleshooting

All source files shall compile without any compilation errors

## Description

### Directive Definition

*All source files shall compile without any compilation errors*.

### Rationale

A conforming compiler is permitted to produce an object module despite the presence of compilation errors. However, execution of the resulting program can produce unexpected behavior.

### Polyspace Implementation

The software raises a violation of this directive if it finds a compilation error.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

Run-time failures shall be minimized

## Description

### Directive Definition

*Run-time failures shall be minimized.*

### Rationale

To optimize the size and speed of executable code, the C standard implements limited run-time failure checks. To reduce run-time failures, check these errors:

- Arithmetic errors
- Pointer arithmetic
- Array bound errors
- Function parameters
- Pointer dereferencing
- Dynamic memory

### Polyspace Implementation

Polyspace reports a violation of this directive if runtime issues exist in your code, including:

- `Integer division by zero`
- `Float division by zero`
- `Integer conversion overflow`
- `Unsigned integer conversion overflow`
- `Sign change integer conversion overflow`
- `Float conversion overflow`

Assembly language shall be encapsulated and isolated

## Description

### Directive Definition

*Assembly language shall be encapsulated and isolated*.

### Rationale

Encapsulating assembly language is beneficial because:

- Encapsulating assembly instructions in a C source files clearly marks the boundary between C and assembly, making the code easier to read.
- The name, and documentation, of the encapsulating macro or function makes the intent of the assembly language clear.
- All uses of assembly language for a given purpose can share encapsulation, which improves maintainability.
- You can easily substitute the assembly language for a different target or for static analysis purposes.

### Polyspace Implementation

Polyspace reports a violation of this rule if assembly language code is used without encapsulation. It is not a violation if the assembly code is encapsulated in:

- Assembly language functions. Consider this code:

  ```
  asm int h(int tt)  //Compliant
  {
    % reg val;
    mtmsr val;
    return 3;
  };

  void f(void) {
    int x;
    x = h(3);
  }
  ```

  The function `h()` is declared as an `asm` function which encapsulate the assembly code. Polyspace does not report a violation.
- `#pragma` directives. For example, in this code:

  ```
  #pragma inline_asm(h)
  int h(int tt)  //Compliant
  {
    % reg val;
    mtmsr val;
    return 3;
  };
  ```

```
void f(void) {
  int x;
  x = h(3);
}
```

The `#inline_asm` pragma designates the function `h()` as an assembly language function. Polyspace does not report a violation.

- Macros. For instance:

```
#define FUNC_H\
asm\
{\
 % reg val; \
  mtmsr val;\
  return 3; \
}; \

void f(void) {
  int x;
  x = FUNC_H(3);
}
```

The macro `FUNC_H` encapsulates the assembly code. Polyspace does not report a violation. You can also define such macros at the command line during the Polyspace analysis by using the options `Preprocessor definitions (-D)`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Assembly Language Code in C Function

```
enum boolVal {TRUE, FALSE};
enum boolVal isTaskActive;
void taskHandler(void);

void taskHandler(void) {
    isTaskActive = FALSE;
    // Software interrupt for task switching
    asm volatile   /* Non-compliant */
    (
        "SWI &02"     /* Service #1: calculate run-time */
    );
    return;
}
```

In this example, the rule violation occurs because the assembly language code is embedded directly in a C function `taskHandler` that contains other C language statements.

#### Correction — Encapsulate Assembly Code in Macro

One correction is to encapsulate the assembly language code in a macro and invoke the macro in the function `taskHandler`.

```
#define  RUN_TIME_CALC \
asm volatile \
    ( \
        "SWI &02"     /* Service #1: calculate run-Time */ \
    )\

enum boolVal {TRUE, FALSE};
enum boolVal isTaskActive;
void taskHandler(void);

void taskHandler(void) {
    isTaskActive = FALSE;
    RUN_TIME_CALC;
    return;
}
```

Sections of code should not be "commented out"

## Description

### Directive Definition

*Sections of code should not be "commented out"*.

### Rationale

C comments enclosed in `/* */` do not support nesting. A comment beginning with `/*` ends at the first `*/` even when the `*/` is intended as the end of a later nested comment. If a section of code that is commented out already contains comments, you can encounter compilation errors (or at least comment out less code than you intend).

Commenting out code is not a good practice. The commented out code can remain out of sync with the surrounding code without causing compilation errors. Later, if you uncomment the code, you can encounter unexpected issues.

Use comments only to explain aspects of the code that are not apparent from the code itself.

### Polyspace Implementation

The checker uses internal heuristics to detect commented out code. For instance, characters such as `#`, `;`, `{` or `}` indicate comments that might potentially contain code. These comments are then evaluated against other metrics to determine the likelihood of code masquerading as comment. For instance, several successive words without a symbol in between reduces this likelihood.

The checker does not flag the following comments even if they contain code:

- Doxygen comments beginning with `/**`, `/*!`, `///` or `//!`.
- Comments that repeat the same symbol more than five times, for instance, the symbol = here:

  ```
  /* =====================================
   * A comment
   * =====================================*/
  ```
- Comments on the first line of a file.
- Comments that mix the C style (`/* */`) and C++ style (`//`).
- Comments that contain one or more `@` symbol. If the `@` symbol is placed in a nested comment that contains code, Polyspace flags it. For instance:.

  ```
  int* q;
  //@Error int foo(void);
  //...
  void bar(void){
      /*
      int*p =  (int*) malloc(int); // Error @allocation
      */
  }
  ```

In the preceding code, Polyspace flags the second comment block containing the commented out `malloc` operation, and ignores the first comment.

The checker considers that these comments are meant for documentation purposes or entered deliberately with some forethought.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code Commented Out

```
#include <stdlib.h>
/* =====================================
 * usage:print32_tInteger();
 * =====================================*/
int32_t getRandInt();
void print32_t(int32_t);

//Error@ int32_t val = getRandInt();
void print32_tInteger() {
    /* int32_t val = getRandInt(); //Noncompliant
     * val++;  // contact support @..
     * print32_t(val); */
    print32_t(getRandInt());
}
```

This example contains several comments that contains code.

- The first comment block documents the usage of the function `print32_tInteger()`. Because the comment uses the symbol = more than five times, Polyspace does not flag this comment.
- The second comment documents the source of error in the code. Because the code contains the symbol `@`, Polyspace ignores the comment.
- The third comment block comments out code that might contain errors. This comment does not document anything and simply excludes code from compilation. Polyspace flags this code block. Because the `@` symbol is in a nested comment, Polyspace does not ignore the comment.

Identifiers in the same name space with overlapping visibility should be typographically unambiguous

## Description

### Directive Definition

*Identifiers in the same name space with overlapping visibility should be typographically unambiguous.*

### Rationale

What “unambiguous” means depends on the alphabet and language in which source code is written. When you use identifiers that are typographically close, you can confuse between them.

For the Latin alphabet as used in English words, at a minimum, the identifiers should not differ by:

- The interchange of a lowercase letter with its uppercase equivalent.
- The presence or absence of the underscore character.
- The interchange of the letter `O` and the digit `0`.
- The interchange of the letter `I` and the digit `1`.
- The interchange of the letter `I` and the letter `l`.
- The interchange of the letter `S` and the digit `5`.
- The interchange of the letter `Z` and the digit `2`.
- The interchange of the letter `n` and the letter `h`.
- The interchange of the letter `B` and the digit `8`.
- The interchange of the letters `rn` and the letter `m`.

### Polyspace Implementation

The checker flags identifiers in the same scope that differ from each other only in the above characters. Polyspace ignores identifiers that are defined in macros starting with `do`, `for`, `switch`, and `while`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Typographically Ambiguous Identifiers

```
void func(void) {
    int id1_numval;
    int id1_num_val;  /* Non-compliant */

    int id2_numval;
    int id2_numVal;   /* Non-compliant */

    int id3_lvalue;
    int id3_Ivalue;   /* Non-compliant */

    int id4_xyZ;
    int id4_xy2;      /* Non-compliant */

    int id5_zerO;
    int id5_zer0;     /* Non-compliant */

    int id6_rn;
    int id6_m;        /* Non-compliant */
}
```

In this example, the rule is violated when identifiers that can be confused for each other are used.

`typedefs` that indicate size and signedness should be used in place of the basic numerical types

## Description

### Directive Definition

*`typedefs` that indicate size and signedness should be used in place of the basic numerical types.*

### Rationale

When the amount of memory being allocated is important, using specific-length types makes it clear how much storage is being reserved for each object.

### Polyspace Implementation

The rule checker flags use of basic data types in variable or function declarations and definitions. The rule enforces use of `typedefs` instead.

The rule checker does not flag the use of basic types in the `typedef` statements themselves.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Direct Use of Basic Types in Definitions

```
typedef unsigned int uint32_t;

int x = 0;        /* Non compliant */
uint32_t y = 0;  /* Compliant */
```

In this example, the declaration of `x` is noncompliant because it uses a basic type directly.

If a function returns error information, then that error information shall be tested

## Description

### Directive Definition

*If a function returns error information, then that error information shall be tested*.

### Rationale

If you do not check the return value of functions that indicate error information through their return values, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

### Polyspace Implementation

The checker raises a violation when you call sensitive standard functions that return information about possible errors and you do one of the following:

- Ignore the return value.

  You simply do not assign the return value to a variable, or explicitly cast the return value to `void`.
- Use an output from the function (return value or argument passed by reference) without testing the return value for errors.

The checker considers a function as sensitive if the function call is prone to failure because of reasons such as:

- Exhausted system resources (for example, when allocating resources).
- Changed privileges or permissions.
- Tainted sources when reading, writing, or converting data from external sources.
- Unsupported features despite an existing API.

The checker only considers functions where the *return value* indicates if the function completed without errors.

Some of these functions can perform critical tasks such as:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

For functions that are not critical, the checker allows casting the function return value to `void`.

This directive is only partially supported.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Sensitive Function Return Ignored

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>
#include <cstdlib>
#define fatal_error() abort()

void initialize_1() {
    pthread_attr_t attr;
    pthread_attr_init(&attr); //Noncompliant
}

void initialize_2() {
    pthread_attr_t attr;
   (void)pthread_attr_init(&attr); //Compliant
}

void initialize_3() {
    pthread_attr_t attr;
    int result;
    result = pthread_attr_init(&attr); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}

int read_file_1(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r");
  return 0; //Noncompliant

}
int read_file_2(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r"); //Compliant
  if (in==NULL){
      // Handle error
  }
  return 0;
}
```

This example shows a call to the sensitive functions `pthread_attr_init` and `fmemopen`. Polyspace raises a flag if:

- You implicitly ignore the return of the sensitive function. Explicitly ignoring the output of sensitive functions is not flagged.
- You obtain the return value of a sensitive function but do not test the value before exiting the relevant scope. The violation is raised on the exit statement.

To be compliant, you can explicitly cast their return value to `void` or test the return values to check for errors.

### Critical Function Return Ignored

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked_1() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res); //Noncompliant
}

void returnnotchecked_2() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), the rule checker still raises a violation. The other critical function, `pthread_join`, returns a value that is ignored implicitly.

To be compliant, check the return value of these critical functions to verify the function performed as expected.

If a pointer to a structure or union is never dereferenced within a translation unit, then the implementation of the object should be hidden

## Description

### Rule Definition

*If a pointer to a structure or union is never dereferenced within a translation unit, then the implementation of the object should be hidden.*

### Rationale

If a pointer to a structure or union is not dereferenced in a file, the implementation details of the structure or union need not be available in the translation unit for the file. You can hide the implementation details such as structure members and protect them from unintentional changes.

Define an opaque type that can be referenced via pointers but whose contents cannot be accessed.

### Polyspace Implementation

If a structure or union is defined in a file or a header file included in the file, a pointer to this structure or union declared but the pointer never dereferenced in the file, the checker flags a coding rule violation. The structure or union definition should not be visible to this file.

If you see a violation of this rule on a structure definition, identify if you have defined a pointer to the structure in the same file or in a header file included in the file. Then check if you dereference the pointer anywhere in the file. If you do not dereference the pointer, the structure definition should be hidden from this file and included header files.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Object Implementation Revealed

`file.h`: Contains structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct  {
  int a;
} myStruct;

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

myStruct* getObj(void);
void useObj(myStruct*);

void func() {
  myStruct *sPtr = getObj();
  useObj(sPtr);
}
```

In this example, the pointer to the type `myStruct` is not dereferenced. The pointer is simply obtained from the `getObj` function and passed to the `useObj` function.

The implementation of `myStruct` is visible in the translation unit consisting of `file.c` and `file.h`.

**Correction — Define Opaque Type**

One possible correction is to define an opaque data type in the header file `file.h`. The opaque data type `ptrMyStruct` points to the `myStruct` structure without revealing what the structure contains. The structure `myStruct` itself can be defined in a separate translation unit, in this case, consisting of the file `file2.c`. The common header file `file.h` must be included in both `file.c` and `file2.c` for linking the structure definition to the opaque type definition.

`file.h`: Does not contain structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct myStruct *ptrMyStruct;

ptrMyStruct getObj(void);
void useObj(ptrMyStruct);

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

void func() {
  ptrMyStruct sPtr = getObj();
  useObj(sPtr);
}
```

`file2.c`: Includes `file.h` and dereferences structure.

```
#include "file.h"

struct myStruct {
  int a;
};

void useObj(ptrMyStruct ptr) {
    (ptr->a)++;
}
```

A function should be used in preference to a function-like macro where they are interchangeable

## Description

### Directive Definition

*A function should be used in preference to a function-like macro where they are interchangeable.*

### Rationale

In most circumstances, use functions instead of macros. Functions perform argument type-checking and evaluate their arguments once, avoiding problems with potential multiple side effects.

### Polyspace Implementation

Polyspace considers all function-like macro definitions.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

# MISRA C:2012 Dir 4.12

Dynamic memory allocation shall not be used

## Description

### Rule Definition

*Dynamic memory allocation shall not be used.*

### Rationale

Using dynamic memory allocation and deallocation routines provided by the Standard Library or third-party libraries can cause undefined behavior. For instance:

- You use `free` to deallocate memory that you did not allocate with `malloc`, `calloc`, or `realloc`.
- You use a pointer that points to a freed memory location.
- You access allocated memory that has no value stored into it.

Dynamic memory allocation and deallocation routines from third-party libraries are likely to exhibit similar undefined behavior.

If you choose to use dynamic memory allocation and deallocation routines, ensure that your program behavior is predictable. For example, ensure that you safely handle allocation failure due to insufficient memory.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `malloc`, `calloc`, `realloc` and `free`

```
#include <stdlib.h>

static int foo(void);

typedef struct struct_1 {
    int a;
    char c;
} S_1;

static int foo(void) {

    S_1 * ad_1;
    int  * ad_2;
    int  * ad_3;

    ad_1 = (S_1*)calloc(100U, sizeof(S_1));        /* Non-compliant */
    ad_2 = malloc(100U * sizeof(int));             /* Non-compliant */
    ad_3 = realloc(ad_3, 60U * sizeof(long));      /* Non-compliant */
    free(ad_1);                                    /* Non-compliant */
    free(ad_2);                                    /* Non-compliant */
    free(ad_3);                                    /* Non-compliant */

    return 1;
}
```

In this example, the rule is violated when the functions `malloc`, `calloc`, `realloc` and `free` are used.

Precautions shall be taken in order to prevent the contents of a header file being included more than once

## Description

### Directive Definition

*Precautions shall be taken in order to prevent the contents of a header file being included more than once*.

### Rationale

When a translation unit contains a complex hierarchy of nested header files, it is possible for a particular header file to be included more than once, leading to confusion. If this multiple inclusion produces multiple or conflicting definitions, then your program can have undefined or erroneous behavior.

For instance, suppose that a header file contains:

```
#ifdef _WIN64
   int env_var;
#elseif
   long int env_var;
#endif
```

If the header file is contained in two inclusion paths, one that defines the macro `_WIN64` and another that undefines it, you can have conflicting definitions of `env_var`.

### Polyspace Implementation

If you include a header file whose contents are not guarded from multiple inclusion, the analysis raises a violation of this directive. The violation is shown at the beginning of the header file.

You can guard the contents of a header file from multiple inclusion by using one of the following methods:

```
<start-of-file>
#ifndef <control macro>
#define <control macro>
    /* Contents of file */
#endif
<end-of-file>
```

or

```
<start-of-file>
#ifdef <control macro>
#error ...
#else
#define <control macro>
```

```
    /* Contents of file */
#endif
<end-of-file>
```

Unless you use one of these methods, Polyspace flags the header file inclusion as noncompliant.

#### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code After Macro Guard

```
#ifndef  __MY_MACRO__
#define __MY_MACRO__
    void func(void);
#endif
void func2(void);
```

If a header file contains this code, it is noncompliant because the macro guard does not cover the entire content of the header file. The line `void func2(void)` is outside the guard.

**Note** You can have comments outside the macro guard.

### Code Before Macro Guard

```
void func(void);
#ifndef  __MY_MACRO__
#define __MY_MACRO__
    void func2(void);
#endif
```

If a header file contains this code, it is noncompliant because the macro guard does not cover the entire content of the header file. The line `void func(void)` is outside the guard.

**Note** You can have comments outside the macro guard.

### Mismatch in Macro Guard

```
#ifndef  __MY_MACRO__
#define __MY_MARCO__
    void func(void);
    void func2(void);
#endif
```

If a header file contains this code, it is noncompliant because the macro name in the `#ifndef` statement is different from the name in the following `#define` statement.

The validity of values passed to library functions shall be checked

## Description

### Directive Definition

*The validity of values passed to library functions shall be checked*.

### Rationale

Many Standard C functions do not check the validity of parameters passed to them. Even if checks are performed by a compiler, there is no guarantee that the checks are adequate. For example, you should not pass negative numbers to `sqrt` or `log`.

### Polyspace Implementation

Polyspace reports violation of this directive if any of these issues are detected:

- `Invalid use of standard library floating point routine`.
- `Invalid use of standard library routine`.
- `Standard function call with incorrect arguments`.
- `Invalid use of standard library integer routine`. Polyspace does not report a violation of this directive on invalid use of some integer library routines such as `isalnum`, `isalpha`, or `tolower`.
- `Invalid use of standard library memory routine`. Polyspace does not report a violation of this directive on invalid use of some memory library routines such as `memchr`, `memcmp`, or `memset`.
- `Invalid use of standard library string routine`. Polyspace does not report a violation of this directive on invalid use of some string library routines such as `strncat`, `strncpy`, or `strcpy`.

**Tip** To mass-justify all results related to the same library function, use the **Detail** column on the **Results List** pane. Click the column header so that all results with the same entry are grouped together. Select the first result and then select the last result while holding the `Shift` key. Assign a status to one of the results. If you do not see the **Detail** column, right-click any other column header and enable this column.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

Functions which are designed to provide operations on a resource should be called in an appropriate sequence

## Description

### Directive Definition

*Functions which are designed to provide operations on a resource should be called in an appropriate sequence*.

### Rationale

You typically use functions operating on a resource in the following way:

1. You allocate the resource.

   For example, you open a file or critical section.
2. You use the resource.

   For example, you read from the file or perform operations in the critical section.
3. You deallocate the resource.

   For example, you close the file or critical section.

For your functions to operate as you expect, perform the steps in sequence. For instance, if you call a resource allocation function on a certain execution path, you must call a deallocation function on that path.

### Polyspace Implementation

Polyspace Bug Finder detects a violation of this rule if you specify multitasking options and your code contains one of these defects:

- `Missing lock`: A task calls an unlock function before calling the corresponding lock function.
- `Missing unlock`: A task calls a lock function but ends without a call to the corresponding unlock function.
- `Double lock`: A task calls a lock function twice without an intermediate call to an unlock function.
- `Double unlock`: A task calls an unlock function twice without an intermediate call to a lock function.

For more information on the multitasking options, see “Multitasking”.

### Extend Checker

You might be using multithreading functions that are not supported by Polyspace. Extend this checker by mapping the functions of your multithreading functions to their known POSIX equivalent. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Multitasking: Lock Function That Is Missing Unlock Function

```
typedef signed int int32_t;
typedef signed short int16_t;

typedef struct tag_mutex_t {
    int32_t value;
} mutex_t;

extern mutex_t mutex_lock   ( void );
extern void  mutex_unlock (  mutex_t m );

extern int16_t x;
void func(void);

void task1(void) {
     func();
}

void task2(void) {
     func();
}

void func ( void ) {
    mutex_t m = mutex_lock ( );  /* Non-compliant */

    if ( x > 0 )  {
        mutex_unlock ( m );
    }  else  {
        /* Mutex not unlocked on this path */
    }
}
```

In this example, the rule is violated when:

- You specify that the functions `mutex_lock` and `mutex_unlock` are paired.

  `mutex_lock` begins a critical section and `mutex_unlock` ends it.
- The function `mutex_lock` is called. However, if `x <= 0`, the function `mutex_unlock` is not called.

To enable detection of this rule violation, you must specify these analysis options.

| Option | Specification |
|---|---|
| **Configure multitasking manually** | ☑ |

| Option | Specification | |
|---|---|---|
| **Entry points** | `task1`<br>`task2` | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | `mutex_lock` | `mutex_unlock` |

For more information on the options, see:

- `Tasks (-entry-points)`
- `Critical section details (-critical-section-begin -critical-section-end)`

# MISRA C:2012 Dir 4.14

The validity of values received from external sources shall be checked

## Description

### Directive Definition

*The validity of values received from external sources shall be checked.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The values originating from external sources can be invalid because of errors or deliberate modification by attackers. Before using the data, you must check the data for validity.

For instance:

- Before using an external input as an array index, you must check if the input can potentially cause an array bounds error.
- Before using an external variable to control a loop, you must check if the variable can potentially result in an infinite loop.

### Polyspace Implementation

The rule checker looks for these issues:

- `Array access with tainted index`.
- `Command executed from externally controlled path`.
- `Execution of externally controlled command`.
- `Host change using externally controlled elements`.
- `Library loaded from externally controlled path`.
- `Loop bounded with tainted value`.
- `Memory allocation with tainted size`.
- `Pointer dereference with tainted offset`.
- `Tainted division operand`.
- `Tainted modulo operand`.
- `Tainted NULL or non-null-terminated string`.
- `Tainted sign change conversion`.
- `Tainted size of variable length array`.
- `Tainted string format`.
- `Use of externally controlled environment variable`.
- `Use of tainted pointer`.
- Using an externally obtained string without a terminating null character in places where a null-terminated string is expected. Such use might result in undefined behavior. For instance, in this

code, the function `printf()` expects string with a terminating null character. Using the character array `str`, which is not terminated by a null character, results in undefined behavior.

```
char str[10];
scanf("%10c", str);
printf("%s",str);//Null terminated string expected
```

- Using an externally obtained indeterminate string. For instance, a string might be indeterminate if you invoke an `fgets()` family function to set the value of the string but the function call fails:

```
char buffer[10];
fgets(buffer, sizeof(buffer), stdin); //buffer is indeterminate if fgets() fails
printf("%s",buffer); // Possible undefined behvior
```

Because the function `printf()` expects a string with a terminating null character, using `buffer` with this function can result in undefined behavior.

#### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Validity of External Values Not Checked

```
#include <stdio.h>

void f1(char from_user[])
{
        char input [128];
        (void) sscanf (from_user, "%128c", input);
        (void) sprintf ("%s", input);/*Noncompliant*/
}
```

In this example, the `sscanf` statement is noncompliant as there is no check to ensure that the user input is null terminated. The subsequent `sprintf` statement that outputs the string can potentially lead to an array bounds error (buffer overrun).

#### Print Invalid External Input String

In this example, the functions `scanf()` and `fgets()` read two `char` arrays and then print the arrays by calling `printf()`. Because the input strings are obtained externally, they might be indeterminate or lack a terminating null character. Printing such strings by using `printf()` results in undefined behavior. Polyspace reports violations of this rule.

```
#include <stdio.h>
void echo_in() {
       //...
    char buffer[10];
    scanf("%10c", buffer);
    //...
    printf("%s", buffer); //Noncompliant - buffer is not null-terminated
    //...
    fgets(buffer, sizeof(buffer), stdin);
      //...
    printf("%s",buffer); //Noncompliant - buffer might be indeterminate
}
```

# MISRA C:2012 Rule 1.1

The program shall contain no violations of the standard C syntax and constraints, and shall not exceed the implementation’s translation limits

## Description

### Rule Definition

*The program shall contain no violations of the standard C syntax and constraints, and shall not exceed the implementation’s translation limits*.

### Polyspace Implementation

The rule checker checks for the issues below. Note that:

- The specifications can depend on the version of the C standard used in the analysis. See `C standard version (-c-version)`.
- You can change some of the limits used by the checker using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

| Issue | C Standard Dependence | Additional Information |
|---|---|---|
| An integer constant falls outside the range of `long int` (if the constant is signed) or `unsigned long int` (if the constant is unsigned). | Checked for C90 only. | The rule checker uses your specifications for the size of a `long int` variable (typically 32 bits). See also `Target processor type (-target)`. |
| An array of size zero is used. | Checked for C90 only. | |
| The number of macros defined in a translation unit exceeds the limit specified in the standard. | Number of macro definitions allowed:<br>• C90: 1024<br>• C99 and later: 4095 | A translation unit consists of a source file together with headers included directly or indirectly in the source file. These are the files necessary to create the smallest object file during compilation. The rule checker requires that the number of macros in a source plus included headers must not exceed the limit specified in the standard. |
| The depth of nesting in control flow statements (like `if`, `while`, etc.) exceeds the limit specified in the standard. | Maximum nesting depth allowed:<br>• C90: 15<br>• C99 and later: 127 | |

| Issue | C Standard Dependence | Additional Information |
|---|---|---|
| The number of levels of inclusion using include files exceeds the limit specified in the standard. | Maximum number of levels of inclusion allowed:<br>• C90: 8<br>• C99 and later: 15 | |
| The number of members of a structure or union exceeds the limit specified in the standard. | Maximum number of members in a structure or union:<br>• C90: 127<br>• C99 and later: 1023 | |
| The number of levels of nesting in a structure exceeds the limit specified in the standard. | Maximum depth of nesting:<br>• C90: 15<br>• C99 and later: 63 | |
| The number of constants in a single enumeration exceeds the limit specified in the standard. | Maximum number of enumeration constants allowed:<br>• C90: 127<br>• C99 and later: 1023 | |
| An assembly language statement is used. | Checked for all C standards. | |
| A nonstandard preprocessor directive is used. | Checked for all C standards. | The rule checker flags uses of preprocessor directives that are not found in the C standard, for instance, `#ident`, `#alias` and `#assert`. |
| Unrecognized text follows a preprocessor directive. | Checked for all C standards. | The rule checker flags extraneous text following a preprocessor directive (line beginning with #). For instance:<br>`#include <header> code` |
| Unnamed unions or empty `structs` are used. | Checked for C90. | |
| An `enum` contains a trailing comma. | Checked for C90. | |

Standard compilation error messages do not lead to a violation of this MISRA rule.

**Tip** To mass-justify all results that come from the same cause, use the **Detail** column on the **Results List** pane. Click the column header so that all results with the same entry are grouped together. Select the first result and then select the last result while holding the `Shift` key. Assign a status to one of the results. If you do not see the **Detail** column, right-click any other column header and enable this column.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Nonstandard C Syntax

```
#include <stdio.h>
#ident "@(#) Hello World"//noncompliant
extern int func(void);

void foo(void){
    int n = 2;
    asm ("leal (%0,%0,4),%0"
         : "=r" (n)
         : "0" (n));

    // standard inline assembly
    asm ("movq $60, %rax\n\t"
         "movq $2,  %rdi\n\t"
         "syscall");
}
```

The translation unit uses the nonstandard preprocessor directive `#ident`. Polyspace Flags the nonstandard syntax.

# MISRA C:2012 Rule 1.2

Language extensions should not be used

## Description

### Rule Definition

*Language extensions should not be used*.

### Rationale

If a program uses language extensions, its portability is reduced. Even if you document the language extensions, the documentation might not describe the behavior in all circumstances.

### Polyspace Implementation

The rule checker flags these language extensions, depending on the version of the C standard used in the analysis. See `C standard version (-c-version)`.

- C90:
  - `long long int` type including constants
  - `long double` type
  - `inline` keyword
  - `_Bool` keyword
  - `short long int` type
  - Hexadecimal floating-point constants
  - Universal character names
  - Designated initializers
  - Local label declarations
  - `typeof` operator
  - Casts to union
  - Compound literals
  - Statements and declarations in expressions
  - `__func__` predefined identifier
  - `_Pragma` preprocessing operator
  - Macros with variable arguments list
  - `asm` functions
- C99:
  - `short long int` type
  - Local label declarations
  - `typeof` operator
  - Casts to union

- Statements and declarations in expressions
- `asm` functions

**Troubleshooting**

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 1.3

There shall be no occurrence of undefined or critical unspecified behaviour

## Description

### Rule Definition

*There shall be no occurrence of undefined or critical unspecified behaviour.*

### Rationale

C code that results in undefined or critical unspecified behavior might produce unexpected or incorrect results. Such code might behave differently in different implementations. Issues caused by undefined behavior in the code might be difficult to analyze because compilers might optimize the code assuming that undefined behavior does not occur.

**Note** Many MISRA C:2012 rules address specific undefined or critical unspecified behaviors. This rule applies to any undefined or critical unspecified behavior that is not addressed in any other rule.

### Polyspace Implementation

Polyspace flags these instances of undefined or critical undefined behavior:

- Use of `offsetof` on bit fields.
- Use of `offsetof` when the second argument is not a `struct` field of the first argument.
- Use of `defined` without an identifier.
- Use of an array of incomplete types.
- Use of a function like macros by using incorrect number of arguments.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Undefined Behaviors

```
#include <stddef.h>
static int bar = 0;
extern int bar;         /* Violation (8.8)*/

struct str {
  char a:8;
  char b[10];
  char c;
};
void foo() {
  offsetof(struct str, a);//Noncompliant
  offsetof(struct str, d);//Noncompliant
}
```

In this example, the function `foo` uses the macro `offsetof` on the bit field `str.a`. This behavior is undefined. Polyspace flags it. The function then calls `offsetof` on `str.d`. Because `d` is not a field of `str`, Polyspace flags it. These issues might cause compilation errors.

The variable `bar` is declared with both internal and external linkage. According to the C99 standard, declaring a variable to have both internal and external storage in the same file is undefined behavior. Polyspace flags this undefined behavior as a violation of rule 8.8. See `MISRA C:2012 Rule 8.8`.

# MISRA C:2012 Rule 1.4

Emergent language features shall not be used

## Description

### Rule Definition

*Emergent language features shall not be used*.

### Rationale

Some new language features in the C11 Standard have undefined, unspecified or implementation-defined behavior. These features might also exhibit well-defined behavior that defies developer expectations. Though rule 1.3 and directive 1.1 prohibits undefined and implementation-defined behavior, to avoid well-defined behavior that defies expectations, some language features are summarily discouraged using rule 1.4.

### Polyspace Implementation

The rule forbids use of the following language features:

- The `_Generic` operator.
- The `_Noreturn` function specifier and the `<stdnoreturn.h>` header file
- The `_Atomic` type specifier and the facilities provided by `<stdatomic.h>` (for instance, the macros beginning with `ATOMIC_` and functions beginning with `atomic_` implemented as macros in `<stdatomic.h>`).
- The `_Thread_local` storage class specifier and the facilities provided by `<threads.h>` (for instance, types such as `thrd_t` and functions such as `thrd_create`).
- The `_Alignas` alignment specifier, the `_Alignof` operator and the `<stdalign.h>` header file, and facilities therein (such as the `alignas` and `alignof` macros).
- All facilities in Annex K of the C11 Standard about 'Bound-checking interfaces', other than defining `__STDC_WANT_LIB_EXT1__` to '0'

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Facilities in Annex K of C11 Standard

```
#define __STDC_WANT_LIB_EXT1__ 1 //Noncompliant
#include <string.h>

void Copying_functions(void) {
    char buf1[10];
    char buf2[10];
    errno_t e;  //Noncompliant
    e = memcpy_s(buf1,sizeof(buf1),buf2,5); //Noncompliant
    e = memmove_s(buf1,sizeof(buf1),buf2,5); //Noncompliant
    e = strcpy_s(buf1,sizeof(buf1),buf2); //Noncompliant
    e = strncpy_s(buf1,sizeof(buf1),buf2,5); //Noncompliant
}
```

In this example, the macro `__STDC_WANT_LIB_EXT1__` is set to 1 so that the type `errno_t` as defined in the header `stdlib.h` can be used (in accordance with Annex K of the C11 Standard).

The checker flags both the setting of the macro to 1 and the definition of the `errno_t` variable, along with other functions from Annex K.

# MISRA C:2012 Rule 2.1

A project shall not contain unreachable code

## Description

### Rule Definition

*A project shall not contain unreachable code*.

### Rationale

Unless a program exhibits any undefined behavior, unreachable code cannot execute. The unreachable code cannot affect the program output. The presence of unreachable code can indicate an error in the program logic. Unreachable code that the compiler does not remove wastes resources, for example:

- It occupies space in the target machine memory.
- Its presence can cause a compiler to select longer, slower jump instructions when transferring control around the unreachable code.
- Within a loop, it can prevent the entire loop from residing in an instruction cache.

### Polyspace Implementation

Polyspace reports a defect if a statement in your code is not reachable.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code Following `return` Statement

```
enum light { red, amber, red_amber, green };

enum light next_light ( enum light color )
{
    enum light res;

    switch ( color )
    {
    case red:
        res = red_amber;
        break;
    case red_amber:
        res = green;
        break;
    case green:
        res = amber;
        break;
    case amber:
        res = red;
        break;
    default:
    {
        error_handler ();
        break;
    }
    }

    res = color;
    return res;
    res = color;     /* Non-compliant */
}
```

In this example, the rule is violated because there is an unreachable operation following the `return` statement.

# MISRA C:2012 Rule 2.2

There shall be no dead code

## Description

### Rule Definition

*There shall be no dead code.*

### Rationale

If an operation is reachable but removing the operation does not affect program behavior, the operation constitutes dead code.

The presence of dead code can indicate an error in the program logic. Because a compiler can remove dead code, its presence can cause confusion for code reviewers.

### Polyspace Implementation

The rule checker reports rule violations on operations whose removal does not affect program behavior. The most common situation is an operation whose result is not used subsequently. For instance:

- You might perform an operation but not assign the result to a variable, even a temporary one.
- You might assign the result of an operation to a variable but not use the variable subsequently.
- You might assign a value to a variable and but not use the value subsequently. For more details, see `Write without a further read`.
- You might assign the result of an operation to a variable but immediately afterwards overwrite the variable value.

Other less common situations include calls to empty functions or redundant constant operations. Some of these operations involving constants occur in generated code and might be optimized away by your compiler. For instance, the operation `2u * 1u` is a redundant operation that a compiler is likely to optimize to `2u`. That is, the operation is unlikely to happen at run time. Irrespective of possible compiler optimizations, the rule checker reports a violation on the operation.

Polyspace does not flag an unused return of a non-`void` function because the function might have other side effects besides returning a value. Removing the function call might impact program behavior.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Redundant Operations

```
extern volatile unsigned int v;
extern char *p;
```

```
void f ( void ) {
    unsigned int x;

    ( void ) v;      /* Compliant - Exception*/
    ( int ) v;       /* Non-compliant  */
    v >> 3;          /* Non-compliant  */

    x = 3;           /* Non-compliant  */

    *p++;            /* Non-compliant  */
    ( *p )++;        /* Compliant  */
}
```

In this example, the rule is violated when an operation is performed on a variable, but the result of that operation is not used. For instance,

- The operations `(int)` and `>>` on the variable `v` are redundant because the results are not used.
- The operation `=` is redundant because the local variable `x` is not read after the operation.
- The operation `*` on `p++` is redundant because the result is not used.

The rule is not violated when:

- A variable is cast to `void`. The cast indicates that you are intentionally not using the value.
- The result of an operation is used. For instance, the operation `*` on `p` is not redundant, because `*p` is incremented.

### Redundant Function Call

```
void g ( void ) {
               /* Compliant  */
}

void h ( void) {
     g( );     /* Non-compliant */
}
```

In this example, `g` is an empty function. Though the function itself does not violate the rule, a call to the function violates the rule.

# MISRA C:2012 Rule 2.3

A project should not contain unused type declarations

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

### Rule Definition

*A project should not contain unused type declarations*.

### Rationale

If a type is declared but not used, a reviewer does not know if the type is redundant or if it is unused by mistake.

### Additional Message in Report

A project should not contain unused type declarations: type XX is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Local Type

```
signed short unusedType (void){

    typedef signed short myType;   /* Non-compliant */
    return 67;

}

signed short usedType (void){

    typedef signed short myType;  /* Compliant */
    myType tempVar = 67;
    return tempVar;

}
```

In this example, in function `unusedType`, the `typedef` statement defines a new local type `myType`. However, this type is never used in the function. Therefore, the rule is violated.

The rule is not violated in the function `usedType` because the new type `myType` is used.

A project should not contain unused tag declarations

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*A project should not contain unused tag declarations.*

### Rationale

If a tag is declared but not used, a reviewer does not know if the tag is redundant or if it is unused by mistake.

### Additional Message in Report

A project should not contain unused tag declarations: tag *`tag_name`* is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Tag Defined in Function but Not Used

```
void unusedTag ( void )
{
    enum state1 { S_init, S_run, S_sleep };    /* Non-compliant  */
}

void usedTag ( void )
{
    enum state2 { S_init, S_run, S_sleep };    /* Compliant  */
    enum state2 my_State = S_init;
}
```

In this example, in the function `unusedTag`, the tag `state1` is defined but not used. Therefore, the rule is violated.

### Tag Used in `typedef` Only

```
typedef struct record_t        /* Non-compliant  */
{
    unsigned short key;
    unsigned short val;
} record1_t;
```

```
typedef struct               /* Compliant */
{
    unsigned short key;
    unsigned short val;
} record2_t;

record1_t myRecord1_t;
record2_t myRecord2_t;
```

In this example, the tag `record_t` appears only in the `typedef` of `record1_t`. In the rest of the translation unit, the type `record1_t` is used. Therefore, the rule is violated.

A project should not contain unused macro declarations

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*A project should not contain unused macro declarations.*

### Rationale

If a macro is declared but not used, a reviewer does not know if the macro is redundant or if it is unused by mistake.

### Additional Message in Report

A project should not contain unused macro declarations: macro `macro_name` is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Unused Macro Definition

```
void use_macro (void)
{
    #define SIZE 4
    #define DATA 3//Noncompliant

    use_int16(SIZE);
}
```

In this example, the macro `DATA` is never used in the `use_macro` function. Polyspace flags the unused macro.

# MISRA C:2012 Rule 2.6

A function should not contain unused label declarations

## Description

### Rule Definition

*A function should not contain unused label declarations*.

### Rationale

If you declare a label but do not use it, it is not clear to a reviewer of your code if the label is redundant or unused by mistake.

### Additional Message in Report

A function should not contain unused label declarations.

Label *`label_name`* is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Unused Label Declarations

```
void use_var(signed short);

void unused_label ( void )
{
    signed short x = 6;

label1:                         /* Non-compliant - label1 not used */
    use_var ( x );
}

void used_label ( void )
{
    signed short x = 6;

    for (int i=0; i < 5; i++) {
        if ( i==2 ) goto label1;
    }

label1:                        /* Compliant - label1 used */
    use_var ( x );
}
```

In this example, the rule is violated when the label `label1` in function `unused_label` is not used.

# MISRA C:2012 Rule 2.7

There should be no unused parameters in functions

## Description

### Rule Definition

*There should be no unused parameters in functions.*

### Rationale

If a parameter is unused, it is possible that the implementation of the function does not match its specifications. This rule can highlight such mismatches.

### Additional Message in Report

There should be no unused parameters in functions.

Parameter *`parameter_name`* is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Function Parameters

```
double func(int param1, int* param2) { /* Non-compliant */
    return (param1/2.0);
}
```

In this example, the rule is violated because the parameter `param2` is not used.

# MISRA C:2012 Rule 3.1

The character sequences /* and // shall not be used within a comment

## Description

### Rule Definition

*The character sequences /* and // shall not be used within a comment.*

### Rationale

These character sequences are not allowed in code comments because:

- If your code contains a /* or a // in a /* */ comment, it typically means that you have inadvertently commented out code.
- If your code contains a /* in a // comment, it typically means that you have inadvertently uncommented a /* */ comment.

### Polyspace Implementation

You cannot annotate this rule in the source code.

For information on annotations, see “Annotate Code and Hide Known or Acceptable Results”.

### Additional Message in Report

The character sequence /* shall not appear within a comment.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### /* Used in // Comments

```
int x;
int y;
int z;

void non_compliant_comments ( void )
{
    x = y //      /* Non-compliant
        + z
        //  */
        ;
    z++;    //    Compliant with exception: // permitted within a // comment
}

void compliant_comments ( void )
{
    x = y /*      Compliant
      + z
      */
        ;
    z++;    //    Compliant with exception: // is permitted within a // comment
}
```

In this example, in the `non_compliant_comments` function, the `/*` character occurs in what appears to be a `//` comment, violating the rule. Because of the comment structure, the operation that takes place is `x = y + z;`. However, without the two `//`-s, an entirely different operation `x=y;` takes place. It is not clear which operation is intended.

Use a comment format that makes your intention clear. For instance, in the `compliant_comments` function, it is clear that the operation `x=y;` is intended.

# MISRA C:2012 Rule 3.2

Line-splicing shall not be used in `//` comments

## Description

### Rule Definition

*Line-splicing shall not be used in // comments.*

### Rationale

Line-splicing occurs when the `\` character is immediately followed by a new-line character. Line splicing is used for statements that span multiple lines.

If you use line-splicing in a `//` comment, the following line can become part of the comment. In most cases, the `\` is spurious and can cause unintentional commenting out of code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Line Splicing in // Comment

```
#include <stdbool.h>

extern _Bool b;

void func ( void )
{
    unsigned short x = 0;   // Non-compliant - Line-splicing \
    if ( b )
    {
        ++b;
    }
}
```

Because of line-splicing, the statement `if ( b )` is a part of the previous `//` comment. Therefore, the statement `b++` always executes, making the `if` block redundant.

# MISRA C:2012 Rule 4.1

Octal and hexadecimal escape sequences shall be terminated

## Description

### Rule Definition

*Octal and hexadecimal escape sequences shall be terminated*.

### Rationale

There is potential for confusion if an octal or hexadecimal escape sequence is followed by other characters. For example, the character constant `'\x1f'` consists of a single character, whereas the character constant `'\x1g'` consists of the two characters `'\x1'` and `'g'`. The manner in which multi-character constants are represented as integers is implementation-defined.

If every octal or hexadecimal escape sequence in a character constant or string literal is terminated, you reduce potential confusion.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Compliant and Noncompliant Escape Sequences

```
const char *s1 = "\x41g";     /* Non-compliant */
const char *s2 = "\x41" "g";  /* Compliant - Terminated by end of literal */
const char *s3 = "\x41\x67";  /* Compliant - Terminated by another escape sequence*/

int c1 = '\141t';             /* Non-compliant */
int c2 = '\141\t';            /* Compliant - Terminated by another escape sequence*/
```

In this example, the rule is violated when an escape sequence is not terminated with the end of string literal or another escape sequence.

# MISRA C:2012 Rule 4.2

Trigraphs should not be used

## Description

### Rule Definition

*Trigraphs should not be used*.

### Rationale

You denote trigraphs with two question marks followed by a specific third character (for instance,`'??-'` represents a `'~'` (tilde) character and `'??)'` represents a `']'`). These trigraphs can cause accidental confusion with other uses of two question marks.

**Note** Digraphs (`<:  :>`, `<%  %>`, `%:`, `%:%:`) are permitted because they are tokens.

### Polyspace Implementation

The Polyspace analysis converts trigraphs to the equivalent character for the defect analysis. However, Polyspace also raises a MISRA violation.

The standard requires that trigraphs must be transformed *before* comments are removed during preprocessing. Therefore, Polyspace raises a violation of this rule even if a trigraph appears in code comments.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 5.1

External identifiers shall be distinct

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

### Rule Definition

*External identifiers shall be distinct.*

### Rationale

External identifiers are ones declared with global scope or storage class `extern`.

If the two long names are almost identical and differ only in the later part, they can be easily mistaken for each other. The readability of the code is reduced.

### Polyspace Implementation

Polyspace considers two names as distinct if there is a difference between their first 31 characters. For C90, the difference must occur between the first 6 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`. You can change the number of characters compared using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

### Additional Message in Report

External `%s %s` conflicts with the external identifier XX in file YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### C90: First Six Characters of Identifiers Not Unique

```
int engine_temperature_raw;
int engine_temperature_scaled;   /* Non-compliant */
int engin2_temperature;          /* Compliant */
```

In this example, the identifier `engine_temperature_scaled` has the same first six characters as a previous identifier, `engine_temperature_raw`.

### C99: First 31 Characters of Identifiers Not Unique

```
int engine_exhaust_gas_temperature_raw;
int engine_exhaust_gas_temperature_scaled; /* Non-compliant */

int eng_exhaust_gas_temp_raw;
int eng_exhaust_gas_temp_scaled;           /* Compliant */
```

In this example, the identifier `engine_exhaust_gas_temperature_scaled` has the same first 31 characters as a previous identifier, `engine_exhaust_gas_temperature_raw`.

#### C90: First Six Characters Identifiers in Different Translation Units Differ in Case Alone

```
/* file1.c */
int abc = 0;

/* file2.c */
int ABC = 0; /* Non-compliant */
```

In this example, the implementation supports 6 significant case-insensitive characters in *external identifiers*. The identifiers in the two translation are different but are not distinct in their significant characters.

# MISRA C:2012 Rule 5.2

Identifiers declared in the same scope and name space shall be distinct

## Description

### Rule Definition

*Identifiers declared in the same scope and name space shall be distinct.*

### Rationale

If the two long names are almost identical and differ only in the later part, they can be easily mistaken for each other. The readability of the code is reduced.

### Polyspace Implementation

Polyspace considers two names as distinct if there is a difference between their first 63 characters. In C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`. You can change the number of characters compared using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

### Additional Message in Report

Identifier XX has same significant characters as identifier YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### C90: First 31 Characters of Identifiers Not Unique

```
extern int engine_exhaust_gas_temperature_raw;
static int engine_exhaust_gas_temperature_scaled;      /* Non-compliant */

extern double raw_engine_exhaust_gas_temperature;
static double scaled_engine_exhaust_gas_temperature;  /* Compliant */

void func ( void )
{
  /* Not in the same scope */
  int engine_exhaust_gas_temperature_local;            /* Compliant */
}
```

In this example, the identifier `engine_exhaust_gas_temperature_scaled` has the same 31 characters as a previous identifier, `engine_exhaust_gas_temperature_raw`.

The rule does not apply if the two identifiers have the same 31 characters but have different scopes. For instance, `engine_exhaust_gas_temperature_local` has the same 31 characters as `engine_exhaust_gas_temperature_raw` but different scope.

# MISRA C:2012 Rule 5.3

An identifier declared in an inner scope shall not hide an identifier declared in an outer scope

## Description

### Rule Definition

*An identifier declared in an inner scope shall not hide an identifier declared in an outer scope.*

### Rationale

If two identifiers have the same name but different scope, the identifier in the inner scope hides the identifier in the outer scope. All uses of the identifier name refers to the identifier in the inner scope. This behavior forces the developer to keep track of the scope and reduces code readability.

### Polyspace Implementation

Polyspace considers two names as distinct if there is a difference between their first 63 characters. In C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`. You can change the number of characters compared using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

If the identifier that is hidden is declared in a Standard Library header and you do not provide the header for the analysis, the issue is not shown. To see potential conflicts with identifiers declared in a Standard Library header, provide your compiler implementation of the headers for the Polyspace analysis. See “Provide Standard Library Headers for Polyspace Analysis”.

### Additional Message in Report

Variable XX hides variable XX (FILE line LINE column COLUMN).

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Local Variable Hidden by Another Local Variable in Inner Block

```
typedef signed short int16_t;

void func( void )
{
    int16_t i;
    {
        int16_t i;                /* Non-compliant */
        i = 3;
    }
}
```

In this example, the identifier `i` defined in the inner block in `func` hides the identifier `i` with function scope.

It is not immediately clear to a reader which `i` is referred to in the statement `i=3`.

#### Global Variable Hidden by Function Parameter

```
typedef signed short int16_t;

struct astruct
{
    int16_t m;
};

extern void g ( struct astruct *p );
int16_t xyz = 0;

void func ( struct astruct xyz )  /* Non-compliant */
{
    g ( &xyz );
}
```

In this example, the parameter `xyz` of function `func` hides the global variable `xyz`.

It is not immediately clear to a reader which `xyz` is referred to in the statement `g (&xyz )`.

# MISRA C:2012 Rule 5.4

Macro identifiers shall be distinct

## Description

### Rule Definition

*Macro identifiers shall be distinct.*

### Rationale

The names of macro identifiers must be distinct from both other macro identifiers and their parameters.

### Polyspace Implementation

The checker raises a violation if two macros that have the same first 63 characters are defined with different values. The checker does not raise a violation if:

- Two macros with the same first 63 characters are defined with the same value (even an empty value).
- The same macro is defined with different values but the macro is undefined in between.

The cutoff of 63 characters applies to a C99-based analysis. In C90, the cutoff is 31 characters. In other words, the checker considers two macros as effectively the same if there is no difference in their first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`. You can change the number of characters compared using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

### Additional Message in Report

- Macro identifiers shall be distinct. Macro XX has same significant characters as macro YY.
- Macro identifiers shall be distinct. Macro parameter XX has same significant characters as macro parameter YY in macro ZZ.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### C90: First 31 Characters of Macro Names Not Unique

```
#define engine_exhaust_gas_temperature_raw egt_r
#define engine_exhaust_gas_temperature_scaled egt_s   /* Non-compliant */

#define engine_exhaust_gas_temp_raw egt_r
#define engine_exhaust_gas_temp_scaled egt_s          /* Compliant */
```

In this example, the macro `engine_exhaust_gas_temperature_scaled egt_s` has the same first 31 characters as a previous macro `engine_exhaust_gas_temperature_scaled`.

# MISRA C:2012 Rule 5.5

Identifiers shall be distinct from macro names

## Description

### Rule Definition

*Identifiers shall be distinct from macro names.*

### Rationale

The rule requires that macro names that exist only prior to processing must be different from identifier names that also exist after preprocessing. Keeping macro names and identifiers distinct help avoid confusion.

### Polyspace Implementation

Polyspace considers two names as distinct if there is a difference between their first 63 characters. In C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`. You can change the number of characters compared using the option `-code-behavior-specifications`. See `-code-behavior-specifications`.

### Additional Message in Report

Identifier XX has same significant characters as macro YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Macro Names Same as Identifier Names

```
#define Sum_1(x, y) ( ( x ) + ( y ) )
short Sum_1;                    /* Non-compliant */

#define Sum_2(x, y) ( ( x ) + ( y ) )
short x = Sum_2 ( 1, 2 );       /* Compliant */
```

In this example, `Sum_1` is both the name of an identifier and a macro. `Sum_2` is used only as a macro.

### C90: First 31 Characters of Macro Name Same as Identifier Name

```
#define low_pressure_turbine_temperature_1 lp_tb_temp_1
static int low_pressure_turbine_temperature_2;   /* Non-compliant  */
```

In this example, the identifier `low_pressure_turbine_temperature_2` has the same first 31 characters as a previous macro `low_pressure_turbine_temperature_1`.

# MISRA C:2012 Rule 5.6

A typedef name shall be a unique identifier

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*A typedef name shall be a unique identifier.*

### Rationale

Reusing a `typedef` name as another `typedef` or as the name of a function, object or `enum` constant can cause developer confusion.

### Additional Message in Report

XX conflicts with the typedef name YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### typedef Names Reused

```
void func ( void ){
  {
    typedef unsigned char u8_t;
  }
  {
    typedef unsigned char u8_t; /* Non-compliant */
  }
}

typedef float mass;
void func1 ( void ){
  float mass = 0.0f;            /* Non-compliant */
}
```

In this example, the `typedef` name `u8_t` is used twice. The `typedef` name `mass` is also used as an identifier name.

### typedef Name Same as Structure Name

```
typedef struct list{          /* Compliant - exception */
  struct list *next;
  unsigned short element;
} list;
```

```
typedef struct{
  struct chain{               /* Non-compliant */
    struct chain *list2;
    unsigned short element;
  } s1;
  unsigned short length;
} chain;
```

In this example, the `typedef` name `list` is the same as the original name of the `struct` type. The rule allows this exceptional case.

However, the `typedef` name `chain` is not the same as the original name of the `struct` type. The name `chain` is associated with a different `struct` type. Therefore, it clashes with the `typedef` name.

# MISRA C:2012 Rule 5.8

Identifiers that define objects or functions with external linkage shall be unique

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*Identifiers that define objects or functions with external linkage shall be unique.*

### Rationale

External identifiers are those declared with global scope or with storage class `extern`. Reusing an external identifier name can cause developer confusion.

Identifiers defined within a function have smaller scope. Even if names of such identifiers are not unique, they are not likely to cause confusion.

### Additional Message in Report

- Object XX conflicts with the object name YY.
- Function XX conflicts with the function name YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Check Information

**Group:** Identifiers
**Category:** Required
**AGC Category:** Required

# MISRA C:2012 Rule 5.9

Identifiers that define objects or functions with internal linkage should be unique

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

### Rule Definition

*Identifiers that define objects or functions with internal linkage should be unique*.

### Rationale

Identifiers that have internal linkage are accessible only in the translation unit where they are declared. These identifiers are typically declared as `static`. If such identifiers are nonunique, the code might become difficult to understand and lead to unexpected results.

### Polyspace Implementation

Polyspace flags the `static` variable names that are nonunique within the same translation unit.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Nonunique Identifiers

```
#include<stdint.h>
#include <assert.h>
static int testGlobal;
void foo(){
static char testGlobal;//Noncompliant
if(1){
    static char testGlobal;//Noncompliant
}
}
```

In this example, the identifier `testGlobal` is used for declaring three variables in three different scopes. Because the identifiers are `static` and share a nonunique name, Polyspace flags the repetitions of the identifier.

# MISRA C:2012 Rule 6.1

Bit-fields shall only be declared with an appropriate type

## Description

### Rule Definition

*Bit-fields shall only be declared with an appropriate type*.

### Rationale

Using `int` for a bit-field type is implementation-defined because bit-fields of type `int` can be either `signed` or `unsigned`.

The use of `enum`, `short char`, or any other type of bit-field is not permitted in C90 because the behavior is undefined.

In C99, the implementation can potentially define other integer types that are permitted in bit-field declarations.

### Polyspace Implementation

The checker flags data types for bit-fields other than these allowed types:

- C90: `signed int` or `unsigned int` (or `typedef`-s that resolve to these types)
- C99: `signed int`, `unsigned int` or `_Bool` (or `typedef`-s that resolve to these types)

The results depend on the version of the C standard used in the analysis. See `C standard version (-c-version)`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 6.2

Single-bit named bit fields shall not be of a signed type

## Description

### Rule Definition

*Single-bit named bit fields shall not be of a signed type*.

### Rationale

According to the C99 Standard Section 6.2.6.2, a single-bit signed bit-field has one sign bit and no value bits. In any representation of integers, zero value bits cannot specify a meaningful value.

A single-bit signed bit-field is therefore unlikely to behave in a useful way. Its presence is likely to indicate programmer confusion.

Although the C90 Standard does not provide much detail regarding the representation of types, the same single-bit bit-field considerations apply.

### Polyspace Implementation

This rule does not apply to unnamed bit fields because their values cannot be accessed.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 7.1

Octal constants shall not be used

## Description

### Rule Definition

*Octal constants shall not be used*.

### Rationale

Octal constants are denoted by a leading zero. Developers can mistake an octal constant as a decimal constant with a redundant leading zero.

### Polyspace Implementation

If you use octal constants in a macro definition, the rule checker flags the issue even if the macro is not used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Example - Use of octal constants

```
#define CST     021             /* Noncompliant */
#define VALUE   010             /* Noncompliant */
#if 010 == 01                   /* Noncompliant*/
#define CST 021                 /* Noncompliant */
#endif

extern short code[5];
static char* str2 = "abcd\0efg";  /* Compliant */

void main(void) {
    int value1 = 0;               /* Compliant */
    int value2 = 01;              /* Noncompliant*/
    int value3 = 1;               /* Compliant */
    int value4 = '\109';          /* Compliant */

    code[1] = 109;                /* Compliant     - decimal 109 */
    code[2] = 100;                /* Compliant     - decimal 100 */
    code[3] = 052;                /* Noncompliant */
    code[4] = 071;                /* Noncompliant */

    if (value1 != CST) {
        value1 = !(value1 != 0);  /* Compliant */
    }
}
```

In this example, Polyspace flags the use of octal constants.

# MISRA C:2012 Rule 7.2

A “u” or “U” suffix shall be applied to all integer constants that are represented in an unsigned type

## Description

### Rule Definition

*A “u” or “U” suffix shall be applied to all integer constants that are represented in an unsigned type*.

### Rationale

The signedness of a constant is determined from:

- Value of the constant.
- Base of the constant: octal, decimal or hexadecimal.
- Size of the various types.
- Any suffixes used.

Unless you use a suffix `u` or `U`, another developer looking at your code cannot determine easily whether a constant is signed or unsigned.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use Suffix to Specify Unsigned Type

```
const unsigned long C[] = {
    0x9421FFD0, /*Noncompliant*/
    0x5322E762,
    0x80000000, /*Noncompliant*/
    0x7FFFFFFF,
    0x00000001,
    0x83241947, /*Noncompliant*/
    0x57112957,
    0x2640EA23
};

const unsigned long D[] = {
    0x9421FFD0U, /*Compliant*/
    0x80000000U, /*Compliant*/
    0x83241947U, /*Compliant*/
};
```

In this example, Polyspace flags the unsigned members of `C`. For instance, `0x9421FFD0` is an unsigned number in a 32 bit environment because it exceeds the capacity of a signed integer. Because the unsigned number lacks the suffix `u` or `U`, Polyspace flags it. In `D`, the unsigned numbers use the suffix and are not flagged.

## Check Information

# MISRA C:2012 Rule 7.3

The lowercase character “l” shall not be used in a literal suffix

## Description

### Rule Definition

*The lowercase character “l” shall not be used in a literal suffix.*

### Rationale

The lowercase character “l” can be confused with the digit “1”. Use the uppercase “L” instead.

### Polyspace Implementation

Polyspace reports a violation if you use the lowercase character "l" in a literal suffix. Violations of this rule are not reported on unused macros.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Lowercase "l" in Literal Suffix

```
#define PI 3.14159l// Compliant- Not flagged because
                    // the macro is unused
#define EULERNUM 2.71828l//Noncompliant- Flagged because
                         // macro is used
void func(long);
void foo(void){
    long a = 10l;//Noncompliant
    long b = 10L;//Compliant
    long c = 10lL;//Noncompliant
    func(EULERNUM);
}
```

In this example, Polyspace flags the literals that have a lowercase "l" in their suffix. Polyspace does not flag unused macros that have "l" in their suffix.

# MISRA C:2012 Rule 7.4

A string literal shall not be assigned to an object unless the object’s type is “pointer to const-qualified char”

## Description

### Rule Definition

*A string literal shall not be assigned to an object unless the object’s type is “pointer to const-qualified char”.*

### Rationale

This rule prevents assignments that allow modification of a string literal.

An attempt to modify a string literal can result in undefined behavior. For example, some implementations can store string literals in read-only memory. An attempt to modify the string literal can result in an exception or crash.

### Polyspace Implementation

The rule checker flags assignment of string literals to:

- Pointers with data type other than `const char*`.
- Arrays with data type other than `const char`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Assignment of String Literal

```
char *str1 = "xxxxxx";            // Non-Compliant
const char *str2 = "xxxxxx";      // Compliant

void checkSystem1(char*);
void checkSystem2(const char*);

void main() {
 checkSystem1("xxxxxx");    // Non-Compliant
 checkSystem2("xxxxxx");    // Compliant
}
```

In this example, the rule is not violated when string literals are assigned to `const char*` pointers, either directly or through copy of function arguments. The rule is violated only when the `const` qualifier is not used.

# MISRA C:2012 Rule 8.1

Types shall be explicitly specified

## Description

### Rule Definition

*Types shall be explicitly specified*.

### Rationale

In some circumstances, you can omit types from the C90 standard. In those cases, the `int` type is implicitly specified. However, the omission of an explicit type can lead to confusion. For example, in the declaration `extern void foo (char c, const k);`, the type of `k` is `const int`, but you might expect `const char`.

You might be using an implicit type in:

- Object declarations
- Parameter declarations
- Member declarations
- `typedef` declarations
- Function return types

### Polyspace Implementation

The rule checker flags situations where a function parameter or return type is not explicitly specified.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Implicit Types

```
static foo(int a);  /* Non compliant */
static void bar(void);      /* Compliant */
```

In this example, the rule is violated because the return type of `foo` is implicit.

# MISRA C:2012 Rule 8.2

Function types shall be in prototype form with named parameters

## Description

### Rule Definition

*Function types shall be in prototype form with named parameters.*

### Rationale

The rule requires that you specify names and data types for all the parameters in a declaration. The parameter names provide useful information regarding the function interface. A mismatch between a declaration and definition can indicate a programming error. For instance, you mixed up parameters when defining the function. By insisting on parameter names, the rule allows a code reviewer to detect this mismatch.

### Polyspace Implementation

The rule checker shows a violation if the parameters in a function declaration or definition are missing names or data types.

### Additional Message in Report

- Too many arguments to `function_name`.
- Too few arguments to `function_name`.
- Function types shall be in prototype form with named parameters.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function Prototype Without Named Parameters

```
extern int func(int);   /* Non compliant */
extern int func2(int n);   /* Compliant */

extern int func3();   /* Non compliant */
extern int func4(void);   /* Compliant */
```

In this example, the declarations of `func` and `func3` are noncompliant because the parameters are missing or do not have names.

# MISRA C:2012 Rule 8.3

All declarations of an object or function shall use the same names and type qualifiers

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*All declarations of an object or function shall use the same names and type qualifiers*.

### Rationale

Consistently using parameter names and types across declarations of the same object or function encourages stronger typing. It is easier to check that the same function interface is used across all declarations.

### Polyspace Implementation

The rule checker detects situations where parameter names or data types are different between multiple declarations or the declaration and the definition. The checker considers declarations in all translation units and flags issues that are not likely to be detected by a compiler.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Mismatch in Parameter Names

```
extern int div (int num, int den);

int div(int den, int num) { /* Non compliant */
    return(num/den);
}
```

In this example, the rule is violated because the parameter names in the declaration and definition are switched.

### Mismatch in Parameter Data Types

```
typedef unsigned short width;
typedef unsigned short height;
typedef unsigned int area;

extern area calculate(width w, height h);

area calculate(width w, width h) { /* Non compliant */
    return w*h;
}
```

In this example, the rule is violated because the second argument of the `calculate` function has data type:

- `height` in the declaration.
- `width` in the definition.

The rule is violated even though the underlying type of `height` and `width` are identical.

# MISRA C:2012 Rule 8.4

A compatible declaration shall be visible when an object or function with external linkage is defined

## Description

### Rule Definition

*A compatible declaration shall be visible when an object or function with external linkage is defined.*

### Rationale

If a declaration is visible when an object or function is defined, it allows the compiler to check that the declaration and the definition are compatible.

This rule with `MISRA C:2012 Rule 8.5` enforces the practice of declaring an object (or function) in a header file and including the header file in source files that define or use the object (or function).

### Polyspace Implementation

The rule checker detects situations where:

- An object or function is defined without a previous declaration.
- There is a data type mismatch between the object or function declaration and definition. Such a mismatch also causes a compilation error.

The checker now flags tentative definitions (variables declared without an `extern` specifier and not explicitly defined). To avoid the rule violation, declare the variable `static` (defined in one file only), or declare the variable `extern` and follow the declaration with a definition.

### Additional Message in Report

- Global definition of *`variable_name`* variable has no previous declaration.
- Function *`function_name`* has no visible compatible prototype at definition.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Definition Without Previous Declaration

Header file:

```
/* file.h */
extern int var2;
void func2(void);
```

Source file:

```
/* file.c */
#include "file.h"

int var1 = 0;    /* Non compliant */
int var2 = 0;    /* Compliant */

void func1(void) {   /* Non compliant */
}

void func2(void) {   /* Compliant */
}
```

In this example, the definitions of `var1` and `func1` are noncompliant because they are not preceded by declarations.

#### Mismatch in Parameter Data Types

```
void func(int param1, int param2);

void func(int param1, unsigned int param2) { /* Non compliant */
}
```

In this example, the definition of `func` has a different parameter type from its declaration. The declaration mismatch might cause a compilation error. Polyspace flags the mismatch.

# MISRA C:2012 Rule 8.5

An external object or function shall be declared once in one and only one file

## Description

### Rule Definition

*An external object or function shall be declared once in one and only one file.*

### Rationale

Declaring an identifier in a header file enables you to include the header file in any translation unit where the identifier is defined or used. Modularizing the declarations in header files helps maintain consistency between:

- The declaration and the definition.
- The declarations in different translation units.

The rule enforces the practice of declaring external objects or functions in header files.

### Polyspace Implementation

The rule checker checks explicit and implicit `extern` declarations (tentative definitions are ignored). The checker flags variables or functions:

- Declared `extern` in a nonheader file
- Declared multiple times, for instance, once in a header and once in a nonheader file.

This checker:

- Ignores compiler-specific, nonportable ways of overriding function declarations, such as `pragma weak` or `__attribute__((weak))`.
- Ignores typedefs and function declarations that are not used in the code.
- Considers redeclaration as a rule violation. For instance, if you declare a weak symbol in your code, and then redeclare the symbol later, Polyspace reports a violation. If you do not want to fix such violations, add a comment to your result or code to avoid another review. See:
  - "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
  - "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Extern Declaration in Nonheader File

In this example, the declaration of external function `func2()` is noncompliant because it occurs in a nonheader file. The other external object and function declarations occur in a header file and comply with this rule. To fix this issue, declare `func2()` in a header file.

Header file:

```
/* header.h */
extern int var;
extern void func1(void);   /* Compliant */
```

Source file:

```
/* module.c */
#include "header.h"

extern void func2(void);   /* Noncompliant */

/* Definitions */
int var = 0;
void func1(void) {}
```

### Violation Caused by Explicit Declaration and Implicit Declaration

In this example, the function `func()` is declared in `header1.h`. In `header2.h`, the function is called. In `module2.c`, the file `header2.h` is included, but `header1.h` is not included, perhaps inadvertently. Because `module2.c` includes a call to `func()` but no declaration, the compiler generates an implicit declaration for the function during compilation. The file `module1.c` includes `header1.h`, which contains an explicit declaration. Having an explicit and an implicit declaration for the same external function is noncompliant with this rule. Polyspace raises a violation. Polyspace reports a defect. In the **Result Details** section, Polyspace flags :

- The explicit declaration in `header1.h`
- The function call in `module2.c`, which triggers the creation of the implicit declaration.

```
//header1.h

extern void func(void);//Noncompliant
```

```
//header2.h

#define __STATIC_INLINE static inline

__STATIC_INLINE void Reset(void)
{
    //...
    func();
}
```

```
//module1.c
#include "header2.h"
#include "header1.h"

void foo(void)
{
}
```

```
//module2.c
#include "header2.h"

void bar(void)
{
}
```

To fix this violation, include the file `header1.h` in `module2.c`.

### Violation Caused by Implicit Declaration

In this example, the declaration of the function `func()` is in the header `header.h`. The source files `module1.c` and `module2.c` contains calls to `func()`, but the header file is not included in these source files, perhaps by mistake. As a result, the compiler creates two implicit declaration of `func()`, causing a violation of this rule. Polyspace reports the violation. In the **Result Details** section, Polyspace flags the function calls that trigger the creation of the implicit declarations.

```
//header.h

extern void func(void);
```

```
//module1.c

void foo(void)
{
    func();
}
```

```
//module2.c

void bar(void)
{
    func(); //Noncompliant
}
```

To fix this violation, include the file `header.h` in `module1.c` and `module2.c`.

An identifier with external linkage shall have exactly one external definition

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*An identifier with external linkage shall have exactly one external definition.*

### Rationale

If you use an identifier for which multiple definitions exist in different files or no definition exists, the behavior is undefined.

Multiple definitions in different files are not permitted by this rule even if the definitions are the same.

### Polyspace Implementation

The checker flags multiple definitions only if the definitions occur in different files.

The checker does not consider tentative definitions as definitions. For instance, the following code does not violate the rule:

```
int val;
int val=1;
```

The checker does not show a violation if a function is not defined at all but declared with external linkage and called in the source code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Variable Multiply Defined

First source file:

```
/* file1.c */
extern int var = 1;
```

Second source file:

```
/* file2.c */
int var = 0;   /* Non compliant */
```

In this example, the global variable `var` is multiply defined. Unless explicitly specified with the `static` qualifier, the variables have external linkage.

### Function Multiply Defined

Header file:

```
/* file.h */
int func(int param);
```

First source file:

```
/* file1.c */
#include "file.h"

int func(int param) {
    return param+1;
}
```

Second source file:

```
/* file2.c */
#include "file.h"

int func(int param) {  /* Non compliant */
    return param-1;
}
```

In this example, the function `func` is multiply defined. Unless explicitly specified with the `static` qualifier, the functions have external linkage.

# MISRA C:2012 Rule 8.7

Functions and objects should not be defined with external linkage if they are referenced in only one translation unit

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

### Rule Definition

*Functions and objects should not be defined with external linkage if they are referenced in only one translation unit.*

### Rationale

Compliance with this rule avoids confusion between your identifier and an identical identifier in another translation unit or library. If you restrict or reduce the visibility of an object by giving it internal linkage or no linkage, you or someone else is less likely to access the object inadvertently.

### Polyspace Implementation

The rule checker flags:

- Objects that are defined at file scope without the `static` specifier but used only in one file.
- Functions that are defined without the `static` specifier but called only in one file.

If you intend to use the object or function in one file only, declare it static.

If your code does not contain a `main` function and you use options such as `Variables to initialize (-main-generator-writes-variables)` with value `custom` to explicitly specify a set of variables to initialize, the checker does not flag those variables. The checker assumes that in a real application, the file containing the `main` must initialize the variables in addition to any file that currently uses them. Therefore, the variables are used in more than one translation unit.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable with External Linkage Used in One File

Header file:

```
/* file.h */
extern int var;
```

First source file:

```
/* file1.c */
#include "file.h"

int var;    /* Compliant */
int var2;   /* Non compliant */
static int var3; /* Compliant */

void reset(void);

void reset(void) {
    var = 0;
    var2 = 0;
    var3 = 0;
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment(int var2);

void increment(int var2) {
    var++;
    var2++;
}
```

In this example:

- The declaration of `var` is compliant because `var` is declared with external linkage and used in multiple files.
- The declaration of `var2` is noncompliant because `var2` is declared with external linkage but used in one file only.

  It might appear that `var2` is defined in both files. However, in the second file, `var2` is a parameter with no linkage and is not the same as the `var2` in the first file.
- The declaration of `var3` is compliant because `var3` is declared with internal linkage (with the `static` specifier) and used in one file only.

### Function with External Linkage Used in One File

Header file:

```
/* file.h */
extern int var;
extern void increment1 (void);
```

First source file:

```
/* file1.c */
#include "file.h"

int var;
```

```
void increment2(void);
static void increment3(void);
void func(void);

void increment2(void) { /* Non compliant */
    var+=2;
}

static void increment3(void) { /* Compliant */
    var+=3;
}

void func(void) {
    increment1();
    increment2();
    increment3();
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment1(void) { /* Compliant */
    var++;
}
```

In this example:

- The definition of `increment1` is compliant because `increment1` is defined with external linkage and called in a different file.
- The declaration of `increment2` is noncompliant because `increment2` is defined with external linkage but called in the same file and nowhere else.
- The declaration of `increment3` is compliant because `increment3` is defined with internal linkage (with the `static` specifier) and called in the same file and nowhere else.

# MISRA C:2012 Rule 8.8

The static storage class specifier shall be used in all declarations of objects and functions that have internal linkage

## Description

### Rule Definition

*The static storage class specifier shall be used in all declarations of objects and functions that have internal linkage.*

### Rationale

If you do not use the `static` specifier consistently in all declarations of objects with internal linkage, you might declare the same object with external and internal linkage.

In this situation, the linkage follows the earlier specification that is visible (C99 Standard, Section 6.2.2). For instance, if the earlier specification indicates internal linkage, the object has internal linkage even though the latter specification indicates external linkage. If you notice the latter specification alone, you might expect otherwise.

### Polyspace Implementation

The rule checker detects situations where:

- The same object is declared multiple times with different storage specifiers.
- The same function is declared and defined with different storage specifiers.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Linkage Conflict Between Variable Declarations

```
static int foo = 0;
extern int foo;         /* Non-compliant */

extern int hhh;
static int hhh;         /* Non-compliant */
```

In this example, the first line defines `foo` with internal linkage. The first line is compliant because the example uses the `static` keyword. The second line does not use `static` in the declaration, so the declaration is noncompliant. By comparison, the third line declares `hhh` with an `extern` keyword creating external linkage. The fourth line declares `hhh` with internal linkage, but this declaration conflicts with the first declaration of `hhh`.

#### Correction — Consistent `static` and `extern` Use

One possible correction is to use `static` and `extern` consistently:

```
static int foo = 0;
static int foo;

extern int hhh;
extern int hhh;
```

#### Linkage Conflict Between Function Declaration and Definition

```
static int fee(void);  /* Compliant - declaration: internal linkage */
int fee(void){         /* Non-compliant */
  return 1;
}

static int ggg(int);  /* Compliant - declaration: internal linkage */
extern int ggg(int x){  /* Non-compliant */
  return 1 + x;
}
```

This example shows two internal linkage violations. Because `fee` and `ggg` have internal linkage, you must use a `static` class specifier in the definition to be compliant with MISRA.

# MISRA C:2012 Rule 8.9

An object should be defined at block scope if its identifier only appears in a single function

## Description

### Rule Definition

*An object should be defined at block scope if its identifier only appears in a single function.*

### Rationale

If you define an object at block scope, you or someone else is less likely to access the object inadvertently outside the block.

### Polyspace Implementation

The rule checker flags `static` objects that are accessed in one function only but declared at file scope.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Object Declared at File Scope but Used in One Function

```
static int ctr;   /* Non compliant */

int checkStatus(void);
void incrementCount(void);

void incrementCount(void) {
    ctr=0;
    while(1) {
        if(checkStatus())
            ctr++;
    }
}
```

In this example, the declaration of `ctr` is noncompliant because it is declared at file scope but used only in the function `incrementCount`. Declare `ctr` in the body of `incrementCount` to be MISRA C-compliant.

# MISRA C:2012 Rule 8.10

An inline function shall be declared with the static storage class

## Description

### Rule Definition

*An inline function shall be declared with the static storage class.*

### Rationale

If you call an inline function that is declared with external linkage but not defined in the same translation unit, the function might not be inlined. You might not see the reduction in execution time that you expect from inlining.

If you want to make an inline function available to several translation units, you can still define it with the `static` specifier. In this case, place the definition in a header file. Include the header file in all the files where you want the function inlined.

### Polyspace Implementation

The rule checker flags definitions that contain the `inline` specifier without an accompanying `static` specifier.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Inlining Functions with External Linkage

```
inline double mult(int val);
inline double mult(int val) {   /* Non compliant */
    return val * 2.0;
}

static inline double div(int val);
static inline double div(int val) {  /* Compliant */
    return val / 2.0;
}
```

In this example, the definition of `mult` is noncompliant because it is inlined without the `static` storage specifier.

# MISRA C:2012 Rule 8.11

When an array with external linkage is declared, its size should be explicitly specified

## Description

### Rule Definition

*When an array with external linkage is declared, its size should be explicitly specified*.

### Rationale

Although it is possible to declare an array with an incomplete type and access its elements, it is safer to state the size of the array explicitly. If you provide size information for each declaration, a code reviewer can check multiple declarations for their consistency. With size information, a static analysis tool can perform array bounds analysis without analyzing more than one unit.

### Polyspace Implementation

The rule checker flags arrays declared with the `extern` specifier if the declaration does not explicitly specify the array size.

### Additional Message in Report

Size of array *`array_name`* should be explicitly stated. When an array with external linkage is declared, its size should be explicitly specified.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Array Declarations

```
#include <stdint.h>

extern int32_t array1[10];    /*  Compliant  */
extern int32_t array2[];      /*  Non-compliant  */
```

In this example, two arrays are declared `array1` and `array2`. `array1` has external linkage (the `extern` keyword) and a size of 10. `array2` also has external linkage, but no specified size. `array2` is noncompliant because for arrays with external linkage, you must explicitly specify a size.

# MISRA C:2012 Rule 8.12

Within an enumerator list, the value of an implicitly-specified enumeration constant shall be unique

## Description

### Rule Definition

*Within an enumerator list, the value of an implicitly-specified enumeration constant shall be unique*.

### Rationale

An implicitly specified enumeration constant has a value one greater than its predecessor. If the first enumeration constant is implicitly specified, then its value is 0. An explicitly specified enumeration constant has the specified value.

If implicitly and explicitly specified constants are mixed within an enumeration list, it is possible for your program to replicate values. Such replications can be unintentional and can cause unexpected behavior.

### Polyspace Implementation

The rule checker flags an enumeration if it has an implicitly specified enumeration constant with the same value as another enumeration constant.

### Additional Message in Report

The constant *`constant1`* has same value as the constant *`constant2`*.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Replication of Value in Implicitly Specified Enum Constants

```
enum color1 {red_1, blue_1, green_1};   /* Compliant */
enum color2 {red_2 = 1, blue_2 = 2, green_2 = 3};       /* Compliant */
enum color3 {red_3 = 1, blue_3, green_3};     /* Compliant */
enum color4 {red_4, blue_4, green_4 = 1};     /* Non Compliant */
enum color5 {red_5 = 2, blue_5, green_5 = 2};     /* Compliant */
enum color6 {red_6 = 2, blue_6, green_6 = 2, yellow_6};     /* Non Compliant */
```

Compliant situations:

- `color1`: All constants are implicitly specified.
- `color2`: All constants are explicitly specified.
- `color3`: Though there is a mix of implicit and explicit specification, all constants have unique values.

- `color5`: The implicitly specified constants have unique values.

Noncompliant situations:

- `color4`: The implicitly specified constant `blue_4` has the same value as `green_4`.
- `color6`: The implicitly specified constant `blue_6` has the same value as `yellow_6`.

# MISRA C:2012 Rule 8.13

A pointer should point to a const-qualified type whenever possible

## Description

### Rule Definition

*A pointer should point to a const-qualified type whenever possible*.

### Rationale

This rule ensures that you do not inadvertently use pointers to modify objects.

### Polyspace Implementation

The rule checker flags a pointer to a non-`const` function parameter if the pointer does not modify the addressed object. The assumption is that the pointer is not meant to modify the object and so must point to a `const`-qualified type. Polyspace does not raise a flag if the data pointed to by a non`const` pointer is modified by using a copy of the pointer.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pointer That Should Point to `const`-Qualified Types

```
#include <string.h>

typedef unsigned short uint16_t;

uint16_t ptr_ex(uint16_t *p) {      /* Non-compliant */
    return *p;
}

char last_char(char * const s){     /* Non-compliant */
    return s[strlen(s) - 1u];
}

uint16_t first(uint16_t a[5]){      /* Non-compliant */
    return a[0];
}
```

This example shows three different noncompliant pointer parameters.

- In the `ptr_ex` function, `p` does not modify an object. However, the type to which `p` points is not `const`-qualified, so it is noncompliant.
- In `last_char`, the pointer `s` is `const`-qualified but the type it points to is not. This parameter is noncompliant because `s` does not modify an object.

- The function `first` does not modify the elements of the array `a`. However, the element type is not `const`-qualified, so `a` is also noncompliant.

#### Correction — Use `const` Keywords

One possible correction is to add `const` qualifiers to the definitions.

```
#include <string.h>

typedef unsigned short uint16_t;

uint16_t ptr_ex(const uint16_t *p){     /* Compliant */
    return *p;
}

char last_char(const char * const s){   /* Compliant */
    return s[strlen( s ) - 1u];
}

uint16_t first(const uint16_t a[5]) {   /* Compliant */
    return a[0];
}
```

# MISRA C:2012 Rule 8.14

The restrict type qualifier shall not be used

## Description

### Rule Definition

*The restrict type qualifier shall not be used*.

### Rationale

When you use a `restrict` qualifier carefully, it improves the efficiency of code generated by a compiler. It can also improve static analysis. However, when using the `restrict` qualifier, it is difficult to make sure that the memory areas operated on by two or more pointers do not overlap.

### Polyspace Implementation

The rule checker flags all uses of the `restrict` qualifier.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `restrict` Qualifier

```
void f(int n, int * restrict p, int * restrict q)/*Noncompliant*/
{
}
```

In this example, both uses of the `restrict` qualifier are flagged.

# MISRA C:2012 Rule 9.1

The value of an object with automatic storage duration shall not be read before it has been set

## Description

**Message in Report:**

### Rule Definition

*The value of an object with automatic storage duration shall not be read before it has been set.*

### Rationale

A variable with an automatic storage duration is allocated memory at the beginning of an enclosing code block and deallocated at the end. All non-global variables have this storage duration, except those declared `static` or `extern`.

Variables with automatic storage duration are not automatically initialized and have indeterminate values. Therefore, you must not read such a variable before you have set its value through a write operation.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains these issues:

- `Non-initialized variable`
- `Non-initialized pointer`

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Read Before Initialization

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }
    return val; //Noncompliant

}
```

### Pointer Dereferenced Before Initialization

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j; //Noncompliant

    return pi;
}
```

# MISRA C:2012 Rule 9.2

The initializer for an aggregate or union shall be enclosed in braces

## Description

### Rule Definition

*The initializer for an aggregate or union shall be enclosed in braces.*

### Rationale

The rule applies to both objects and subobjects. For example, when initializing a structure that contains an array, the values assigned to the structure must be enclosed in braces. Within these braces, the values assigned to the array must be enclosed in another pair of braces.

Enclosing initializers in braces improves clarity of code that contains complex data structures such as multidimensional arrays and arrays of structures.

**Tip** To avoid nested braces for subobjects, use the syntax `{0}`, which sets all values to zero.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Initialization of Two-dimensional Arrays

```
void initialize(void) {
    int x[4][2] = {{0,0},{1,0},{0,1},{1,1}}; /* Compliant */
    int y[4][2] = {{0},{1,0},{0,1},{1,1}};   /* Compliant */
    int z[4][2] = {0};                       /* Compliant */
    int w[4][2] = {0,0,1,0,0,1,1,1};         /* Non-compliant */
}
```

In this example, the rule is not violated when:

- Initializers for each row of the array are enclosed in braces.
- The syntax `{0}` initializes all elements to zero.

The rule is violated when a separate pair of braces is not used to enclose the initializers for each row.

## Check Information

# MISRA C:2012 Rule 9.3

Arrays shall not be partially initialized

## Description

### Rule Definition

*Arrays shall not be partially initialized*.

### Rationale

Providing an explicit initialization for each array element makes it clear that every element has been considered.

### Polyspace Implementation

The checker reports a violation of this rule if an array is partially initialized at declaration. The checker allows initialization of all values using the shorthand notation `{0}`, for instance:

```
float dat2[3*3] = {0};
```

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Partial and Complete Initializations

```
void func(void) {
    int x[3] = {0,1,2};              /* Compliant */
    int y[3] = {0,1};                /* Non-compliant */
    int z[3] = {0};                  /* Compliant - exception */
    int a[30] = {[1] = 1,[15]=1};    /* Compliant - exception */
    int b[30] = {[1] = 1, 1};        /* Non-compliant */
    char c[20] = "Hello World";      /* Compliant - exception */
}
```

In this example, the rule is not violated when each array element is explicitly initialized.

The rule is violated when some elements of the array are implicitly initialized. Exceptions include the following:

- The initializer has the form `{0}`, which initializes all elements to zero.
- The array initializer consists *only* of designated initializers. Typically, you use this approach for sparse initialization.
- The array is initialized using a string literal.

# MISRA C:2012 Rule 9.4

An element of an object shall not be initialized more than once

## Description

### Rule Definition

*An element of an object shall not be initialized more than once*.

### Rationale

Designated initializers allow explicitly initializing elements of objects such as arrays in any order. However, using designated initializers, one can inadvertently initialize the same element twice and therefore overwrite the first initialization.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Array Initialization Using Designated Initializers

```
void func(void) {
    int a[5] = {-2,-1,0,1,2};               /* Compliant */
    int b[5] = {[0]=-2, [1]=-1, [2]=0, [3]=1, [4]=2}; /* Compliant */
    int c[5] = {[0]=-2, [1]=-1, [1]=0, [3]=1, [4]=2}; /* Non-compliant */

}
```

In this example, the rule is violated when the array element `c[1]` is initialized twice using a designated initializer.

### Structure Initialization Using Designated Initializers

```
struct myStruct {
    int a;
    int b;
    int c;
    int d;
};

void func(void) {
    struct myStruct struct1 = {-4,-2,2,4}; /* Compliant */
    struct myStruct struct2 = {.a=-4, .b=-2, .c=2, .d=4}; /* Compliant */
    struct myStruct struct3 = {.a=-4, .b=-2, .b=2, .d=4}; /* Non-compliant */
}
```

In this example, the rule is violated when `struct3.b` is initialized twice using a designated initializer.

# MISRA C:2012 Rule 9.5

Where designated initializers are used to initialize an array object the size of the array shall be specified explicitly

## Description

### Rule Definition

*Where designated initializers are used to initialize an array object the size of the array shall be specified explicitly.*

### Rationale

If the size of an array is not specified explicitly, it is determined by the highest index of the elements that are initialized. When using long designated initializers, it might not be immediately apparent which element has the highest index.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using Designated Initializers Without Specifying Array Size

```
int a[5] = {[0]= 1, [2] = 1, [4]= 1, [1] = 1};        /* Compliant */
int b[] = {[0]= 1, [2] = 1, [4]= 1, [1] = 1};         /* Non-compliant */
int c[] = {[0]= 1, [1] = 1, [2]= 1, [3]=0, [4] = 1};  /* Non-compliant */

void display(int);

void main() {
    func(a,5);
    func(b,5);
    func(c,5);
}

void func(int* arr, int size) {
    for(int i=0; i<size; i++)
        display(arr[i]);
}
```

In this example, the rule is violated when the arrays b and c are initialized using designated initializers but the array size is not specified.

# MISRA C:2012 Rule 10.1

Operands shall not be of an inappropriate essential type

## Description

### Rule Definition

*Operands shall not be of an inappropriate essential type.*

### Rationale

#### What Are Essential Types?

An essential type category defines the essential type of an object or expression.

| Essential type category | Standard types |
|---|---|
| Essentially Boolean | `bool` or `_Bool` (defined in `stdbool.h`)<br>You can also define types that are essentially Boolean using the option `Effective boolean types (-boolean-types)`. |
| Essentially character | `char` |
| Essentially enum | named `enum` |
| Essentially signed | signed `char`, signed `short`, signed `int`, signed `long`, signed `long long` |
| Essentially unsigned | unsigned `char`, unsigned `short`, unsigned `int`, unsigned `long`, unsigned `long long` |
| Essentially floating | `float`, `double`, `long double` |

#### Amplification and Rationale

For operands of some operators, you cannot use certain essential types. In the table below, each row represents an operator/operand combination. If the essential type column is not empty for that row, there is a MISRA restriction when using that type as the operand. The number in the table corresponds to the rationale list after the table.

| Operation | | Essential type category of arithmetic operand | | | | | |
|---|---|---|---|---|---|---|---|
| **Operator** | **Operand** | **Boolean** | **character** | **enum** | **signed** | **unsigned** | **floating** |
| `[ ]` | integer | 3 | 4 | | | | 1 |
| `+` (unary) | | 3 | 4 | 5 | | | |
| `-` (unary) | | 3 | 4 | 5 | | 8 | |
| `+ -` | either | 3 | | 5 | | | |
| `* /` | either | 3 | 4 | 5 | | | |
| `%` | either | 3 | 4 | 5 | | | 1 |
| `< > <= >=` | either | 3 | | | | | |

| Operation | | Essential type category of arithmetic operand | | | | | |
|---|---|---|---|---|---|---|---|
| `== !=` | either | | | | | | |
| `! && \|\|` | any | | 2 | 2 | 2 | 2 | 2 |
| `<< >>` | left | 3 | 4 | 5,6 | 6 | | 1 |
| `<< >>` | right | 3 | 4 | 7 | 7 | | 1 |
| `~ & \| ^` | any | 3 | 4 | 5,6 | 6 | | 1 |
| `?:` | 1st | | 2 | 2 | 2 | 2 | 2 |
| `?:` | 2nd and 3rd | | | | | | |

**1** An expression of essentially floating type for these operands is a constraint violation.

**2** When an operand is interpreted as a Boolean value, use an expression of essentially Boolean type.

**3** When an operand is interpreted as a numeric value, do not use an operand of essentially Boolean type.

**4** When an operand is interpreted as a numeric value, do not use an operand of essentially character type. The numeric values of character data are implementation-defined.

**5** In an arithmetic operation, do not use an operand of essentially enum type. An enum object uses an implementation-defined integer type. An operation involving an enum object can therefore yield a result with an unexpected type.

**6** Perform only shift and bitwise operations on operands of essentially unsigned type. When you use shift and bitwise operations on essentially signed types, the resulting numeric value is implementation-defined.

**7** To avoid undefined behavior on negative shifts, use an essentially unsigned right-hand operand.

**8** For the unary minus operator, do not use an operand of essentially unsigned type. The implemented size of int determines the signedness of the result.

Note that for a bit-field type, if the bit-field is implemented as:

- A Boolean, the bit-field is essentially Boolean.
- Signed or unsigned type, the bit-field is essentially signed or unsigned respectively.

  The type of the bit-field is the smallest type that can represent the bit-field. For instance, the type `stmp` here is essentially 8 bits integer:

  ```
  typedef signed int mybitfield;
  typedef struct { mybitfield f1 : 1; } stmp;
  ```

### Additional Message in Report

The *`operand_name`* operand of the *`operator_name`* operator is of an inappropriate essential type category *`category_name`*.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Violation of Rule 10.1, Rationale 2: Inappropriate Operand Types for Operators That Take Essentially Boolean Operands

```
#include<stdbool.h>
extern float f32a;
extern char cha;
extern signed char s8a;
extern unsigned char u8a,u8b,ru8a;
enum enuma { a1, a2, a3 } ena, enb;
extern bool bla, blb, rbla;
void foo(void) {

    rbla = cha && bla;        /* Non-compliant: cha is essentially char  */
    enb = ena ? a1 : a2;      /* Non-compliant: ena is essentially enum  */
    rbla = s8a && bla;        /* Non-compliant: s8a is essentially signed char  */
    ena = u8a ? a1 : a2;      /* Non-compliant: u8a is essentially unsigned char  */
    rbla = f32a && bla;       /* Non-compliant: f32a is essentially float */
    rbla = bla && blb;        /* Compliant */
    ru8a = bla ? u8a : u8b;   /* Compliant */
}
```

In the noncompliant examples, rule 10.1 is violated because:

- The operator && expects only essentially Boolean operands. However, at least one of the operands used has a different type.
- The first operand of `?:` is expected to be essentially Boolean. However, a different operand type is used.

**Note** For Polyspace to detect the rule violation, you must define the type name `boolean` as an effective Boolean type. For more information, see `Effective boolean types (-boolean-types)`.

### Violation of Rule 10.1, Rationale 3: Inappropriate Boolean Operands

```
#include<stdbool.h>
enum enuma { a1, a2, a3 } ena;
enum { K1 = 1, K2 = 2 };    /* Essentially signed */
extern char cha, chb;
extern bool bla, blb, rbla;
extern signed char rs8a, s8a;
extern unsigned char u8a;

void foo(void) {

  rbla = bla * blb;      /* Non-compliant - Boolean used as a numeric value */
  rbla = bla > blb;      /* Non-compliant - Boolean used as a numeric value */

  rbla = bla && blb;     /* Compliant */
  rbla = cha > chb;      /* Compliant */
  rbla = ena > a1;       /* Compliant */
  rbla = u8a > 0U;       /* Compliant */
  rs8a = K1 * s8a;       /* Compliant - K1 obtained from anonymous enum */

}
```

In the noncompliant examples, rule 10.1 is violated because the operators * and > do not expect essentially Boolean operands. However, the operands used here are essentially Boolean.

**Note** For Polyspace to detect the rule violation, you must define the type name `boolean` as an effective Boolean type. For more information, see `Effective boolean types (-boolean-types)`.

### Violation of Rule 10.1, Rationale 4: Inappropriate Character Operands

```
extern char rcha, cha, chb;
extern unsigned char ru8a, u8a;

void foo(void) {

  rcha = cha & chb;      /* Non-compliant - char type used as a numeric value */
  rcha = cha << 1;       /* Non-compliant - char type used as a numeric value */

  ru8a = u8a & 2U;       /* Compliant */
  ru8a = u8a << 2U;      /* Compliant */

}
```

In the noncompliant examples, rule 10.1 is violated because the operators & and << do not expect essentially character operands. However, at least one of the operands used here has essentially character type.

### Violation of Rule 10.1, Rationale 5: Inappropriate Enum Operands

```
typedef unsigned char boolean;

enum enuma { a1, a2, a3 } rena, ena, enb;

void foo(void) {

  ena--;             /* Non-Compliant - arithmetic operation with enum type*/
  rena = ena * a1;   /* Non-Compliant - arithmetic operation with enum type*/
  ena += a1;         /* Non-Compliant - arithmetic operation with enum type*/

}
```

In the noncompliant examples, rule 10.1 is violated because the arithmetic operators --, * and += do not expect essentially enum operands. However, at least one of the operands used here has essentially enum type.

### Violation of Rule 10.1, Rationale 6: Inappropriate Signed Operand for Bitwise Operations

```
extern signed char s8a;
extern unsigned char ru8a, u8a;

void foo(void) {

  ru8a = s8a & 2;       /* Non-compliant - bitwise operation on signed type */
  ru8a = 2 << 3U;       /* Non-compliant - shift operation on signed type */

  ru8a = u8a << 2U;     /* Compliant */

}
```

In the noncompliant examples, rule 10.1 is violated because the & and << operations must not be performed on essentially signed operands. However, the operands used here are signed.

### Violation of Rule 10.1, Rationale 7: Inappropriate Signed Right Operand for Shift Operations

```
extern signed char s8a;
extern unsigned char ru8a, u8a;

void foo(void) {

  ru8a = u8a << s8a;    /* Non-compliant - shift magnitude uses signed type */
  ru8a = u8a << -1;     /* Non-compliant - shift magnitude uses signed type */

  ru8a = u8a << 2U;     /* Compliant */
  ru8a = u8a << 1;      /* Compliant - exception */

}
```

In the noncompliant examples, rule 10.1 is violated because the operation << does not expect an essentially signed right operand. However, the right operands used here are signed.

# MISRA C:2012 Rule 10.2

Expressions of essentially character type shall not be used inappropriately in addition and subtraction operations

## Description

### Rule Definition

*Expressions of essentially character type shall not be used inappropriately in addition and subtraction operations*.

### Rationale

Essentially character type expressions are `char` variables. Do not use `char` in arithmetic operations because the data does not represent numeric values.

It is appropriate to use `char` with addition and subtraction operations only in the following cases:

- When one operand of the addition (+) operation is a `char` and the other is a signed or unsigned `char`, `short`, `int`, `long` or `long long`. In this case, the operation returns a `char`.
- When the first operand of the subtraction (-) operation is a `char` and the second is a signed or unsigned `char`, `short`, `int`, `long` or `long long`. If both operands are `char`, the operation returns a *standard* type. Otherwise, the operation returns a `char`.

The above uses allow manipulation of character data such as conversion between lowercase and uppercase characters or conversion between digits and their ordinal values.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Additional Message in Report

- The *`operand_name`* operand of the `+` operator applied to an expression of essentially character type shall have essentially signed or unsigned type.
- The right operand of the `-` operator applied to an expression of essentially character type shall have essentially signed or unsigned or character type.
- The left operand of the `-` operator shall have essentially character type if the right operand has essentially character type.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Inappropriate use of `char` with Addition and Subtraction Operators

```
#include<stdint.h>
typedef double float64_t;
extern uint8_t u8a;
extern int8_t s8a;
extern int16_t s16a;
extern int32_t s32a;
extern float64_t fla;

void foo ( void )
{
    char cha;

    s16a = s16a - 'a';  /* Noncompliant*/

    cha = '0' + fla;    /* Noncompliant*/

    cha = cha  + ':';   /* Noncompliant*/
}
```

- You cannot subtract a `char`-type variable from an integer. When you subtract `'a'` from the integer `s16a`, Polyspace raises a violation.
- In addition operations, `char` type variables can only be added to integer type variables. When you add the floating point number `fla` to `'0'`, Polyspace raises a violation.
- The arithmetic operation `cha+':'` is not a conversion from upper to lower case or from digit to cardinal value. Polyspace raises a violation when `char` variables are used in arithmetic expressions.

### Permissible use of `char` in Arithmetic Operation

```
#include<stdint.h>
typedef double float64_t;
extern uint8_t u8a;
extern int8_t s8a;
extern int16_t s16a;
extern int32_t s32a;
void foo ( void )
{
    char cha;

    cha = '0' + u8a;     /* Compliant*/

    cha = s8a + '0';     /* Compliant*/

    s32a = cha  - '0';   /* Compliant*/

    cha = '0' - s8a;     /* Compliant*/

    cha++;               /* Compliant*/
}
```

`char` type variables can be used in certain addition or subtraction operations to perform `char` data manipulations. For instance:

- You can add an unsigned integer `u8a` to the `char` type data `'0'` to convert from `'0'` to a different character.
- Similarly, you can add the signed integer `s8a` to `'0'` to perform a desired character conversion.
- You can also subtract `s8a` from the `char` data `'0'`.
- Incrementing and decrementing `char` data is also permissible.

## Check Information

"Essential Types in MISRA C:2012 Rules 10.x"

# MISRA C:2012 Rule 10.3

The value of an expression shall not be assigned to an object with a narrower essential type or of a different essential type category

## Description

### Rule Definition

*The value of an expression shall not be assigned to an object with a narrower essential type or of a different essential type category.*

### Rationale

The use of implicit conversions between types can lead to unintended results, including possible loss of value, sign, or precision.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Polyspace Implementation

The checker raises a violation if an expression is assigned to a variable with a narrower essential type or a different essential type category.

The checker does not raise a violation of this rule:

- If an object is assigned the constant zero corresponding to its essential type. This acceptable zero value is `0` for integral types, `0.0` for a `double`, and `'\0'` for `char`.
- When a variable of aggregate type such as an array is initialized using the shorthand notation `{0}`, for instance:

  ```
  float dat2[3*3] = {0};
  ```
- If the macros `TRUE`/`true` and `FALSE`/`false` with the corresponding boolean value is assigned to a `bool` variable. Polyspace raises a violation if these macros are spelled with mixed case.
- If a signed constant is assigned to an unsigned variable but the signed constant has the same representation as its unsigned equivalent. For instance, the checker does not flag statements such as:

  ```
  unsigned int u = 1;
  ```

Code generation tools might use the boolean values `true/false` with integer literals `1/0` interchangeably, resulting in violation of this rule. Because this rule is advisory when used in AGC mode, you might want to justify such defects. See “Annotate Code and Hide Known or Acceptable Results”.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Initializing Variables to Zero

```
#include<stdint.h>
#include <stdbool.h>
#define FALSE 0
#define TRUE 1
void init_integer(){
    int8_t a1= 0;
    int16_t a2= 0;
    int32_t a3= 0;
    uint8_t a4= 0;
    uint16_t a5= 0;
    uint32_t a6= 0;
}
void initiate(){
    float b = 0.0/*Noncompliant*/;
    double c = 0.0;
    bool flag1 = FALSE;
    bool flag2 = FALSE;
    char ch = 0 /*Noncompliant*/;
    char ch2 = '\0';
    unsigned char uch = 0;
}
```

This example shows how to initiate variables with a zero constant.

- For integral types of various sizes, initiating the variables with `0` is compliant with this rule.
- Initiating the `double` with `0.0` and the `char` with `'\0'` are also compliant with this rule.
- Because the essential type of a `char` is not integral, initiating the `char` object `ch` with `0` is not compliant with this rule.
- The essential type of an `unsigned char` is integral. Initiating the `unsigned char uch` with `0` is compliant with this rule.

`MISRA C:2012 Rule 10.4` | `MISRA C:2012 Rule 10.5` | `MISRA C:2012 Rule 10.6` | `Check MISRA C:2012 (-misra3)`

### Topics

"Check for and Review Coding Standard Violations"
"Software Quality Objective Subsets (C:2012)"
"Essential Types in MISRA C:2012 Rules 10.x"

# MISRA C:2012 Rule 10.4

Both operands of an operator in which the usual arithmetic conversions are performed shall have the same essential type category

## Description

### Rule Definition

*Both operands of an operator in which the usual arithmetic conversions are performed shall have the same essential type category*.

### Rationale

The use of implicit conversions between types can lead to unintended results, including possible loss of value, sign, or precision.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Polyspace Implementation

The checker raises a violation of this rule if the two operands of an operation have different essential types. The checker message states the types detected on the two sides of the operation.

The checker does not raise a violation of this rule:

- If one of the operands is the constant zero.
- If one of the operands is a signed constant and the other operand is unsigned, and the signed constant has the same representation as its unsigned equivalent.

  For instance, the statement `u8b = u8a + 3;`, where `u8a` and `u8b` are `unsigned char` variables, does not violate the rule because the constants `3` and `3U` have the same representation.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Operands with Different Essential Types

```
#define S64_MAX (9223372036854775807LL)
#define S64_MIN (-9223372036854775808LL)
long long input_s64_a, input_s64_b, result_s64;

void my_func(void){
   if (input_s64_a < S64_MIN + input_s64_b) { //Noncompliant: 2 violations
      result_s64 = S64_MIN;
   }
}
```

In this example, the type of `S64_MIN` is essentially unsigned. The value `9223372036854775808LL` is one more than the largest value that can be represented by a 64-bit variable. Therefore, the value overflows and the result wraps around to a negative value, so `-9223372036854775808LL` is essentially unsigned.

The operation `input_s64_a < S64_MIN + input_s64_b` violates the rule twice.

- The `+` operation violates the rule. The left operand is essentially unsigned and the right operand is signed.
- The `<` operation also violates the rule. As a result of type promotion, the result of the `+` operation is essentially unsigned. Now, the left operand of the `<` operation is essentially signed but the right operand is essentially unsigned.

# MISRA C:2012 Rule 10.5

The value of an expression should not be cast to an inappropriate essential type

## Description

### Rule Definition

*The value of an expression should not be cast to an inappropriate essential type.*

### Rationale

### Converting Between Variable Types

| | | From | | | | | |
|---|---|---|---|---|---|---|---|
| | | **Boolean** | **character** | **enum** | **signed** | **unsigned** | **floating** |
| To | **Boolean** | | Avoid | Avoid | Avoid | Avoid | Avoid |
| | **character** | Avoid | | | | | Avoid |
| | **enum** | Avoid | Avoid | Avoid | Avoid | Avoid | Avoid |
| | **signed** | Avoid | | | | | |
| | **unsigned** | Avoid | | | | | |
| | **floating** | Avoid | Avoid | | | | |

Some inappropriate explicit casts are:

- In C99, the result of a cast of assignment to `_Bool` is always 0 or 1. This result is not necessarily the case when casting to another type which is defined as essentially Boolean.
- A cast to an essential enum type may result in a value that does not lie within the set of enumeration constants for that type.
- A cast from essential Boolean to any other type is unlikely to be meaningful.
- Converting between floating and character types is not meaningful as there is no precise mapping between the two representations.

Some acceptable explicit casts are:

- To change the type in which a subsequent arithmetic operation is performed.
- To truncate a value deliberately.
- To make a type conversion explicit in the interests of clarity.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

# MISRA C:2012 Rule 10.6

The value of a composite expression shall not be assigned to an object with wider essential type

## Description

### Rule Definition

*The value of a composite expression shall not be assigned to an object with wider essential type.*

### Rationale

A *composite expression* is a nonconstant expression using a composite operator. In the Essential Type Model, composite operators are:

- Multiplicative (`*`, `/`, `%`)
- Additive (binary `+`, binary `-`)
- Bitwise (&, `|`, `^`)
- Shift (<<, >>)
- Conditional (`?`, `:`)

Unary operators such as ~ and unary `+` or `-` are also considered composite operators.

If you assign the result of a composite expression to a larger type, the implicit conversion can result in loss of value, sign, precision, or layout.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** The Essential Type Model
**Category:** Required
**AGC Category:** Advisory

# MISRA C:2012 Rule 10.7

If a composite expression is used as one operand of an operator in which the usual arithmetic conversions are performed then the other operand shall not have wider essential type

## Description

### Rule Definition

*If a composite expression is used as one operand of an operator in which the usual arithmetic conversions are performed, then the other operand shall not have wider essential type.*

### Rationale

A *composite expression* is a nonconstant expression using a composite operator. In the Essential Type Model, composite operators are:

- Multiplicative (`*`, `/`, `%`)
- Additive (binary `+`, binary `-`)
- Bitwise (&, `|`, `^`)
- Shift (<<, >>)
- Conditional (`?`, `:`)

Restricting implicit conversion on composite expressions mean that sequences of arithmetic operations within expressions must use the same essential type. This restriction reduces confusion and avoids loss of value, sign, precision, or layout. However, this rule does not imply that all operands in an expression are of the same essential type.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Additional Message in Report

- The right operand shall not have wider essential type than the left operand which is a composite expression.
- The left operand shall not have wider essential type than the right operand which is a composite expression.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** The Essential Type Model
**Category:** Required
**AGC Category:** Advisory

## See Also

“Check for and Review Coding Standard Violations”
“Software Quality Objective Subsets (C:2012)”
“Essential Types in MISRA C:2012 Rules 10.x”

# MISRA C:2012 Rule 10.8

The value of a composite expression shall not be cast to a different essential type category or a wider essential type

## Description

### Rule Definition

*The value of a composite expression shall not be cast to a different essential type category or a wider essential type.*

### Rationale

A *composite expression* is a non-constant expression using a composite operator. In the Essential Type Model, composite operators are:

- Multiplicative (`*`, `/`, `%`)
- Additive (binary `+`, binary `-`)
- Bitwise (&, `|`, `^`)
- Shift (<<, >>)
- Conditional (`?`, `:`)

Unary operators such as ~ and unary `+` or `-` are also considered composite operators.

Casting to a wider type is not permitted because the result may vary between implementations. Consider this expression:

```
(uint32_t) (u16a +u16b);
```

On a 16-bit machine the addition is performed in 16 bits. The result is wrapped before it is cast to 32 bits. On a 32-bit machine, the addition takes place in 32 bits and preserves high-order bits that are lost on a 16-bit machine. Casting to a narrower type with the same essential type category is acceptable as the explicit truncation of the results always leads to the same loss of information.

For more information on essential types, see `MISRA C:2012 Rule 10.1`.

### Polyspace Implementation

The rule checker raises a defect only if the result of a composite expression is cast to a different or wider essential type. Unary operators are not considered as composite operators.

For instance, in this example, a violation is shown in the first assignment to `i` but not the second. In the first assignment, a composite expression `i+1` is directly cast from a signed to an unsigned type. In the second assignment, the composite expression is first cast to the same type and then the result is cast to a different type.

```
typedef int int32_T;
typedef unsigned char uint8_T;
...
...
int32_T i;
```

```
i = (uint8_T)(i+1); /* Noncompliant */
i = (uint8_T)((int32_T)(i+1)); /* Compliant */
```

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Casting to Different or Wider Essential Type

```
extern unsigned short ru16a, u16a, u16b;
extern unsigned int   u32a, ru32a;
extern signed int     s32a, s32b;

void foo(void)
{
  ru16a  = (unsigned short) (u32a + u32a);/* Compliant                           */
  ru16a += (unsigned short) s32a;    /* Compliant - s32a is not composite        */
  ru32a  = (unsigned int) (u16a + u16b);  /* Noncompliant - wider essential type */
}
```

In this example, rule 10.8 is violated in the following cases:

- `s32a` and `s32b` are essentially `signed` variables. However, the result `( s32a + s32b )` is cast to an essentially `unsigned` type.
- `u16a` and `u16b` are essentially `unsigned short` variables. However, the result `( s32a + s32b )` is cast to a wider essential type, `unsigned int`.

# MISRA C:2012 Rule 11.1

Conversions shall not be performed between a pointer to a function and any other type

## Description

### Rule Definition

*Conversions shall not be performed between a pointer to a function and any other type.*

### Rationale

The rule forbids the following two conversions:

- Conversion from a function pointer to any other type. This conversion causes undefined behavior.
- Conversion from a function pointer to another function pointer, if the function pointers have different argument and return types.

  The conversion is forbidden because calling a function through a pointer with incompatible type results in undefined behavior.

### Polyspace Implementation

Polyspace considers both explicit and implicit casts when checking this rule. However, casts from `NULL` or `(void*)0` do not violate this rule.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Cast between two function pointers

```
typedef void (*fp16) (short n);
typedef void (*fp32) (int n);

#include <stdlib.h>                     /* To obtain macro  NULL */

void func(void) {   /* Exception 1 - Can convert a null pointer
                     * constant into a pointer to a function */
  fp16 fp1 = NULL;                 /* Compliant - exception  */
  fp16 fp2 = (fp16) fp1;           /* Compliant */
  fp32 fp3 = (fp32) fp1;           /* Non-compliant */
  if (fp2 != NULL) {}              /* Compliant - exception  */
  fp16 fp4 = (fp16) 0x8000;        /* Non-compliant - integer to
                                    * function pointer */}
```

In this example, the rule is violated when:

- The pointer `fp1` of type `fp16` is cast to type `fp32`. The function pointer types `fp16` and `fp32` have different argument types.

- An integer is cast to type `fp16`.

The rule is not violated when function pointers `fp1` and `fp2` are cast to `NULL`.

# MISRA C:2012 Rule 11.2

Conversions shall not be performed between a pointer to an incomplete type and any other type

## Description

### Rule Definition

*Conversions shall not be performed between a pointer to an incomplete type and any other type.*

### Rationale

An incomplete type is a type that does not contain sufficient information to determine its size. For example, the statement `struct s;` describes an incomplete type because the fields of `s` are not defined. The size of a variable of type `s` cannot be determined.

Conversions to or from a pointer to an incomplete type result in undefined behavior. Typically, a pointer to an incomplete type is used to hide the full representation of an object. This encapsulation is broken if another pointer is implicitly or explicitly cast to such a pointer.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Casts from incomplete type

```
#include <stdio.h>
struct s *sp;
struct t *tp;
short  *ip;
struct ct *ctp1;
struct ct *ctp2;

void foo(void) {

    ip = (short *) sp;            /* Non-compliant */
    sp = (struct s *) 1234;       /* Non-compliant */
    tp = (struct t *) sp;         /* Non-compliant */
    ctp1 = (struct ct *) ctp2;    /* Compliant */

    /* You can convert a null pointer constant to
     * a pointer to an incomplete type */
    sp = NULL;                    /* Compliant - exception  */

    /* A pointer to an incomplete type may be converted into void */
    struct s *f(void);
    (void) f();                   /* Compliant - exception  */

}
```

In this example, types `s`, `t` and `ct` are incomplete. The rule is violated when:

- The variable `sp` with an incomplete type is cast to a basic type.
- The variable `sp` with an incomplete type is cast to a different incomplete type `t`.

The rule is not violated when:

- The variable `ctp2` with an incomplete type is cast to the same incomplete type.
- The `NULL` pointer is cast to the variable `sp` with an incomplete type.
- The return value of `f` with incomplete type is cast to `void`.

# MISRA C:2012 Rule 11.3

A cast shall not be performed between a pointer to object type and a pointer to a different object type

## Description

### Rule Definition

*A cast shall not be performed between a pointer to object type and a pointer to a different object type.*

### Rationale

If a pointer to an object is cast into a pointer to a different object, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.

Even if the conversion produces a pointer that is correctly aligned, the behavior can be undefined if the pointer is used to access an object.

Exception: You can convert a pointer to object type into a pointer to one of the following types:

- `char`
- `signed char`
- `unsigned char`

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant: Cast to Pointer Pointing to Object of Wider Type

```
signed   char *p1;
unsigned int *p2;

void foo(void){
  p2 = ( unsigned int * ) p1;     /* Non-compliant */
}
```

In this example, `p1` can point to a `signed char` object. However, `p1` is cast to a pointer that points to an object of wider type, `unsigned int`.

### Noncompliant: Cast to Pointer Pointing to Object of Narrower Type

```
extern unsigned int read_value ( void );
extern void display ( unsigned int n );

void foo ( void ){
  unsigned int u = read_value ( );
  unsigned short *hi_p = ( unsigned short * ) &u;    /* Non-compliant  */
  *hi_p = 0;
  display ( u );
}
```

In this example, u is an unsigned int variable. &u is cast to a pointer that points to an object of narrower type, unsigned short.

On a big-endian machine, the statement *hi_p = 0 attempts to clear the high bits of the memory location that &u points to. But, from the result of display(u), you might find that the high bits have not been cleared.

#### Noncompliant: Implicit Casting

```
typedef struct {
    int iNum1;
}A;

typedef struct {
    int iNum2;
}B;

void bar(A*);

void foo() {
    B wrappedNum2;
    bar(&wrappedNum2); /* Noncompliant*/

}
```

In this example, the B type struct object wrappedNum2 is implicitly cast into an A type struct object in the call to bar. Polyspace flags the implicit casting.

#### Compliant: Cast Adding a Type Qualifier

```
const short *p;
const volatile short *q;
void foo (void){
  q = ( const volatile short * ) p;  /* Compliant */
}
```

In this example, both p and q can point to short objects. The cast between them adds a volatile qualifier only and is therefore compliant.

# MISRA C:2012 Rule 11.4

A conversion should not be performed between a pointer to object and an integer type

## Description

### Rule Definition

*A conversion should not be performed between a pointer to object and an integer type.*

### Rationale

Conversion between integers and pointers can cause errors or undefined behavior.

- If an integer is cast to a pointer, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.
- If a pointer is cast to an integer, the resulting value can be outside the allowed range for the integer type.

### Polyspace Implementation

Casts or implicit conversions from `NULL` or `(void*)0` do not generate a warning.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Casts between pointer and integer

```
#include <stdbool.h>

typedef unsigned char      uint8_t;
typedef          char      char_t;
typedef unsigned short     uint16_t;
typedef signed   int       int32_t;

typedef _Bool bool_t;
uint8_t *PORTA = (uint8_t *) 0x0002;            /* Non-compliant */

void foo(void) {

    char_t c = 1;
    char_t *pc = &c;                              /* Compliant */

    uint16_t ui16   = 7U;
    uint16_t *pui16 = &ui16;                      /* Compliant */
    pui16 = (uint16_t *) ui16;                    /* Non-compliant */
    uint16_t *p;
    int32_t addr = (int32_t) p;                  /* Non-compliant */
    bool_t b = (bool_t) p;                       /* Non-compliant */
    enum etag { A, B } e = ( enum etag ) p;      /* Non-compliant */
}
```

In this example, the rule is violated when:

- The integer `0x0002` is cast to a pointer.

  If the integer defines an absolute address, it is more common to assign the address to a pointer in a header file. To avoid the assignment being flagged, you can then exclude headers files from coding rules checking. For more information, see `Do not generate results for (-do-not-generate-results-for)`.
- The pointer `p` is cast to integer types such as `int32_t`, `bool_t` or `enum etag`.

The rule is not violated when the address `&ui16` is assigned to a pointer.

# MISRA C:2012 Rule 11.5

A conversion should not be performed from pointer to void into pointer to object

## Description

### Rule Definition

*A conversion should not be performed from pointer to void into pointer to object.*

### Rationale

If a pointer to void is cast into a pointer to an object, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior. However, such a cast can sometimes be necessary, for example, when using memory allocation functions.

### Polyspace Implementation

Casts or implicit conversions from NULL or (void*)0 do not generate a warning.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Cast from Pointer to void

```
void foo(void) {

    unsigned int  u32a = 0;
    unsigned int  *p32 = &u32a;
    void          *p;
    unsigned int  *p16;

    p   = p32;                /* Compliant - pointer to uint32_t
                               *            into pointer to void */
    p16 = p;                  /* Non-compliant */

    p   = (void *) p16;       /* Compliant */
    p32 = (unsigned int *) p; /* Non-compliant */
}
```

In this example, the rule is violated when the pointer p of type void* is cast to pointers to other types.

The rule is not violated when p16 and p32, which are pointers to non-void types, are cast to void*.

"Check for and Review Coding Standard Violations"
"Software Quality Objective Subsets (C:2012)"

# MISRA C:2012 Rule 11.6

A cast shall not be performed between pointer to void and an arithmetic type

## Description

### Rule Definition

*A cast shall not be performed between pointer to void and an arithmetic type*.

### Rationale

Conversion between integer types and pointers to `void` can cause errors or undefined behavior.

- If an integer type is cast to a pointer, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.
- If a pointer is cast to an arithmetic type, the resulting value can be outside the allowed range for the type.

Conversion between non-integer arithmetic types and pointers to `void` is undefined.

### Polyspace Implementation

Casts or implicit conversions from `NULL` or `(void*)0` do not generate a warning.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Casts Between Pointer to void and Arithmetic Types

```
void foo(void) {

    void          *p;
    unsigned int  u;
    unsigned short r;

    p = (void *) 0x1234u;            /* Non-compliant - undefined */
    u = (unsigned int) p;            /* Non-compliant - undefined */

    p = (void *) 0;                  /* Compliant - Exception */

}
```

In this example, `p` is a pointer to `void`. The rule is violated when:

- An integer value is cast to `p`.
- `p` is cast to an `unsigned int` type.

The rule is not violated if an integer constant with value 0 is cast to a pointer to `void`.

## Check Information

"Check for and Review Coding Standard Violations"
"Software Quality Objective Subsets (C:2012)"

# MISRA C:2012 Rule 11.7

A cast shall not be performed between pointer to object and a non-integer arithmetic type

## Description

### Rule Definition

*A cast shall not be performed between pointer to object and a non-integer arithmetic type.*

### Rationale

This rule covers types that are essentially Boolean, character, enum or floating.

- If an essentially Boolean, character or enum variable is cast to a pointer, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior. If a pointer is cast to one of those types, the resulting value can be outside the allowed range for the type.
- Casts to or from a pointer to a floating type results in undefined behavior.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Casts from Pointer to Non-Integer Arithmetic Types

```
int foo(void) {

    short *p;
    float  f;
    long  *l;

    f = (float)   p;              /* Non-compliant */
    p = (short *) f;              /* Non-compliant */

    l = (long *)  p;              /* Compliant */
}
```

In this example, the rule is violated when:

- The pointer `p` is cast to `float`.
- A `float` variable is cast to a pointer to `short`.

Casting between a pointer and a non-integerer variable might cause a compilation failure. Polyspace flags such casts.

The rule is not violated when the pointer `p` is cast to `long*`.

# MISRA C:2012 Rule 11.8

A cast shall not remove any const or volatile qualification from the type pointed to by a pointer

## Description

### Rule Definition

*A cast shall not remove any const or volatile qualification from the type pointed to by a pointer.*

### Rationale

This rule forbids:

- Casts from a pointer to a `const` object to a pointer that does not point to a `const` object.
- Casts from a pointer to a `volatile` object to a pointer that does not point to a `volatile` object.

Such casts violate type qualification. For example, the `const` qualifier indicates the read-only status of an object. If a cast removes the qualifier, the object is no longer read-only.

### Polyspace Implementation

Polyspace flags both implicit and explicit conversions that violate this rule.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Casts That Remove Qualifiers

```
void foo(void) {

    /* Cast on simple type */
    unsigned short           x;
    unsigned short * const   cpi = &x;  /* const pointer */
    unsigned short * const  *pcpi;   /* pointer to const pointer */
    unsigned short **ppi;
    const unsigned short    *pci;    /* pointer to const */
    volatile unsigned short *pvi;    /* pointer to volatile  */
    unsigned short          *pi;

    pi = cpi;                        /* Compliant - no cast required */
    pi  = (unsigned short *)  pci;   /* Non-compliant */
    pi  = (unsigned short *)  pvi;   /* Non-compliant */
    ppi = (unsigned short **)pcpi;   /* Non-compliant */
}
```

In this example:

- The variables `pci` and `pcpi` have the `const` qualifier in their type. The rule is violated when the variables are cast to types that do not have the `const` qualifier.

- The variable `pvi` has a `volatile` qualifier in its type. The rule is violated when the variable is cast to a type that does not have the `volatile` qualifier.

Even though `cpi` has a `const` qualifier in its type, the rule is not violated in the statement `p=cpi;`. The assignment does not cause a type conversion because both `p` and `cpi` have type `unsigned short`.

# MISRA C:2012 Rule 11.9

The macro NULL shall be the only permitted form of integer null pointer constant

## Description

### Rule Definition

*The macro NULL shall be the only permitted form of integer null pointer constant.*

### Rationale

The following expressions allow the use of a null pointer constant:

- Assignment to a pointer
- The == or != operation, where one operand is a pointer
- The ?: operation, where one of the operands on either side of : is a pointer

Using NULL rather than 0 makes it clear that a null pointer constant was intended.

### Polyspace Implementation

The checker flags the assignment of the constant zero to pointers, equalities (or inequalities) comparing pointers with the constant zero, and other similar expressions listed in the MISRA C: 2012 documentation.

Following the updates in MISRA C: 2012 Technical Corrigendum 1, the checker allows the use of {0} to initialize aggregates containing only pointers, for instance, arrays of pointers or structures (or unions) with only a pointer field. If an aggregate contains multiple fields, the initialization is still flagged. In these cases, you should use the macro NULL for pointer fields and 0 for integer fields to distinguish between them.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using 0 in Pointer Assignments and Comparisons

```
void main(void) {

    int *p1 = 0;               /* Non-compliant */
    int *p2 = ( void * ) 0;   /* Compliant     */

#define MY_NULL_1 0    /* Non-compliant */
#define MY_NULL_2 ( void * ) 0

    if ( p1 == MY_NULL_1 )
    { }
    if ( p2 == MY_NULL_2 )    /* Compliant     */
    { }

}
```

In this example, the rule is violated when the constant 0 is used instead of `(void*) 0` for pointer assignments and comparisons.

### Initialization of Aggregates with Pointer Members Using {0}

```
void init () {
    int *myArray[5] = {0}; //Compliant

    struct structPtr {
        int *ptr;
    } structPtr = {0}; //Compliant

    struct StructIntPtr {
        int data;
        int *ptr;
    } StructIntPtr = {0,0}; //Non-compliant
}
```

Following the updates in MISRA C: 2012 Technical Corrigendum 1, the checker allows the use of {0} to initialize aggregates containing only pointers such as:

- Arrays of pointers, for instance, `myArray`
- Structures with one pointer field only, for instance, `structPtr`

If an aggregate contains multiple fields, such as `StructIntPtr`, the initialization is still flagged. In these cases, you should use the macro NULL for pointer fields and 0 for integer fields to distinguish between them.

# MISRA C:2012 Rule 12.1

The precedence of operators within expressions should be made explicit

## Description

### Rule Definition

*The precedence of operators within expressions should be made explicit.*

### Rationale

The C language has a large number of operators and their precedence is not intuitive. Inexperienced programmers can easily make mistakes. Remove any ambiguity by using parentheses to explicitly define operator precedence.

The following table list the MISRA C definition of operator precedence for this rule.

| Description | Operator and Operand | Precedence |
|---|---|---|
| Primary | identifier, constant, string literal, (expression) | 16 |
| Postfix | `[] ()` (function call) `. -> ++`(post-increment) `--`(post-decrement) `() {}`(C99: compound literals) | 15 |
| Unary | `++`(pre-increment) `--`(pre-decrement) `& * + - ~ ! sizeof _Alignof defined` (preprocessor) | 14 |
| Cast | `()` | 13 |
| Multiplicative | `* / %` | 12 |
| Additive | `+ -` | 11 |
| Bitwise shift | `<< >>` | 10 |
| Relational | `<> <= >=` | 9 |
| Equality | `== !=` | 8 |
| Bitwise AND | `&` | 7 |
| Bitwise XOR | `^` | 6 |
| Bitwise OR | `\|` | 5 |
| Logical AND | `&&` | 4 |
| Logical OR | `\|\|` | 3 |
| Conditional | `?:` | 2 |
| Assignment | `= *= /= += -= <<= >>= &= ^= \|=` | 1 |
| Comma | `,` | 0 |

### Additional Message in Report

Operand of logical %s is not a primary expression. The precedence of operators within expressions should be made explicit.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Ambiguous Precedence in Multi-Operation Expressions

```
int a, b, c, d, x;

void foo(void) {
  x = sizeof a + b;                    /* Non-compliant - MISRA-12.1 */

  x = a == b ? a : a - b;              /* Non-compliant - MISRA-12.1 */

  x = a <<  b + c ;                    /* Non-compliant - MISRA-12.1 */

  if (a || b && c) { }                 /* Non-compliant - MISRA-12.1 */

  if ( (a>x) && (b>x) || (c>x) )   { }  /* Non-compliant - MISRA-12.1 */
}
```

This example shows various violations of MISRA rule 12.1. In each violation, if you do not know the order of operations, the code could execute unexpectedly.

#### Correction — Clarify With Parentheses

To comply with this MISRA rule, add parentheses around individual operations in the expressions. One possible solution is shown here.

```
int a, b, c, d, x;

void foo(void) {
  x = sizeof(a) + b;

  x = ( a == b ) ? a : ( a - b );

  x = a << ( b + c );

  if ( ( a || b ) && c) { }

  if ( ((a>x) && (b>x)) || (c>x) ) { }
}
```

### Ambiguous Precedence In Preprocessing Expressions

```
# if defined X && X + Y > Z    /* Non-compliant - MISRA-12.1 */
# endif
```

In this example, a violation of MISRA rule 12.1 is shown in preprocessing code. In this violation, if you do not know the correct order of operations, the results can be unexpected and cause problems.

#### Correction — Clarify with Parentheses

To comply with this MISRA rule, add parentheses around individual operations in the expressions. One possible solution is shown here.

```
# if defined (X) && ( (X + Y) > Z )
# endif
```

**Compliant Expressions Without Parentheses**

```
int a, b, c, x,i = 0;
struct {int a; } s, *ps, *pp[2];

void foo(void) {
    ps = &s;
    pp[i]-> a;          /* Compliant - no need to write (pp[i])->a */
    *ps++;              /* Compliant - no need to write *( p++ ) */

    x = f ( a + b, c ); /* Compliant - no need to write f ( (a+b),c) */

    x = a, b;           /* Compliant - parsed as ( x = a ), b */

    if (a && b && c ){  /* Compliant - all operators have
                    * the same precedence */
    }
}
```

In this example, the expressions shown have multiple operations. However, these expressions are compliant because operator precedence is already clear.

# MISRA C:2012 Rule 12.2

The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand

## Description

### Rule Definition

*The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand.*

### Rationale

Consider this statement:

```
var = abc << num;
```

If `abc` is a 16-bit integer, then `num` must be in the range 0–15, (nonnegative and less than 16). If `num` is negative or greater than 16, then the shift behavior is undefined.

### Polyspace Implementation

Polyspace raises a violation when the right operand of a shift operator exceeds the range defined in this rule. When the right operand is a variable, the violation is raised unless all possible value of the operand remains within the range defined in this rule.

When a preprocessor directive performs a shift operation on a number literal, Polyspace assumes that the number is 64 bits wide. The valid shift range for such a number is between 0 and 63. For instance:

```
#if (1 << 64) //Noncompliant
//...
#endif
```

When bitfields are within a complex expression, Polyspace extends this check onto the bitfield field width or the width of the base type.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Shift Operations That Have Unacceptable Right Operand

```
void foo(void) {
  int i;
  unsigned int BitPack = 0U;

  for (i = 0; i < 32; i++) {
    BitPack |= (1U << ((unsigned int)i));  //Noncompliant
  }
}
```

In this example, the left operand 1U of the shift operator has an essential type `unsigned char`. Acceptable values for the right operand lies in the range from zero to seven. Because the right operand `i` ranges from zero to 31, Polyspace flags the shift operation.

# MISRA C:2012 Rule 12.3

The comma operator should not be used

## Description

### Rule Definition

*The comma operator should not be used*.

### Rationale

The comma operator can be detrimental to readability. You can often write the same code in another form.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Comma Usage in C Code

```
typedef signed int abc, xyz, jkl;
static void func1 ( abc, xyz, jkl );       /* Compliant - case 1 */
int foo(void)
{
    volatile int rd = 1;                   /* Compliant - case 2*/
    int var=0, foo=0, k=0, n=2, p, t[10];  /* Compliant - case 3*/
    int abc = 0, xyz = abc + 1;            /* Compliant - case 4*/
    int jkl = ( abc + xyz, abc + xyz );    /* Noncompliant - case 1*/
    var = 1, foo += var, n = 3;          /* Noncompliant - case 2*/
    var = (n = 1, foo = 2);              /* Noncompliant - case 3*/
    for ( int *ptr = &t[ 0 ],var = 0 ;
          var < n; ++var, ++ptr){}    /* Noncompliant - case 4*/
    if ((abc,xyz)<0) { return 1; }         /* Noncompliant - case 5*/
}
```

In this example, the code shows various uses of commas in C code.

#### Noncompliant Cases

| Case | Reason for noncompliance |
|---|---|
| 1 | When reading the code, it is not immediately obvious what `jkl` is initialized to. For example, you could infer that `jkl` has a value `abc+xyz`, `(abc+xyz)*(abc+xyz)`, `f((abc+xyz),(abc+xyz))`, and so on. |
| 2 | When reading the code, it is not immediately obvious whether `foo` has a value 0 or 1 after the statement. |
| 3 | When reading the code, it is not immediately obvious what value is assigned to `var`. |

| Case | Reason for noncompliance |
|---|---|
| 4 | When reading the code, it is not immediately obvious which values control the `for` loop. |
| 5 | When reading the code, it is not immediately obvious whether the `if` statement depends on `abc`, `xyz`, or both. |

#### Compliant Cases

| Case | Reason for compliance |
|---|---|
| 1 | Using commas to call functions with variables is allowed. |
| 2 | Comma operator is not used. |
| 3 & 4 | When using the comma for initialization, the variables and their values are immediately obvious. |

# MISRA C:2012 Rule 12.4

Evaluation of constant expressions should not lead to unsigned integer wrap-around

## Description

### Rule Definition

*Evaluation of constant expressions should not lead to unsigned integer wrap-around*.

### Rationale

Unsigned integer expressions do not strictly overflow, but instead wraparound. Although there may be good reasons to use modulo arithmetic at run time, intentional use at compile time is less likely and might imply logic errors.

### Polyspace Implementation

Polyspace flags the constant expressions that might wraparound.

Different compilers might define compile-time constants differently. In the following code, `c+1u` is considered a constant expression by GCC compilers, but not by the standard C compiler.

```
const uint16_t c = 0xffffu;
uint16_t y = c + 1u;
```

Whether you see a violation of this rule in the preceding code might depend on your compiler.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unsigned Integer Wraparounds in Constant Expression

```
#define DELAY        1000000000u
#define WIDTH        4000000000u

static void fixed_pulse ( void )
{
   int off_time32 = DELAY + WIDTH;    /*Noncompliant*/
   //...
}

static void f4 ( void )
{   const int c = 0xffffffffu;
    int y = c + 1u;                 /* Compliant*/

    //...
}
```

In this example, the constant expressions `DELAY + WIDTH;` might lead to wraparounds when compiled with the standard C compiler. Polyspace flags this expression. If you compile this code with other compilers such as GCC, the expression `c+1u` might show violations of this rule.

# MISRA C:2012 Rule 12.5

The `sizeof` operator shall not have an operand which is a function parameter declared as “array of type”

## Description

### Rule Definition

*The `sizeof` operator shall not have an operand which is a function parameter declared as “array of type”.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The `sizeof` operator acting on an array normally returns the array size in bytes. For instance, in the following code, `sizeof(arr)` returns the size of `arr` in bytes.

```
int32_t arr[4];
size_t numberOfElements = sizeof (arr) / sizeof(arr[0]);
```

However, when the array is a function parameter, it degenerates to a pointer. The `sizeof` operator acting on the array returns the corresponding pointer size and not the array size.

The use of `sizeof` operator on an array that is a function parameter typically indicates an unintended programming error.

### Additional Message in Report

The `sizeof` operator shall not have an operand which is a function parameter declared as “array of type”.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Use of `sizeof` Operator

```
#include <stdint.h>
int32_t glbA[] = { 1, 2, 3, 4, 5 };
void f (int32_t A[4])
{
     uint32_t numElements = sizeof(A) / sizeof(int32_t);  /* Non-compliant */
    uint32_t numElements_glbA = sizeof(glbA) / sizeof(glbA[0]);  /* Compliant */
}
```

In this example, the variable `numElements` always has the same value of 1, irrespective of the number of members that appear to be in the array (4 in this case), because `A` has type `int32_t *` and not `int32_t[4]`.

The variable numElements_glbA has the expected vale of 5 because the sizeof operator acts on the global array glbA.

# MISRA C:2012 Rule 13.1

Initializer lists shall not contain persistent side effects

## Description

### Rule Definition

*Initializer lists shall not contain persistent side effects.*

### Rationale

C99 permits initializer lists with expressions that can be evaluated only at run-time. However, the order in which elements of the list are evaluated is not defined. If one element of the list modifies the value of a variable which is used in another element, the ambiguity in order of evaluation causes undefined values. Therefore, this rule requires that expressions occurring in an initializer list cannot modify the variables used in them.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Initializers with Persistent Side Effect

```
volatile int v;
int x;
int y;

void f(void) {
    int arr[2] = {x+y,x-y};  /* Compliant */
    int arr2[2] = {v,v};    /* Non-compliant */
    int arr3[2] = {x++,x+y};    /* Non-compliant */
}
```

In this example, the rule is not violated in the first initialization because the initializer does not modify either `x` or `y`. The rule is violated in the other initializations.

- In the second initialization, because `v` is volatile, the initializer can modify `v`. The initialization of `arr2` is different depending on which array element is initialized first.
- In the third initialization, the initializer modifies the variable `x`. The initialization of `arr3` is different depending on whether `x++` is evaluated earlier or later.

# MISRA C:2012 Rule 13.2

The value of an expression and its persistent side effects shall be the same under all permitted evaluation orders

## Description

### Rule Definition

*The value of an expression and its persistent side effects shall be the same under all permitted evaluation orders*.

### Rationale

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

### Polyspace Implementation

Polyspace raises a violation if an expression satisfies any of these conditions:

- The same variable is modified more than once in the expression or it is both read and written.
- The expression allows more than one order of evaluation.
- The expression contains a single `volatile` object that occurs multiple times.
- The expression contains more than one `volatile` object.

Because `volatile` objects can change their value at anytime, an expression containing multiple `volatile` variables or multiple instances of the same `volatile` variable might have different results depending on the order of evaluation.

### Additional Message in Report

The value of 'XX' depends on the order of evaluation. The value of volatile 'XX' depends on the order of evaluation because of multiple accesses.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Modified More Than Once in Expression

```
int a[10], b[10];
#define COPY_ELEMENT(index) (a[(index)]=b[(index)])

void main () {
    int i=0, k=0;

    COPY_ELEMENT (k);         /* Compliant */
    COPY_ELEMENT (i++); /* Noncompliant  */
}
```

In this example, the rule is violated by the statement `COPY_ELEMENT(i++)` because `i++` occurs twice and the order of evaluation of the two expressions is unspecified.

#### Variable Modified and Used in Multiple Function Arguments

```
void f (unsigned int param1, unsigned int param2) {}

void main () {
    unsigned int i=0;
    f ( i++, i );                 /* Non-compliant */
}
```

In this example, the rule is violated because it is unspecified whether the operation `i++` occurs before or after the second argument is passed to `f`. The call `f(i++,i)` can translate to either `f(0,0)` or `f(0,1)`.

#### Multiple `volatile` Variables in Expression

```
struct {
    volatile float x;
    volatile float y;
} volData;

float xCopy;
float yCopy;
float res, res2;

void function4(void) {
    res = volData.x + volData.y;         //Noncompliant
    res = volData.x * volData.x;      //Noncompliant
    xCopy = volData.x;
    yCopy = volData.y;
    res = xCopy + yCopy;  //Compliant
}
```

In this example, the expression `volData.x + volData.y` is noncompliant because the expression involves multiple volatile objects. The expression consists of three operations: accessing the value of `volData.x`, accessing the value of `volData.y`, and the addition. The values of the volatile fields `x` and `y` in the `volData` structure might change at any time. The value of `res` might vary depending on which variable is read first. Because the C standard does not specify the order in which the variables are read, the value of `res` might depend on the hardware and software that you use. Polyspace flags one of the `volatile` objects in the expression. Similarly, Polyspace flags one of the `volatile` objects in the expression `volData.x * volData.x`.

To avoid the violation, assign the volatile variables to nonvolatile temporary variables and use these temporary variables in the expression.

# MISRA C:2012 Rule 13.3

A full expression containing an increment (++) or decrement (--) operator should have no other potential side effects other than that caused by the increment or decrement operator

## Description

### Rule Definition

*A full expression containing an increment (++) or decrement (--) operator should have no other potential side effects other than that caused by the increment or decrement operator.*

### Rationale

The rule is violated if the following happens in the same line of code:

- The increment or decrement operator acts on a variable.
- Another read or write operation is performed on the variable.

For example, the line y=x++ violates this rule. The ++ and = operator both act on x.

Although the operator precedence rules determine the order of evaluation, placing the ++ and another operator in the same line can reduce the readability of the code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Increment Operator Used in Expression with Other Side Effects

```
int input(void);
int choice(void);
int operation(int, int);

int func() {
    int x = input(), y = input(), res;
    int ch = choice();
    if (choice == -1)
        return(x++);           /* Non-compliant */
    if (choice == 0) {
        res = x++ + y++;           /* Non-compliant */
        return(res);
    }
    else if (choice == 1) {
        x++;                   /* Compliant */
        y++;                   /* Compliant */
        return (x+y);
    }
    else {
        res = operation(x++,y);           /* Non-compliant */
        return(res);
    }
}
```

In this example, the rule is violated when the expressions containing the `++` operator have side effects other than that caused by the operator. For example, in the expression `return(x++)`, the other side-effect is the `return` operation.

# MISRA C:2012 Rule 13.4

The result of an assignment operator should not be used

## Description

### Rule Definition

*The result of an assignment operator should not be used.*

### Rationale

The rule is violated if the following happens in the same line of code:

- The assignment operator acts on a variable.
- Another read or operation is performed on the result of the assignment.

For example, the line `a[x]=a[x=y];` violates this rule. The `[]` operator acts on the result of the assignment `x=y`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Result of Assignment Used

```
int x, y, b, c, d;
int a[10];
unsigned int bool_var, false=0, true=1;

int foo(void) {

    x = y;            /* Compliant - x is not used */

    a[x] = a[x = y];  /* Non-compliant - Value of x=y is used */

    if ( bool_var = false )/* Non-compliant - bool_var=false is used */
{}

    if ( bool_var == false ) {}   /* Compliant */

    if ( ( 0u == 0u ) || ( bool_var = true ) )/* Non-compliant */
                    /*- even though (bool_var=true) is not evaluated */
 {}

    if ( ( x = f () ) != 0 )/* Non-compliant - value of x=f() is used */
 {}
    a[b += c] = a[b];/* Non-compliant - value of b += c is used */
    b = c = d = 0; /* Non-compliant - value of d=0 and c=d=0 are used */

}
```

In this example, the rule is violated when the result of an assignment is used.

# MISRA C:2012 Rule 13.5

The right hand operand of a logical && or || operator shall not contain persistent side effects

## Description

### Rule Definition

*The right hand operand of a logical && or || operator shall not contain persistent side effects*.

### Rationale

The right operand of an `||` operator is not evaluated if the left operand is true. The right operand of an && operator is not evaluated if the left operand is false. In these cases, if the right operand modifies the value of a variable, the modification does not take place. Following the operation, if you expect a modified value of the variable, the modification might not always happen.

### Polyspace Implementation

The rule checker reports situations where the right hand side of a logical `||` or && operator has persistent side effects. For instance, if the right hand side contains a function call and the function modifies a global variable, the rule checker reports a violation.

The rule checker does not report a violation if the right hand side contains a call to a pure function, that is, a function without side effects. The checker considers a function as pure if the function only performs simple operations such as:

- Reading a nonvolatile parameter or global variable.
- Writing to a local variable.

In addition to simple operations, if the function contains a call to another function, the checker attempts to determine if the callee is a pure function. If the callee is determined to be a pure function, the checker propagates this information and tags the calling function as a pure function (as long as the other operations in the calling function are simple operations).

The rule checker does not consider a function as pure if the function does one of the following:

- Writes to a global variable or the dereference of a parameter.
- Reads or writes to a volatile variable, or contains an `asm` block.

To determine if a function is pure, the checker needs to analyze the function definition. The checker looks for function definitions only within the same translation unit as the function call (a translation unit is a source file plus all headers included in the source). If a function definition is not found in the current translation unit, the checker does not report a violation of this rule.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Right Operand of Logical Operator with Persistent Side Effects

```
int check (int arg) {
    static int count;
    if(arg > 0) {
        count++;                  /* Persistent side effect */
        return 1;
    }
    else
        return 0;
}

int getSwitch(void);
int getVal(void);

void main(void) {
    int val = getVal();
    int mySwitch = getSwitch();
    int checkResult;

    if(mySwitch && check(val)) {   /* Non-compliant */
    }

    checkResult = check(val);
    if(checkResult && mySwitch) {  /* Compliant */
    }

    if(check(val) && mySwitch) {   /* Compliant */
    }
}
```

In this example, the rule is violated when the right operand of the && operation contains a function call. The function call has a persistent side effect because the static variable `count` is modified in the function body. Depending on `mySwitch`, this modification might or might not happen.

The rule is not violated when the left operand contains a function call. Alternatively, to avoid the rule violation, assign the result of the function call to a variable. Use this variable in the logical operation in place of the function call.

# MISRA C:2012 Rule 13.6

The operand of the sizeof operator shall not contain any expression which has potential side effects

## Description

### Rule Definition

*The operand of the sizeof operator shall not contain any expression which has potential side effects*.

### Rationale

The argument of a `sizeof` operator is usually not evaluated at run time. If the argument is an expression, you might wrongly expect that the expression is evaluated.

### Polyspace Implementation

The rule is not violated if the argument is a `volatile` variable.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Expressions in `sizeof` Operator

```
#include <stddef.h>
int x;
int y[40];
struct S {
    int a;
    int b;
};
struct S myStruct;

void main() {
    size_t sizeOfType;
    sizeOfType = sizeof(x);         /* Compliant */
    sizeOfType = sizeof(y);         /* Compliant */
    sizeOfType = sizeof(myStruct);  /* Compliant */
    sizeOfType = sizeof(x++);       /* Non-compliant */
}
```

In this example, the rule is violated when the expression `x++` is used as argument of `sizeof` operator.

# MISRA C:2012 Rule 14.1

A loop counter shall not have essentially floating type

## Description

### Rule Definition

*A loop counter shall not have essentially floating type.*

### Rationale

When using a floating-point loop counter, accumulation of rounding errors can cause the actual number of iterations to be different than the number of iterations you expect.. This rounding error can happen when a loop step that is not a power of the floating-point radix is rounded to a value that can be represented by a float.

Even if a loop with a floating-point loop counter appears to behave correctly on one implementation, it can give a different number of iterations on another implementation.

### Polyspace Implementation

If the loop counter is a variable symbol, Polyspace checks that the counter is not a float.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `for` Loop Counters

```
int main(void){
    unsigned int counter = 0u;
    int result = 0;
    float foo;

    // Float loop counters
    for(float foo = 0.0f; foo < 1.0f; foo +=0.001f){/* Non-compliant*/
        ++counter;
    }

    float fff = 0.0f;
    for(fff = 0.0f; fff <12.0f; fff += 1.0f){/* Non-compliant*/
        result++;
    }

    // Integer loop count
    for(unsigned int count = 0u; count < 1000u; ++count){/* Compliant */
        foo = (float) count * 0.001f;
    }
}
```

In this example, the three `for` loops show three different loop counters. The first and second `for` loops use float variables as loop counters, and therefore are not compliant. The third loop uses the integer `count` as the loop counter. Even though `count` is used as a float inside the loop, the variable remains an integer when acting as the loop index. Therefore, this `for` loop is compliant.

### `while` Loop Counters

This example shows two `while` loops. The loops use floating-point variables in the `while`-loop conditions:

- The first `while` loop uses the floating-point variable `foo` in the loop condition and inside the loop. When `foo` is updated in the loop, floating-point rounding errors can cause unexpected behavior. Polyspace reports a violation.
- The second `while` loop uses the floating point array `buffer` and two integers `iter1` and `inter2` in the loop condition. Polyspace identifies `iter1` and `iter2` as the loop counters. Because these loop counters are not floating point variables, Polyspace does not report a violation.

```
int main(void){
    unsigned int iter1 =0;
    int iter2;
    float foo;
    double buffer[2];
    double tmp;

    foo = 0.0f;
    while (foo < 1.0f){/* Non-compliant - foo used as a loop counter */
        foo += 0.001f;
    }

    //...
    while((iter1+1 < 2)&& (buffer[iter1]<buffer[iter2])){ //Compliant - loop counter is integer
        // swap buffer[iter1] and buffer[iter2]
        tmp = buffer[iter2];
        buffer[iter2] = buffer[iter1];
        buffer[iter1] = tmp;
        iter2 = iter1;
        iter1++;
    }

    return 1;
}
```

# MISRA C:2012 Rule 14.2

A for loop shall be well-formed

## Description

### Rule Definition

*A for loop shall be well-formed.*

### Rationale

The `for` loop provides a flexible looping facility. You can perform other operations besides the loop counter initialization, termination, and increment in the control statement, and increment the loop counter anywhere inside the loop body. However, using a restricted loop format makes your code easier to review and to analyze.

### Polyspace Implementation

A for loop consists of a control statement with three clauses and a loop body. The checker raises a violation if:

- The first clause does not contain an initialization (except for when the clause is empty). The checker considers the last assigned variable of the first `for`-loop clause as the loop counter. If the first clause is empty, the checker considers the variable incremented or decremented in the third clause as the loop counter.
- The second clause does not contain a comparison operation involving the loop counter.
- The third clause contains an operation other than incrementing or decrementing the loop counter (separated by a comma from the increment or decrement).
- The loop counter has a data type that is not an integer or a pointer type.
- The loop counter is incremented inside the loop body.

Polyspace does not raise a violation when the second clause includes a binary operation that involves the loop counter.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Altering the Loop Counter Inside the Loop

```
void foo(void){

    for(short index=0; index < 5; index++){  /* Non-compliant */
        index = index + 3;       /* Altering the loop counter */
    }
}
```

In this example, the loop counter `index` changes inside the `for` loop. It is hard to determine when the loop terminates.

#### Correction — Use Another Variable to Terminate Early

One possible correction is to use an extra flag to terminate the loop early.

In this correction, the second clause of the `for` loop depends on the counter value, `index < 5`, and upon an additional flag, `!flag`. With the additional flag, the for loop definition and counter remain readable, and you can escape the loop early.

```
#define FALSE 0
#define TRUE  1

void foo(void){

    int flag = FALSE;

    for(short index=0; (index < 5) && !flag; index++){ /* Compliant */
        if((index % 4) == 0){
            flag = TRUE;        /* allows early termination of loop */
        }
    }
}
```

#### `for` Loops With Empty Clauses

```
void foo(void){
    for(short index = 0; ; index++) {}   /* Non-compliant */

    for(short index = 0; index < 10;) {} /* Non-compliant */

    short index;
    for(; index < 10;) {}     /* Non-compliant */

    for(; index < 10; index++) {} /* Compliant */

    for(;;){}
          /* Compliant - Exception all three clauses can be empty */
}
```

This example shows `for` loops definitions with a variety of missing clauses. To be compliant, initialize the first clause variable before the `for` loop (line 9). However, you cannot have a `for` loop without the second or third clause.

The one exception is a `for` loop with all three clauses empty, so as to allow for infinite loops.

# MISRA C:2012 Rule 14.3

Controlling expressions shall not be invariant

## Description

### Rule Definition

*Controlling expressions shall not be invariant*.

### Rationale

If the controlling expression, for example an `if` condition, has a constant value, the non-changing value can point to a programming error.

### Polyspace Implementation

The checker flags conditions in `if` or `while` statements or conditions that appear as the first operands of ternary operators (`?:`) if the conditions are invariant, for instance, evaluate always to true or false.

Polyspace Bug Finder flags some violations of MISRA C 14.3 through the `Dead code` and `Useless if` checkers.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 14.4

The controlling expression of an if statement and the controlling expression of an iteration-statement shall have essentially Boolean type

## Description

### Rule Definition

*The controlling expression of an if statement and the controlling expression of an iteration-statement shall have essentially Boolean type*

### Rationale

Strong typing requires the controlling expression on an `if` statement or iteration statement to have *essentially Boolean* type.

### Polyspace Implementation

Polyspace does not flag integer constants, for example `if(2)`.

The analysis recognizes the Boolean types, `bool` or `_Bool` (defined in `stdbool.h`)

You can also define types that are essentially Boolean using the option `Effective boolean types (-boolean-types)`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Controlling Expression in `if`, `while`, and `for`

```
#include <stdbool.h>
#include <stdlib.h>

#define TRUE 1

typedef _Bool bool_t;
extern bool_t flag;

void foo(void){
    int *p = 1;
    int *q = 0;
    int i = 0;
    while(p){}           /* Non-compliant - p is a pointer */

    while(q != NULL){}   /* Compliant */

    while(TRUE){}        /* Compliant */
    while(flag){}        /* Compliant */

    if(i){}              /* Non-compliant - int32_t is not boolean */

    if(i != 0){}         /* Compliant */

    for(int i=-10; i;i++){}   /* Non-compliant - int32_t is not boolean */

    for(int i=0; i<10;i++){}  /* Compliant */
}
```

This example shows various controlling expressions in `while`, `if`, and `for` statements.

The noncompliant statements (the first `while`, `if`, and `for` examples), use a single non-Boolean variable. If you use a single variable as the controlling statement, it must be essentially Boolean (lines 17 and 19). Boolean expressions are also compliant with MISRA.

# MISRA C:2012 Rule 15.1

The goto statement should not be used

## Description

### Rule Definition

*The goto statement should not be used*.

### Rationale

Unrestricted use of `goto` statements makes the program unstructured and difficult to understand.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `goto` Statements

```
void foo(void) {
    int i = 0, result = 0;

label1:
    for ( i; i < 5; i++ ) {
        if (i > 2) goto label2;     /* Non-compliant */
    }

label2: {
        result++;
        goto label1;                /* Non-compliant */
    }
}
```

In this example, the rule is violated when `goto` statements are used.

# MISRA C:2012 Rule 15.2

The goto statement shall jump to a label declared later in the same function

## Description

### Rule Definition

*The goto statement shall jump to a label declared later in the same function.*

### Rationale

Unrestricted use of `goto` statements makes the program unstructured and difficult to understand. You can use a forward `goto` statement together with a backward one to implement iterations. Restricting backward `goto` statements ensures that you use only iteration statements provided by the language such as `for` or `while` to implement iterations. This restriction reduces visual complexity of the code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Backward goto Statements

```
void foo(void) {
    int i = 0, result = 0;

label1:
    for ( i; i < 5; i++ ) {
        if (i > 2) goto label2;   /* Compliant */
    }

label2: {
        result++;
        goto label1;               /* Non-compliant */
    }
}
```

In this example, the rule is violated when a `goto` statement causes a backward jump to `label1`.

The rule is not violated when a `goto` statement causes a forward jump to `label2`.

# MISRA C:2012 Rule 15.3

Any label referenced by a goto statement shall be declared in the same block, or in any block enclosing the goto statement

## Description

### Rule Definition

*Any label referenced by a goto statement shall be declared in the same block, or in any block enclosing the goto statement.*

### Rationale

Unrestricted use of `goto` statements makes the program unstructured and difficult to understand. Restricting use of `goto` statements to jump between blocks or into nested blocks reduces visual code complexity.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `goto` Statements Jump Inside Block

```
void f1(int a) {
    if(a <= 0) {
        goto L2;        /* Non-compliant - L2 in different block*/
    }

    goto L1;            /* Compliant - L1 in same block*/

    if(a == 0) {
        goto L1;        /* Compliant - L1 in outer block*/
    }

    goto L2;            /* Non-compliant - L2 in inner block*/

    L1: if(a > 0) {
            L2:;
    }
}
```

In this example, `goto` statements cause jumps to different labels. The rule is violated when:

- The label occurs in a block different from the block containing the `goto` statement.

  The block containing the label neither encloses nor is enclosed by the current block.
- The label occurs in a block enclosed by the block containing the `goto` statement.

The rule is not violated when:

- The label occurs in the same block as the block containing the `goto` statement..
- The label occurs in a block that encloses the block containing the `goto` statement..

### `goto` Statements in `switch` Block

```
void f2 ( int x, int z ) {
    int y = 0;

    switch(x) {
    case 0:
        if(x == y) {
            goto L1;  /* Non-compliant - switch-clauses are treated as blocks */
        }
        break;
    case 1:
        y = x;
        L1: ++x;
        break;
    default:
        break;
    }

}
```

In this example, the label for the `goto` statement appears to occur in a block that encloses the block containing the `goto` statement. However, for the purposes of this rule, the software considers that each `case` statement begins a new block. Therefore, the `goto` statement violates the rule.

# MISRA C:2012 Rule 15.4

There should be no more than one break or goto statement used to terminate any iteration statement

## Description

### Rule Definition

*There should be no more than one break or goto statement used to terminate any iteration statement.*

### Rationale

If you use one `break` or `goto` statement in your loop, you have one secondary exit point from the loop. Restricting number of exits from a loop in this way reduces visual complexity of your code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### `break` Statements in Inner and Outer Loops

```
volatile int stop;

int func(int *arr, int size, int sat) {
    int i,j;
    int sum = 0;
    for (i=0; i< size; i++) {   /* Compliant  */
        if(sum >= sat)
            break;
        for (j=0; j< i; j++) {  /* Compliant */
            if(stop)
                break;
            sum += arr[j];
        }
    }
}
```

In this example, the rule is not violated in both the inner and outer loop because both loops have one `break` statement each.

### `break` and `goto` Statements in Loop

```
volatile int stop;

void displayStopMessage();

int func(int *arr, int size, int sat) {
    int i;
    int sum = 0;
    for (i=0; i< size; i++) {
        if(sum >= sat)
```

```
            break;
        if(stop)
            goto L1;   /* Non-compliant  */
        sum += arr[i];
    }

    L1: displayStopMessage();
}
```

In this example, the rule is violated because the `for` loop has one `break` statement and one `goto` statement.

### `goto` Statement in Inner Loop and `break` Statement in Outer Loop

```
volatile int stop;

void displayMessage();

int func(int *arr, int size, int sat) {
    int i,j;
    int sum = 0;
    for (i=0; i< size; i++) {
        if(sum >= sat)
            break;
        for (j=0; j< i; j++) { /* Compliant */
            if(stop)
                goto L1;  /* Non-compliant */
            sum += arr[i];
        }
    }

    L1: displayMessage();
}
```

In this example, the rule is not violated in the inner loop because you can exit the loop only through the one `goto` statement. However, the rule is violated in the outer loop because you can exit the loop through either the `break` statement or the `goto` statement in the inner loop.

# MISRA C:2012 Rule 15.5

A function should have a single point of exit at the end

## Description

### Rule Definition

*A function should have a single point of exit at the end.*

### Rationale

This rule requires that a `return` statement must occur as the last statement in the function body. Otherwise, the following issues can occur:

- Code following a `return` statement can be unintentionally omitted.
- If a function that modifies some of its arguments has early `return` statements, when reading the code, it is not immediately clear which modifications actually occur.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### More Than One `return` Statement in Function

```
#define MAX ((unsigned int)2147483647)
#define NULL (void*)0

typedef unsigned int bool_t;
bool_t false = 0;
bool_t true = 1;

bool_t f1(unsigned short n, char *p) {          /* Non-compliant */
    if(n > MAX) {
        return false;
    }

    if(p == NULL) {
        return false;
    }

    return true;
}
```

In this example, the rule is violated because there are three `return` statements.

#### Correction — Use Variable to Store Return Value

One possible correction is to store the return value in a variable and return this variable just before the function ends.

```
#define MAX ((unsigned int)2147483647)
#define NULL (void*)0

typedef unsigned int bool_t;
bool_t false = 0;
bool_t true = 1;
bool_t return_value;

bool_t f2 (unsigned short n, char *p) {         /* Compliant */
    return_value = true;
    if(n > MAX) {
        return_value = false;
    }

    if(p == NULL) {
        return_value = false;
    }

    return return_value;
}
```

# MISRA C:2012 Rule 15.6

The body of an iteration-statement or a selection-statement shall be a compound statement

## Description

### Rule Definition

*The body of an iteration-statement or a selection-statement shall be a compound- statement.*

### Rationale

If the block of code associated with an iteration or selection statement is not contained in braces, you can make mistakes about the association. For example:

- You can wrongly associate a line of code with an iteration or selection statement because of its indentation.
- You can accidentally place a semicolon following the iteration or selection statement. Because of the semicolon, the line following the statement is no longer associated with the statement even though you intended otherwise.

This checker enforces the practice of adding braces following a selection or iteration statement even for a single line in the body. Later, when more lines are added, the developer adding them does not need to note the absence of braces and include them.

### Polyspace Implementation

The checker flags `for` loops where the first token following a `for` statement is not a left brace, for instance:

```
for (i=init_val; i > 0; i--)
   if (arr[i] < 0)
      arr[i] = 0;
```

Similar checks are performed for `if`, `else if`, `else`, `switch`, `for` and `do..while` statements.

The second line of the message on the **Result Details** pane indicates which statement is violating the rule. For instance, in the preceding example, there are two violations. The second line of the message points to the `for` loop for one violation and the `if` condition for another.

### Additional Message in Report

- The else keyword shall be followed by either a compound statement, or another if statement.
- An if (expression) construct shall be followed by a compound statement.
- The statement forming the body of a while statement shall be a compound statement.
- The statement forming the body of a do ... while statement shall be a compound statement.
- The statement forming the body of a for statement shall be a compound statement.
- The statement forming the body of a switch statement shall be a compound statement.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Iteration Block

```
int data_available = 1;
void f1(void) {
    while(data_available)                /* Non-compliant */
        process_data();

    while(data_available) {              /* Compliant */
        process_data();
    }
}
```

In this example, the second `while` block is enclosed in braces and does not violate the rule.

### Nested Selection Statements

```
#include<stdbool.h>
void f1(bool flag_1, bool flag_2) {
    if(flag_1)                           /* Non-compliant */
        if(flag_2)                       /* Non-compliant */
            action_1();
    else                                 /* Non-compliant */
            action_2();
}
```

In this example, the rule is violated because the `if` or `else` blocks are not enclosed in braces. Unless indented as above, it is easy to associate the `else` statement with the inner `if`.

#### Correction — Place Selection Statement Block in Braces

One possible correction is to enclose each block associated with an `if` or `else` statement in braces.

```
#include<stdbool.h>
void f1(bool flag_1, bool flag_2) {
    if(flag_1) {                         /* Compliant */
        if(flag_2) {                       /* Compliant */
            action_1();
        }
    }
    else {                               /* Compliant */
        action_2();
    }
}
```

### Spurious Semicolon After Iteration Statement

```
#include<stdbool.h>
void f1(bool flag_1) {
    while(flag_1);                       /* Non-compliant */
    {
        flag_1 = action_1();
    }
}
```

In this example, the rule is violated even though the `while` statement is followed by a block in braces. The semicolon following the `while` statement causes the block to dissociated from the `while` statement.

The rule helps detect such spurious semicolons.

# MISRA C:2012 Rule 15.7

All if … else if constructs shall be terminated with an else statement

## Description

### Rule Definition

*All if … else if constructs shall be terminated with an else statement.*

### Rationale

Unless there is a terminating `else` statement in an `if...elseif...else` construct, during code review, it is difficult to tell if you considered all possible results for the `if` condition.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing `else` Block

```
#include<stdbool.h>
void action_1(void);
void action_2(void);

void f1(bool flag_1, bool flag_2) {
    if(flag_1) {
        action_1();
    }
    else if(flag_2) {/* Non-compliant */
        action_2();
    }
}
```

In this example, the rule is violated because the `if ... else if` construct does not have a terminating `else` block.

#### Correction — Add `else` Block

To avoid the rule violation, add a terminating `else` block. This `else` block can, for instance, handle exceptions or be empty.

```
#include<stdbool.h>
bool ERROR = 0;
void action_1(void);
void action_2(void);

void f1(bool flag_1, bool flag_2) {
    if(flag_1) {
        action_1();
    }
    else if(flag_2) {
        action_2();
    }else{
        // Can be empty
        ERROR = 1;
    }
}
```

# MISRA C:2012 Rule 16.1

All switch statements shall be well-formed

## Description

### Rule Definition

*All switch statements shall be well-formed*

### Rationale

The syntax for switch statements in C is not particularly rigorous and can allow complex, unstructured behavior. This rule and other rules impose a simple consistent structure on the `switch` statement.

### Polyspace Implementation

Following the MISRA specifications, the coding rules checker also raises a violation of rule 16.1 if a `switch` statement violates one of these rules: 16.2, 16.3, 16.4, 16.5 or 16.6.

### Additional Message in Report

All messages in report file begin with "MISRA-C switch statements syntax normative restriction."

- Initializers shall not be used in switch clauses.
- The child statement of a switch shall be a compound statement.
- All switch clauses shall appear at the same level.
- A switch clause shall only contain switch labels and switch clauses, and no other code.
- A switch statement shall only contain switch labels and switch clauses, and no other code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 16.2

A switch label shall only be used when the most closely-enclosing compound statement is the body of a switch statement

## Description

### Rule Definition

*A switch label shall only be used when the most closely-enclosing compound statement is the body of a switch statement*

### Rationale

The C Standard permits placing a switch label (for instance, `case` or `default`) before any statement contained in the body of a switch statement. This flexibility can lead to unstructured code. To prevent unstructured code, make sure a switch label appears only at the outermost level of the body of a switch statement.

### Additional Message in Report

All messages in report file begin with "MISRA-C switch statements syntax normative restriction."

- Initializers shall not be used in switch clauses.
- The child statement of a switch shall be a compound statement.
- All switch clauses shall appear at the same level.
- A switch clause shall only contain switch labels and switch clauses, and no other code.
- A switch statement shall only contain switch labels and switch clauses, and no other code.

# MISRA C:2012 Rule 16.3

An unconditional break statement shall terminate every switch-clause

## Description

### Rule Definition

*An unconditional break statement shall terminate every switch-clause*

### Rationale

A *switch-clause* is a case containing at least one statement. Two consecutive labels without an intervening statement is compliant with MISRA.

If you fail to end your switch-clauses with a break statement, then control flow “falls” into the next statement. This next statement can be another switch-clause, or the end of the switch. This behavior is sometimes intentional, but more often it is an error. If you add additional cases later, an unterminated switch-clause can cause problems.

### Polyspace Implementation

Polyspace raises a warning for each noncompliant `case` clause.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

# MISRA C:2012 Rule 16.4

Every switch statement shall have a default label

## Description

### Rule Definition

*Every switch statement shall have a default label*

### Rationale

The requirement for a `default` label is defensive programming. Even if your switch covers all possible values, there is no guarantee that the input takes one of these values. Statements following the `default` label take some appropriate action. If the `default` label requires no action, use comments to describe why there are no specific actions.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Switch Statement Without `default`

```
short func1(short xyz){

    switch(xyz){      /* Non-compliant - default label is required */
        case 0:
            ++xyz;
            break;
        case 1:
        case 2:
            break;
    }
    return xyz;
}
```

In this example, the switch statement does not include a `default` label, and is therefore noncompliant.

#### Correction — Add `default` With Error Flag

One possible correction is to use the `default` label to flag input errors. If your switch-clauses cover all expected input, then the default cases flags any input errors.

```
short func1(short xyz){
int errorflag = 0;
    switch(xyz){      /* Compliant */
        case 0:
            ++xyz;
            break;
        case 1:
```

```
        case 2:
            break;
        default:
            errorflag = 1;
            break;
    }
    if (errorflag == 1)
        return errorflag;
    else
        return xyz;
}
```

### Switch Statement for Enumerated Inputs

```
enum Colors{
    RED, GREEN, BLUE
};

enum Colors func2(enum Colors color){
    enum Colors next;

    switch(color){      /* Non-compliant - default label is required */
        case RED:
            next = GREEN;
            break;
        case GREEN:
            next = BLUE;
            break;
        case BLUE:
            next = RED;
            break;
    }
    return next;
}
```

In this example, the switch statement does not include a `default` label, and is therefore noncompliant. Even though this switch statement handles all values of the enumeration, there is no guarantee that color takes one of the those values.

#### Correction — Add `default`

To be compliant, add the `default` label to the end of your switch. You can use this case to flag unexpected inputs.

```
enum Colors{
    RED, GREEN, BLUE, ERROR
};

enum Colors func2(enum Colors color){
    enum Colors next;

    switch(color){      /* Compliant */
        case RED:
            next = GREEN;
            break;
        case GREEN:
            next = BLUE;
            break;
        case BLUE:
            next = RED;
            break;
        default:
            next = ERROR;
            break;
    }

    return next;
}
```

# MISRA C:2012 Rule 16.5

A default label shall appear as either the first or the last switch label of a switch statement

## Description

### Rule Definition

*A default label shall appear as either the first or the last switch label of a switch statement.*

### Rationale

Using this rule, you can easily locate the `default` label within a `switch` statement.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Default Case in `switch` Statements

```
void foo(int var){

    switch(var){
        default:   /* Compliant - default is the first label */
        case 0:
            ++var;
            break;
        case 1:
        case 2:
            break;
    }

    switch(var){
        case 0:
            ++var;
            break;
        default:    /* Non-compliant - default is mixed with the case labels */
        case 1:
        case 2:
            break;
    }

    switch(var){
        case 0:
            ++var;
            break;
        case 1:
        case 2:
        default:     /* Compliant - default is the last label */
            break;
    }
    switch(var){
        case 0:
            ++var;
            break;
        case 1:
        case 2:
            break;
        default:      /* Compliant - default is the last label */
            var = 0;
            break;
    }
}
```

This example shows the same switch statement several times, each with `default` in a different place. As the first, third, and fourth switch statements show, `default` must be the first or last label. `default` can be part of a compound switch-clause (for instance, the third `switch` example), but it must be the last listed.

# MISRA C:2012 Rule 16.7

A switch-expression shall not have essentially Boolean type

## Description

### Rule Definition

*A switch-expression shall not have essentially Boolean type*

### Rationale

The C Standard requires the controlling expression to a `switch` statement to have an integer type. Because C implements Boolean values with integer types, it is possible to have a Boolean expression control a `switch` statement. For controlling flow with Boolean types, an `if-else` construction is more appropriate.

### Polyspace Implementation

The analysis recognizes the Boolean types, `bool` or `_Bool` (defined in `stdbool.h`)

You can also define types that are essentially Boolean using the option `Effective boolean types (-boolean-types)`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

# MISRA C:2012 Rule 17.1

The features of <stdarg.h> shall not be used

## Description

### Rule Definition

*The features of <stdarg.h> shall not be used..*

### Rationale

The rule forbids use of va_list, va_arg, va_start, va_end, and va_copy.

You can use these features in ways where the behavior is not defined in the Standard. For instance:

- You invoke va_start in a function but do not invoke the corresponding va_end before the function block ends.
- You invoke va_arg in different functions on the same variable of type va_list.
- va_arg has the syntax type va_arg (va_list ap, type).

  You invoke va_arg with a type that is incompatible with the actual type of the argument retrieved from ap.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of va_start, va_list, va_arg, and va_end

```
#include<stdarg.h>
void f2(int n, ...) {
    int i;
    double val;
    va_list vl;                         /* Non-compliant */

    va_start(vl, n);                    /* Non-compliant */

    for(i = 0; i < n; i++)
    {
        val = va_arg(vl, double);         /* Non-compliant */
    }

    va_end(vl);                         /* Non-compliant */
}
```

In this example, the rule is violated because va_start, va_list, va_arg and va_end are used.

### Undefined Behavior of va_arg

```
#include <stdarg.h>
void h(va_list ap) {                    /* Non-compliant */
    double y;

    y = va_arg(ap, double );              /* Non-compliant */
}

void g(unsigned short n, ...) {
    unsigned int x;
    va_list ap;                         /* Non-compliant */

    va_start(ap, n);                    /* Non-compliant */
    x = va_arg(ap, unsigned int);       /* Non-compliant */

    h(ap);

    /* Undefined - ap is indeterminate because va_arg used in h () */
    x = va_arg(ap, unsigned int);       /* Non-compliant */

}

void f(void) {
    /* undefined - uint32_t:double type mismatch when g uses va_arg () */
    g(1, 2.0, 3.0);
}
```

In this example, `va_arg` is used on the same variable `ap` of type `va_list` in both functions `g` and `h`. In `g`, the second argument is `unsigned int` and in `h`, the second argument is `double`. This type mismatch causes undefined behavior.

# MISRA C:2012 Rule 17.2

Functions shall not call themselves, either directly or indirectly

## Description

### Rule Definition

*Functions shall not call themselves, either directly or indirectly.*

### Rationale

Variables local to a function are stored in the call stack. If a function calls itself directly or indirectly several times, the available stack space can be exceeded, causing serious failure. Unless the recursion is tightly controlled, it is difficult to determine the maximum stack space required.

### Polyspace Implementation

The checker reports each function that calls itself, directly or indirectly. Even if several functions are involved in one recursion cycle, each function is individually reported.

You can calculate the total number of recursion cycles using the code complexity metric `Number of Recursions`.

### Additional Message in Report

**Message in Report:** Function XX is called indirectly by YY.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Direct and Indirect Recursion

```
void foo1(int);
void foo2(int);

void foo1( int n ) {     /* Non-compliant - Indirect recursion foo1->foo2->foo1... */
    if (n > 0) {
        foo2(n);
        foo1(n);               /* Non-compliant - Direct recursion */
        n--;
    }
}

void foo2( int n ) { /* Non-compliant - Indirect recursion foo2->foo1->foo2... */
    foo1(n);
}
```

In this example, the rule is violated because of:

- Direct recursion `foo1` → `foo1`.
- Indirect recursion `foo1` → `foo2` → `foo1`.

- Indirect recursion `foo2` → `foo1` → `foo2`.

Note that the location of the rule violation is different for direct and indirect recursions:

- When a function calls itself directly, the rule violation is shown on the function call.
- When several functions are involved in an indirect recursion chain, for every function in the chain, a rule violation is shown on the function signature in the function body.

### Check Information

**Group:** Function
**Category:** Required
**AGC Category:** Required

## Version History

**Introduced in R2014b**

# MISRA C:2012 Rule 17.3

A function shall not be declared implicitly

## Description

### Rule Definition

*A function shall not be declared implicitly.*

### Rationale

An implicit declaration occurs when you call a function before declaring or defining it. When you declare a function explicitly before calling it, the compiler can match the argument and return types with the parameter types in the declaration. If an implicit declaration occurs, the compiler makes assumptions about the argument and return types. For instance, it assumes a return type of `int`. The assumptions might not agree with what you expect and cause undesired type conversions.

### Additional Message in Report

Function 'XX' has no complete visible prototype at call.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function Not Declared Before Call

```
#include <math.h>

extern double power3 (double val, int exponent);
int getChoice(void);

double func() {
    double res;
    int ch = getChoice();
    if(ch == 0) {
        res = power(2.0, 10);    /* Non-compliant */
    }
    else if( ch==1) {
        res = power2(2.0, 10);   /* Non-compliant */
    }
    else {
        res = power3(2.0, 10);   /* Compliant */
        return res;
    }
}

double power2 (double val, int exponent) {
    return (pow(val, exponent));
}
```

In this example, the rule is violated when a function that is not declared is called in the code. Even if a function definition exists later in the code, the rule violation occurs.

The rule is not violated when the function is declared before it is called in the code. If the function definition exists in another file and is available only during the link phase, you can declare the function in one of the following ways:

- Declare the function with the `extern` keyword in the current file.
- Declare the function in a header file and include the header file in the current file.

# MISRA C:2012 Rule 17.4

All exit paths from a function with non-void return type shall have an explicit return statement with an expression

## Description

### Rule Definition

*All exit paths from a function with non-void return type shall have an explicit return statement with an expression.*

### Rationale

If a non-`void` function does not explicitly return a value but the calling function uses the return value, the behavior is undefined. To prevent this behavior:

- You must provide `return` statements with an explicit expression.
- You must ensure that during run time, at least one `return` statement executes.

### Additional Message in Report

Missing return value for non-void function 'XX'.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing Return Statement Along Certain Execution Paths

```
int absolute(int v) {
    if(v < 0) {
        return v;
    }
} // Non-compliant
```

In this example, the rule is violated because a `return` statement does not exist on all execution paths. If `v >= 0`, then the control returns to the calling function without an explicit return value.

### Return Statement Without Explicit Expression

```
#define SIZE 10
int table[SIZE];

unsigned short lookup(unsigned short v) {
    if((v < 0) || (v > SIZE)) {
        return; // Non-compliant
    }
    return table[v];
}
```

In this example, the rule is violated because the `return` statement in the `if` block does not have an explicit expression.

### Check Information

**Group:** Function
**Category:** Mandatory
**AGC Category:** Mandatory

# MISRA C:2012 Rule 17.5

The function argument corresponding to a parameter declared to have an array type shall have an appropriate number of elements

## Description

### Rule Definition

*The function argument corresponding to a parameter declared to have an array type shall have an appropriate number of elements.*

### Rationale

If you use an array declarator for a function parameter instead of a pointer, the function interface is clearer because you can state the minimum expected array size. If you do not state a size, the expectation is that the function can handle an array of any size. In such cases, the size value is typically another parameter of the function, or the array is terminated with a sentinel value.

However, it is legal in C to specify an array size but pass an array of smaller size. This rule prevents you from passing an array of size smaller than the size you declared.

### Additional Message in Report

The function argument corresponding to a parameter declared to have an array type shall have an appropriate number of elements.

The argument type has *actual_size* elements whereas the parameter type expects *expected_size* elements.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Array Size Passed to Function

```
void func(int arr[4]);

int main() {
    int arrSmall[3] = {1,2,3};
    int arr[4] = {1,2,3,4};
    int arrLarge[5] ={1,2,3,4,5};

    func(arrSmall);      /* Non-compliant */
    func(arr);           /* Compliant */
    func(arrLarge);      /* Compliant */

    return 0;
}
```

In this example, the rule is violated when `arrSmall`, which has size 3, is passed to `func`, which expects at least 4 elements.

# MISRA C:2012 Rule 17.6

The declaration of an array parameter shall not contain the static keyword between the [ ]

## Description

### Rule Definition

*The declaration of an array parameter shall not contain the static keyword between the [ ].*

### Rationale

If you use the `static` keyword within `[]` for an array parameter of a function, you can inform a C99 compiler that the array contains a minimum number of elements. The compiler can use this information to generate efficient code for certain processors. However, in your function call, if you provide less than the specified minimum number, the behavior is not defined.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of `static` Keyword Within `[]` in Array Parameter

```
extern int arr1[20];
extern int arr2[10];

unsigned int total (unsigned int n,
                    unsigned int arr[static 20]) { // Non-compliant

    unsigned int i;
    unsigned int sum = 0;

    for (i=0U; i < n; i++) {
        sum+= arr[i];
    }

    return sum;
}

void func (void) {
    int res, res2;
    res = total (10U, arr1); //Undefined behavior
    res2 = total (20U, arr2);
}
```

In this example, the rule is violated when the `static` keyword is used within `[]` in the array parameter of function `total`. Even if you call `total` with array arguments where the behavior is well-defined, the rule violation occurs.

# MISRA C:2012 Rule 17.7

The value returned by a function having non-void return type shall be used

## Description

### Rule Definition

*The value returned by a function having non-void return type shall be used*.

### Rationale

You can unintentionally call a function with a non-`void` return type but not use the return value. Because the compiler allows the call, you might not catch the omission. This rule forbids calls to a non-`void` function where the return value is not used. If you do not intend to use the return value of a function, explicitly cast the return value to `void`.

### Polyspace Implementation

The checker flags functions with non-`void` return if the return value is not used or not explicitly cast to a `void` type.

The checker does not flag the functions `memcpy`, `memset`, `memmove`, `strcpy`, `strncpy`, `strcat`, `strncat` because these functions simply return a pointer to their first arguments.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Used and Unused Return Values

```
unsigned int cutOff(unsigned int val) {
    if (val > 10 && val < 100) {
        return val;
    }
    else {
        return 0;
    }
}

unsigned int getVal(void);

void func2(void) {
    unsigned int val = getVal(), res;
    cutOff(val);           /* Non-compliant */
    res = cutOff(val);     /* Compliant */
    (void)cutOff(val);     /* Compliant */
}
```

In this example, the rule is violated when the return value of `cutOff` is not used subsequently.

The rule is not violated when the return value is:

- Assigned to another variable.
- Explicitly cast to `void`.

# MISRA C:2012 Rule 17.8

A function parameter should not be modified

## Description

### Rule Definition

*A function parameter should not be modified.*

### Rationale

When you modify a parameter, the function argument corresponding to the parameter is not modified. However, you or another programmer unfamiliar with C can expect by mistake that the argument is also modified when you modify the parameter.

### Polyspace Implementation

Polyspace reports a violation of this rule when you modify the function parameters in the body of the function. Polyspace does not report a violation of this rule when a function parameter is passed by address as `const` to another function.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function Parameter Modified

In this example, the rule is violated when the parameter `param1` is modified. Polyspace reports a violation. Because `param3` is passed to `foo` as a `const`, it is not modified. Polyspace does not report a violation.

```
int input(void);
int foo(const int*);
void func(int param1, int* param2, int param3) {

    param1 = input();   /* Non-compliant */
    *param2 = input();  /* Compliant */
    foo(&param3); /*Compliant*/
}
```

The rule is not violated when a pointer parameter, such as `param2` is modified.

# MISRA C:2012 Rule 18.1

A pointer resulting from arithmetic on a pointer operand shall address an element of the same array as that pointer operand

## Description

### Rule Definition

*A pointer resulting from arithmetic on a pointer operand shall address an element of the same array as that pointer operand.*

### Rationale

Using an invalid array subscript can lead to erroneous behavior of the program. Run-time derived array subscripts are especially troublesome because they cannot be easily checked by manual review or static analysis.

The C Standard defines the creation of a pointer to one beyond the end of the array. The rule permits the C Standard. Dereferencing a pointer to one beyond the end of an array causes undefined behavior and is noncompliant.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains these issues:

- `Array access out of bounds`
- `Pointer access out of bounds`

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 18.2

Subtraction between pointers shall only be applied to pointers that address elements of the same array

## Description

### Rule Definition

*Subtraction between pointers shall only be applied to pointers that address elements of the same array.*

### Rationale

This rule applies to expressions of the form `pointer_expression1 - pointer_expression2`. The behavior is undefined if `pointer_expression1` and `pointer_expression2`:

- Do not point to elements of the same array,
- Or do not point to the element one beyond the end of the array.

### Polyspace Implementation

Polyspace reports a violation of this rule when you subtract pointers that are null or that point to elements in different arrays.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Subtracting Pointers

```
#include <stddef.h>
#include <stdint.h>

void f1 (int32_t *ptr)
{
    int32_t a1[10];
    int32_t a2[10];
    int32_t *p1 = &a1[ 1];
    int32_t *p2 = &a2[10];
    ptrdiff_t diff1, diff2, diff3;

    diff1 =  p1 - a1;   // Compliant
    diff2 =  p2 - a2;   // Compliant
    diff3 =  p1 - p2;   // Noncompliant
}
```

In this example, the three subtraction expressions show the difference between compliant and noncompliant pointer subtractions. The `diff1` and `diff2` subtractions are compliant because the pointers point to the same array. The diff3 subtraction is not compliant because p1 and p2 point to different arrays.

### Noncompliant Pointer Subtraction

```
#include <stddef.h>
#include <stdint.h>

void f1()
{
    int32_t var1, var2 = 20;
    int32_t* i;
    int32_t* j;

    i = &var1;
    j = &var2;

    int32_t diff4;

    diff4 = i - j;    //Noncompliant
}
```

In this example, the diff4 subtraction is not compliant because the pointers i and j are not pointers to an array.

# MISRA C:2012 Rule 18.3

The relational operators >, >=, < and <= shall not be applied to objects of pointer type except where they point into the same object

## Description

### Rule Definition

*The relational operators >, >=, <, and <= shall not be applied to objects of pointer type except where they point into the same object.*

### Rationale

If two pointers do not point to the same object, comparisons between the pointers produces undefined behavior.

You can address the element beyond the end of an array, but you cannot access this element.

### Polyspace Implementation

Polyspace reports a violation of this rule when you compare pointers that are null or that point to elements in different arrays. The relational operators for the comparison are >, <, >=, and <=.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Pointer and Array Comparisons

```
void f1(void){
    int arr1[10];
    int arr2[10];
    int *ptr1 = arr1;

    if(ptr1 < arr2){}    /* Non-compliant */
    if(ptr1 < arr1){}    /* Compliant */
}
```

In this example, `ptr1` is a pointer to `arr1`. To be compliant with rule 18.3, you can compare only `ptr1` with `arr1`. Therefore, the comparison between `ptr1` and `arr2` is noncompliant.

### Structure Comparisons

```
struct limits{
  int lower_bound;
  int upper_bound;
};

void func2(void){
    struct limits lim_1 = { 2, 5 };
    struct limits lim_2 = { 10, 5 };

    if(&lim_1.lower_bound <= &lim_2.upper_bound){}  /* Non-compliant *
    if(&lim_1.lower_bound <= &lim_1.upper_bound){}  /* Compliant */
}
```

This example defines two `limits` structures, `lim1` and `lim2`, and compares the elements. To be compliant with rule 18.3, you can compare only the structure elements within a structure. The first comparison compares the `lower_bound` of `lim1` and the `upper_bound` of `lim2`. This comparison is noncompliant because the `lim_1.lower_bound` and `lim_2.upper_bound` are elements of two different structures.

# MISRA C:2012 Rule 18.4

The +, -, += and -= operators should not be applied to an expression of pointer type

## Description

### Rule Definition

*The +, -, += and -= operators should not be applied to an expression of pointer type.*

### Rationale

The preferred form of pointer arithmetic is using the array subscript syntax `ptr[expr]`. This syntax is clear and less prone to error than pointer manipulation. With pointer manipulation, any explicitly calculated pointer value has the potential to access unintended or invalid memory addresses. Array indexing can also access unintended or invalid memory, but it is easier to review.

To a new C programmer, the expression `ptr+1` can be mistakenly interpreted as one plus the address of `ptr`. However, the new memory address depends on the size, in bytes, of the pointer's target. This confusion can lead to unexpected behavior.

When used with caution, pointer manipulation using `++` can be more natural (for instance, sequentially accessing locations during a memory test).

### Polyspace Implementation

Polyspace flags operations on pointers, for example, `Pointer + Integer`, `Integer + Pointer`, `Pointer - Integer`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Pointers and Array Expressions

```
void fun1(void){
    unsigned char arr[10];
    unsigned char *ptr;
    unsigned char index = 0U;

    index = index + 1U;   /* Compliant - rule only applies to pointers */

    arr[index] = 0U;      /* Compliant */
    ptr = &arr[5];        /* Compliant */
    ptr = arr;
    ptr++;                /* Compliant - increment operator not + */
    *(ptr + 5) = 0U;      /* Non-compliant */
    ptr[5] = 0U;          /* Compliant */
}
```

This example shows various operations with pointers and arrays. The only operation in this example that is noncompliant is using the + operator directly with a pointer (line 12).

### Adding Array Elements Inside a `for` Loop

```
void fun2(void){
    unsigned char array_2_2[2][2] = {{1U, 2U}, {4U, 5U}};
    unsigned char i = 0U;
    unsigned char j = 0U;
    unsigned char sum = 0U;

    for(i = 0u; i < 2U; i++){
        unsigned char *row = array_2_2[ i ];

        for(j = 0u; j < 2U; j++){
            sum += row[ j ];                   /* Compliant */
        }
    }
}
```

In this example, the second `for` loop uses the array pointer `row` in an arithmetic expression. However, this usage is compliant because it uses the array index form.

### Pointers and Array Expressions

```
void fun3(unsigned char *ptr1, unsigned char ptr2[ ]){
    ptr1++;                /* Compliant */
    ptr1 = ptr1 - 5;       /* Non-compliant */
    ptr1 -= 5;             /* Non-compliant */
    ptr1[2] = 0U;          /* Compliant */

    ptr2++;                /* Compliant */
    ptr2 = ptr2 + 3;       /* Non-compliant */
    ptr2 += 3;             /* Non-compliant */
    ptr2[3] = 0U;          /* Compliant */
}
```

This example shows the offending operators used on pointers and arrays. Notice that the same types of expressions are compliant and noncompliant for both pointers and arrays.

If `ptr1` does not point to an array with at least six elements, and `ptr2` does not point to an array with at least 4 elements, this example violates rule 18.1.

# MISRA C:2012 Rule 18.5

Declarations should contain no more than two levels of pointer nesting

## Description

### Rule Definition

*Declarations should contain no more than two levels of pointer nesting*.

### Rationale

The use of more than two levels of pointer nesting can seriously impair the ability to understand the behavior of the code. Avoid this usage.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pointer Nesting

```
typedef char *INTPTR;

void function(char ** arrPar[ ])    /* Non-compliant - 3 levels */
{
    char   **  obj2;            /* Compliant */
    char   *** obj3;            /* Non-compliant */
    INTPTR *   obj4;            /* Compliant */
    INTPTR * const * const obj5;    /* Non-compliant */
    char   ** arr[10];            /* Compliant */
    char   ** (*parr)[10];        /* Compliant */
    char   *  (**pparr)[10];        /* Compliant */
}

struct s{
    char *   s1;                /* Compliant */
    char **  s2;                /* Compliant */
    char *** s3;                /* Non-compliant */
};

struct s *   ps1;            /* Compliant */
struct s **  ps2;            /* Compliant */
struct s *** ps3;            /* Non-compliant */

char **  (  *pfunc1)(void);        /* Compliant */
char **  ( **pfunc2)(void);        /* Compliant */
char **  (***pfunc3)(void);        /* Non-compliant */
char *** ( **pfunc4)(void);        /* Non-compliant */
```

This example shows various pointer declarations and nesting levels. Any pointer with more than two levels of nesting is considered noncompliant.

# MISRA C:2012 Rule 18.6

The address of an object with automatic storage shall not be copied to another object that persists after the first object has ceased to exist

## Description

### Rule Definition

*The address of an object with automatic storage shall not be copied to another object that persists after the first object has ceased to exist.*

### Rationale

The address of an object becomes indeterminate when the lifetime of that object expires. Any use of an indeterminate address results in undefined behavior.

### Polyspace Implementation

Polyspace flags a violation when assigning an address to a global variable, returning a local variable address, or returning a parameter address.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Address of Local Variables

```
char *func(void){
    char local_auto;
    return &local_auto ; /* Non-compliant
                          * &local_auto is indeterminate */
}
```

In this example, because `local_auto` is a local variable, after the function returns, the address of `local_auto` is indeterminate.

### Copying Pointer Addresses to Local Variables

```
char *sp;

void f(unsigned short u){
    g(&u);
}

void h(void){
    static unsigned short *q;

    unsigned short x =0u;
    q = &x;  /* Non-compliant -
```

```
              * &x stored in object with greater lifetime */
}
```

In this example, the function h stores the address of a local variable x in the a static variable q. The lifetime of the static variable q persists after the lifetime of the local variable x ends. Copying x into q is noncompliant with this rule and Polyspace flags the variable x.

# MISRA C:2012 Rule 18.8

Variable-length array types shall not be used

## Description

### Rule Definition

*Variable-length array types shall not be used*.

### Rationale

When the size of an array declared in a block or function prototype is not an integer constant expression, you specify variable array types. Variable array types are typically implemented as a variable size object stored on the stack. Using variable type arrays can make it impossible to determine statistically the amount of memory for the stack requires.

If the size of a variable-length array is negative or zero, the behavior is undefined.

If a variable-length array must be compatible with another array type, then the size of the array types must be identical and positive integers. If your array does not meet these requirements, the behavior is undefined.

If you use a variable-length array type in a `sizeof`, it is uncertain if the array size is evaluated or not.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** Pointers and Arrays<br>

# MISRA C:2012 Rule 19.1

An object shall not be assigned or copied to an overlapping object

## Description

### Rule Definition

*An object shall not be assigned or copied to an overlapping object.*

### Rationale

When you assign an object to another object with overlapping memory, the behavior is undefined. The exceptions are:

- You assign an object to another object with exactly overlapping memory and compatible type.
- You copy one object to another using `memmove`.

### Additional Message in Report

- An object shall not be assigned or copied to an overlapping object.
- Destination and source of XX overlap, the behavior is undefined.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Assignment of Union Members

```
void func (void) {
    union {
        short i;
        int j;
    } a = {0}, b = {1};

    a.j = a.i;   /* Non-compliant */
    a = b;       /* Compliant */
}
```

In this example, the rule is violated when `a.i` is assigned to `a.j` because the two variables have overlapping regions of memory.

### Assignment of Array Segments

```
#include <string.h>

int arr[10];

void func(void) {
    memcpy (&arr[5], &arr[4], 2u * sizeof(arr[0]));    /* Non-compliant */
    memcpy (&arr[5], &arr[4], sizeof(arr[0]));         /* Compliant */
    memcpy (&arr[1], &arr[4], 2u * sizeof(arr[0]));    /* Compliant */
}
```

In this example, memory equal to twice `sizeof(arr[0])` is the memory space taken up by two array elements. If that memory space begins from `&a[4]` and `&a[5]`, the two memory regions overlap. The rule is violated when the `memcpy` function is used to copy the contents of these two overlapping memory regions.

#### Assignment Between Members of Same Aggregate Object

```
typedef struct
{
    char init_string[21];
    char new_string[101];
} string_aggr;

string_aggr my_string_aggr;

void copy()
{
    strncpy(&my_string_aggr.new_string[0], /* Non-compliant */
            &my_string_aggr.init_string[0], 100U);
}
```

In this example, the member `init_string` of the aggregate structure `my_string_aggr` consists of 21 characters. But, more than 21 characters of this member are copied to the adjoining member `new_string`, resulting in an overlapping copy.

# MISRA C:2012 Rule 19.2

The union keyword should not be used

## Description

### Rule Definition

*The union keyword should not be used*.

### Rationale

If you write to a union member and read the same union member, the behavior is well-defined. But if you read a different member, the behavior depends on the relative sizes of the members. For instance:

- If you read a union member with wider memory size, the value you read is unspecified.
- Otherwise, the value is implementation-dependent.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Possible Problems with union Keyword

```
unsigned int zext(unsigned int s)
{
    union                /* Non-compliant */
    {
        unsigned int ul;
        unsigned short us;
    } tmp;

    tmp.us = s;
    return tmp.ul;       /* Unspecified value */
}
```

In this example, the 16-bit `short` field `tmp.us` is written but the wider 32-bit `int` field `tmp.ul` is read. Using the `union` keyword can cause such unspecified behavior. Therefore, the rule forbids using the `union` keyword.

# MISRA C:2012 Rule 20.1

#include directives should only be preceded by preprocessor directives or comments

## Description

### Rule Definition

*#include directives should only be preceded by preprocessor directives or comments.*

### Rationale

For better code readability, group all `#include` directives in a file at the top of the source file. Undefined behavior can occur if you use `#include` to include a standard header file within a declaration or definition or if you use part of the Standard Library before including the related standard header files.

### Polyspace Implementation

Polyspace flags text that precedes an `#include` directive. Polyspace ignores preprocessor directives, comments, spaces, or new line characters. Polyspace also ignores code that is hidden by using conditional compilation directives such as `#if` or `#ifdef`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Placing Code Before #include Directives

```
#if DEBUG

assert(0);

#endif

#include<stdlib> //Compliant

int x;

#include <conio> //Noncompliant
```

In this example, the first `#include` statement is preceded by an `assert` statement. Because the `assert` statement is hidden by the `#if` condition, Polyspace does not flag the `#include` statement. The second `#include` statement follows a variable declaration that is not hidden. Polyspace flags the second `#include` statement.

# MISRA C:2012 Rule 20.2

The ', " or \ characters and the /* or // character sequences shall not occur in a header file name

## Description

### Rule Definition

*The ', " or \ characters and the /* or // character sequences shall not occur in a header file name*.

### Rationale

The program's behavior is undefined if:

- You use `'`, `"`, `\`, `/*` or `//` between `< >` delimiters in a header name preprocessing token.
- You use `'`, `\`, `/*` or `//` between `"` delimiters in a header name preprocessing token.

Although `\` results in undefined behavior, many implementations accept `/` in its place.

### Polyspace Implementation

Polyspace flags the characters `'`, `"`, `\`, `/*` or `//` between < and > in `#include <filename>`.

Polyspace flags the characters `'`, `\`, `/*` or `//` between `"` and `"` in `#include "filename"`.

### Additional Message in Report

The ', "or \ characters and the /* or // character sequences shall not occur in a header file name.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

# MISRA C:2012 Rule 20.3

The #include directive shall be followed by either a <filename> or "filename" sequence

## Description

### Rule Definition

*The #include directive shall be followed by either a <filename> or "filename" sequence*.

### Rationale

This rule applies only after macro replacement.

The behavior is undefined if an `#include` directive does not use one of the following forms:

- `#include <filename>`
- `#include "filename"`

### Additional Message in Report

- ‘#include' expects "FILENAME" or <FILENAME>
- ‘#include_next' expects "FILENAME" or <FILENAME>
- ‘#include' does not expect string concatenation.
- ‘#include_next' does not expect string concatenation.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 20.4

A macro shall not be defined with the same name as a keyword

## Description

### Rule Definition

*A macro shall not be defined with the same name as a keyword.*

### Rationale

Using macros to change the meaning of keywords can be confusing. The behavior is undefined if you include a standard header while a macro is defined with the same name as a keyword.

### Additional Message in Report

- The macro *macro_name* shall not be redefined.
- The macro *macro_name* shall not be undefined.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Redefining int keyword

```
#include <stdlib.h>
#define int some_other_type /* Non-compliant - int keyword behavior altered */

//...
```

In this example, the #define violates Rule 20.4 because it alters the behavior of the int keyword. The inclusion of the standard header results in undefined behavior.

#### Correction — Rename keyword

One possible correction is to use a different keyword:

```
#include <stdlib.h>
#define int_mine some_other_type

//...
```

### Redefining keywords versus statements

```
#define while(E) for ( ; (E) ; )  /* Non-compliant - while redefined*/
#define unless(E) if ( !(E) )     /* Compliant*/

#define seq(S1, S2) do{ S1; S2;} while(false)  /* Compliant*/
#define compound(S) {S;}                       /* Compliant*/
//...
```

In this example, it is noncompliant to redefine the keyword `while`, but it is compliant to define a macro that expands to statements.

### Redefining keywords in different standards

```
#define inline // Non-compliant
```

In this example, redefining `inline` is compliant in C90, but not in C99 because `inline` is not a keyword in C90.

# MISRA C:2012 Rule 20.6

Tokens that look like a preprocessing directive shall not occur within a macro argument

## Description

### Rule Definition

*Tokens that look like a preprocessing directive shall not occur within a macro argument.*

### Rationale

An argument containing sequences of tokens that otherwise act as preprocessing directives leads to undefined behavior.

### Polyspace Implementation

Polyspace looks for the # character in a macro arguments (outside a string or character constant).

### Additional Message in Report

Macro argument shall not look like a preprocessing directive.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Macro Expansion Causing Non-Compliance

```
#define M( A ) printf ( #A )

#include <stdio.h>

void foo(void){
    M(
#ifdef SW         /* Non-compliant */
    "Message 1"
#else
    "Message 2"   /* Compliant - SW not defined */
#endif            /* Non-compliant */
    );
}
```

This example shows a macro definition and the macro usage. `#ifdef SW` and `#endif` are noncompliant because they look like a preprocessing directive. Polyspace does not flag `#else "Message 2"` because after macro expansion, Polyspace knows `SW` is not defined. The expanded macro is `printf ("\"Message 2\"");`

# MISRA C:2012 Rule 20.7

Expressions resulting from the expansion of macro parameters shall be enclosed in parentheses

## Description

### Rule Definition

*Expressions resulting from the expansion of macro parameters shall be enclosed in parentheses.*

### Rationale

If you do not use parentheses, then it is possible that operator precedence does not give the results that you want when macro substitution occurs.

If you are not using a macro parameter as an expression, then the parentheses are not necessary because no operators are involved in the macro.

### Additional Message in Report

Expanded macro parameter *`param`* shall be enclosed in parentheses.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Macro Expressions

```
#define mac1(x, y) (x * y)
#define mac2(x, y) ((x) * (y))

void foo(void){
    int r;

    r = mac1(1 + 2, 3 + 4);       /* Non-compliant */
    r = mac1((1 + 2), (3 + 4));   /* Compliant */

    r = mac2(1 + 2, 3 + 4);       /* Compliant */
}
```

In this example, `mac1` and `mac2` are two defined macro expressions. The definition of `mac1` does not enclose the arguments in parentheses. In line 7, the macro expands to `r = (1 + 2 * 3 + 4);` This expression can be `(1 + (2 * 3) + 4)` or `(1 + 2) * (3 + 4)`. However, without parentheses, the program does not know the intended expression. Line 8 uses parentheses, so the line expands to `(1 + 2) * (3 + 4)`. This macro expression is compliant.

The definition of `mac2` does enclose the argument in parentheses. Line 10 (the same macro arguments in line 7) expands to `(1 + 2) * (3 + 4)`. This macro and macro expression are compliant.

# MISRA C:2012 Rule 20.8

The controlling expression of a #if or #elif preprocessing directive shall evaluate to 0 or 1

## Description

### Rule Definition

*The controlling expression of a #if or #elif preprocessing directive shall evaluate to 0 or 1*.

### Rationale

Strong typing requires that conditional inclusion preprocessing directives, `#if` or `#elif`, have a controlling expression that evaluates to a Boolean value.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Check Information

**Group:** Preprocessing Directives
**Category:** Required
**AGC Category:** Advisory

# MISRA C:2012 Rule 20.9

All identifiers used in the controlling expression of #if or #elif preprocessing directives shall be #define'd before evaluation

## Description

### Rule Definition

*All identifiers used in the controlling expression of #if or #elif preprocessing directives shall be #define'd before evaluation.*

### Rationale

If attempt to use a macro identifier in a preprocessing directive, and you have not defined that identifier, then the preprocessor assumes that it has a value of zero. This value might not meet developer expectations.

### Additional Message in Report

`Identifier` is not defined.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Macro Identifiers

```
#if M == 0                   /* Non-compliant - Not defined */
#endif

#if defined (M)              /* Compliant - M is not evaluate */
#if M == 0                   /* Compliant - M is known to be defined */
#endif
#endif

#if defined (M) && (M == 0)  /* Compliant
                              * if M defined, M evaluated in ( M == 0 ) */
#endif
```

This example shows various uses of `M` in preprocessing directives. The second and third `#if` clauses check to see if the software defines `M` before evaluating `M`. The first `#if` clause does not check to see if `M` is defined, and because `M` is not defined, the statement is noncompliant.

# MISRA C:2012 Rule 20.10

The # and ## preprocessor operators should not be used

## Description

### Rule Definition

*The # and ## preprocessor operators should not be used*.

### Rationale

The order of evaluation associated with multiple #, multiple ##, or a mix of # and ## preprocessor operators is unspecified. In some cases, it is therefore not possible to predict the result of macro expansion.

The use of ## can result in obscured code.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Check Information

**Group:** Preprocessing Directives<br>
**Category:** Advisory<br>
**AGC Category:** Advisory

"Software Quality Objective Subsets (C:2012)"

# MISRA C:2012 Rule 20.11

A macro parameter immediately following a # operator shall not immediately be followed by a ## operator

## Description

### Rule Definition

*A macro parameter immediately following a # operator shall not immediately be followed by a ## operator.*

### Rationale

The order of evaluation associated with multiple #, multiple ##, or a mix of # and ## preprocessor operators, is unspecified. Rule 20.10 discourages the use of # and ##. The result of a # operator is a string literal. It is extremely unlikely that pasting this result to any other preprocessing token results in a valid token.

### Additional Message in Report

The ## preprocessor operator shall not follow a macro parameter following a # preprocessor operator.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of # and ##

```
#define A( x )    #x             /* Compliant */
#define B( x, y ) x ## y         /* Compliant */
#define C( x, y ) #x ## y     /* Non-compliant */
```

In this example, you can see three uses of the # and ## operators. You can use these preprocessing operators alone (line 1 and line 2), but using # then ## is noncompliant (line 3).

## Check Information

# MISRA C:2012 Rule 20.12

A macro parameter used as an operand to the # or ## operators, which is itself subject to further macro replacement, shall only be used as an operand to these operators

## Description

### Rule Definition

*A macro parameter used as an operand to the # or ## operators, which is itself subject to further macro replacement, shall only be used as an operand to these operators.*

### Rationale

The parameter to # or ## is not expanded prior to being used. The same parameter appearing elsewhere in the replacement text is expanded. If the macro parameter is itself subject to macro replacement, its use in mixed contexts within a macro replacement might not meet developer expectations.

### Additional Message in Report

Expanded macro parameter *`param1`* is also an operand of *`op`* operator.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

# MISRA C:2012 Rule 20.13

A line whose first token is # shall be a valid preprocessing directive

## Description

### Rule Definition

*A line whose first token is # shall be a valid preprocessing directive*

### Rationale

You typically use a preprocessing directive to conditionally exclude source code until a corresponding `#else`, `#elif`, or `#endif` directive is encountered. If your compiler does not detect a preprocessing directive because it is malformed or invalid, you can end up excluding more code than you intended.

If all preprocessing directives are syntactically valid, even in excluded code, this unintended code exclusion cannot happen.

### Additional Message in Report

Directive is not syntactically meaningful.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 20.14

All #else, #elif and #endif preprocessor directives shall reside in the same file as the #if, #ifdef or #ifndef directive to which they are related

## Description

### Rule Definition

*All #else, #elif and #endif preprocessor directives shall reside in the same file as the #if, #ifdef or #ifndef directive to which they are related.*

### Rationale

When conditional compilation directives include or exclude blocks of code and are spread over multiple files, confusion arises. If you terminate an `#if` directive within the same file, you reduce the visual complexity of the code and the chances of an error.

If you terminate `#if` directives within the same file, you can use `#if` directives in included files

### Additional Message in Report

- '#else' not within a conditional.
- '#elseif' not within a conditional.
- '#endif' not within a conditional.

  Unterminated conditional directive.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 21.1

#define and #undef shall not be used on a reserved identifier or reserved macro name

## Description

### Rule Definition

*#define and #undef shall not be used on a reserved identifier or reserved macro name.*

### Rationale

Reserved identifiers and reserved macro names are intended for use by the implementation. Removing or changing the meaning of a reserved macro can result in undefined behavior. This rule applies to the following:

- Identifiers or macro names beginning with an underscore
- Identifiers in file scope described in the C Standard Library
- Macro names described in the C Standard Library as being defined in a standard header

The rule checker can flag different identifiers or macros depending on the version of the C standard used in the analysis. See `C standard version (-c-version)`. For instance, if you run a C99 analysis, the reserved identifiers and macros are defined in the ISO/IEC 9899:1999 standard, Section 7, "Library".

### Additional Message in Report

- The macro *`macro_name`* shall not be redefined.
- The macro *`macro_name`* shall not be undefined.
- The macro *`macro_name`* shall not be defined.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Defining or Undefining Reserved Identifiers

```
#undef __LINE__               /* Non-compliant - begins with _ */
#define _Guard_H 1            /* Non-compliant - begins with _ */
#undef _ BUILTIN_sqrt        /* Non-compliant - implementation may
                               * use _BUILTIN_sqrt for other purposes,
                               * e.g. generating a sqrt instruction */
#define defined               /* Non-compliant - reserved identifier */
#define errno my_errno        /* Non-compliant - library identifier */
#define isneg(x) ( (x) < 0 )  /* Compliant - rule doesn't include
                               * future library directions   */
```

# MISRA C:2012 Rule 21.2

A reserved identifier or reserved macro name shall not be declared

## Description

### Rule Definition

*A reserved identifier or reserved macro name shall not be declared.*

### Rationale

The Standard allows implementations to treat reserved identifiers specially. If you reuse reserved identifiers, you can cause undefined behavior.

### Polyspace Implementation

- If you define a macro name that corresponds to a standard library macro, object, or function, rule 21.1 is violated.
- The rule considers tentative definitions as definitions.

### Additional Message in Report

Identifier 'XX' shall not be reused.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

# MISRA C:2012 Rule 21.20

The pointer returned by the Standard Library functions `asctime`, `ctime`, `gmtime`, `localtime`, `localeconv`, `getenv`, `setlocale` or `strerror` shall not be used following a subsequent call to the same function

## Description

### Rule Definition

*The pointer returned by the Standard Library functions `asctime`, `ctime`, `gmtime`, `localtime`, `localeconv`, `getenv`, `setlocale` or `strerror` shall not be used following a subsequent call to the same function.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The preceding functions return a pointer to an object within the Standard Library. Implementation for this object can use a static buffer that can be modified by a second call to the same function. Therefore the value accessed through a pointer before a subsequent call to the same function can change unexpectedly.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of Return Value from `getenv` After Another Call to `getenv`

```
#include <stdio.h>
#include <locale.h>
#include <string.h>

void f1(void)
{
    const char* res1;
    const char* res2;
    char copy[ 128 ];
    res1 = setlocale(LC_ALL, 0);
    (void) strcpy(copy, res1);
    res2 = setlocale(LC_MONETARY, "French");
    printf("%s\n", res1);    /* Non-compliant */
    printf("%s\n", copy);    /* Compliant */
    printf("%s\n", res2);    /* Compliant */
}
```

In this example:

- The first `printf` statement is non-compliant because the pointer returned by `setlocale` is used following a subsequent call to it when `res2` is assigned.

- The second `printf` statement is compliant because the copy operation performed by `strcpy` is made before a subsequent call to `setlocale` function is made.
- The third `printf` statement is compliant because there is no subsequent call to the `setlocale` function is made before use.

"Software Quality Objective Subsets (C:2012)"

# MISRA C:2012 Rule 21.3

The memory allocation and deallocation functions of `<stdlib.h>` shall not be used

## Description

### Rule Definition

*The memory allocation and deallocation functions of `<stdlib.h>` shall not be used.*

### Rationale

Using memory allocation and deallocation routines can cause undefined behavior. For instance:

- You free memory that you had not allocated dynamically.
- You use a pointer that points to a freed memory location.

### Polyspace Implementation

The checker flags uses of the `calloc`, `malloc`, `realloc`, `aligned_alloc` and `free` functions.

If you define macros with the same names as these dynamic heap memory allocation functions, and you expand the macros in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro <name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `malloc`, `calloc`, `realloc` and `free`

```
#include <stdlib.h>

static int foo(void);

typedef struct struct_1 {
    int a;
    char c;
} S_1;

static int foo(void) {

    S_1 * ad_1;
    int  * ad_2;
    int  * ad_3;
    ad_1 = (S_1*)calloc(100U, sizeof(S_1));        /* Non-compliant */
    ad_2 = malloc(100U * sizeof(int));             /* Non-compliant */
    ad_3 = realloc(ad_3, 60U * sizeof(long));      /* Non-compliant */

    free(ad_1);                                    /* Non-compliant */
    free(ad_2);                                    /* Non-compliant */
    free(ad_3);                                    /* Non-compliant */

    return 1;
}
```

In this example, the rule is violated when the functions `malloc`, `calloc`, `realloc` and `free` are used.

# MISRA C:2012 Rule 21.4

The standard header file <setjmp.h> shall not be used

## Description

### Rule Definition

*The standard header file <setjmp.h> shall not be used*.

### Rationale

Using `setjmp` and `longjmp`, you can bypass normal function call mechanisms and cause undefined behavior.

### Polyspace Implementation

If the `longjmp` function is a macro and the macro is expanded in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro '<name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 21.6

The Standard Library input/output functions shall not be used

## Description

### Rule Definition

*The Standard Library input/output functions shall not be used.*

### Rationale

This rule applies to the functions that are provided by `<stdio.h>` and in C99, their character-wide equivalents provided by `<wchar.h>`. Using these functions can cause unspecified, undefined and implementation-defined behavior.

### Polyspace Implementation

If the Standard Library function is a macro and the macro is expanded in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro '<name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

# MISRA C:2012 Rule 21.7

The Standard Library functions `atof`, `atoi`, `atol`, and `atoll` functions of `<stdlib.h>` shall not be used

## Description

### Rule Definition

*The Standard Library functions `atof`, `atoi`, `atol`, and `atoll` functions of `<stdlib.h>` shall not be used.*

### Rationale

When a string cannot be converted, the behavior of these functions can be undefined.

### Polyspace Implementation

If the function is a macro and the macro is expanded in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro '<name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 21.8

The Standard Library termination functions of `<stdlib.h>` shall not be used

## Description

### Rule Definition

The Standard Library termination functions of `<stdlib.h>` shall not be used.

### Rationale

Using these functions can cause undefined and implementation-defined behaviors.

### Polyspace Implementation

Polyspace flags the use of the `abort`, `exit`, `_Exit`, or `quick_exit` functions that are defined in `<stdlib.h>`.

If these functions are user-defined, Polyspace does not flag them.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unsafe Termination Functions

```
#include<stdlib.h>

void foo(){
     puts("pushed");
    //...
    _Exit(-1);//Noncompliant
}
void bar(){
    puts("pushed");
    //...
    abort();//Noncompliant
}
void foobar(){
    puts("pushed");
    //...
    quick_exit(-1);//Noncompliant
}
```

In this example, unsafe termination functions are invoked to terminate the program. These functions might not perform the essential cleanup operations. For instance, the data pushed to the output stream might become lost because the program is terminated before the streams are closed. Polyspace flags the use of such unsafe termination programs.

# MISRA C:2012 Rule 21.9

The Standard Library library functions `bsearch` and `qsort` of `<stdlib.h>` shall not be used

## Description

### Rule Definition

*The library functions `bsearch` and `qsort` of `<stdlib.h>` shall not be used.*

### Rationale

The comparison function in these library functions can behave inconsistently when the elements being compared are equal. Also, the implementation of `qsort` can be recursive and place unknown demands on the call stack.

### Polyspace Implementation

If the function is a macro and the macro is expanded in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro '<name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C:2012 Rule 21.11

The standard header file <tgmath.h> shall not be used

## Description

### Rule Definition

*The standard header file <tgmath.h> shall not be used*.

### Rationale

Using the facilities of this header file can cause undefined behavior.

### Polyspace Implementation

If the function is a macro and the macro is expanded in the code, this rule is violated. It is assumed that rule 21.2 is not violated.

### Additional Message in Report

- The macro '<name> shall not be used.
- Identifier XX should not be used.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Function in `tgmath.h`

```
#include <tgmath.h>//Noncompliant

float f1,res;

void func(void) {
    res = sqrt(f1); /* Non-compliant */
}
```

In this example, the rule is violated when the `sqrt` macro defined in `tgmath.h` is used.

#### Correction — Use Appropriate Function in `math.h`

For this example, one possible correction is to use the function `sqrtf` defined in `math.h` for `float` arguments.

```
#include <math.h>

float f1, res;
```

```
void func(void) {
 res = sqrtf(f1);
}
```

# MISRA C:2012 Rule 21.12

The exception handling features of `<fenv.h>` should not be used

## Description

### Rule Definition

*The exception handling features of* `<fenv.h>` *should not be used*.

### Rationale

In some cases, the values of the floating-point status flags are unspecified. Attempts to access them can cause undefined behavior.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Features in `<fenv.h>`

```
#include <fenv.h>

void func(float x, float y) {
    float z;

    feclearexcept(FE_DIVBYZERO);              /* Non-compliant */
    z = x/y;

    if(fetestexcept (FE_DIVBYZERO))  {        /* Non-compliant */
    }
    else {
#pragma STDC FENV_ACCESS ON
        z=x*y;
        if(z>x) {
#pragma STDC FENV_ACCESS OFF
            if(fetestexcept (FE_OVERFLOW)) {  /* Non-compliant */
            }
        }
    }
}
```

In this example, the rule is violated when the identifiers `feclearexcept` and `fetestexcept`, and the macros `FE_DIVBYZERO` and `FE_OVERFLOW` are used.

# MISRA C:2012 Rule 21.13

Any value passed to a function in <ctype.h> shall be representable as an unsigned char or be the value EOF

## Description

### Rule Definition

*Any value passed to a function in <ctype.h> shall be representable as an unsigned char or be the value EOF.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

Functions in <ctype.h> have a well-defined behavior only for int arguments whose value is within the range of unsigned char or the negative value equivalent of EOF. The use of other values results in undefined behavior.

### Polyspace Implementation

Polyspace considers that the negative value equivalent of EOF is -1 and does not raise a violation if you pass -1 as argument to a function in ctype.h.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Invalid Arguments for Functions from <ctype.h>

```
#include <stdbool.h>
#include <stdint.h>
#include <stdio.h>
#include <ctype.h>

bool f(uint8_t a)
{
    return (isdigit((int32_t) a)           /* Compliant     */
            &&  isalpha((int32_t) 'b')      /* Compliant     */
            &&  islower(EOF)                /* Compliant     */
            &&  isalpha(256));              /* Non-compliant */
}
```

In this example, the rule is violated when 256, which is an neither an unsigned char or the value EOF, is passed as an input argument to the isalpha function.

**Note** The int casts in the above example are required to comply with Rule 10.3 on page 21-146.

# MISRA C:2012 Rule 21.14

The Standard Library function `memcmp` shall not be used to compare null terminated strings

## Description

### Rule Definition

*The Standard Library function `memcmp` shall not be used to compare null terminated strings.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

If `memcmp` is used to compare two strings and the length of either string is less than the number of bytes compared, the strings can appear different even when they are logically the same. The characters after the null terminator are compared even though they do not form part of the string.

For instance:

```
memcmp(string1, string2, sizeof(string1))
```

can compare bytes after the null terminator if `string1` is longer than `string2`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using `memcmp` for String Comparison

```
extern char buffer1[ 12 ];
extern char buffer2[ 12 ];
void f1(void)
{
    (void) strcpy(buffer1, "abc");
    (void) strcpy(buffer2, "abc");

    if (memcmp(buffer1,    /* Non-compliant */
               buffer2,
               sizeof(buffer1)) != 0) {

    }
}
```

In this example, the comparison in the `if` statement is noncompliant. The strings stored in `buffer1` and `buffer2` can be reported different, but this difference comes from uninitialized characters after the null terminators.

# MISRA C:2012 Rule 21.15

The pointer arguments to the Standard Library functions `memcpy`, `memmove` and `memcmp` shall be pointers to qualified or unqualified versions of compatible types

## Description

### Rule Definition

*The pointer arguments to the Standard Library functions `memcpy`, `memmove` and `memcmp` shall be pointers to qualified or unqualified versions of compatible types.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The functions

```
memcpy( arg1, arg2, num_bytes );
memmove( arg1, arg2, num_bytes );
memcmp( arg1, arg2, num_bytes );
```

perform a byte-by-byte copy, move or comparison between the memory locations that `arg1` and `arg2` point to. A byte-by-byte copy, move or comparison is meaningful only if `arg1` and `arg2` have compatible types.

Using pointers to different data types for `arg1` and `arg2` typically indicates a coding error.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incompatible Argument Types for `memcpy`

```
#include <stdint.h>

void f ( uint8_t s1[ 8 ], uint16_t s2[ 8 ] )
{
    ( void ) memcpy ( s1, s2, 8 ); /* Non-compliant */
}
```

In this example, `s1` and `s2` are pointers to different data types. The `memcpy` statement copies eight bytes from one buffer to another.

Eight bytes represent the entire span of the buffer that `s1` points to, but only part of the buffer that `s2` points to. Therefore, the `memcpy` statement copies only part of `s2` to `s1`, which might be unintended.

# MISRA C:2012 Rule 21.16

The pointer arguments to the Standard Library function memcmp shall point to either a pointer type, an essentially signed type, an essentially unsigned type, an essentially Boolean type or an essentially enum type

## Description

### Rule Definition

*The pointer arguments to the Standard Library function* memcmp *shall point to either a pointer type, an essentially signed type, an essentially unsigned type, an essentially Boolean type or an essentially enum type.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The Standard Library function

```
memcmp ( lhs, rhs, num );
```

performs a byte-by-byte comparison of the first num bytes of the two objects that lhs and rhs point to.

Do not use memcmp for a byte-by-byte comparison of the following.

| Type | Rationale |
|---|---|
| Structures | If members of a structure have different data types, your compiler introduces additional padding for data alignment in memory. The content of these extra padding bytes is meaningless. If you perform a byte-by-byte comparison of structures with memcmp, you compare even the meaningless data stored in the padding. You might reach the false conclusion that two data structures are not equal, even if their corresponding members have the same value. |
| Objects with essentially floating type | The same floating point value can be stored using different representations. If you perform a byte-by-byte comparison of two variables with memcmp, you can reach the false conclusion that the variables are unequal even when they have the same value. The reason is that the values are stored using two different representations. |
| Essentially char arrays | Essentially char arrays are typically used to store strings. In strings, the content in bytes after the null terminator is meaningless. If you perform a byte-by-byte comparison of two strings with memcmp, you might reach the false conclusion that two strings are not equal, even if the bytes before the null terminator store the same value. |

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using memcmp for Comparison of Structures, Unions, and *essentially char* Arrays

```
#include <stdbool.h>
#include <stdint.h>

struct S {
//...
};

bool f1(struct S* s1, struct S* s2)
{
    return (memcmp(s1, s2, sizeof(struct S)) != 0); /* Non-compliant */
}

union U {
    uint32_t range;
    uint32_t height;
};
bool f2(union U* u1, union U* u2)
{
    return (memcmp(u1, u2, sizeof(union U)) != 0); /* Non-compliant */
}

const char a[ 6 ] = "task";
bool f3(const char b[ 6 ])
{
    return (memcmp(a, b, 6) != 0); /* Non-compliant */
}
```

In this example:

- Structures s1 and s2 are compared in the bool_t f1 function. The return value of this function might indicate that s1 and s2 are different due to padding. This comparison is noncompliant.
- Unions u1 and u2 are compared in the bool_t f2 function. The return value of this function might indicate that u1 and u2 are the same due to unintentional comparison of u1.range and u2.height, or u1.height and u2.range. This comparison is noncompliant.
- Essentially char arrays a and b are compared in the bool_t f3 function. The return value of this function might incorrectly indicate that the strings are different because the length of a (four) is less than the number of bytes compared (six). This comparison is noncompliant.

# MISRA C:2012 Rule 21.17

Use of the string handling function from `<string.h>` shall not result in accesses beyond the bounds of the objects referenced by their pointer parameters

## Description

### Rule Definition

*Use of the string handling function from `<string.h>` shall not result in accesses beyond the bounds of the objects referenced by their pointer parameters.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

Incorrect use of a string handling function might result in a read or write access beyond the bounds of the function arguments, resulting in undefined behavior.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pointer Access Out of Bounds from `strcpy` Usage

```
#include <stdio.h>
#include<string.h>

char string[] = "Short";
void f1(const char* str)
{
    (void) strcpy(string, "Too long to fit");      /* Non-compliant */
    if (strlen(str) < (sizeof(string) - 1u)) {
        (void) strcpy(string, str);      /* Compliant */
    }
}

size_t f2(void)
{
    char text[ 5 ] = "Token";
    return strlen(text);    /* Non-compliant */
}
```

In this example:

- The first use of `strcpy` is noncompliant because it attempts to write beyond the end of its destination argument `string`.
- The second use of `strcpy` is compliant because it attempts to write to the destination argument `string` only if the source argument `str` fits.

- The use of `strlen` is noncompliant. `strlen` computes the length of a string up to the null terminator. The character array `text` has no null terminator.

# MISRA C:2012 Rule 21.18

The `size_t` argument passed to any function in `<string.h>` shall have an appropriate value

## Description

### Rule Definition

*The `size_t` argument passed to any function in `<string.h>` shall have an appropriate value.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The value must be positive and not greater than the size of the smallest object passed by pointer to the function. For instance, suppose you use the `strncmp` function to compare two strings `lhs_string` and `rhs_string` as follows:

```
strncmp (lhs_string, rhs_string, num)
```

The third argument `num` must be positive and must not be greater than the size of `lhs_string` or `rhs_string`, whichever is smaller.

Otherwise, using the function can result in read or write access beyond the bounds of the function argument.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect `size_t` Argument for `memcmp`

```
#include <string.h>
char buf1[ 5 ] = "12345";
char buf2[ 10 ] = "1234567890";

void f(void)
{
    if (memcmp(buf1, buf2, 5) == 0) {    /* Compliant */

    }
    if (memcmp(buf1, buf2, 6) == 0) {    /* Non-compliant */

    }
}
```

In this example, the first `if` statement is compliant. The `size_t` argument is five, which is same as the size of the smaller string, `buf1`.

By the same reasoning, the second `if` statement is noncompliant.

# MISRA C:2012 Rule 21.19

The pointers returned by the Standard Library functions `localeconv`, `getenv`, `setlocale` or `strerror` shall only be used as if they have pointer to `const`-qualified type

## Description

### Rule Definition

*The pointers returned by the Standard Library functions `localeconv`, `getenv`, `setlocale` or `strerror` shall only be used as if they have pointer to `const`-qualified type.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The C99 Standard states that if the program modifies the structure pointed to by the value returned by `localeconv`, or the strings returned by `getenv`, `setlocale` or `strerro`, undefined behavior occurs. Treating the pointers returned by the various functions as if they were `const`-qualified allows an analysis tool to detect any attempt to modify an object through one of the pointers. Assigning the return values of the functions to `const`-qualified pointers results in the compiler issuing a diagnostic if an attempt is made to modify an object.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Returning Pointers from`setlocale` and `localeconv`

```
#include <locale.h>
#include <string.h>

void f1(void)
{
    char* s1 = setlocale(LC_ALL, 0);    /* Non-compliant */
    struct lconv* conv = localeconv();  /* Non-compliant */
    s1[ 1 ] = 'A'; /* Non-compliant. Undefined behavior */
    conv->decimal_point = "^"; /* Non-compliant. Undefined behavior */
}

void f2(void)
{
    char str[128];
    (void) strcpy(str, setlocale(LC_ALL, 0));     /* Compliant */
    const struct lconv* conv = localeconv();      /* Compliant */
    conv->decimal_point = "^";                    /* Non-compliant. Constraint violation */
}

void f3(void)
{
    const struct lconv* conv = localeconv();  /* Compliant */
    conv->grouping[ 2 ] = 'x';                /* Non-compliant */
}
```

In the above example:

- The usage of `setlocale` and `localeconv` in the function `f1` are non-compliant as the returned pointers are assigned to non-`const`—qualified pointers.

**Note** The usage of `setlocale` and `localeconv` above are not constraint violations and will therefore not be reported by a compiler. However, an analysis tool will be able to report a violation.

- The usage of `setlocale` in the function `f2` is compliant as `strcpy` takes a `const char *` as its second parameter. The usage of `localeconv` in the function `f2` is compliant as the returned pointers are assigned to a `const`-qualified pointer. Any attempt to modify an object through a pointer will be reported by a compiler or analysis tool as this is a constraint violation.
- The usage of a `const`-qualified pointer in the function `f3` gives compile time protection of the value returned by `localeconv` but the same is not true for the strings it references. Modification of these strings can be detected by an analysis tool.

# MISRA C:2012 Rule 21.21

The Standard Library function `system` of `<stdlib.h>` shall not be used

## Description

### Rule Definition

*The Standard Library function `system` of `<stdlib.h>` shall not be used.*

This rule comes from MISRA C: 2012 Amendment 2.

### Rationale

If the argument of the `system` function is not sanitized, it can cause exploitable vulnerabilities. An attacker can execute arbitrary commands or read and modify data anywhere on the system.

### Polyspace Implementation

The checker flags uses of the Standard Library function `system`.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `system()` Function Called

```
#include <string.h>
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func_noncompliant(char *arg)
{
    char buf[SIZE512];
    int retval=sprintf(buf, "/usr/bin/any_cmd %s", arg);

    if (retval<=0 || retval>SIZE512){
      /* Handle error */
      abort();
    }
    /* Use of system() to pass any_cmd with
    unsanitized argument to command processor */

    if (system(buf) == -1) { //Noncompliant
    /* Handle error */
  }
}

void func_compliant(char *arg)
{
    char *const args[SIZE3] = {"any_cmd", arg, NULL};
    char  *const env[] = {NULL};

    /* Sanitize argument */

    /* Use execve() to execute any_cmd. */

    if (execve("/usr/bin/time", args, env) == -1) { //Compliant
      /* Handle error */
    }
}
```

In this example, in the `func_noncompliant` function, the `system` function passes its argument to the host environment for the command processor to execute. This code is vulnerable to an attack by command-injection.

In the compliant version of the same function, `func_compliant`, the argument of `any_cmd` is sanitized, and then passed to the `execve` function for execution. `exec`-family functions are not vulnerable to command-injection attacks.

# MISRA C:2012 Rule 22.1

All resources obtained dynamically by means of Standard Library functions shall be explicitly released

## Description

### Rule Definition

*All resources obtained dynamically by means of Standard Library functions shall be explicitly released*.

### Rationale

Resources are something that you must return to the system once you have used them. Examples include dynamically allocated memory and file descriptors.

If you do not release resources explicitly as soon as possible, then a failure can occur due to exhaustion of resources.

### Polyspace Implementation

The checker flags uses of:

- Memory-allocation functions such as `malloc` and `aligned_alloc` if the memory is not released.
- File opening functions such as `fopen` if the file is not closed.

You can check for this rule with a Bug Finder analysis only.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Dynamic Memory

```
#include<stdlib.h>

void performOperation(int);

int func1(int num)
{
    int* arr1 = (int*) malloc(num * sizeof(int));

    return 0; /* Non-compliant - memory allocated to arr1 is not released */
}

int func2(int num)
{
    int* arr2 = (int*) malloc(num * sizeof(int));

    free(arr2);
    return 0; /* Compliant - memory allocated to arr2 is released */
}
```

In this example, the rule is violated when memory dynamically allocated using the `malloc` function is not freed using the `free` function before the end of scope.

#### File Pointers

```
#include <stdio.h>
void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" );              /* Non-compliant */
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}

void func2( void ) {
    FILE *fp2;
    fp2 = fopen ( "data1.txt", "w" );
    fprintf ( fp2, "*" );
    fclose(fp2);

    fp2 = fopen ( "data2.txt", "w" );              /* Compliant */
    fprintf ( fp2, "!" );
    fclose ( fp2 );
}
```

In this example, the file pointer `fp1` is pointing to a file `data1.txt`. Before `fp1` is explicitly dissociated from the file stream of `data1.txt`, it is used to access another file `data2.txt`. Therefore, the rule 22.1 is violated.

The rule is not violated in `func2` because file `data1.txt` is closed and the file pointer `fp2` is explicitly dissociated from `data1.txt` before it is reused.

# MISRA C:2012 Rule 22.10

The value of `errno` shall only be tested when the last function to be called was an `errno`-setting function

## Description

### Rule Definition

*The value of `errno` shall only be tested when the last function to be called was an `errno`-setting function.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

Besides the `errno`-setting functions, the Standard does not enforce that other functions set `errno` on errors. Whether these functions set `errno` or not is implementation-dependent.

To detect errors, if you check `errno` alone, the validity of this check also becomes implementation-dependent. On implementations that do not require `errno` setting, even if you check `errno` alone, you can overlook error conditions.

For a list of `errno`-setting functions, see `MISRA C:2012 Rule 22.8`.

For information on how to detect errors, see the documentation for that specific function.

Typically, the functions return an out-of-band error indicator to indicate errors. For instance:

- `fopen` returns a null pointer if an error occurs.
- `signal` returns the `SIG_ERR` error indicator and sets `errno` to a positive value. Check `errno` only after you have checked the function return value.

### Polyspace Implementation

Polyspace raisea a violation of this rule when you check `errno` for error conditions in situations where checking `errno` does not guarantee the absence of errors. In some cases, checking `errno` can lead to false positives.

For instance, you check `errno` following calls to the functions:

- `fopen`: If you follow the ISO Standard, the function might not set `errno` on errors.
- `atof`: If you follow the ISO Standard, the function does not set `errno`.
- `signal`: The `errno` value indicates an error only if the function returns the `SIG_ERR` error indicator.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Test of `errno`

```
#include <stddef.h>
#include <stdlib.h>

typedef double float64_t;

void f(void)
{
    float64_t f64;
    errno = 0;
    f64 = atof("A.12");
    if (0 == errno) { /* Non-compliant */
    }
    errno = 0;
    f64 = strtod("A.12", NULL);
    if (0 == errno) { /* Compliant */
    }
}
```

In this example:

- The first `if` statement is noncompliant because `atof` may or may not set `errno` when an error is detected. `f64` may not have a valid value within this `if` statement.
- The second `if` statement is compliant because `strtod` is an *`errno`-setting function*. `f64` will have a valid value within this `if` statement.

# MISRA C:2012 Rule 22.2

A block of memory shall only be freed if it was allocated by means of a Standard Library function

## Description

### Rule Definition

*A block of memory shall only be freed if it was allocated by means of a Standard Library function.*

### Rationale

The Standard Library functions that allocate memory are `malloc`, `calloc` and `realloc`.

You free a block of memory when you pass its address to the `free` or `realloc` function. The following causes undefined behavior:

- You free a block of memory that you did not allocate.
- You free a block of memory that have already freed before.

### Polyspace Implementation

You can check for this rule with a Bug Finder analysis only.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Memory Not Allocated Is Freed

```
#include <stdlib.h>

void func1(void) {
    int x=0;
    int *ptr=&x;

    free(ptr); /* Non-compliant: ptr is not dynamically allocated */

}
```

In this example, the rule is violated because the `free` function operates on a pointer that does not point to dynamically allocated memory.

### Memory Freed Twice

```
#include <stdlib.h>

void func(int arrSize) {
    int *ptr = (int*) malloc(arrSize* sizeof(int));
    free(ptr);   /* Block of memory freed once */
    free(ptr);   /* Non-compliant - Block of memory freed twice */
}
```

In this example, the rule is violated when the `free` function operates on `ptr` twice without a reallocation in between.

# MISRA C:2012 Rule 22.3

The same file shall not be open for read and write access at the same time on different streams

## Description

### Rule Definition

*The same file shall not be open for read and write access at the same time on different streams.*

### Rationale

If a file is both written and read via different streams, the behavior can be undefined.

### Polyspace Implementation

You can check for this rule with a Bug Finder analysis only.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Opening File That Is Open in Another Stream

```
#include <stdio.h>

void func(void) {
    FILE *fw = fopen("tmp.txt", "r+");
    FILE *fr = fopen("tmp.txt", "r");   /* Non-compliant: File open in stream fw*/
}
```

In this example, the rule is violated when the same file `tmp.txt` is opened in two streams. The `FILE` pointers `fw` and `fr` point to two different streams here.

## Check Information

# MISRA C:2012 Rule 22.4

There shall be no attempt to write to a stream which has been opened as read-only

## Description

### Rule Definition

*There shall be no attempt to write to a stream which has been opened as read-only.*

### Rationale

The Standard does not specify the behavior if an attempt is made to write to a read-only stream.

### Polyspace Implementation

You can check for this rule with a Bug Finder analysis only.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Writing to File Opened as Read-Only

```
#include <stdio.h>

void func1(void) {
    FILE *fp1 = fopen("tmp.txt", "r");
    (void) fprintf(fp1, "Some text"); /* Non-compliant: Read-only stream */
    (void) fclose(fp1);
}

void func2(void) {
    FILE *fp2 = fopen("tmp.txt", "r+");
    (void) fprintf(fp2, "Some text"); /* Compliant */
    (void) fclose(fp2);
}
```

In this example, the file stream associated with `fp1` is opened as read-only. The rule is violated when the stream is written.

# MISRA C:2012 Rule 22.5

A pointer to a FILE object shall not be dereferenced

## Description

### Rule Definition

*A pointer to a FILE object shall not be dereferenced*.

### Rationale

The Standard states that the address of a FILE object used to control a stream can be significant. Copying that object might not give the same behavior. This rule ensures that you cannot perform such a copy.

Directly manipulating a FILE object might be incompatible with its use as a stream designator.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### FILE* Pointer Dereferenced

```
#include <stdio.h>

void func(void) {
    FILE *pf1;
    FILE *pf2;
    FILE f3;

    pf2 = pf1;        /* Compliant */
    f3 = *pf2;        /* Non-compliant */
    pf2->_flags=0;    /* Non-compliant */
 }
```

In this example, the rule is violated when the FILE* pointer pf2 is dereferenced.

## Check Information

# MISRA C:2012 Rule 22.6

The value of a pointer to a `FILE` shall not be used after the associated stream has been closed

## Description

### Rule Definition

*The value of a pointer to a `FILE` shall not be used after the associated stream has been closed.*

### Rationale

The Standard states that the value of a `FILE*` pointer is indeterminate after you close the stream associated with it.

### Polyspace Implementation

You can check for this rule with a Bug Finder analysis only.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of `FILE` Pointer After Closing Stream

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fclose(fp);
        fprintf(fp,"text"); // Non-compliant
    }
}
```

In this example, the stream associated with the `FILE*` pointer `fp` is closed with the `fclose` function. The rule is violated `FILE*` pointer `fp` is used before the stream is re-opened.

# MISRA C:2012 Rule 22.7

The macro EOF shall only be compared with the unmodified return value from any Standard Library function capable of returning EOF

## Description

### Rule Definition

*The macro `EOF` shall only be compared with the unmodified return value from any Standard Library function capable of returning `EOF`.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

The `EOF` value may become indistinguishable from a valid character code if the value returned is converted to another type. In such cases, testing the converted value against `EOF` will not reliably identify if the end of the file has been reached or if an error has occurred.

### Troubleshooting

If you expect a rule violation but do not see it, refer to "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Possibly Misleading Results from Comparison with EOF

```
#include <stdio.h>
#include <stdint.h>

void f1(void)
{
    char ch;
    ch = (char) getchar();
    if (EOF != (int32_t) ch) {    /* Non-compliant */
    }
}

void f2(void)
{
    char ch;
    ch = (char) getchar();
    if (!feof(stdin)) {           /* Compliant */
    }
}

void f3(void)
{
    int32_t i_ch;
    i_ch = getchar();
    if (EOF != i_ch) {            /* Compliant */
```

```
        char ch;
        ch = (char) i_ch;
    }
}
```

In this example:

- The test in the `f1` function is non-compliant. It will not be reliable as the return value is cast to a narrower type before checking for `EOF`.
- The test in the `f2` function is compliant. It shows how *`feof()`* can be used to check for `EOF` when the return value from *`getchar()`* has been subjected to type conversion.
- The test in the `f3` function is compliant. It is reliable as the unconverted return value is used when checking for `EOF`.

# MISRA C:2012 Rule 22.8

The value of `errno` shall be set to zero prior to a call to an `errno`-setting-function

## Description

### Rule Definition

*The value of `errno` shall be set to zero prior to a call to an `errno`-setting-function.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

If an error occurs during a call to an `errno`-setting-function, the function writes a nonzero value to `errno`. Otherwise, `errno` is not modified.

If you do not explicitly set `errno` to zero before a function call, it can contain values from a previous call. Checking `errno` for nonzero values after the function call can give the false impression that an error occurred.

`Errno`-setting functions include:

- `ftell`, `fgetpos`, `fgetwc` and related functions.
- `strtoimax`, `strtol` and related functions.

  The wide-character equivalents such as `wcstoimax` and `wcstol` are also covered.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `errno` Not Reset Before Use

```
#include <stdlib.h>
#include <errno.h>

double val = 0.0;

void f ( void )
{
    val = strtod("1.0",NULL);/*errno is not checked*/
    if ( 0 == errno ) /* Non-compliant*/
    {
        val = strtod("1.0",NULL); /* Compliant - case 1*/
        if ( 0 == errno ) /* Check errno for nonzero values */
        {
        }
    }
    else
    {
        errno = 0;
        val = strtod("1.0",NULL); /* Compliant - case 2*/
        if ( 0 == errno ) /* Check errno for nonzero values */
        {
        }
    }
}
```

In this example, the rule is violated when `strtod` is called but `errno` is not reset prior to the call.

The rule is not violated in the following cases:

- Case 1: `errno` is compared against zero and then `strtod` is called in the `if( 0 == errno )` branch.
- Case 2: `errno` is explicitly set to zero and then `strtod` is called.

# MISRA C:2012 Rule 22.9

The value of `errno` shall be tested against zero after calling an `errno`-setting function

## Description

### Rule Definition

*The value of `errno` shall be tested against zero after calling an `errno`-setting function.*

This rule comes from MISRA C: 2012 Amendment 1.

### Rationale

If an error occurs during a call to an `errno`-setting-function, the function writes a nonzero value to `errno`. Otherwise, `errno` is not modified.

When `errno` is nonzero, the function return value is not likely to be correct. Before using this return value, you must test `errno` for nonzero values.

`Errno`-setting functions include:

- `ftell`, `fgetpos`, `fgetwc` and related functions.
- `strtoimax`, `strtol` and related functions.

  The wide-character equivalents such as `wcstoimax` and `wcstol` are also covered.

### Troubleshooting

If you expect a rule violation but do not see it, refer to “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `errno` Not Tested After Function Call

```
#include <stdlib.h>
#include <errno.h>

void func(void);
double val = 0.0;

void f1 ( void )
{
  errno = 0;
  val = strtod ( "1.0", NULL ); /* Non-compliant */
  func ();

  if ( 0 != errno )
    {
    }

  errno = 0;
  val = strtod ( "1.0", NULL ); /* Compliant */
  if ( 0 == errno )
    {
      func();
    }
}
```

In this example, the rule is violated when `errno` is not checked immediately after the first call to `strtod`. Instead, a second function `func` is called. `func` might use the value in the global variable `val`. The value can be incorrect if an error has occurred during the call to `strtod`.

The rule is not violated when `errno` is checked before operations that potentially use the return value of `strtod`.

# CERT C: Rule PRE30-C

Do not create a universal character name through concatenation

## Description

### Rule Definition

*Do not create a universal character name through concatenation.*

### Polyspace Implementation

The rule checker checks for **Universal character name from token concatenation**.

## Examples

### Universal character name from token concatenation

#### Issue

**Universal character name from token concatenation** occurs when two preprocessing tokens joined with a ## operator create a universal character name. A universal character name begins with `\u` or `\U` followed by hexadecimal digits. It represents a character not found in the basic character set.

For instance, you form the character `\u0401` by joining two tokens:

```
#define assign(uc1, uc2, val) uc1##uc2 = val
...
assign(\u04, 01, 4);
```

#### Risk

The C11 Standard (Sec. 5.1.1.2) states that if a universal character name is formed by token concatenation, the behavior is undefined.

#### Fix

Use the universal character name directly instead of producing it through token concatenation.

#### Example - Universal Character Name from Token Concatenation

```
#define assign(uc1, uc2, val) uc1##uc2 = val

int func(void) {
    int \u0401 = 0;
    assign(\u04, 01, 4);  //Noncompliant
    return \u0401;
}
```

In this example, the `assign` macro, when expanded, joins the two tokens `\u04` and `01` to form the universal character name `\u0401`.

#### Correction — Use Universal Character Name Directly

One possible correction is to use the universal character name `\u0401` directly. The correction redefines the `assign` macro so that it does not join tokens.

```
#define assign(ucn, val) ucn = val

int func(void) {
    int \u0401 = 0;
    assign(\u0401, 4);
    return \u0401;
}
```

Avoid side effects in arguments to unsafe macros

## Description

### Rule Definition

*Avoid side effects in arguments to unsafe macros.*

### Polyspace Implementation

The rule checker checks for **Side effect in arguments to unsafe macro**.

## Examples

### Side effect in arguments to unsafe macro

#### Issue

**Side effect in arguments to unsafe macro** occurs when you call an unsafe macro with an expression that has a side effect.

- *Unsafe macro*: When expanded, an unsafe macro evaluates its arguments multiple times or does not evaluate its argument at all.

  For instance, the `ABS` macro evaluates its argument `x` twice.

  ```
  #define ABS(x) (((x) < 0) ? -(x) : (x))
  ```
- *Side effect*: When evaluated, an expression with a side effect modifies at least one of the variables in the expression.

  For instance, `++n` modifies `n`, but `n+1` does not modify `n`.

  The checker does not consider side effects in nested macros. The checker also does not consider function calls or volatile variable access as side effects.

#### Risk

If you call an unsafe macro with an expression that has a side effect, the expression is evaluated multiple times or not evaluated at all. The side effect can occur multiple times or not occur at all, causing unexpected behavior.

For instance, in the call `MACRO(++n)`, you expect only one increment of the variable `n`. If `MACRO` is an unsafe macro, the increment happens more than once or does not happen at all.

The checker flags expressions with side effects in the `assert` macro because the `assert` macro is disabled in non-debug mode. To compile in non-debug mode, you define the `NDEBUG` macro during compilation. For instance, in GCC, you use the flag `-DNDEBUG`.

#### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result as a macro argument.

For instance, instead of:

```
MACRO(++n);
```

perform the operation in two steps:

```
++n;
MACRO(n);
```

Alternatively, use an inline function instead of a macro. Pass the expression with side effect as argument to the inline function.

The checker considers modifications of a local variable defined only in the block scope of a macro body as a side effect. This defect cannot happen since the variable is visible only in the macro body. If you see a defect of this kind, ignore the defect.

**Example - Macro Argument with Side Effects**

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  int m = ABS(++n); //Noncompliant

  /* ... */
}
```

In this example, the ABS macro evaluates its argument twice. The second evaluation can result in an unintended increment.

**Correction — Separate Evaluation of Expression from Macro Usage**

One possible correction is to first perform the increment, and then pass the result to the macro.

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  ++n;
  int m = ABS(n);

  /* ... */
}
```

**Correction — Evaluate Expression in Inline Function**

Another possible correction is to evaluate the expression in an inline function.

```
static inline int iabs(int x) {
  return (((x) < 0) ? -(x) : (x));
}

void func(int n) {
  /* Validate that n is within the desired range */

int m = iabs(++n);

  /* ... */
}
```

Do not use preprocessor directives in invocations of function-like macros

## Description

### Rule Definition

*Do not use preprocessor directives in invocations of function-like macros.*

### Polyspace Implementation

The rule checker checks for **Preprocessor directive in macro argument**.

## Examples

### Preprocessor directive in macro argument

#### Issue

**Preprocessor directive in macro argument** occurs when you use a preprocessor directive in the argument to a function-like macro or a function that might be implemented as a function-like macro.

For instance, a `#ifdef` statement occurs in the argument to the function like macro `foo()`:

```
#define foo(X) //...
foo(
    #ifdef A
    "A"
    #else
    "B"
    #endif
  );
```

The checker reports a violation on this kind of usage of `#ifdef` statements. Violations are also reported when `#ifdef` statements are used as arguments of library functions that might be implemented as macros. Examples of library functions that might be implemented as macros include `assert()`, `memcpy()`, and `printf()`.

#### Risk

During preprocessing, a function-like macro call is replaced by the macro body and the parameters are replaced by the arguments to the macro call (argument substitution). Suppose a macro `min()` is defined as follows.

```
#define min(X, Y)  ((X) < (Y) ? (X) : (Y))
```

When you call `min(1,2)`, it is replaced by the body `((X) < (Y) ? (X) : (Y))`. `X` and `Y` are replaced by 1 and 2.

According to the C11 Standard (Sec. 6.10.3), if the list of arguments to a function-like macro itself has preprocessing directives, the argument substitution during preprocessing is undefined.

#### Fix

To ensure that the argument substitution happens in an unambiguous manner, use the preprocessor directives outside the function-like macro.

For instance, to execute `foo` with different arguments based on a `#ifdef` directive, call `foo` multiple times within the `#ifdef` directive branches.

```
#ifdef A
    foo("A");
#else
    foo("B")
#endif
```

#### Example - Directives in Function-Like Macros

In this example, the preprocessor directives `#ifdef` and `#endif` occur in the argument to the function-like macro `print()`. Polyspace reports violations on the preprocessor directives in macro arguments.

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
    print(
#ifdef SW //Noncompliant
          "Message 1"
#else
          "Message 2"
#endif //Noncompliant
         );
}
```

#### Correction — Use Directives Outside Macro

One possible correction is to use the function-like macro multiple times in the branches of the `#ifdef` directive.

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
#ifdef SW
        print("Message 1");
#else
        print("Message 2");
#endif
}
```

PRE32-C

# CERT C: Rule DCL30-C

Declare objects with appropriate storage durations

## Description

### Rule Definition

*Declare objects with appropriate storage durations.*

### Polyspace Implementation

The rule checker checks for **Pointer or reference to stack variable leaving scope**.

## Examples

### Pointer or reference to stack variable leaving scope

#### Issue

**Pointer or reference to stack variable leaving scope** occurs when a pointer or reference to a local variable leaves the scope of the variable. For instance:

- A function returns a pointer to a local variable.
- A function performs the assignment `globPtr = &locVar`. `globPtr` is a global pointer variable and `locVar` is a local variable.
- A function performs the assignment `*paramPtr = &locVar`. `paramPtr` is a function parameter that is, for instance, an `int**` pointer and `locVar` is a local `int` variable.
- A C++ method performs the assignment `memPtr = &locVar`. `memPtr` is a pointer data member of the class the method belongs to. `locVar` is a variable local to the method.

The defect also applies to memory allocated using the `alloca` function. The defect does not apply to static, local variables. Polyspace assumes that the local objects within a function definition are in the same scope.

#### Risk

Local variables are allocated an address on the stack. Once the scope of a local variable ends, this address is available for reuse. Using this address to access the local variable value outside the variable scope can cause unexpected behavior.

If a pointer to a local variable leaves the scope of the variable, Polyspace Bug Finder highlights the defect. The defect appears even if you do not use the address stored in the pointer. For maintainable code, it is a good practice to not allow the pointer to leave the variable scope. Even if you do not use the address in the pointer now, someone else using your function can use the address, causing undefined behavior.

#### Fix

Do not allow a pointer or reference to a local variable to leave the variable scope.

#### Example - Pointer to Local Variable Returned from Function

```
void func2(int *ptr) {
    *ptr = 0;
}

int* func1(void) {
    int ret = 0; //Noncompliant
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

In this example, `func1` returns a pointer to local variable `ret`.

In `main`, `ptr` points to the address of the local variable. When `ptr` is accessed in `func2`, the access is illegal because the scope of `ret` is limited to `func1`,

Declare identifiers before using them

## Description

### Rule Definition

*Declare identifiers before using them.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Types not explicitly specified**.
- **Implicit function declaration**.

This violation is reported on each use of a noncompliant identifier.

## Examples

### Types not explicitly specified

#### Issue

The rule checker flags situations where a function parameter or return type is not explicitly specified. To enable checking of this rule, use the value `c90` for the option `C standard version (-c-version)`.

#### Risk

In some circumstances, you can omit types from the C90 standard. In those cases, the `int` type is implicitly specified. However, the omission of an explicit type can lead to confusion. For example, in the declaration `extern void foo (char c, const k);`, the type of `k` is `const int`, but you might expect `const char`.

You might be using an implicit type in:

- Object declarations
- Parameter declarations
- Member declarations
- `typedef` declarations
- Function return types

#### Example - Implicit Types

```
static foo(int a);  /* Non compliant */
static void bar(void);      /* Compliant */
```

In this example, the rule is violated because the return type of `foo` is implicit.

### Implicit function declaration

**Issue**

The issue occurs when you call a function before you declare or define it.

**Risk**

An implicit declaration occurs when you call a function before declaring or defining it. When you declare a function explicitly before calling it, the compiler can match the argument and return types with the parameter types in the declaration. If an implicit declaration occurs, the compiler makes assumptions about the argument and return types. For instance, it assumes a return type of `int`. The assumptions might not agree with what you expect and cause undesired type conversions.

**Example - Function Not Declared Before Call**

```
#include <math.h>

extern double power3 (double val, int exponent);
int getChoice(void);

double func() {
    double res;
    int ch = getChoice();
    if(ch == 0) {
        res = power(2.0, 10);    /* Non-compliant */
    }
    else if( ch==1) {
        res = power2(2.0, 10);   /* Non-compliant */
    }
    else {
        res = power3(2.0, 10);   /* Compliant */
        return res;
    }
}

double power2 (double val, int exponent) {
    return (pow(val, exponent));
}
```

In this example, the rule is violated when a function that is not declared is called in the code. Even if a function definition exists later in the code, the rule violation occurs.

The rule is not violated when the function is declared before it is called in the code. If the function definition exists in another file and is available only during the link phase, you can declare the function in one of the following ways:

- Declare the function with the `extern` keyword in the current file.
- Declare the function in a header file and include the header file in the current file.

# CERT C: Rule DCL36-C

Do not declare an identifier with conflicting linkage classifications

## Description

### Rule Definition

*Do not declare an identifier with conflicting linkage classifications.*

### Polyspace Implementation

The rule checker checks for **Inconsistent use of static and extern in object declarations**.

## Examples

### Inconsistent use of `static` and `extern` in object declarations

#### Issue

The issue occurs when you do not use the `static` storage class specifier consistently in all declarations of object and functions that have internal linkage.

The rule checker detects situations where:

- The same object is declared multiple times with different storage specifiers.
- The same function is declared and defined with different storage specifiers.

#### Risk

If you do not use the `static` specifier consistently in all declarations of objects with internal linkage, you might declare the same object with external and internal linkage.

In this situation, the linkage follows the earlier specification that is visible (C99 Standard, Section 6.2.2). For instance, if the earlier specification indicates internal linkage, the object has internal linkage even though the latter specification indicates external linkage. If you notice the latter specification alone, you might expect otherwise.

#### Example - Linkage Conflict Between Variable Declarations

```
static int foo = 0;
extern int foo;         /* Non-compliant */

extern int hhh;
static int hhh;         /* Non-compliant */
```

In this example, the first line defines `foo` with internal linkage. The first line is compliant because the example uses the `static` keyword. The second line does not use `static` in the declaration, so the declaration is noncompliant. By comparison, the third line declares `hhh` with an `extern` keyword creating external linkage. The fourth line declares `hhh` with internal linkage, but this declaration conflicts with the first declaration of `hhh`.

#### Correction — Consistent `static` and `extern` Use

One possible correction is to use `static` and `extern` consistently:

```
static int foo = 0;
static int foo;

extern int hhh;
extern int hhh;
```

#### Example - Linkage Conflict Between Function Declaration and Definition

```
static int fee(void);  /* Compliant - declaration: internal linkage */
int fee(void){         /* Non-compliant */
  return 1;
}

static int ggg(void);  /* Compliant - declaration: internal linkage */
extern int ggg(void){  /* Non-compliant */
  return 1;
}
```

This example shows two internal linkage violations. Because `fee` and `ggg` have internal linkage, you must use a `static` class specifier to be compliant with MISRA.

# CERT C: Rule DCL37-C

Do not declare or define a reserved identifier

## Description

### Rule Definition

*Do not declare or define a reserved identifier.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Defining and undefining reserved identifiers or macros**.
- **Declaring a reserved identifier or macro name**.

If your code declares or defines a reserved identifier:

- If there is an explicit definition, Polyspace flags it.
- If there is no explicit definition, the compiler makes an implicit definition when your code uses the symbol. Polyspace flags such a use.

This violation is reported once for each noncompliant identifier.

## Examples

### Defining and undefining reserved identifiers or macros

#### Issue

The issue occurs when you use `#define` and `#undef` on a reserved identifier or reserved macro name.

#### Risk

Reserved identifiers and reserved macro names are intended for use by the implementation. Removing or changing the meaning of a reserved macro can result in undefined behavior. This rule applies to the following:

- Identifiers or macro names beginning with an underscore
- Identifiers in file scope described in the C Standard Library (ISO/IEC 9899:1999, Section 7, "Library")
- Macro names described in the C Standard Library as being defined in a standard header (ISO/IEC 9899:1999, Section 7, "Library").

#### Example - Defining or Undefining Reserved Identifiers

```
#undef __LINE__               /* Non-compliant - begins with _ */
#define _Guard_H 1            /* Non-compliant - begins with _ */
#undef _ BUILTIN_sqrt        /* Non-compliant - implementation may
                                * use _BUILTIN_sqrt for other purposes,
                               * e.g. generating a sqrt instruction */
#define defined               /* Non-compliant - reserved identifier */
#define errno my_errno        /* Non-compliant - library identifier */
#define isneg(x) ( (x) < 0 )  /* Compliant - rule doesn't include
                               * future library directions   */
```

#### Declaring a reserved identifier or macro name

**Issue**

The issue occurs when you declare a reserved identifier or macro name.

If you define a macro name that corresponds to a standard library macro, object, or function, Polyspace considers this a violation of the rule.

The rule considers tentative definitions as definitions.

**Risk**

The Standard allows implementations to treat reserved identifiers specially. If you reuse reserved identifiers, you can cause undefined behavior.

# CERT C: Rule DCL38-C

Use the correct syntax when declaring a flexible array member

## Description

### Rule Definition

*Use the correct syntax when declaring a flexible array member.*

### Polyspace Implementation

The rule checker checks for **Incorrect syntax of flexible array member size**.

## Examples

### Incorrect syntax of flexible array member size

#### Issue

**Incorrect syntax of flexible array member size** occurs when you do not use the standard C syntax to define a structure with a flexible array member.

Since C99, you can define a flexible array member with an unspecified size. For instance, `desc` is a flexible array member in this example:

```
struct record {
    size_t len;
    double desc[];
};
```

Prior to C99, you might have used compiler-specific methods to define flexible arrays. For instance, you used arrays of size one or zero:

```
struct record {
    size_t len;
    double desc[0];
};
```

This usage is not compliant with the C standards following C99.

#### Risk

If you define flexible array members by using size zero or one, your implementation is compiler-dependent. For compilers that do not recognize the syntax, an `int` array of size one has buffer for one `int` variable. If you try to write beyond this buffer, you can run into issues stemming from array access out of bounds.

If you use the standard C syntax to define a flexible array member, your implementation is portable across all compilers conforming with the standard.

#### Fix

To implement a flexible array member in a structure, define an array of unspecified size. The structure must have one member besides the array and the array must be the last member of the structure.

#### Example - Flexible Array Member Defined with Size One

```
#include <stdlib.h>

struct flexArrayStruct {
  int num;
  int data[1]; //Noncompliant
};

unsigned int max_size = 100;

void func(unsigned int array_size) {
  if(array_size<= 0 || array_size > max_size)
      exit(1);
  /* Space is allocated for the struct */
  struct flexArrayStruct *structP
    = (struct flexArrayStruct *)
     malloc(sizeof(struct flexArrayStruct)
          + sizeof(int) * (array_size - 1));
  if (structP == NULL) {
    /* Handle malloc failure */
    exit(2);
  }

  structP->num = array_size;

  /*
   * Access data[] as if it had been allocated
   * as data[array_size].
   */
  for (unsigned int i = 0; i < array_size; ++i) {
    structP->data[i] = 1;
  }

  free(structP);
}
```

In this example, the flexible array member `data` is defined with a size value of one. Compilers that do not recognize this syntax treat `data` as a size-one array. The statement `structP->data[i] = 1;` can write to `data` beyond the first array member and cause out of bounds array issues.

#### Correction — Use Standard C Syntax to Define Flexible Array

Define flexible array members with unspecified size.

```
#include <stdlib.h>

struct flexArrayStruct{
  int num;
  int data[];
};
```

```
unsigned int max_size = 100;

void func(unsigned int array_size) {
  if(array_size<=0 || array_size > max_size)
      exit(1);

  /* Allocate space for structure */
  struct flexArrayStruct *structP
    = (struct flexArrayStruct *)
    malloc(sizeof(struct flexArrayStruct)
         + sizeof(int) * array_size);

  if (structP == NULL) {
    /* Handle malloc failure */
    exit(2);
  }

  structP->num = array_size;

  /*
   * Access data[] as if it had been allocated
   * as data[array_size].
   */
  for (unsigned int i = 0; i < array_size; ++i) {
    structP->data[i] = 1;
  }

  free(structP);
}
```

Avoid information leakage in structure padding

## Description

### Rule Definition

*Avoid information leakage in structure padding.*

### Polyspace Implementation

The rule checker checks for **Information leak via structure padding**.

## Examples

### Information leak via structure padding

#### Issue

**Information leak via structure padding** occurs when you do not initialize the padding data of a structure or union before passing it across a trust boundary. A compiler adds padding bytes to the structure or union to ensure a proper memory alignment of its members. The bit-fields of the storage units can also have padding bits.

**Information leak via structure padding** raises a defect when:

- You call an untrusted function with structure or union pointer type argument containing uninitialized padding data.

  All external functions are considered untrusted.
- You copy or assign a structure or union containing uninitialized padding data to an untrusted object.

  All external structure or union objects, the output parameters of all externally linked functions, and the return pointer of all external functions are considered untrusted objects.

#### Risk

The padding bytes of the passed structure or union might contain sensitive information that an untrusted source can access.

#### Fix

- Prevent the addition of padding bytes for memory alignment by using the `pack` pragma or attribute supported by your compiler.
- Explicitly declare and initialize padding bytes as fields within the structure or union.
- Explicitly declare and initialize bit-fields corresponding to padding bits, even if you use the `pack` pragma or attribute supported by your compiler.

#### Example - Structure with Padding Bytes Passed to External Function

```
#include <stddef.h>
#include <stdlib.h>
```

```
#include <string.h>

typedef struct s_padding
{
 /* Padding bytes may be introduced between
 * 'char c' and 'int i'
 */
        char c;
    int i;

/*Padding bits may be introduced around the bit-fields
* even if you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/

    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
/*Padding bytes not initialized*/

    S_Padding s = {'A', 10, 1, 3, {}};
/*Structure passed to external function*/

    copy_object((void *)out_buffer, (void *)&s, sizeof(s)); //Noncompliant
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

In this example, structure `s1` can have padding bytes between the `char c` and `int i` members. The bit-fields of the storage units of the structure can also contain padding bits. The content of the padding bytes and bits is accessible to an untrusted source when `s1` is passed to `func`.

**Correction — Use pack Pragma to Prevent Padding Bytes**

One possible correction in Microsoft Visual Studio is to use `#pragma pack()` to prevent padding bytes between the structure members. To prevent padding bits in the bit-fields of `s1`, explicitly declare and initialize the bit-fields even if you use `#pragma pack()`.

```
 #include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>

#define CHAR_BIT 8

#pragma pack(push, 1)
```

```
typedef struct s_padding
{
/*No Padding bytes when you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
/* Padding bits explicitely declared */
    unsigned int bf_filler : sizeof(unsigned) * CHAR_BIT - 3;
    unsigned char buffer[20];
}

    S_Padding;

#pragma pack(pop)

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
    S_Padding s = {'A', 10, 1, 3, 0 /* padding bits */, {}};
    copy_object((void *)out_buffer, (void *)&s, sizeof(s));
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

Do not create incompatible declarations of the same function or object

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

### Rule Definition

*Do not create incompatible declarations of the same function or object.*

### Polyspace Implementation

The rule checker checks for **Declaration mismatch**.

## Examples

### Declaration mismatch

#### Issue

**Declaration mismatch** occurs when a function or variable declaration does not match other instances of the function or variable.

#### Risk

When a mismatch occurs between two variable declarations in different compilation units, a typical linker follows an algorithm to pick one declaration for the variable. If you expect a variable declaration that is different from the one chosen by the linker, you can see unexpected results when the variable is used.

A similar issue can occur with mismatch in function declarations.

#### Fix

The fix depends on the type of declaration mismatch. If both declarations indeed refer to the same object, use the same declaration. If the declarations refer to different objects, change the names of the one of the variables. If you change a variable name, remember to make the change in all places that use the variable.

Sometimes, declaration mismatches can occur because the declarations are affected by previous preprocessing directives. For instance, a declaration occurs in a macro, and the macro is defined on one inclusion path but undefined in another. These declaration mismatches can be tricky to debug. Identify the divergence between the two inclusion paths and fix the conflicting macro definitions.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Inconsistent Declarations in Two Files

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
double foo(void); //Noncompliant

int bar(void) {
    return (int)foo();
}
```

In this example, *file1.c* declares `foo()` as returning an integer. In *file2.c*, `foo()` is declared as returning a double. This difference might cause a compilation failure. Polyspace raises a defect on the second instance of `foo` in *file2*.

#### Correction — Align the Function Return Values

One possible correction is to change the function declarations so that they match. In this example, by changing the declaration of `foo` in *file2.c* to match *file1.c*, the defect is fixed.

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
int foo(void);

int bar(void) {
    return foo();
}
```

#### Example - Inconsistent Structure Alignment

*test1.c*

```
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*test2.c*

```
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square; //Noncompliant

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

In this example, a declaration mismatch defect is raised on `square` in *square.h* because Polyspace infers that `square` in *square.h* does not have the same alignment as `square` in *test2.c*. This error occurs because the `#pragma pack(1)` statement in *circle.h* declares specific alignment. In *test2.c*, *circle.h* is included before *square.h*. Therefore, the `#pragma pack(1)` statement from *circle.h* is not reset to the default alignment after the `aCircle` structure. Because of this omission, *test2.c* infers that the `aSquare square` structure also has an alignment of `1` byte. This defect might cause a compilation failure.

#### Correction — Close Packing Statements

One possible correction is to reset the structure alignment after the `aCircle` struct declaration. For the GNU or Microsoft Visual compilers, fix the defect by adding a `#pragma pack()` statement at the end of *circle.h*.

*test1.c*

```
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*test2.c*

```
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;

#pragma pack()
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

Other compilers require different `#pragma pack` syntax. For your syntax, see the documentation for your compiler.

#### Correction — Use the `Ignore pragma pack directives` Option

One possible correction is to add the `Ignore pragma pack directives` option to your Bug Finder analysis. If you want the structure alignment to change for each structure, and you do not want to see this **Declaration mismatch** defect, use this correction.

1. On the Configuration pane, select the **Advanced Settings** pane.
2. In the **Other** box, enter `-ignore-pragma-pack`.

3 Rerun your analysis.

The **Declaration mismatch** defect is resolved.

Do not declare variables inside a switch statement before the first case label

## Description

### Rule Definition

*Do not declare variables inside a switch statement before the first case label.*

### Polyspace Implementation

The rule checker checks for **variable declaration before first `case` label**.

## Examples

### Variable declaration before first case label

**Issue**

The issue occurs when you define a variable in a `switch` block before the first `case` label.

**Risk**

In a `switch` block, control jumps to one of the `case` labels or a `default` label, depending on the control expression of the `switch` statement. If you define a variable before the first `case` label, the compiler ignores the variable declaration. Read operations on this variable can lead to indeterminate values.

**Example — Noncompliant Variable Declaration**

```
void bar(int iTemp){
    //...
}
void foo(){
    //...
    int bFlag;
    //...
    switch(bFlag){
        int temp;  //Noncompliant
        bar (temp);
    case 0:
            //...
        break;
    case 1:
            //...
        break;

    }

}
```

In this example, the variable `temp` is declared before the first `case` label. The compiler ignores this declaration. If you perform a read operation on `temp` in one of the case blocks, the operation might lead to indeterminate values. Polyspace flags the variable declaration.

#### Example — Compliant switch Statement

To fix the preceding issue, move the variable declaration out of the `switch` statement.

```
void bar(int iTemp){
    //...
}
void foo(){
    //...
    int bFlag;
    //...
    int temp;//Compliant
    bar (temp);
    switch(bFlag){

    case 0://...
        break;
    case 1:
        break;
    }
}
```

Do not depend on the order of evaluation for side effects

## Description

### Rule Definition

*Do not depend on the order of evaluation for side effects.*

### Polyspace Implementation

The rule checker checks for **Expression value depends on order of evaluation or of side effects**.

## Examples

### Expression value depends on order of evaluation or of side effects

**Issue**

The issue occurs when the value of an expression and its persistent side effects is not the same under all permitted evaluation orders.

An expression can have different values under the following conditions:

- The same variable is modified more than once in the expression, or is both read and written.
- The expression allows more than one order of evaluation.
- The expression contains a single `volatile` object that occurs multiple times.
- The expression contains more than one `volatile` object.

Therefore, this rule forbids expressions where a variable is modified more than once and can cause different results under different orders of evaluation.

**Risk**

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

**Example - Variable Modified More Than Once in Expression**

```
int a[10], b[10];
#define COPY_ELEMENT(index) (a[(index)]=b[(index)])

void main () {
    int i=0, k=0;

    COPY_ELEMENT (k);         /* Compliant */
    COPY_ELEMENT (i++);       /* Noncompliant  */
}
```

In this example, the rule is violated by the statement `COPY_ELEMENT(i++)` because `i++` occurs twice and the order of evaluation of the two expressions is unspecified.

#### Example - Variable Modified and Used in Multiple Function Arguments

```
void f (unsigned int param1, unsigned int param2) {}

void main () {
    unsigned int i=0;
    f ( i++, i );                 /* Non-compliant */
}
```

In this example, the rule is violated because it is unspecified whether the operation `i++` occurs before or after the second argument is passed to `f`. The call `f(i++,i)` can translate to either `f(0,0)` or `f(0,1)`.

#### Multiple `volatile` Objects in an Expression

```
volatile int a, b;
int mathOp(int x, int y);

int foo(void){
    int temp = mathOp(5,a) + mathOp(6,b);//Noncompliant
    return temp * mathOp(a,a);//Noncompliant
}
```

In this example, this rule is violated twice.

- The declaration of `temp` uses two `volatile` objects in the expression. Because the value of `volatile` objects might change at any time, the expression might evaluate to different values depending on the order of evaluation. Polyspace flags the second `volatile` object in the expression.
- The `return` statement uses the same `volatile` object twice. Because the expression might have different results depending on the order of evaluation, Polyspace raises this defect.

Do not access a volatile object through a nonvolatile reference

## Description

### Rule Definition

*Do not access a volatile object through a nonvolatile reference.*

### Polyspace Implementation

The rule checker checks for **Cast to pointer that removes volatile qualification**.

## Examples

### Cast to pointer that removes `volatile` qualification

**Issue**

Polyspace flags both implicit and explicit conversions that violate this rule.

**Risk**

This rule forbids casts from a pointer to a `volatile` object to a pointer that does not point to a `volatile` object. Such casts violate type qualification.

**Example - Casts That Remove Qualifiers**

```
void foo(void) {
    volatile unsigned short *pvi;    /* pointer to volatile  */
    unsigned short          *pi;

    pi  = (unsigned short *)  pvi;   /* Non-compliant */

}
```

In this example, the variable `pvi` has a `volatile` qualifier in its type. The rule is violated when the variable is cast to a type that does not have the `volatile` qualifier.

Do not read uninitialized memory

## Description

### Rule Definition

*Do not read uninitialized memory.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Non-initialized pointer**.
- **Non-initialized variable**.

### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See “Extend Checkers for Initialization to Check Function Arguments Passed by Pointers”.
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Non-initialized pointer

#### Issue

**Non-initialized pointer** occurs when a pointer is not assigned an address before dereference.

#### Risk

Unless a pointer is explicitly assigned an address, it points to an unpredictable location.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned an address to the pointer but the assignment is unreachable.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a pointer to NULL when declaring the pointer.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Non-initialized pointer error**

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL) 
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j;                     //Noncompliant
    /* Defect: Writing to uninitialized pointer */

    return pi;
}
```

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not.

**Correction — Initialize Pointer on Every Execution Path**

One possible correction is to assign an address to `pi` when `prev` is not `NULL`.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL) 
       {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
       }
    /* Fix: Initialize pi in branches of if statement  */
    else 
        pi = prev;

    *pi = j;

    return pi;
}
```

### Non-initialized variable

#### Issue

**Non-initialized variable** occurs when a variable is not initialized before its value is read.

#### Risk

Unless a variable is explicitly initialized, the variable value is unpredictable. You cannot rely on the variable having a specific value.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned a value to the variable but the assignment is unreachable or you assigned a value to the variable in one of two branches of a conditional statement. Fix the unreachable code or missing assignment.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a variable at declaration.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Non-initialized variable error

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;               //Noncompliant
    /* Defect: val does not have a value if command is not 2 */
}
```

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

#### Correction — Initialize During Declaration

One possible correction is to initialize `val` during declaration so that the initialization is not bypassed on some execution paths.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    /* Fix: Initialize val */
    int val=0;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
 }
```

`val` is assigned an initial value of 0. When `command` is not equal to 2, the function `get_sensor_value` returns this value.

Do not dereference null pointers

## Description

### Rule Definition

*Do not dereference null pointers.*

### Polyspace Implementation

The rule checker checks for **Null pointer**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Null pointer

#### Issue

**Null pointer** occurs when you use a pointer with a value of `NULL` as if it points to a valid memory location.

#### Risk

Dereferencing a null pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

#### Fix

Check a pointer for `NULL` before dereference.

If the issue occurs despite an earlier check for `NULL`, look for intermediate events between the check and the subsequent dereference. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

#### Example - Null pointer error

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
```

```
{
 int* p=NULL;

 *p=arr[0]; //Noncompliant
 /* Defect: Null pointer dereference */

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

The pointer `p` is initialized with value of `NULL`. However, when the value `arr[0]` is written to `*p`, `p` is assumed to point to a valid memory location.

**Correction — Assign Address to Null Pointer Before Dereference**

One possible correction is to initialize `p` with a valid memory address before dereference.

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 /* Fix: Assign address to null pointer */
 int* p=&arr[0];

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

EXP34-C

# CERT C: Rule EXP35-C

Do not modify objects with temporary lifetime

## Description

### Rule Definition

*Do not modify objects with temporary lifetime.*

### Polyspace Implementation

The rule checker checks for **Accessing object with temporary lifetime**.

## Examples

### Accessing object with temporary lifetime

#### Issue

**Accessing object with temporary lifetime** occurs when you attempt to read from or write to an object with temporary lifetime that is returned by a function call. In a structure or union returned by a function, and containing an array, the array members are temporary objects. The lifetime of temporary objects ends:

- When the full expression or full declarator containing the call ends, as defined in the C11 Standard.
- After the next sequence point, as defined in the C90 and C99 Standards. A sequence point is a point in the execution of a program where all previous evaluations are complete and no subsequent evaluation has started yet.

For C++ code, **Accessing object with temporary lifetime** raises a defect only when you write to an object with a temporary lifetime.

If the temporary lifetime object is returned by address, no defect is raised.

#### Risk

Modifying objects with temporary lifetime is undefined behavior and can cause abnormal program termination and portability issues.

#### Fix

Assign the object returned from the function call to a local variable. The content of the temporary lifetime object is copied to the variable. You can now modify it safely.

#### Example - Modifying Temporary Lifetime Object Returned by Function Call

```
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6
```

```
struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

/* func_temp() returns a struct value containing
* an array with a temporary lifetime.
*/
int func(void) {

/*Writing to temporary lifetime object is
 undefined behavior
 */
    return ++(func_temp().a[0]);  //Noncompliant
}

void main(void) {
    (void)func();
}
```

In this example, `func_temp()` returns by value a structure with an array member `a`. This member has temporary lifetime. Incrementing it is undefined behavior.

**Correction — Assign Returned Value to Local Variable Before Writing**

One possible correction is to assign the return of the call to `func_temp()` to a local variable. The content of the temporary object `a` is copied to the variable, which you can safely increment.

```
 #include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

int func(void) {

/* Assign object returned by function call to
 *local variable
 */
    struct S_Array s = func_temp();

/* Local variable can safely be
 *incremented
 */
    ++(s.a[0]);
    return s.a[0];
}

void main(void) {
    (void)func();
}
```

Do not cast pointers into more strictly aligned pointer types

## Description

### Rule Definition

*Do not cast pointers into more strictly aligned pointer types.*

### Polyspace Implementation

This checker checks for **Source buffer misaligned with destination buffer**

## Examples

### Source buffer misaligned with destination buffer

#### Issue

The issue **Source buffer misaligned with destination buffer** occurs when the source pointer and the target pointer in a pointer-to-pointer conversion do not align. The misalignment occurs for reasons such as:

- The source pointer points to a buffer that is smaller than what the target pointer points to.
- The source pointer points to a buffer that is larger than what the target pointer points to, but the buffer size is not an exact multiple of the destination buffer size.
- The source pointer is a `void *` pointer and the target pointer is not. Polyspace does not report violations on casts and implicit conversion from `NULL` and `(void*)0`.

Polyspace does not report violations of this rule if:

- You use an environment that allows conversion between misaligned pointers. For instance, in 32bit and 64bit `x86` environment, converting `char*` into `uint16_t*` does not terminate a program abnormally.
- You use a source pointer that aligns correctly to the target type. For instance:
  - You use the `alignas` specifier to match the alignment of the source pointer with that of the target pointer.
  - You use pointers returned by functions such as `aligned_alloc()`, `malloc()`, and `realloc()`. These pointers matches the alignment of the target pointer.

#### Risk

If the alignment of a pointer changes in a pointer-to-pointer conversion, dereferencing the converted pointer causes abnormal program termination.

#### Fix

Avoid changing the alignment of a pointer in a pointer-to-pointer conversion.

**Example — Change in Pointer Alignment During Conversion**

```
#include <string.h>
struct record {
  int len;
  /* ... */
};

int copyBuffer (char *data, int offset)
{
  struct record *tmp;
  struct record dest;
  tmp = (struct record *) (data + offset);   //Noncompliant
  memcpy (&dest, tmp, sizeof (dest));
  /* ... */

  return dest.len;
}
```

In this example, the function copyBuffer converts a char* pointer into a struct record* pointer, followed by a memcpy operation. The memcpy operation assumes a struct record* alignment of tmp, which leads to undefined behavior. The rule checker reports a violation of this rule.

To avoid the issue, use data + offset as the source argument of the memcpy operation instead of using an intermediate struct record* pointer.

**Example — Conversion from void* to int***

```
int *lookup (void *loc)
{
  /* ... */
  return loc; //Noncompliant
}

void search (char *pos)
{
  int *found = lookup (pos);
}
```

In this example, the lookup function has a void* parameter, but converts the parameter into an int* pointer when returning. In the function search(), calling the function lookup() with a char* pointer results in a conversion between a char* pointer and an int* pointer. Polyspace reports a violation of this rule.

**Example — Use alignas Specifier to Avoid Alignment Mismatch**

This example aligns the char pointer char_p as an int by using the alignas specifier. Because char_p is aligned as an int, converting it to an int* does not violate this rule.

```
#include <stdalign.h>
#include <assert.h>

void foo(void) {
  /* Align char_p to the alignment of an int */
  alignas(int) char char_p = 'a';
  int *int_p = (int *)&char_p; //Compliant
  char *char_new = (char *)int_p;
  /* Both char_new and &char_p point to equally aligned objects */
}
```

## Check Information

EXP36-C

# CERT C: Rule EXP37-C

Call functions with the correct number and type of arguments

## Description

### Rule Definition

*Call functions with the correct number and type of arguments.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Bad file access mode or status**.
- **Unreliable cast of function pointer**.
- **Standard function call with incorrect arguments**.
- **Unsupported complex arguments**
- **Function declaration mismatch**
- **Incompatible argument**

## Examples

### Bad file access mode or status

#### Issue

**Bad file access mode or status** occurs when you use functions in the `fopen` or `open` group with invalid or incompatible file access modes, file creation flags, or file status flags as arguments. For instance, for the `open` function, examples of valid:

- Access modes include `O_RDONLY`, `O_WRONLY`, and `O_RDWR`
- File creation flags include `O_CREAT`, `O_EXCL`, `O_NOCTTY`, and `O_TRUNC`.
- File status flags include `O_APPEND`, `O_ASYNC`, `O_CLOEXEC`, `O_DIRECT`, `O_DIRECTORY`, `O_LARGEFILE`, `O_NOATIME`, `O_NOFOLLOW`, `O_NONBLOCK`, `O_NDELAY`, `O_SHLOCK`, `O_EXLOCK`, `O_FSYNC`, `O_SYNC` and so on.

The defect can occur in the following situations.

| Situation | Risk | Fix |
|---|---|---|
| You pass an empty or invalid access mode to the `fopen` function.<br>According to the ANSI C standard, the valid access modes for `fopen` are:<br>• `r`,`r+`<br>• `w`,`w+`<br>• `a`,`a+`<br>• `rb`, `wb`, `ab`<br>• `r+b`, `w+b`, `a+b`<br>• `rb+`, `wb+`, `ab+` | `fopen` has undefined behavior for invalid access modes.<br>Some implementations allow extension of the access mode such as:<br>• GNU: `rb+cmxe,ccs=utf`<br>• Visual C++: `a+t`, where `t` specifies a text mode.<br>However, your access mode string must begin with one of the valid sequences. | Pass a valid access mode to `fopen`. |
| You pass the status flag `O_APPEND` to the `open` function without combining it with either `O_WRONLY` or `O_RDWR`. | `O_APPEND` indicates that you intend to add new content at the end of a file. However, without `O_WRONLY` or `O_RDWR`, you cannot write to the file.<br>The `open` function does not return -1 for this logical error. | Pass either `O_APPEND\|O_WRONLY` or `O_APPEND\|O_RDWR` as access mode. |
| You pass the status flags `O_APPEND` and `O_TRUNC` together to the `open` function. | `O_APPEND` indicates that you intend to add new content at the end of a file. However, `O_TRUNC` indicates that you intend to truncate the file to zero. Therefore, the two modes cannot operate together.<br>The `open` function does not return -1 for this logical error. | Depending on what you intend to do, pass one of the two modes. |
| You pass the status flag `O_ASYNC` to the `open` function. | On certain implementations, the mode `O_ASYNC` does not enable signal-driven I/O operations. | Use the `fcntl(pathname, F_SETFL, O_ASYNC);` instead. |

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.

- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Invalid Access Mode with fopen

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "rw"); //Noncompliant
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

In this example, the access mode `rw` is invalid. Because `r` indicates that you open the file for reading and `w` indicates that you create a new file for writing, the two access modes are incompatible.

#### Correction — Use Either r or w as Access Mode

One possible correction is to use the access mode corresponding to what you intend to do.

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "w");
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

### Unreliable cast of function pointer

#### Issue

**Unreliable cast of function pointer** occurs when a function pointer is cast to another function pointer that has different argument or return type.

This defect applies only if the code language for the project is C.

#### Risk

If you cast a function pointer to another function pointer with different argument or return type and then use the latter function pointer to call a function, the behavior is undefined.

#### Fix

Avoid a cast between two function pointers with mismatch in argument or return types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.

- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Unreliable cast of function pointer error**

```
#include <stdio.h>
#include <math.h>
#include <stdio.h>
#define PI 3.142

double Calculate_Sum(int (*fptr)(double))
{
    double  sum = 0.0;
    double  y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);  //Noncompliant
    /* Defect: fp implicitly cast to int(*) (double) */

    printf("sum(sin): %f\n", sum);
    return 0;
}
```

The function pointer `fp` is declared as `double (*)(double)`. However in passing it to function `Calculate_Sum`, `fp` is implicitly cast to `int (*)(double)`.

**Correction — Avoid Function Pointer Cast**

One possible correction is to check that the function pointer in the definition of `Calculate_Sum` has the same argument and return type as `fp`. This step makes sure that `fp` is not implicitly cast to a different argument or return type.

```
#include <stdio.h>
#include <math.h>
#include <stdio.h>
# define PI 3.142

/*Fix: fptr has same argument and return type everywhere*/
double Calculate_Sum(double (*fptr)(double))
{
    double  sum = 0.0;
    double y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);
    printf("sum(sin): %f\n", sum);

    return 0;
}
```

### Standard function call with incorrect arguments

#### Issue

**Standard function call with incorrect arguments** occurs when the arguments to certain standard functions do not meet the requirements for their use in the functions.

For instance, the arguments to these functions can be invalid in the following ways.

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| String manipulation functions such as `strlen` and `strcpy` | The pointer arguments do not point to a `NULL`-terminated string. | The behavior of the function is undefined. | Pass a `NULL`-terminated string to string manipulation functions. |
| File handling functions in `stdio.h` such as `fputc` and `fread` | The `FILE*` pointer argument can have the value `NULL`. | The behavior of the function is undefined. | Test the `FILE*` pointer for `NULL` before using it as function argument. |
| File handling functions in `unistd.h` such as `lseek` and `read` | The file descriptor argument can be -1. | The behavior of the function is undefined.<br>Most implementations of the `open` function return a file descriptor value of -1. In addition, they set `errno` to indicate that an error has occurred when opening a file. | Test the return value of the `open` function for -1 before using it as argument for `read` or `lseek`.<br>If the return value is -1, check the value of `errno` to see which error has occurred. |

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| | The file descriptor argument represents a closed file descriptor. | The behavior of the function is undefined. | Close the file descriptor only after you have completely finished using it. Alternatively, reopen the file descriptor before using it as function argument. |
| Directory name generation functions such as `mkdtemp` and `mkstemps` | The last six characters of the string template are not XXXXXX. | The function replaces the last six characters with a string that makes the file name unique. If the last six characters are not XXXXXX, the function cannot generate a unique enough directory name. | Test if the last six characters of a string are XXXXXX before using the string as function argument. |
| Functions related to environment variables such as `getenv` and `setenv` | The string argument is `""`. | The behavior is implementation-defined. | Test the string argument for `""` before using it as `getenv` or `setenv` argument. |
| | The string argument terminates with an equal sign, =. For instance, `"C="` instead of `"C"`. | The behavior is implementation-defined. | Do not terminate the string argument with =. |
| String handling functions such as `strtok` and `strstr` | • `strtok`: The delimiter argument is `""`.<br>• `strstr`: The search string argument is `""`. | Some implementations do not handle these edge cases. | Test the string for `""` before using it as function argument. |

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - NULL Pointer Passed as strnlen Argument

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};

int func() {
    char* s = NULL;
    return strnlen(s, SIZE20); //Noncompliant
}
```

In this example, a NULL pointer is passed as strnlen argument instead of a NULL-terminated string.

Before running analysis on the code, specify a GNU compiler. See Compiler (-compiler).

#### Correction — Pass NULL-terminated String

Pass a NULL-terminated string as the first argument of strnlen.

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};

int func() {
    char* s = "";
    return strnlen(s, SIZE20);
}
```

### Unsupported complex arguments

#### Issue

**Unsupported complex arguments** occurs when these functions are called with a complex argument:

- atan2
- erf
- fdim
- fmin
- ilogb
- llround
- logb
- nextafter
- rint
- tgamma

- `cbrt`
- `erfc`
- `floor`
- `fmod`
- `ldexp`
- `log10`
- `lrint`
- `nexttoward`
- `round`
- `trunc`
- `ceil`
- `exp2`
- `fma`
- `frexp`
- `lgamma`
- `log1p`
- `round`
- `remainder`
- `scalbn`
- `copysign`
- `expm1`
- `fmax`
- `hypot`
- `llrint`
- `log2`
- `nearbyint`
- `remquo`
- `scalbln`

**Risk**

Calling any of the preceding functions with a `complex` argument is undefined behavior in the C++ standard, which might lead to unexpected results. Because some mathematical functions support `complex` arguments while the functions in the preceding list do not, the unexpected results might be difficult to debug. Performing some of these mathematical operations on a `complex` number might not be mathematically sound, which indicates an issue in the underlying logic of your code.

**Fix**

Avoid calling the preceding functions with a `complex` input argument. To perform the preceding mathematical operations on a complex number, define alternative functions that support `complex` arguments.

**Example — Calling `log2` and `trunc` Functions with Complex Arguments**

```
#include <complex.h>
#include <tgmath.h>
```

```
typedef double complex cDouble;
cDouble Noncompliant (void)
{
    cDouble Z = 2.0 + 4.0 * I;
    cDouble result = log2 (Z); //Noncompliant
    return trunc(result);//Noncompliant
}
```

In this example, the function `Noncompliant` calculates the base two logarithm of a complex number, truncates the result, and returns it. The functions `log2` and `trunc` do not support a complex argument. Polyspace flags these operations. To run this example, specify `gnu6.x` as the compiler. For instance, in the command line, use the option `-compiler gnu6.x`.

#### Correction — Define Functions That Support Complex Arguments

One possible correction is to define alternative functions that support complex numbers. For instance, while `log2` does not support `complex` numbers, the function `log` does. Define a function `complexLog2` that uses `log` to calculate the base two logarithm of a complex number. Similarly, `trunc` does not support `complex` numbers and the mathematical rule for truncating a complex number is not well-defined. Define a function `complexTrunc` that truncates a complex number by truncating its real and imaginary parts separately.

```
#include <complex.h>
#include <tgmath.h>
typedef double complex cDouble;

cDouble complexLog2(cDouble z) {
    return log (z) / log (2);  // Compliant
}

cDouble complexTrunc(cDouble z){
    return trunc(creal(z)) + I*trunc(cimag(z));  //Compliant
}

cDouble Compliant (void)
{
    cDouble Z = 2.0 + 4.0 * I;
    cDouble result = complexLog2 (Z); //Compliant
    return complexTrunc(result);//Compliant
}
```

### Function declaration mismatch

#### Issue

**Function declaration mismatch** occurs when the prototype of a function does not match its definition. If a function lacks a prototype in the file where it is called, Polyspace deduces its prototype based on the signature of the call. If the deduced prototype does not match the definition of the function, Polyspace raises this defect. The prototype of a variadic function cannot be deduced from its function call. If you call a variadic function without specifying its prototype in the same file, Polyspace raises this defect.

When deducing the prototype of a function from a call to such a function, Polyspace makes these assumptions:

- The number of arguments of the deduced prototype is equal to the input argument of the function call.

- The argument types of the deduced prototype are set by implicitly promoting the argument types of the function call. For instance, both signed and unsigned `char` or `short` type arguments are promoted to `int`. Similarly `float` type arguments are promoted to `double`.
- Type mismatch between the arguments of the function definition and the function prototype might depend on your environment. Polyspace considers two types as compatible if they have the same size and signedness in the environment that you use. For instance, if your specify `-target` as i386, Polyspace considers `long` and `int` as compatible types.

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

**Risk**

According to the C standard, function declaration mismatch might result in undefined behavior even though such code might compile successfully producing only warnings during compilation. Because code with this issue might compile successfully, function declaration mismatches might result in unexpected results that are difficult to diagnose.

**Fix**

- Before you call a function, provide its complete prototype, even if you define the function later in the same file.
- Avoid any mismatch between the number arguments in the function prototype declaration and the function definition.
- Avoid any mismatch between the argument types of the function prototype declaration and the function definition.

When complete prototypes of the called functions are provided, the compiler tries to resolve any function declaration mismatches through implicit casting. If the compiler fails to resolve the mismatch, the compilation fails, which prevents unexpected behavior. To fix such compile errors, call the functions using argument types and numbers that match the function definition.

**Example — Function Calls That Lack Prototypes**

```
// file1.c
void foo(int iVar){
    //...
}
void bar(float fVar1, float fVar2){
    //...
}
void bar2(float fVar1){
    //...
}
void fubar(const char* str,...){
    //...
}
void foo2(char cVar){
    //...
}
void call_variadic(){
    fubar("String");
}
```

```
//file2.c
void bar2(float);
void foo2(int);
void call_funcs(){
    int iTemp;
    float fTemp;
    foo();//Noncompliant
    bar(fTemp,fTemp);//Noncompliant
    fubar("String"); //Noncompliant
    bar2(iTemp);//Compliant
    foo2(iTemp); //Noncompliant
}
```

In this example, the functions foo, foo2, bar, bar2, and fubar are defined in the file file1.c. These functions are then called in the file file2.c.

- The function foo is defined in file1.c with one int input and called in file2.c without any input. Because file2.c does not have a prototype for foo, Polyspace deduces a prototype based on the call foo(), which takes no input. This deduced prototype does not match the function declaration in file1.c. Polyspace flags the call.
- The function bar is defined in file1.c with two float inputs and called in file2.c with two float inputs. Because file2.c does not have a prototype for bar, Polyspace deduces a prototype based on the call bar(fTemp,fTemp). By promoting the argument types of the function call, the signature of this deduced prototype is bar(double, double), which does not match the function declaration in file1.c. Polyspace flags the call.
- The function bar2 is defined in file1.c with one float input. The complete prototype for bar2, which matches the definition, is provided in file2.c. Because a complete prototype is present in this file, when bar2 is called with an incorrect input, the compiler implicitly converts the int input iTemp into a float. Because the call to the function matches the declaration after an implicit conversion facilitated by the prototype, Polyspace does not flag the call.
- The function foo2 is defined in file1.c with a char input. Its prototype in file2.c is defined with a int input. Because the definition and the prototype do not match, Polyspace flags the call to foo2.
- The variadic function fubar is defined in file1.c. The call to it in call_variadic is compliant because the call comes after the definition. The function fubar does not have a prototype in file2.c. Because the function takes a variable number of inputs, its prototype cannot be deduced. The call to fubar in file2.c lacks a prototype and Polyspace flags the call.

#### Correction — Compliant Function Calls

The fix for this defect is to declare complete prototypes for the called functions in all compilation modules. It is a best practice to combine the function prototype declarations in a header file, and then include it in files where the functions are called. In this case, resolve the flagged issues by including such a header file prototype.h in file2.c. Once a correct prototype is declared, the call foo() in file2.c causes a compilation failure because the compiler cannot resolve the mismatch between the call and the declared prototype. Call foo with an int to resolve the compilation failure.

```
// file1.c
void foo(int iVar){
    //...
}
void bar(float fVar1, float fVar2){
    //...
}
void bar2(float fVar1){
    //...
}
void fubar(const char* str,...){
    //...
}
void foo2(char cVar){
    //...
}
void call_variadic(){
    fubar("String");
}
```

```
//prototypes.h
void foo(int iVar);
void bar(float fVar1, float fVar2);
void fubar(const char* str,...);
void bar2(float);
void foo2(char);
void call_variadic(void);
void call_funcs(void);
```

```
//file2.c
#include"prototype.h"
void call_funcs(){
    int iTemp;
    float fTemp;
    //foo(); This call results in compile failure
    foo(iTemp);//Compliant
    bar(fTemp,fTemp);//Compliant
    fubar("String"); //Compliant
    bar2(iTemp);//Compliant
    foo2('a'); //Compliant
}
```

### Incompatible argument

#### Issue

**Incompatible argument** occurs when an external function is called by using an argument that is not compatible with the prototype. The compatibility of types might depend on the set of hardware and software that you use. For instance, consider this code:

```
extern long foo(int);

long bar(long i) {
    return foo(i); //Noncompliant: calls foo(int) with a long
}
```

The external function `foo` is called with a `long` when an `int` is expected. In environments where the size of an `int` is smaller than the size of a `long`, this function call is incompatible with the prototype, resulting in a defect.

#### Risk

Calling external functions with arguments that are incompatible with the parameter is undefined behavior. Depending on your environment, the code might compile but behave in an unexpected way.

#### Fix

When calling external functions, use argument types that are smaller or equal in size compared to the parameter type defined in the prototype. Check the sizes of various integer types in your environment to determine compatibility of argument and parameter types.

#### Example — Call External Functions with Incompatible argument

```
extern long foo1(int);
extern long foo2(long);
void bar(){
    int varI;
    long varL;
    foo1(varL);//Noncompliant
    foo2(varI);//Compliant
}
```

In this example, the external function `foo1` is called with a `long` argument, while the prototype specifies the parameter as an `int`. In `x86` architecture, the size of `long` is larger than the size of `int`. The call `foo1(varL)` might result in undefined behavior. Polyspace flags the call. The call `foo2(varI)` uses an `int` argument while the parameter is specified as a `long`. This type of mismatch is compliant with this rule because the size of `int` is not larger than the size of `long`.

To run this example in Polyspace, use these options:

- `-lang c`
- `-target x86_64`

See `Target processor type (-target)`.

#### Correction — Cast Variables Explicitly to Match Argument to Parameter

To fix this issue, cast the argument of `foo1` explicitly so that argument type and parameter type matches.

```
extern long foo1(int);
extern long foo2(long);
void bar(){
    int varI;
    long varL;
    foo1((int)varL);//Compliant
    foo2(varI);//Compliant
}
```

Do not access a variable through a pointer of an incompatible type

## Description

### Rule Definition

*Do not access a variable through a pointer of an incompatible type.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Cast to pointer pointing to object of different type**
- **Reading memory reallocated from object of another type without reinitializing first**

.

## Examples

### Cast to pointer pointing to object of different type

#### Issue

The issue occurs when you perform a cast between a pointer to an object type and a pointer to a different object type.

#### Risk

If a pointer to an object is cast into a pointer to a different object, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.

Even if the conversion produces a pointer that is correctly aligned, the behavior can be undefined if the pointer is used to access an object.

Exception: You can convert a pointer to object type into a pointer to one of the following types:

- `char`
- `signed char`
- `unsigned char`

#### Example - Noncompliant: Cast to Pointer Pointing to Object of Wider Type

```
signed   char *p1;
unsigned int *p2;

void foo(void){
  p2 = ( unsigned int * ) p1;     /* Non-compliant */
}
```

In this example, `p1` can point to a `signed char` object. However, `p1` is cast to a pointer that points to an object of wider type, `unsigned int`.

#### Example - Noncompliant: Cast to Pointer Pointing to Object of Narrower Type

```
extern unsigned int read_value ( void );
extern void display ( unsigned int n );

void foo ( void ){
  unsigned int u = read_value ( );
  unsigned short *hi_p = ( unsigned short * ) &u;    /* Non-compliant  */
  *hi_p = 0;
  display ( u );
}
```

In this example, u is an `unsigned int` variable. &u is cast to a pointer that points to an object of narrower type, `unsigned short`.

On a big-endian machine, the statement `*hi_p = 0` attempts to clear the high bits of the memory location that &u points to. But, from the result of `display(u)`, you might find that the high bits have not been cleared.

#### Example - Compliant: Cast Adding a Type Qualifier

```
const short *p;
const volatile short *q;
void foo (void){
  q = ( const volatile short * ) p;  /* Compliant */
}
```

In this example, both p and q can point to `short` objects. The cast between them adds a `volatile` qualifier only and is therefore compliant.

### Reading memory reallocated from object of another type without reinitializing first

#### Issue

This issue occurs when you do the following in sequence:

1. Reallocate memory to an object with a type that is different from the original allocation.

   For instance, in this code snippet, a memory originally allocated to a pointer with type `struct A*` is reallocated to a pointer with type `struct B*`:

   ```
   struct A;
   struct B;

   struct A *Aptr = (struct A*) malloc(sizeof(struct A));
   struct B *Bptr = (struct B*) realloc(Aptr, sizeof(struct B));
   ```
2. Read from this reallocated memory without reinitializing the memory first.

   Read accesses on the pointer to the reallocated memory can happen through pointer dereference or array indexing. Passing the pointer to a function that takes a pointer to a `const`-qualified object as the corresponding parameter also counts as a read access.

#### Risk

Reading from reallocated memory that has not been reinitialized leads to undefined behavior.

#### Fix

Reinitialize memory after reallocation and before the first read access.

The checker considers any write access on the pointer to the reallocated memory as satisfying the reinitialization requirement (even if the object might only be partially reinitialized). Write accesses on the pointer to the reallocated memory can happen through pointer dereference or array indexing. Passing the pointer to a function that takes a pointer to a non-`const`-qualified object as the corresponding parameter also counts as a write access.

**Example – Noncompliant: Reading from Reallocated Memory Without Reinitializing First**

```
#include<stdlib.h>

struct group {
    char *groupFirst;
    int groupSize;
};

struct groupWithID {
    int groupID;
    char *groupFirst;
    int groupSize;
};

char* readName();
int readSize();

void createGroup(int nextAvailableID) {
    struct group *aGroup;
    struct groupWithID *aGroupWithID;

    aGroup = (struct group*) malloc(sizeof(struct group));

    if(!aGroup) {
        /*Handle error*/
    }

    aGroup->groupFirst = readName();
    aGroup->groupSize  = readSize();

    /* Reassign to group with ID */
    aGroupWithID = (struct groupWithID*) realloc(aGroup, sizeof(struct groupWithID));
    if(!aGroupWithID) {
        free(aGroup);
        /*Handle error*/
    }

    if(aGroupWithID -> groupSize > 0) { /* Noncompliant */
        /* ... */
    }

    /* ...*/
    free(aGroupWithID);
}
```

In this example, the memory allocated to a `group*` pointer using the `malloc` function is reallocated to a `groupWithID*` pointer using the `realloc` function. There is a read access on the reallocated memory before the memory is reinitialized.

#### Correction – Reinitialize Memory After Reallocation and Before First Read

Reinitialize the memory assigned to the `groupWithID*` pointer before the first read access. All bits of the memory can be reinitialized using the `memset` function.

```
#include<stdlib.h>
#include<string.h>

struct group {
    char *groupFirst;
    int groupSize;
};

struct groupWithID {
    int groupID;
    char *groupFirst;
    int groupSize;
};

char* readName();
int readSize();

void createGroup(int nextAvailableID) {
    struct group *aGroup;
    struct groupWithID *aGroupWithID;

    aGroup = (struct group*) malloc(sizeof(struct group));

    if(!aGroup) {
        /*Handle error*/
    }

    aGroup->groupFirst = readName();
    aGroup->groupSize  = readSize();

    /* Reassign to group with ID */
    aGroupWithID = (struct groupWithID*) realloc(aGroup, sizeof(struct groupWithID));
    if(!aGroupWithID) {
        free(aGroup);
        /*Handle error*/
    }

    memset(aGroupWithID, 0 , sizeof(struct groupWithID));
    /* Reinitialize group */
    if(aGroupWithID -> groupSize > 0) {
        /* ... */
    }

    /* ...*/
    free(aGroupWithID);
}
```

Do not modify constant objects

## Description

### Rule Definition

*Do not modify constant objects.*

### Polyspace Implementation

The rule checker checks for **Writing to const qualified object**.

## Examples

### Writing to const qualified object

#### Issue

**Writing to `const` qualified object** occurs when you do one of the following:

- Use a `const`-qualified object as the destination of an assignment.
- Pass a `const`-qualified object to a function that modifies the argument.

For instance, the defect can occur in the following situations:

- You pass a `const`-qualified object as first argument of one of the following functions:
  - `mkstemp`
  - `mkostemp`
  - `mkostemps`
  - `mkdtemp`
- You pass a `const`-qualified object as the destination argument of one of the following functions:
  - `strcpy`
  - `strncpy`
  - `strcat`
  - `memset`
- You perform a write operation on a `const`-qualified object.

#### Risk

The risk depends upon the modifications made to the `const`-qualified object.

| Situation | Risk |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | These functions replace the last six characters of their first argument with a string. Therefore, they expect a modifiable `char` array as their first argument. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | These functions modify their destination argument. Therefore, they expect a modifiable `char` array as their destination argument. |
| Writing to the object | The `const` qualifier implies an agreement that the value of the object will not be modified. By writing to a `const`-qualified object, you break the agreement. The result of the operation is undefined. |

#### Fix

The fix depends on the modification made to the `const`-qualified object.

| Situation | Fix |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | Pass a non-`const` object as first argument of the function. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | Pass a non-`const` object as destination argument of the function. |
| Writing to the object | Perform the write operation on a non-`const` object. |

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Writing to `const`-Qualified Object

```
#include <string.h>

const char* buffer = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string); //Noncompliant
}
```

In this example, because `buffer` is `const`-qualified, `strchr(buffer,'X')` returns a `const`-qualified `char*` pointer. When this `char*` pointer is used as the destination argument of `strcpy`, a **Writing to const qualified object** error appears.

#### Correction — Copy const-Qualified Object to Non-const Object

One possible correction is to assign the constant string to a non-const object and use the non-const object as destination argument of strchr.

```
#include <string.h>

char buffer[] = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

Do not compare padding data

## Description

### Rule Definition

*Do not compare padding data.*

### Polyspace Implementation

The rule checker checks for **Memory comparison of padding data**.

## Examples

### Memory comparison of padding data

#### Issue

**Memory comparison of padding data** occurs when you use the memcmp function to compare two structures as a whole. In the process, you compare meaningless data stored in the structure padding.

For instance:

```
typedef struct structType {
    char member1;
    int member2;
    //...
}myStruct;

myStruct var1;
myStruct var2;
//...
if(memcmp(&var1,&var2,sizeof(var1)))
{//...}
```

#### Risk

If members of a structure have different data types, your compiler introduces additional padding for data alignment in memory. For an example of padding, see Higher Estimate of Size of Local Variables.

The content of these extra padding bytes is meaningless. The C Standard allows the content of these bytes to be indeterminate, giving different compilers latitude to implement their own padding. If you perform a byte-by-byte comparison of structures with memcmp, you compare even the meaningless data stored in the padding. You might reach the false conclusion that two data structures are not equal, even if their corresponding members have the same value.

#### Fix

Instead of comparing two structures in one attempt, compare the structures member by member.

For efficient code, write a function that does the comparison member by member. Use this function for comparing two structures.

You can use `memcmp` for byte-by-byte comparison of structures only if you know that the structures do not contain padding. Typically, to prevent padding, you use specific attributes or pragmas such as `#pragma pack`. However, these attributes or pragmas are not supported by all compilers and make your code implementation-dependent. If your structures contain bit-fields, using these attributes or pragmas cannot prevent padding.

**Example - Structures Compared with `memcmp`**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{

    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    if (0 == memcmp(left, right, sizeof(S_Padding)))  //Noncompliant
    {
        return 1;
    }
    else
        return 0;
}
```

In this example, `memcmp` compares byte-by-byte the two structures that `left` and `right` point to. Even if the values stored in the structure members are the same, the comparison can show an inequality if the meaningless values in the padding bytes are not the same.

**Correction — Compare Structures Member by Member**

One possible correction is to compare individual structure members.

**Note** You can compare entire arrays by using `memcmp`. All members of an array have the same data type. Padding bytes are not required to store arrays.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{
    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    return ((left->c == right->c) &&
            (left->i == right->i) &&
            (left->bf1 == right->bf1) &&
            (left->bf2 == right->bf2) &&
            (memcmp(left->buffer, right->buffer, 20) == 0));
}
```

Avoid undefined behavior when using restrict-qualified pointers

## Description

### Rule Definition

*Avoid undefined behavior when using restrict-qualified pointers.*

### Polyspace Implementation

The rule checker checks for **Overlapping access by `restrict`-qualified pointers**.

## Examples

### Overlapping Access by `restrict`-Qualified Pointers

#### Issue

**Overlapping access by `restrict`-qualified pointers** occurs when any of these is true:

- Two `restrict`-qualified pointers modify objects that have overlapping memory addresses.
- In a function, one or more `const restrict`-qualified pointer might modify a non`const restrict`-qualified pointer but when calling the function, the `const` and `nonconst` arguments are the same or are derived from the same pointer.
- A standard library function is called by using restrict-qualified pointers that overlap.
- A `restrict`-qualified pointer is assigned to another `restrict`-qualified pointer within the same scope.

#### Risk

The `restrict` qualifier on a pointer implies that within a block, only this pointer (or other pointers created from this pointer) can access the pointed object. You cannot create a second pointer independently of the `restrict`-qualified pointer to point to the object.

This specification requires that two `restrict`-qualified pointers cannot point to the same or overlapping objects. Two `restrict`-qualified pointers accessing the same memory address or object results in undefined behavior.

#### Fix

If you assign a `restrict`-qualified pointer to another pointer, make sure that the destination pointer itself is not `restrict`-qualified. The `restrict` qualifier assists the compiler in optimizing the code. Removing all instances of this qualifier does not change the observable code behavior.

#### Example — Assignment Between `restrict`-qualified Pointers in the Same Scope

```
int *restrict rptr1;
int *restrict rptr2;
int *         ptr;
extern int arr[];
```

```
void func (void)
{
  arr[0] = 0;
  arr[1] = 1;
  rptr1 = &arr[0];
  rptr2 = &arr[1];
  rptr2 = rptr1;  //Non-compliant
  ptr   = rptr1;  //Compliant
  /* ... */

}
```

In this example, `rptr1` and `rptr2` are `restrict`-qualified pointers that point to different locations in the same array `arr`. Assigning one such `restrict`-qualified pointer to another in the same scope causes a rule violation.

**Example — `restrict`-Qualified Function Parameters**

```
#include <stddef.h>
#include <stdio.h>
void addArray (size_t n, int *restrict res,
               const int *restrict lhs, const int *restrict rhs)
{
  for (size_t i = 0; i < n; ++i) {
    res[i] = lhs[i] + rhs[i];
  }
}
void foo (void)
{
  int a[100];
  memset(&a, 0, 100);
  addArray (100, a, a, a);//Noncompliant
}
```

In this example, the function `addArray()` is defined with three `restrict` qualified parameters `lhs`, `rhs`, and `res`. The parameters `lhs` and `rhs` are `const restrict` pointers. The function `addArray()` is then invoked by using the same pointer `a` as all three parameters. As a result, the `const restrict` qualified pointers `lhs` and `rhs` might attempt to access the memory associated with the non-`const restrict` qualified pointer `res`. This overlapping access between `lhs` and `res` as well as that between `rhs` and `res` are undefined behaviors. Polyspace raises two violations on the function call.

**Example — Invoking Library Functions by Using `restrict`-Qualified Pointers**

```
#include <string.h>

void func(void) {
  char c_str[]= "test string";
  char *ptr1 = c_str;
  char *ptr2;

  ptr2 = ptr1 + 3;
  /* Undefined behavior because of overlapping objects */
  memcpy(ptr2, ptr1, 6);//Noncompliant
  /* ... */
}
```

In this example, the function `memcpy` has two `restrict`-qualified pointers as input parameters This function copies six bytes from the location pointed to by `ptr1` into the location pointed to by `ptr2`.

Because the distance between `ptr1` and `ptr2` is three bytes, the `memcpy` function call results in two `restrict`-qualified pointers attempting to modify overlapping memory. This overlapping access results in undefined behavior. Polyspace flags the call to `memcpy`.

**Example — Assignments Between Restricted Pointers**

```
void func(void) {
  int *restrict p1;
  int *restrict p2 = p1; /* Undefined behavior */ //Noncompliant
 }
```

In this example, the `restrict`-qualified pointer `p1` is assigned to another `restrict`-qualified pointer in the same scope. Such assignments result in undefined behavior, which Polyspace flags. To resolve the issue, declare `p2` in a separate nested scope. For example:

```
void func(void) {
  int *restrict p1;
  {
      int *restrict p2 = p1;//Compliant
  }
 }
```

Do not rely on side effects in operands to sizeof, _Alignof, or _Generic

## Description

### Rule Definition

*Do not rely on side effects in operands to sizeof, _Alignof, or _Generic.*

### Polyspace Implementation

The rule checker checks for **Side effect of expression ignored**.

## Examples

### Side effect of expression ignored

#### Issue

**Side effect of expression ignored** occurs when the `sizeof`, `_Alignof`, or `_Generic` operator operates on an expression with a side effect. When evaluated, an expression with side effect modifies at least one of the variables in the expression.

For instance, the defect checker does not flag `sizeof(n+1)` because `n+1` does not modify `n`. The checker flags `sizeof(n++)` because `n++` is intended to modify `n`.

The check also applies to the C++ operator `alignof` and its C extensions, `__alignof__` and `__typeof__`.

#### Risk

The expression in a `_Alignof` or `_Generic` operator is not evaluated. The expression in a `sizeof` operator is evaluated only if it is required for calculating the size of a variable-length array, for instance, `sizeof(a[n++])`.

When an expression with a side effect is not evaluated, the variable modification from the side effect does not happen. If you rely on the modification, you can see unexpected results.

#### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result in a `sizeof`, `_Alignof`, or `_Generic` operator.

For instance, instead of:

```
a = sizeof(n++);
```

perform the operation in two steps:

```
n++;
a = sizeof(n);
```

The checker considers a function call as an expression with a side effect. Even if the function does not have side effects now, it might have side effects on later additions. The code is more maintainable if you call the function outside the `sizeof` operator.

#### Example - Increment Operator in `sizeof`

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    unsigned int b = (unsigned int)sizeof(++a); //Noncompliant
    printf ("%u, %u\n", a, b);
}
```

In this example, `sizeof` operates on `++a`, which is intended to modify `a`. Because the expression is not evaluated, the modification does not happen. The `printf` statement shows that `a` still has the value `1`.

#### Correction — Perform Increment Outside `sizeof`

One possible correction is to perform the increment first, and then provide the result to the `sizeof` operator.

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    ++a;
    unsigned int b = (unsigned int)sizeof (a);
    printf ("%u, %u\n", a, b);
}
```

Do not perform assignments in selection statements

## Description

### Rule Definition

*Do not perform assignments in selection statements.*

### Polyspace Implementation

The rule checker checks for **Invalid use of = (assignment) operator**.

## Examples

### Invalid use of = (assignment) operator

#### Issue

**Invalid use of = operator** occurs when an assignment is made inside the predicate of a conditional, such as `if` or `while`.

In C and C++, a single equal sign is an assignment not a comparison. Using a single equal sign in a conditional statement can indicate a typo or a mistake.

#### Risk

- Conditional statement tests the wrong values— The single equal sign operation assigns the value of the right operand to the left operand. Then, because this assignment is inside the predicate of a conditional, the program checks whether the new value of the left operand is nonzero or not NULL.
- Maintenance and readability issues — Even if the assignment is intended, someone reading or updating the code can misinterpret the assignment as an equality comparison instead of an assignment.

#### Fix

- If the assignment is a bug, to check for equality, add a second equal sign (==).
- If the assignment inside the conditional statement was intentional, to improve readability, separate the assignment and the test. Move the assignment outside the control statement. In the control statement, simply test the result of the assignment.

  If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

  - “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
  - “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
  - “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Example - Single Equal Sign Inside an `if` Condition

```
#include <stdio.h>

void bad_equals_ex(int alpha, int beta)
{
    if(alpha = beta) //Noncompliant
    {
        printf("Equal\n");
    }
}
```

The equal sign is flagged as a defect because the assignment operator is used within the predicate of the if-statement. The predicate assigns the value `beta` to `alpha`, then implicitly tests whether `alpha` is true or false.

### Correction — Change Expression to Comparison

One possible correction is adding an additional equal sign. This correction changes the assignment to a comparison. The if condition compares whether `alpha` and `beta` are equal.

```
#include <stdio.h>

void equality_test(int alpha, int beta)
{
    if(alpha == beta)
    {
        printf("Equal\n");
    }
}
```

### Correction — Assignment and Comparison Inside the `if` Condition

If an assignment must be made inside the predicate, a possible correction is adding an explicit comparison. This correction assigns the value of `beta` to `alpha`, then explicitly checks whether `alpha` is nonzero. The code is clearer.

```
#include <stdio.h>

int assignment_not_zero(int alpha, int beta)
{
    if((alpha = beta) != 0)
    {
        return alpha;
    }
    else
    {
        return 0;
    }
}
```

### Correction — Move Assignment Outside the `if` Statement

If the assignment can be made outside the control statement, one possible correction is to separate the assignment and comparison. This correction assigns the value of `beta` to `alpha` before the if. Inside the if-condition, only `alpha` is given to test if `alpha` is nonzero or not NULL.

```
#include <stdio.h>
```

```
void assign_and_print(int alpha, int beta)
{
    alpha = beta;
    if(alpha)
    {
        printf("%d", alpha);
    }
}
```

Do not use a bitwise operator with a Boolean-like operand

## Description

### Rule Definition

*Do not use a bitwise operator with a Boolean-like operand.*

### Polyspace Implementation

The rule checker checks for **Use of bitwise operator with a Boolean-like operand**.

## Examples

### Use of bitwise operator with a Boolean-like operand

#### Issue

**Use of bitwise operator with a Boolean-like operand** occurs when you use bitwise operators, such as:

- Bitwise AND (&, &=)
- Bitwise OR (|, |=)
- Bitwise XOR (^, ^=)
- Bitwise NOT(~)

with:

- Boolean type variables
- Outputs of relational or equality expressions

Using Boolean type variables as array indices, in Boolean arithmetic expression, and in shifting operations does not raise this defect.

#### Risk

Boolean-like operands, such as variables of type `bool` and outputs of relational operators typically appear in logical expressions. Using a bitwise operator in an expression containing Boolean variables and relational operators might be a sign of logic error. Because bitwise operators and logical operators look similar, you might inadvertently use a bitwise operator instead of a logical operator. Such logic errors do not raise any compilation error and can introduce bugs in your code that are difficult to find.

#### Fix

Use logical operators in expressions that contain Boolean variables and relational operator. To indicate that you intend to use a bitwise operator in such an expression, use parentheses.

#### Example — Possible Bug Due to Using Bitwise Operator

```
int getuid();
int geteuid();
```

```
void Noncompliant ()
{
    if (getuid () & geteuid () == 0) {//Noncompliant
        /* ... */
    }else{
        /*...*/
    }
}
```

In this example, the `if-else` block is executed conditionally. The conditional statement uses the bitwise AND (&) instead of the logical AND (&&), perhaps by mistake. Consider when the function `geteuid()` evaluates to 0, and `getuid()` evaluates to 2. In this case, the `else` block of code executes if you use & because `2&1` evaluates to `false`. Conversely, the `if` block of code executes when you use && because `2&&1` evaluates to `true`. Using & instead of && might introduce logic errors and bugs in your code that are difficult to find. Polyspace flags the use of bitwise operators in these kinds of expressions where relational operators are also used.

#### Correction — Use Logical Operators with Boolean-Like Operands

One possible correction is to use logical operators in expressions that contain relational operators and Boolean variables.

```
int getuid();
int geteuid();
void Compliant ()
{
    if (getuid () && geteuid () == 0) {
        /* ... */
    }else{
        /*...*/
    }
}
```

EXP46-C

# CERT C: Rule EXP47-C

Do not call va_arg with an argument of the incorrect type

## Description

### Rule Definition

*Do not call va_arg with an argument of the incorrect type.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Incorrect data type passed to va_arg**.
- **Too many va_arg calls for current argument list**.

## Examples

### Incorrect data type passed to va_arg

#### Issue

**Incorrect data type passed to va_arg** when the data type in a va_arg call does not match the data type of the variadic function argument that va_arg reads.

For instance, you pass an unsigned char argument to a variadic function func. Because of default argument promotion, the argument is promoted to int. When you use a va_arg call that reads an unsigned char argument, a type mismatch occurs.

```
void func (int n, ...) {
   //...
   va_list args;
   va_arg(args, unsigned char);
   //...
}

void main(void) {
   unsigned char c;
   func(1,c);
}
```

#### Risk

In a variadic function (function with variable number of arguments), you use va_arg to read each argument from the variable argument list (va_list). The va_arg use does not guarantee that there actually exists an argument to read or that the argument data type matches the data type in the va_arg call. You have to make sure that both conditions are true.

Reading an incorrect type with a va_arg call can result in undefined behavior. Because function arguments reside on the stack, you might access an unwanted area of the stack.

#### Fix

Make sure that the data type of the argument passed to the variadic function matches the data type in the `va_arg` call.

Arguments of a variadic function undergo default argument promotions. The argument data types of a variadic function cannot be determined from a prototype. The arguments of such functions undergo default argument promotions (see Sec. 6.5.2.2 and 7.15.1.1 in the C99 Standard). Integer arguments undergo integer promotion and arguments of type `float` are promoted to `double`. For integer arguments, if a data type can be represented by an `int`, for instance, `char` or `short`, it is promoted to an `int`. Otherwise, it is promoted to an `unsigned int`. All other arguments do not undergo promotion.

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for `MISRA C:2012 Rule 17.1` or `MISRA C++:2008 Rule 8-4-1` to detect use of variadic functions.

#### Example - `char` Used as Function Argument Type and va_arg argument

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, unsigned char); //Noncompliant
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

In this example, `func` takes an `unsigned char` argument, which undergoes default argument promotion to `int`. The data type in the `va_arg` call is still `unsigned char`, which does not match the `int` argument type.

#### Correction — Use `int` as va_arg Argument

One possible correction is to read an `int` argument with `va_arg`.

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

### Too many va_arg calls for current argument list

#### Issue

**Too many va_arg calls for current argument list** occurs when the number of calls to va_arg exceeds the number of arguments passed to the corresponding variadic function. The analysis raises a defect only when the variadic function is called.

**Too many va_arg calls for current argument list** does not raise a defect when:

- The number of calls to va_arg inside the variadic function is indeterminate. For example, if the calls are from an external source.
- The va_list used in va_arg is invalid.

#### Risk

When you call va_arg and there is no next argument available in va_list, the behavior is undefined. The call to va_arg might corrupt data or return an unexpected result.

#### Fix

Ensure that you pass the correct number of arguments to the variadic function.

#### Example - No Argument Available When Calling va_arg

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/
int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {
/* No further argument available
* in va_list when calling va_arg
*/

            result += va_arg(ap, int); //Noncompliant
        }
    }
    va_end(ap);
    return result;
}
```

```
void func(void) {

    (void)variadic_func(2, 100);

}
```

In this example, the named argument and only one variadic argument are passed to `variadic_func()` when it is called inside `func()`. On the second call to `va_arg`, no further variadic argument is available in `ap` and the behavior is undefined.

#### Correction — Pass Correct Number of Arguments to Variadic Function

One possible correction is to ensure that you pass the correct number of arguments to the variadic function.

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/

int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {

/* The correct number of arguments is
* passed to va_list when variadic_func()
* is called inside func()
*/
            result += va_arg(ap, int);
        }
    }
    va_end(ap);
    return result;
}

void func(void) {

    (void)variadic_func(2, 100, 200);

}
```

Ensure that unsigned integer operations do not wrap

## Description

### Rule Definition

*Ensure that unsigned integer operations do not wrap.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Unsigned integer overflow**.
- **Unsigned integer constant overflow**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Unsigned integer overflow

#### Issue

**Unsigned integer overflow** occurs when an operation on unsigned integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

The C11 standard states that unsigned integer overflows result in wrap-around behavior. However, a wrap around behavior might not always be desirable. For instance, if the result of a computation is used as an array size and the computation overflows, the array size is much smaller than expected.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.

- Checking for values that lead to the overflow and performing appropriate error handling. In the error handling code, you can override the default wrap-around behavior for overflows and implement saturation behavior, for instance.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Add One to Maximum Unsigned Integer

```
#include <limits.h>

unsigned int plusplus(void) {

    unsigned uvar = UINT_MAX;
    uvar++; //Noncompliant
    return uvar;
}
```

In the third statement of this function, the variable `uvar` is increased by 1. However, the value of `uvar` is the maximum unsigned integer value, so 1 plus the maximum integer value cannot be represented by an `unsigned int`. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `uvar` is reduced by modulo `UINT_MAX`. The result is `uvar = 1`.

#### Correction — Different Storage Type

One possible correction is to store the operation result in a larger data type. In this example, by returning an `unsigned long long` instead of an `unsigned int`, the overflow error is fixed.

```
#include <limits.h>

unsigned long long plusplus(void) {

    unsigned long long ullvar = UINT_MAX;
    ullvar++;
    return ullvar;
}
```

### Unsigned integer constant overflow

#### Issue

**Unsigned integer constant overflow** occurs when you assign a compile-time constant to a unsigned integer variable whose data type cannot accommodate the value. An `n`-bit unsigned integer holds values in the range `[0, 2`$^n$`-1]`.

For instance, `c` is an 8-bit unsigned `char` variable that cannot hold the value 256.

```
unsigned char c = 256;
```

To determine the sizes of fundamental types, Bug Finder uses your specification for `Target processor type (-target)`.

**Risk**

The C standard states that overflowing unsigned integers must be wrapped around (see, for instance, the C11 standard, section 6.2.5). However, the wrap-around behavior can be unintended and cause unexpected results.

**Fix**

Check if the constant value is what you intended. If the value is correct, use a wider data type for the variable.

**Example - Overflowing Constant from Macro Expansion**

```
#define MAX_UNSIGNED_CHAR 255 //Noncompliant
#define MAX_UNSIGNED_SHORT 65535 //Noncompliant

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned short c2 = MAX_UNSIGNED_SHORT + 1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow.

**Correction — Use Wider Data Type**

One possible correction is to use a wider data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_UNSIGNED_SHORT 65535

void main() {
    unsigned short c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned int c2 = MAX_UNSIGNED_SHORT + 1;
}
```

## Check Information

**Group:** Rule 04. Integers (INT)

# Version History

**Introduced in R2019a**

INT30-C

# CERT C: Rule INT31-C

Ensure that integer conversions do not result in lost or misinterpreted data

## Description

### Rule Definition

*Ensure that integer conversions do not result in lost or misinterpreted data.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer conversion overflow**.
- **Call to memset with unintended value**.
- **Sign change integer conversion overflow**.
- **Tainted sign change conversion**.
- **Unsigned integer conversion overflow**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer conversion overflow**, **Sign change integer conversion overflow**, or **Unsigned integer conversion overflow**. To check for these issues caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- A default Bug Finder analysis might not flag a **Tainted sign change conversion** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Integer conversion overflow

#### Issue

**Integer conversion overflow** occurs when converting an integer to a smaller integer type. If the variable does not have enough bytes to represent the original value, the conversion overflows. For instance, if you perform a comparison between implementation-defined type `time_t` and a signed integer, Polyspace reports a violation because `time_t` might be implemented as an unsigned integer.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer conversion overflows result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Converting from `int` to `char`

```
char convert(void) {

    int num = 1000000;

    return (char)num; //Noncompliant
}
```

In the return statement, the integer variable `num` is converted to a `char`. However, an 8-bit or 16-bit character cannot represent 1000000 because it requires at least 20 bits. So the conversion operation overflows.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number.

```
long convert(void) {

    int num = 1000000;

    return (long)num;
}
```

### Call to memset with unintended value

#### Issue

**Call to memset with unintended value** occurs when Polyspace Bug Finder detects a use of the `memset` or `wmemset` function with possibly incorrect arguments.

`void *memset (void *ptr, int value, size_t num)` fills the first `num` bytes of the memory block that `ptr` points to with the specified `value`. If the argument `value` is incorrect, the memory block is initialized with an unintended value.

The unintended initialization can occur in the following cases.

| Issue | Risk | Possible Fix |
|---|---|---|
| The second argument is `'0'` instead of `0` or `'\0'`. | The ASCII value of character `'0'` is `48` (decimal), `0x30` (hexadecimal), `069` (octal) but not `0` (or `'\0'`) . | If you want to initialize with `'0'`, use one of the ASCII values. Otherwise, use `0` or `'\0'`. |
| The second and third arguments are probably reversed. For instance, the third argument is a literal and the second argument is not a literal. | If the order is reversed, a memory block of unintended size is initialized with incorrect arguments. | Reverse the order of the arguments. |
| The second argument cannot be represented in a byte. | If the second argument cannot be represented in a byte, and you expect each byte of a memory block to be filled with that argument, the initialization does not occur as intended. | Apply a bit mask to the argument to produce a wrapped or truncated result that can be represented in a byte. When you apply a bit mask, make sure that it produces an expected result.<br>For instance, replace `memset(a, -13, sizeof(a))` with `memset(a, (-13) & 0xFF, sizeof(a))`. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Value Cannot Be Represented in a Byte**

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE];
    int c = -2;
    memset(buf, (char)c, sizeof(buf)); //Noncompliant
}
```

In this example, `(char)c` cannot be represented in a byte.

**Correction — Apply Cast**

One possible correction is to apply a cast so that the result can be represented in a byte. However, check that the result of the cast is an acceptable initialization value. Polyspace still flags the call to `memset` because the casting the signed integer c to an unsigned character overflows.

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE   ];
    int c = -2;
    memset(buf, (unsigned char)c, sizeof(buf));  //Noncompliant
}
```

**Correction — Avoid Using `memset`**

One possible correction is to reserve the use of `memset` only for setting or clearing all bits in a buffer. For instance, in this code, `memset` is called to clear the bits of the character array `buf`.

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE   ];
    int c = -2;
    memset(buf, 0, sizeof(buf));//Compliant
    /* After clearing buf, use it in operations*/
}
```

### Sign change integer conversion overflow

**Issue**

**Sign change integer conversion overflow** occurs when converting an unsigned integer to a signed integer. If the variable does not have enough bytes to represent both the original constant and the sign bit, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do

not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Convert from `unsigned char` to `char`

```
char sign_change(void) {
    unsigned char count = 255;

    return (char)count; //Noncompliant
}
```

In the return statement, the unsigned character variable `count` is converted to a signed character. However, `char` has 8 bits, 1 for the sign of the constant and 7 to represent the number. The conversion operation overflows because 255 uses 8 bits.

#### Correction — Change conversion types

One possible correction is using a larger integer type. By using an `int`, there are enough bits to represent the sign and the number value.

```
int sign_change(void) {
    unsigned char count = 255;

    return (int)count;
}
```

### Tainted sign change conversion

#### Issue

**Tainted sign change conversion** looks for values from unsecure sources that are converted, implicitly or explicitly, from signed to unsigned values.

For example, functions that use `size_t` as arguments implicitly convert the argument to an unsigned integer. Some functions that implicitly convert `size_t` are:

```
bcmp
memcpy
memmove
strncmp
strncpy
calloc
malloc
memalign
```

#### Risk

If you convert a small negative number to unsigned, the result is a large positive number. The large positive number can create security vulnerabilities. For example, if you use the unsigned value in:

- Memory size routines — causes allocating memory issues.
- String manipulation routines — causes buffer overflow.
- Loop boundaries — causes infinite loops.

#### Fix

To avoid converting unsigned negative values, check that the value being converted is within an acceptable range. For example, if the value represents a size, validate that the value is not negative and less than the maximum value size.

#### Example - Set Memory Value with Size Argument

```
#include <stdlib.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void bug_taintedsignchange(int size) {
    char str[SIZE128] = "";
    if (size<SIZE128) {
        memset(str, 'c', size);  //Noncompliant
    }
}
```

In this example, a `char` buffer is created and filled using `memset`. The size argument to `memset` is an input argument to the function.

The call to `memset` implicitly converts `size` to unsigned integer. If `size` is a large negative number, the absolute value could be too large to represent as an integer, causing a buffer overflow.

#### Correction — Check Value of `size`

One possible correction is to check if `size` is inside the valid range. This correction checks if `size` is greater than zero and less than the buffer size before calling `memset`.

```
#include <stdlib.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void corrected_taintedsignchange(int size) {
    char str[SIZE128] = "";
    if (size>0 && size<SIZE128) {
        memset(str, 'c', size);
    }
}
```

### Unsigned integer conversion overflow

#### Issue

**Unsigned integer conversion overflow** occurs when converting an unsigned integer to a smaller unsigned integer type. If the variable does not have enough bytes to represent the original constant, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer conversion overflows result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Converting from `int` to `char`

```
unsigned char convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned char)unum;   //Noncompliant
}
```

In the return statement, the unsigned integer variable `unum` is converted to an unsigned character type. However, the conversion overflows because 1000000 requires at least 20 bits. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `unum` is reduced by modulo `2^8` because a character data type can only represent `2^8-1`.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number. For example, `long`.

```
unsigned long convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned long)unum;
}
```

## Check Information

# CERT C: Rule INT32-C

Ensure that operations on signed integers do not result in overflow

## Description

### Rule Definition

*Ensure that operations on signed integers do not result in overflow.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer overflow**.
- **Tainted division operand**.
- **Tainted modulo operand**.

### Extend Checker

When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer overflow**. To check for these issues caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`. W

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++;              //Noncompliant
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

### Tainted division operand

#### Issue

**Tainted division operand** detects division operations where one or both of the integer operands is from an unsecure source.

#### Risk

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

#### Fix

Before performing the division, validate the values of the operands. Check for denominators of `0` or `-1`, and numerators of the minimum integer value.

#### Example - Division of Function Arguments

```
#include <limits.h>
#include <stdio.h>

extern void print_int(int);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    int r =  num/denum;  //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include <limits.h>
#include <stdio.h>

extern void print_long(long);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    long res= 0;
    if (denum!=0 && !(num==INT_MIN && denum==-1)) {
        res = num/denum;
    }
    print_long(res);
    return res;
}
```

### Tainted modulo operand

#### Issue

**Tainted modulo operand** checks the operands of remainder `%` operations. Bug Finder flags modulo operations with one or more tainted operands.

#### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is `-1`, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

#### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of `0` and `-1`. Check both operands for negative values.

#### Example - Modulo with Unsecure Input

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d",&userden);
    int rem =  128%userden;  //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using a user input. The user input is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d",&userden);
    int rem = 0;
    if (userden > 0) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

INT32-C

# CERT C: Rule INT33-C

Ensure that division and remainder operations do not result in divide-by-zero errors

## Description

### Rule Definition

*Ensure that division and remainder operations do not result in divide-by-zero errors.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer division by zero**.
- **Tainted division operand**.
- **Tainted modulo operand**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer division by zero**. To check for these issues caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- A default Bug Finder analysis might not flag a **Tainted division operand** or **Tainted modulo operand** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Integer division by zero

#### Issue

**Integer division by zero** occurs when the denominator of a division or modulo operation can be a zero-valued integer.

#### Risk

A division by zero can result in a program crash.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the denominator variable acquires a zero value. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.

#### Example - Dividing an Integer by Zero

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    result = num/denom; //Noncompliant

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    if (denom != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
int fraction(int num)
{
    int denom = 2;
    int result = 0;
    result = num/denom;

    return result;
}
```

#### Example - Modulo Operation with Zero

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        arr[i] = input % i; //Noncompliant
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

In this example, Polyspace flags the modulo operation as a division by zero. Because modulo is inherently a division operation, the divisor (right hand argument) cannot be zero. The modulo operation uses the `for` loop index as the divisor. However, the `for` loop starts at zero, which cannot be an iterator.

#### Correction — Check Divisor Before Operation

One possible correction is checking the divisor before the modulo operation. In this example, see if the index `i` is zero before the modulo operation.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        if(i != 0)
        {
             arr[i] = input % i;
        }
        else
        {
             arr[i] = input;
        }
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

#### Correction — Change Divisor

Another possible correction is changing the divisor to a nonzero integer. In this example, add one to the index before the `%` operation to avoid dividing by zero.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
         arr[i] = input % (i+1);
    }
    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

### Tainted division operand

#### Issue

**Tainted division operand** detects division operations where one or both of the integer operands is from an unsecure source.

#### Risk

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

#### Fix

Before performing the division, validate the values of the operands. Check for denominators of `0` or `-1`, and numerators of the minimum integer value.

#### Example - Division of Function Arguments

```
#include<stdio.h>
extern void print_int(int);

int taintedintdivision(void) {
    int num, den;
    scanf("%lf %lf",&num, &den);
    int r =  num/den;  //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include<stdio.h>
#include <limits.h>
extern void print_int(int);

int taintedintdivision(void) {
    int num, den;
    scanf("%lf %lf",&num, &den);
    int r = 0;
    if (den!=0 && !(num=INT_MIN && den==-1)){
        r =  num/den;
    }
    print_int(r);
    return r;
}
```

### Tainted modulo operand

#### Issue

**Tainted modulo operand** checks the operands of remainder `%` operations. Bug Finder flags modulo operations with one or more tainted operands.

#### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is `-1`, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

#### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of `0` and `-1`. Check both operands for negative values.

#### Example - Modulo with UInsecure Input

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d",&userden);
    int rem =  128%userden;  //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using a user input. The input is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d",&userden);
    int rem = 0;
    if (userden > 0) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

Do not shift an expression by a negative number of bits or by greater than or equal to the number of bits that exist in the operand

## Description

### Rule Definition

*Do not shift an expression by a negative number of bits or by greater than or equal to the number of bits that exist in the operand.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Shift of a negative value**.
- **Shift operation overflow**.

### Extend Checker

When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect a **Shift of a negative value** or **Shift operation overflow**. To check for these issues caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Shift of a negative value

#### Issue

**Shift of a negative value** occurs when a bit-wise shift is used on a variable that can have negative values.

#### Risk

Shifts on negative values overwrite the sign bit that identifies a number as negative. The shift operation can result in unexpected values.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being shifted acquires negative values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

To fix the defect, check for negative values before the bit-wise shift operation and perform appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Shifting a negative variable

```
int shifting(int val)
{
    int res = -1;
    return res << val; //Noncompliant
}
```

In the return statement, the variable `res` is shifted a certain number of bits to the left. However, because `res` is negative, the shift might overwrite the sign bit.

#### Correction — Change the Data Type

One possible correction is to change the data type of the shifted variable to unsigned. This correction eliminates the sign bit, so left shifting does not change the sign of the variable.

```
int shifting(int val)
{
    unsigned int res = -1;
    return res << val;
}
```

### Shift operation overflow

#### Issue

**Shift operation overflow** occurs when a shift operation can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Shift operation overflows can result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the shift operation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

You can fix the defect by:

- Using a bigger data type for the result of the shift operation so that all values can be accommodated.

- Checking for values that lead to the overflow and performing appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Left Shift of Integer**

```
int left_shift(void) {

    int foo = 33;
    return 1 << foo;  //Noncompliant
}
```

In the return statement of this function, bit-wise shift operation is performed shifting 1 `foo` bits to the left. However, an `int` has only 32 bits, so the range of the shift must be between 0 and 31. Therefore, this shift operation causes an overflow.

**Correction — Different storage type**

One possible correction is to store the shift operation result in a larger data type. In this example, by returning a `long long` instead of an `int`, the overflow defect is fixed.

```
long long left_shift(void) {

    int foo = 33;
    return 1LL << foo;
}
```

INT34-C

# CERT C: Rule INT35-C

Use correct integer precisions

## Description

### Rule Definition

*Use correct integer precisions.*

### Polyspace Implementation

The rule checker checks for **Integer precision exceeded**.

## Examples

### Integer precision exceeded

#### Issue

**Integer precision exceeded** occurs when an integer expression uses the integer size in an operation that exceeds the integer precision. On some architectures, the size of an integer in memory can include sign and padding bits. On these architectures, the integer size is larger than the precision which is just the number of bits that represent the value of the integer.

#### Risk

Using the size of an integer in an operation on the integer precision can result in integer overflow, wrap around, or unexpected results. For instance, an unsigned integer can be stored in memory in 64 bits, but uses only 48 bits to represent its value. A 56 bits left-shift operation on this integer is undefined behavior.

Assuming that the size of an integer is equal to its precision can also result in program portability issues between different architectures.

#### Fix

Do not use the size of an integer instead of its precision. To determine the integer precision, implement a precision computation routine or use a builtin function such as `__builtin_popcount()`.

#### Example - Using Size of `unsigned int` for Left Shift Operation

```
#include <limits.h>

unsigned int func(unsigned int exp)
{
    if (exp >= sizeof(unsigned int) * CHAR_BIT) {
        /* Handle error */
    }
    return 1U << exp; //Noncompliant
}
```

In this example, the function uses a left shift operation to return the value of 2 raised to the power of `exp`. The operation shifts the bits of `1U` by `exp` positions to the left. The `if` statement ensures that the operation does not shift the bits by a number of positions `exp` greater than the size of an `unsigned int`. However, if `unsigned int` contains padding bits, the value returned by `sizeof()` is larger than the precision of `unsigned int`. As a result, some values of `exp` might be too large, and the shift operation might be undefined behavior.

#### Correction — Implement Function to Compute Precision of `unsigned int`

One possible correction is to implement a function `popcount()` that computes the precision of `unsigned int` by counting the number of set bits.

```
#include <stddef.h>
#include <stdint.h>
#include <limits.h>

size_t popcount(uintmax_t);
#define PRECISION(umax_value) popcount(umax_value)

unsigned int func(unsigned int exp)
{
    if (exp >= PRECISION(UINT_MAX)) {
        /* Handle error */
    }
    return 1 << exp;
}

size_t popcount(uintmax_t num)
{
    size_t precision = 0;
    while (num != 0) {
        if (num % 2 == 1) {
            precision++;
        }
        num >>= 1;
    }
    return precision;
}
```

INT35-C

# CERT C: Rule INT36-C

Converting a pointer to integer or integer to pointer

## Description

### Rule Definition

*Converting a pointer to integer or integer to pointer.*

### Polyspace Implementation

The rule checker checks for **Conversion between pointer and integer**

## Examples

### Conversion between pointer and integer

#### Issue

**Conversion between pointer and integer** is raised when any of these conditions is true:

- A pointer type is converted into an integral type with smaller size. When converting a pointer of the types `intptr_t` or `uintprt_t` into integral types `enum`, `ptrdiff_t`, or `pid_t`, Polyspace raises a defect if the size of pointers and integer types are different in your environment. In `i386` environment, both pointers and integer types have a size of 32 bits. In this environment, Polyspace does not flag conversion from a pointer to an integer of same size. But in `x86_64` environment where pointers are 64 bits and unsigned integers are 32 bits, Polyspace flags conversion from pointers to integers of different sizes.
- An integral type is converted into a raw pointer type. Polyspace flags conversion from integral types to raw pointers regardless of their sizes. For instance, if an integer originates from a pointer and then later, is cast into a pointer, Polyspace flags the conversion from integer to pointer. In this case, the integer and the pointer are of the same size, but the conversion is still flagged.

#### Risk

The mapping between pointers and integers is not always consistent with the addressing structure of the environment.

Converting from pointers to integers can create:

- Truncated or out of range integer values.
- Invalid integer types.

Converting from integers to pointers can create:

- Misaligned pointers or misaligned objects.
- Invalid pointer addresses.

### Fix

Where possible, avoid pointer-to-integer or integer-to-pointer conversions. If you want to convert a `void` pointer to an integer, so that you do not change the value, use types:

- C99 — `intptr_t` or `uintptr_t`
- C90 — `size_t` or `ssize_t`

### Example — Integer to Pointer Conversions

```
unsigned int* badintptrcast(void)
{
    int* ptr;
    unsigned long long int_same_as_ptr ;
    unsigned int int_smaller_than_ptr;

    unsigned int* ptr0 = (unsigned int*)0xdeadbeef; //Noncompliant

    /*int to ptr of same size*/
    ptr = (int*)int_same_as_ptr;  //Noncompliant

    /*int to ptr of different size*/
    ptr = (int*)int_smaller_than_ptr;  //Noncompliant

    return (unsigned int*)(ptr0 - (unsigned int*)ptr);  //Noncompliant
}
```

In this example, Polyspace flags the conversions that might be unsafe. For instance:

- The conversion of `0xdeadbeef` to `unsigned int*` causes alignment issues for the pointer. Polyspace flags the conversion.
- The conversion of the `int_same_as_ptr` and `int_smaller_than_ptr` to `int*` pointers might result in invalid pointer address. Polyspace flags these conversion.
- The `return` statement casts `ptrdiff_t` to a pointer. This pointer might not point to an invalid address. Polyspace flags the conversion.

### Correction — Use `intptr_t`

One possible correction is to use `intptr_t` types to store addresses. When storing the result of subtracting two pointers, use the type `ptrdiff_t`.

```
#include<stdint.h>
#include<stddef.h>
ptrdiff_t badintptrcast(void)
{
    intptr_t ptr;
    unsigned long long int_same_as_ptr ;
    unsigned int int_smaller_than_ptr;

    intptr_t ptr0 = (intptr_t)0xdeadbeef; //Compliant

    /*int to ptr of same size*/
    ptr = (intptr_t)int_same_as_ptr;  //Compliant

    /*int to ptr of different size*/
    ptr = (intptr_t)int_smaller_than_ptr;  //Compliant
    int offset = 0;
    return (ptrdiff_t)(ptr0 - offset);//Compliant

}
```

Do not use floating-point variables as loop counters

## Description

### Rule Definition

*Do not use floating-point variables as loop counters.*

### Polyspace Implementation

The rule checker checks for **Use of float variable as loop counter**.

## Examples

### Use of float variable as loop counter

#### Issue

The issue occurs when a loop counter has a floating type.

If the `for` index is a variable symbol, Polyspace checks that it is not a float.

#### Risk

When using a floating-point loop counter, accumulation of rounding errors can result in a mismatch between the expected and actual number of iterations. This rounding error can happen when a loop step that is not a power of the floating point radix is rounded to a value that can be represented by a float.

Even if a loop with a floating-point loop counter appears to behave correctly on one implementation, it can give a different number of iteration on another implementation.

#### Example - `for` Loop Counters

In this example, the three `for` loops show three different loop counters. The first and second `for` loops use float variables as loop counters, and therefore are not compliant. The third loop uses the integer `count` as the loop counter. Even though `count` is used as a float inside the loop, the variable remains an integer when acting as the loop index. Therefore, this `for` loop is compliant.

```
int main(void){
    unsigned int counter = 0u;
    int result = 0;
    float foo;

    // Float loop counters
    for(float foo = 0.0f; foo < 1.0f; foo +=0.001f){ /*Non-compliant*/
        /*counter = 1000 at the end of the loop */
        ++counter;
    }

    float fff = 0.0f;
    for(fff = 0.0f; fff <12.0f; fff += 1.0f){    /* Non-compliant*/
        result++;
    }

    // Integer loop count
    for(unsigned int count = 0u; count < 1000u; ++count){ /* Compliant */
        foo = (float) count * 0.001f;
    }
}
```

### `while` Loop Counters

This example shows two `while` loops both of which use floating point variables in the `while`-loop conditions:

- The first `while` loop uses the floating point variable `foo` in the condition and inside the loop. Because `foo` changes, floating-point rounding errors can cause unexpected behavior. Polyspace reports a violation.
- In the second while loop, the floating point array `buffer` is used in the loop condition. Polyspace identifies `iter1` and `iter2` as the loop variable. Because the loop variables are not floating point variables, a violation is not reported.

```
int main(void){
    unsigned int iter1 =0;
    int iter2;
    float foo;
    double buffer[2];
    double tmp;

    foo = 0.0f;
    while (foo < 1.0f){/* Non-compliant - foo used as a loop counter */
        foo += 0.001f;
    }

    //...
    while((iter1+1 < 2)&& (buffer[iter1]<buffer[iter2])){ //Compliant - loop counter is integer
        // swap buffer[iter1] and buffer[iter2]
        tmp = buffer[iter2];
        buffer[iter2] = buffer[iter1];
        buffer[iter1] = tmp;
        iter2 = iter1;
        iter1++;
    }

    return 1;
}
```

Prevent or detect domain and range errors in math functions

## Description

### Rule Definition

*Prevent or detect domain and range errors in math functions.*

### Polyspace Implementation

The rule checker checks for **Invalid use of standard library floating point routine**.

### Extend Checker

Extend this checker to check for defects caused by specific values and invalid use of functions from a custom library. For instance:

- You might be using a custom library of mathematical floating point functions. If a custom library function have the same domain and range as another function from the standard library, you can extend this checker to check the custom library function. See “Extend Bug Finder Checkers for Standard Library Functions to Custom Libraries”.
- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Invalid use of standard library floating point routine

#### Issue

**Invalid use of standard library floating point routine** occurs when you use invalid arguments with a floating point function from the standard library. This defect picks up:

- Rounding and absolute value routines

  `ceil, fabs, floor, fmod`
- Fractions and division routines

  `fmod, modf`
- Exponents and log routines

  `frexp, ldexp, sqrt, pow, exp, log, log10`
- Trigonometry function routines

  `cos, sin, tan, acos, asin, atan, atan2, cosh, sinh, tanh, acosh, asinh, atanh`

#### Risk

Domain errors on standard library floating point functions result in implementation-defined values. If you use the function return value in subsequent computations, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the function argument acquires invalid values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

It is a good practice to handle for domain errors before using a standard library floating point function. For instance, before calling the `acos` function, check if the argument is in [-1.0, 1.0] and handle the error.

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

#### Example – Domain Error

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    return acos(degree); //Noncompliant
}
```

The input value to `acos` must be in the interval `[-1,1]`. This input argument, `degree`, is outside this range.

#### Correction – Change Input Argument

One possible correction is to change the input value to fit the specified range. In this example, change the input value from degrees to radians to fix this defect.

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    double radian = degree * 3.14159 / 180.;
    return acos(radian);
}
```

**Example – Range Error**

```
#include <math.h>
#include <fenv.h>
#include <errno.h>

void calculate_sinh (double x)
{
    double result;
    result = sinh (x);   //Noncompliant
}

void call_sinh_calculator()
{
    double x = 10.e32;
    calculate_sinh(x);
}
```

The `sinh` function is called with a large argument that results in an overflow.

**Correction – Handle Range Errors**

You cannot prevent range errors but only handle them later.

For instance, if a range error occurs, the function `sinh` sets `errno` to nonzero values on certain implementations. In those implementations, you can check `errno` for non-zero values to handle error conditions.

The following function uses the error handling recommendations given in FLP32-C.

```
#include <math.h>
#include <fenv.h>
#include <errno.h>

void calculate_sinh (double x)
{
    double result;
    result = sinh (x);   //Noncompliant
    if ((math_errhandling & MATH_ERRNO) && errno != 0) {
        /* Handle range error */
    }
    else if ((math_errhandling & MATH_ERREXCEPT) && fetestexcept (FE_INVALID | FE_DIVBYZERO | FE_
        /* Handle range error */
    }
}

void call_sinh_calculator()
{
    double x = 10.e32;
    calculate_sinh(x);
}
```

Note that the rule checker continues to report the range error even if it is handled later. In this case, you can mark the error as justified. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.

- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

Ensure that floating-point conversions are within range of the new type

## Description

### Rule Definition

*Ensure that floating-point conversions are within range of the new type.*

### Polyspace Implementation

This checker checks for:

- **Float conversion overflow**
- **Floating point to integer conversion overflow**

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Float conversion overflow

#### Issue

**Float conversion overflow** occurs when converting a floating point value to a smaller floating point data type. If the variable does not have enough memory to represent the original value, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing conversion in subsequent computations and do not account for the overflow, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being converted acquires its current value You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller floating point types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaN`s. Operations that results in infinities and `NaN`s might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

#### Example - Converting from `double` to `float`

```
float convert(void) {

    double diam = 1e100;
    return (float)diam; //Noncompliant
}
```

In the return statement, the variable `diam` of type double (64 bits) is converted to a variable of type float (32 bits). However, the value 1^100 requires more than 32 bits to be precisely represented.

### Floating point to integer conversion overflow

#### Issue

**Floating point to integer conversion overflow** occurs when converting a floating-point value to an integer data type. If the integer part of the value cannot be represented within the storage available for the integer data type, the conversion overflows.

#### Risk

When converting from floating point to integer types, if the floating point value is outside the range that can be represented by the integer type, the behavior is undefined (C Standard 6.3.14 and 6.3.15).

#### Fix

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

  A check for overflowing values on a `float` variable `var` can be like this:

```
if  isnan(var)
    || popcount(INT_MAX) < log2f(fabsf(var))
    || (var != 0.0F && fabsf(var) < FLT_MIN)){
        // Handle error
    }
    else {
        // Perform operations on var
    }
```

The check determines if the floating point value is representable within an integer type:

- The value is not NaN.
- The number of bits required to store the value is less than the number of bits in `INT_MAX` (the largest integer that the `int` type can represent). The `popcount` function (not defined here) counts the number of 1's (or set bits) in a number.
- The floating point value is not lower than the smallest representable floating-point value.

**Example – Floating Point Value Converted to Integer Without Handling Overflows**

```
void func(float fVar) {
  int iVar;
  iVar = fVar; //Noncompliant //Noncompliant
}
```

In this example, the floating point value of `fVar` is not checked for overflows before converting to an integer type. Since the argument `fVar` can contain values that are not representable within the `int` data type, the analysis flags a potential overflow.

Note that `func` is not called in this example, and the overflow is only a possibility. To see issues of these types, add the analysis option `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

Preserve precision when converting integral values to floating-point type

## Description

### Rule Definition

*Preserve precision when converting integral values to floating-point type.*

### Polyspace Implementation

The rule checker checks for **Precision loss in integer to float conversion**.

## Examples

### Precision loss in integer to float conversion

#### Issue

**Precision loss from integer to float conversion** occurs when you cast an integer value to a floating-point type that cannot represent the original integer value.

For instance, the `long int` value `1234567890L` is too large for a variable of type `float` .

#### Risk

If the floating-point type cannot represent the integer value, the behavior is undefined (see C11 standard, 6.3.1.4, paragraph 2). For instance, least significant bits of the variable value can be dropped leading to unexpected results.

#### Fix

Convert to a floating-point type that can represent the integer value.

For instance, if the `float` data type cannot represent the integer value, use the `double` data type instead.

When writing a function that converts an integer to floating point type, before the conversion, check if the integer value can be represented in the floating-point type. For instance, `DBL_MANT_DIG * log2(FLT_RADIX)` represents the number of base-2 digits in the type `double`. Before conversion to the type `double`, check if this number is greater than or equal to the precision of the integer that you are converting. To determine the precision of an integer `num`, use this code:

```
size_t precision = 0;
while (num != 0) {
   if (num % 2 == 1) {
     precision++;
   }
   num >>= 1;
}
```

Some implementations provide a builtin function to determine the precision of an integer. For instance, GCC provides the function `__builtin_popcount`.

**Example - Conversion of Large Integer to Floating-Point Type**

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  float approx = big; //Noncompliant
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

In this example, the `long int` variable `big` is converted to `float`.

**Correction — Use a Wider Floating-Point Type**

One possible correction is to convert to the `double` data type instead of `float`.

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  double approx = big;
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

Do not use object representations to compare floating-point values

## Description

### Rule Definition

*Do not use object representations to compare floating-point values.*

### Polyspace Implementation

The rule checker checks for **Memory comparison of float-point values**.

## Examples

### Memory comparison of float-point values

**Issue**

**Memory comparison of float-point values** occurs when you compare the object representation of floating-point values or the object representation of structures containing floating-point members. When you use the functions `memcmp`, `bcmp`, or `wmemcmp` to perform the bit pattern comparison, the defect is raised.

**Risk**

The object representation of floating-point values uses specific bit patterns to encode those values. Floating-point values that are equal, for instance `-0.0` and `0.0` in the IEC 60559 standard, can have different bit patterns in their object representation. Similarly, floating-point values that are not equal can have the same bit pattern in their object representation.

**Fix**

When you compare structures containing floating-point members, compare the structure members individually.

To compare two floating-point values, use the `==` or `!=` operators. If you follow a standard that discourages the use of these operators, such as MISRA, ensure that the difference between the floating-point values is within an acceptable range.

**Example - Using `memcmp` to Compare Structures with Floating-Point Members**

```
#include <string.h>

typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

int func_cmp(myStruct *s1, myStruct *s2) {
/* Comparison between structures containing
* floating-point members */
    return memcmp  //Noncompliant
        ((const void *)s1, (const void *)s2, sizeof(myStruct));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

In this example, `func_cmp()` calls `memcmp()` to compare the object representations of structures `s1` and `s2`. The comparison might be inaccurate because the structures contain floating-point members.

#### Correction — Compare Structure Members Individually

One possible correction is to compare the structure members individually and to ensure that the difference between the floating-point values is within an acceptable range defined by `ESP`.

```
 #include <string.h>

typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

#define ESP 0.00001

int func_cmp(myStruct *s1, myStruct *s2) {

/*Structure members are compared individually */
    return ((s1->i == s2->i) &&
            (fabsf(s1->f - s2->f) <= ESP));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

Do not form or use out-of-bounds pointers or array subscripts

## Description

### Rule Definition

*Do not form or use out-of-bounds pointers or array subscripts.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access out of bounds**.
- **Pointer access out of bounds**.
- **Array access with tainted index**.
- **Pointer dereference with tainted offset**.

### Extend Checker

A default Bug Finder analysis might not flag an **Array access out of bounds** issue when the input values are unknown and only a subset of inputs cause the issue. To check for the **Array access out of bounds** issue caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

A default Bug Finder analysis might not flag an **Array access with tainted index** or **Pointer dereference with tainted offset** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Array access out of bounds

#### Issue

**Array access out of bounds** occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.

- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Array Access Out of Bounds Error

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);    //Noncompliant
    /* Defect: Value of i is greater than allowed value of 9 */
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

#### Correction — Keep Array Index Within Array Bounds

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];

   for (i = 0; i < 10; i++)
    {
        if (i < 2)
            fib[i] = 1;
        else
            fib[i] = fib[i-1] + fib[i-2];
    }

    /* Fix: Print fib[9] instead of fib[10] */
    printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.

- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

**Fix**

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

**Example - Use Index to Return Buffer Value**

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];   //Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The function does not check to see if `num` is inside the range of `tab`.

**Correction — Check Range Before Use**

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

### Pointer dereference with tainted offset

**Issue**

**Pointer dereference with tainted offset** detects pointer dereferencing, either reading or writing, using an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

#### Fix

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

#### Example - Dereference Pointer Array

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset]; //Noncompliant
        free(pint);
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `offset`. The value of `offset` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of `offset`. Continue with the pointer dereferencing only if `offset` is inside the valid range.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

Ensure size arguments for variable length arrays are in a valid range

## Description

### Rule Definition

*Ensure size arguments for variable length arrays are in a valid range.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Memory allocation with tainted size**.
- **Tainted size of variable length array**.

### Extend Checker

A default Bug Finder analysis might not flag a **Memory allocation with tainted size** or **Tainted size of variable length array** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Memory allocation with tainted size

#### Issue

**Memory allocation with tainted size** checks memory allocation functions, such as `calloc` or `malloc`, for size arguments from unsecured sources.

#### Risk

Uncontrolled memory allocation can cause your program to request too much system memory. This consequence can lead to a crash due to an out-of-memory condition, or assigning too many resources.

#### Fix

Before allocating memory, check the value of your arguments to check that they do not exceed the bounds.

#### Example - Allocate Memory Using Input Argument

```
#include<stdio.h>
#include <stdlib.h>

int* bug_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = (int*)malloc(size); //Noncompliant
    return p;
}
```

In this example, malloc allocates size amount of memory for the pointer p. size is an outside variable, so could be any size value. If the size is larger than the amount of memory you have available, your program could crash.

#### Correction — Check Size of Memory to be Allocated

One possible correction is to check the size of the memory that you want to allocate before performing the malloc operation. This example checks to see if the size is positive and less than the maximum size.

```
#include<stdio.h>
#include <stdlib.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int* corrected_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = NULL;
    if (size>0 && size<SIZE128) {          /* Fix: Check entry range before use */
        p = (int*)malloc((unsigned int)size);
    }
    return p;
}
```

### Tainted size of variable length array

#### Issue

**Tainted size of variable length array** detects variable length arrays (VLA) whose size is from an unsecure source.

#### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

#### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

#### Example - Input Argument Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
#define LIM 40

long squaredSum(int size) {

    int tabvla[size]; //Noncompliant
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

**Correction — Check VLA Size**

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 10 and less than 100, before creating the VLA

```
#include <stdio.h>
#include <stdlib.h>
#define LIM 40

long squaredSum(int size) {
    long res = 0;
    if (size>0 && size<LIM){
        int tabvla[size];
        for (int i=0 ; i<size || i<LIM-1 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }else{
        res = -1;
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

Do not subtract or compare two pointers that do not refer to the same array

## Description

### Rule Definition

*Do not subtract or compare two pointers that do not refer to the same array.*

### Polyspace Implementation

The rule checker checks for **Subtraction or comparison between pointers to different arrays**.

## Examples

### Subtraction or comparison between pointers to different arrays

#### Issue

**Subtraction or comparison between pointers to different arrays** occurs when you subtract or compare pointers that are null or that point to elements in different arrays. The relational operators for the comparison are >, <, >=, and <=.

#### Risk

When you subtract two pointers to elements in the same array, the result is the difference between the subscripts of the two array elements. Similarly, when you compare two pointers to array elements, the result is the positions of the pointers relative to each other. If the pointers are null or point to different arrays, a subtraction or comparison operation is undefined. If you use the subtraction result as a buffer index, it can cause a buffer overflow.

#### Fix

Before you subtract or use relational operators to compare pointers to array elements, check that they are non-null and that they point to the same array.

#### Example - Subtraction Between Pointers to Elements in Different Arrays

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int end;
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation is undefined unless array nums
    is adjacent to variable end in memory. */
    free_elements = &end - next_num_ptr;  //Noncompliant
    return free_elements;
}
```

In this example, the array `nums` is incrementally filled. Pointer subtraction is then used to determine how many free elements remain. Unless `end` points to a memory location one past the last element of `nums`, the subtraction operation is undefined.

**Correction — Subtract Pointers to the Same Array**

Subtract the pointer to the last element that was filled from the pointer to the last element in the array.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation involves pointers to the same array. */
    free_elements = &(nums[SIZE20 - 1]) - next_num_ptr;

    return free_elements + 1;
}
```

Do not add or subtract an integer to a pointer to a non-array object

## Description

### Rule Definition

*Do not add or subtract an integer to a pointer to a non-array object.*

### Polyspace Implementation

The rule checker checks for **Invalid assumptions about memory organization**.

## Examples

### Invalid assumptions about memory organization

#### Issue

**Invalid assumptions about memory organization** occurs when you compute the address of a variable in the stack by adding or subtracting from the address of another non-array variable.

#### Risk

When you compute the address of a variable in the stack by adding or subtracting from the address of another variable, you assume a certain memory organization. If your assumption is incorrect, accessing the computed address can be invalid.

#### Fix

Do not perform an access that relies on assumptions about memory organization.

If you want to justify this violation, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Reliance on Memory Organization

```
void func(void) {
    int var1 = 0x00000011, var2;
    *(&var1 + 1) = 0; //Noncompliant
}
```

In this example, the programmer relies on the assumption that `&var1 + 1` provides the address of `var2`. Therefore, an **Invalid assumptions about memory organization** appears on the `+` operation. In addition, a **Pointer access out of bounds** error also appears on the dereference.

#### Correction — Do Not Rely on Memory Organization

One possible correction is not perform direct computation on addresses to access separately declared variables.

Guarantee that library functions do not form invalid pointers

## Description

### Rule Definition

*Guarantee that library functions do not form invalid pointers.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Mismatch between data length and size**.
- **Invalid use of standard library memory routine**.
- **Possible misuse of sizeof**.
- **Buffer overflow from incorrect string format specifier**.
- **Invalid use of standard library string routine**.
- **Destination buffer overflow in string manipulation**.
- **Destination buffer underflow in string manipulation**.

## Examples

### Mismatch between data length and size

#### Issue

**Mismatch between data length and size** looks for memory copying functions such as `memcpy`, `memset`, or `memmove`. If you do not control the length argument and data buffer argument properly, Bug Finder raises a defect.

#### Risk

If an attacker can manipulate the data buffer or length argument, the attacker can cause buffer overflow by making the actual data size smaller than the length.

This mismatch in length allows the attacker to copy memory past the data buffer to a new location. If the extra memory contains sensitive information, the attacker can now access that data.

This defect is similar to the SSL Heartbleed bug.

#### Fix

When copying or manipulating memory, compute the length argument directly from the data so that the sizes match.

#### Example - Copy Buffer of Data

```
#include <stdlib.h>
#include <string.h>
```

```
typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    memcpy(&(beta.data[num]), os->data + 2, length); //Noncompliant

    return(1);
}
```

This function copies the buffer `alpha` into a buffer `beta`. However, the `length` variable is not related to `data+2`.

#### Correction — Check Buffer Length

One possible correction is to check the length of your buffer against the maximum value minus 2. This check ensures that you have enough space to copy the data to the `beta` structure.

```
#include <stdlib.h>
#include <string.h>

typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    if (length<(os->max -2)) {
        memcpy(&(beta.data[num]), os->data + 2, length);
    }

    return(1);

}
```

### Invalid use of standard library memory routine

#### Issue

**Invalid use of standard library memory routine** occurs when a memory library function is called with invalid arguments. For instance, the memcpy function copies to an array that cannot accommodate the number of bytes copied.

#### Risk

Use of a memory library function with invalid arguments can result in issues such as buffer overflow.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library Memory Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  char str1[10],str2[5];

  printf("Enter string:\n");
  scanf("%9s",str1);

  memcpy(str2,str1,6);  //Noncompliant
  /* Defect: Arguments of memcpy invalid: str2 has size < 6 */

  return str2;
 }
```

The size of string str2 is 5, but six characters of string str1 are copied into str2 using the memcpy function.

#### Correction — Call Function with Valid Arguments

One possible correction is to adjust the size of str2 so that it accommodates the characters copied with the memcpy function.

```
#include <string.h>
#include <stdio.h>
```

```
char* Copy_First_Six_Letters(void)
 {
  /* Fix: Declare str2 with size 6 */
  char str1[10],str2[6];

  printf("Enter string:\n");
  scanf("%9s",str1);

  memcpy(str2,str1,6);
  return str2;
 }
```

### Possible misuse of sizeof

#### Issue

**Possible misuse of sizeof** occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

#### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

#### Fix

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

  The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.

- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

#### Example - `sizeof` Used Incorrectly to Determine Array Size

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++)    { //Noncompliant
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

#### Correction — Determine Array Size in Another Way

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf); //Noncompliant
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_String(void)
{
 char *res;
 char gbuffer[5],text[20]="ABCDEFGHIJKL";

 res=strcpy(gbuffer,text);  //Noncompliant
 /* Error: Size of text is less than gbuffer */
```

```
  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>
```

```
void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string); //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

**Correction — Use `snprintf` Instead of `sprintf`**

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Destination buffer underflow in string manipulation

**Issue**

**Destination buffer underflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at a negative offset from the beginning of the buffer.

For instance, for the function `sprintf(char* buffer, const char* format)`, you obtain the `buffer` from an operation `buffer = (char*)arr; ... buffer += offset;`. `arr` is an array and `offset` is a negative value.

**Risk**

Buffer underflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer underflow also introduces the risk of code injection.

**Fix**

If the destination buffer argument results from pointer arithmetic, see if you are decrementing a pointer. Fix the pointer decrement by modifying either the original value before decrement or the decrement value.

**Example - Buffer Underflow in `sprintf` Use**

```
#include <stdio.h>
#define offset -2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";

    sprintf(&buffer[offset], fmt_string);      //Noncompliant
}
```

In this example, `&buffer[offset]` is at a negative offset from the memory allocated to `buffer`.

#### Correction — Change Pointer Decrementer

One possible correction is to change the value of `offset`.

```
#include <stdio.h>
#define offset 2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";

    sprintf(&buffer[offset], fmt_string);
}
```

Do not add or subtract a scaled integer to a pointer

## Description

### Rule Definition

*Do not add or subtract a scaled integer to a pointer.*

### Polyspace Implementation

The rule checker checks for **Incorrect pointer scaling**.

## Examples

### Incorrect pointer scaling

#### Issue

**Incorrect pointer scaling** occurs when Polyspace Bug Finder considers that you are ignoring the implicit scaling in pointer arithmetic.

For instance, the defect can occur in the following situations.

| Situation | Risk | Possible Fix |
|---|---|---|
| You use the `sizeof` operator in arithmetic operations on a pointer. | The `sizeof` operator returns the size of a data type in number of bytes.<br>Pointer arithmetic is already implicitly scaled by the size of the data type of the pointed variable. Therefore, the use of `sizeof` in pointer arithmetic produces unintended results. | Do not use `sizeof` operator in pointer arithmetic. |
| You perform arithmetic operations on a pointer, and then apply a cast. | Pointer arithmetic is implicitly scaled. If you do not consider this implicit scaling, casting the result of a pointer arithmetic produces unintended results. | Apply the cast before the pointer arithmetic. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Example — Use of sizeof Operator

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;

    int value_in_position_2 = *(ptr + 2*(sizeof(int)));//Noncompliant //Noncompliant
}
```

In this example, the operation `2*(sizeof(int))` returns twice the size of an `int` variable in bytes. However, because pointer arithmetic is implicitly scaled, the number of bytes by which `ptr` is offset is `2*(sizeof(int))*(sizeof(int))`.

In this example, the incorrect scaling shifts `ptr` outside the bounds of the array. Therefore, a **Pointer access out of bounds** error appears on the * operation.

### Correction — Remove sizeof Operator

One possible correction is to remove the `sizeof` operator.

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;

    int value_in_position_2 = *(ptr + 2);
}
```

### Example — Cast Following Pointer Arithmetic

```
int func(void) {
    int x = 0;
    char r = *(char *)(&x + 1); //Noncompliant
    return r;
}
```

In this example, the operation `&x + 1` offsets `&x` by `sizeof(int)`. Following the operation, the resulting pointer points outside the allowed buffer. When you dereference the pointer, a **Pointer access out of bounds** error appears on the * operation.

### Correction — Apply Cast Before Pointer Arithmetic

If you want to access the second byte of `x`, first cast `&x` to a `char*` pointer and then perform the pointer arithmetic. The resulting pointer is offset by `sizeof(char)` bytes and still points within the allowed buffer, whose size is `sizeof(int)` bytes.

```
int func(void) {
    int x = 0;
    char r = *((char *)(&x )+ 1);
    return r;
}
```

**Example — Use of sizeof in Function Arguments**

```
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
enum { WCHAR_BUF = 128 };
FILE* pFile;
//...
void func2_ko (void)
{
    wchar_t error_msg[WCHAR_BUF];
    wcscpy (error_msg, L"Error: ");
    fgetws (error_msg + wcslen (error_msg)   //Noncompliant
           * sizeof (wchar_t), WCHAR_BUF - 7, pFile);
}
```

In this example, an error message is read from the file pointer pFile stream and copied to error_msg after an offset. The intended offset here is wcslen(error_msg), which is already implicitly scaled when it is added to the wchar pointer error_msg. Because the offset is then explicitly scaled again by using sizeof, Polyspace flags the incorrect scaling.

**Correction — Remove sizeof Operator**

One possible correction is to remove the sizeof operator.

```
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
enum { WCHAR_BUF = 128 };
const wchar_t ERROR_PREFIX[8] = L"Error: ";
FILE* pFile;
//...

void func2_ok (void)
{
  const size_t prefix_len = wcslen (ERROR_PREFIX);
  wchar_t error_msg[WCHAR_BUF];
  wcscpy (error_msg, ERROR_PREFIX);
  fgetws (error_msg + prefix_len, WCHAR_BUF - prefix_len, pFile);  //Compliant
  /* ... */
}
```

**Example — Implicitly Scaled Offset When Calling memset**

```
#include <string.h>
#include <stdlib.h>
#include <stddef.h>

#define bigNum unsigned long long

struct Collection {
    bigNum bn_A;
    bigNum bn_B;
    bigNum bn_C;
    int ci_1;
    int ci_2;
};

void foo(void) {
    size_t offset = offsetof(struct Collection, bn_B);
    struct Collection *s = (struct Collection *)malloc(sizeof(struct Collection));
    if (s == NULL) {
        /* Handle malloc() error */
    }

    memset(s + offset, 0, sizeof(struct Collection) - offset); //Noncompliant
    /* ... */
    free(s);
    s = NULL;
}
```

In this example, `offset` is calculated by calling `offsetof`, and then added to `s`. The variable `offset` is the byte offset of `bn_B` in `struct Collection`. When setting memory by using `memset`, instead of offsetting the location by bytes, `offset` is implicitly scaled by the size. The implicit scaling might cause unexpected results. Polyspace raises a violation.

#### Correction — Calculate Offset by Using `unsigned char*`

The violation is caused by the fact that `offset` is scaled by the type of `s`. Avoid the violation by declaring `s` as `unsigned char*`, which is scaled by a factor of one.

```
#include <string.h>
#include <stdlib.h>
#include <stddef.h>

#define bigNum unsigned long long

struct Collection {
    bigNum bn_A;
    bigNum bn_B;
    bigNum bn_C;
    int ci_1;
    int ci_2;
};

void foo(void) {
    size_t offset = offsetof(struct Collection, bn_B);
    unsigned char *s = (unsigned char *)malloc(sizeof(struct Collection));
    if (s == NULL) {
        /* Handle malloc() error */
    }

    memset(s + offset, 0, sizeof(struct Collection) - offset); //Compliant
    /* ... */
    free(s);
    s = NULL;
}
```

Do not attempt to modify string literals

## Description

### Rule Definition

*Do not attempt to modify string literals.*

### Polyspace Implementation

The rule checker checks for **Writing to const qualified object**.

## Examples

### Writing to const qualified object

#### Issue

**Writing to `const` qualified object** occurs when you do one of the following:

- Use a `const`-qualified object as the destination of an assignment.
- Pass a `const`-qualified object to a function that modifies the argument.

For instance, the defect can occur in the following situations:

- You pass a `const`-qualified object as first argument of one of the following functions:
  - `mkstemp`
  - `mkostemp`
  - `mkostemps`
  - `mkdtemp`
- You pass a `const`-qualified object as the destination argument of one of the following functions:
  - `strcpy`
  - `strncpy`
  - `strcat`
  - `memset`
- You perform a write operation on a `const`-qualified object.

#### Risk

The risk depends upon the modifications made to the `const`-qualified object.

| Situation | Risk |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | These functions replace the last six characters of their first argument with a string. Therefore, they expect a modifiable `char` array as their first argument. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | These functions modify their destination argument. Therefore, they expect a modifiable `char` array as their destination argument. |
| Writing to the object | The `const` qualifier implies an agreement that the value of the object will not be modified. By writing to a `const`-qualified object, you break the agreement. The result of the operation is undefined. |

#### Fix

The fix depends on the modification made to the `const`-qualified object.

| Situation | Fix |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | Pass a non-`const` object as first argument of the function. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | Pass a non-`const` object as destination argument of the function. |
| Writing to the object | Perform the write operation on a non-`const` object. |

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Writing to `const`-Qualified Object

```
#include <string.h>

const char* buffer = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string); //Noncompliant
}
```

In this example, because `buffer` is `const`-qualified, `strchr(buffer,'X')` returns a `const`-qualified `char*` pointer. When this `char*` pointer is used as the destination argument of `strcpy`, a **Writing to const qualified object** error appears.

#### Correction — Copy `const`-Qualified Object to Non-`const` Object

One possible correction is to assign the constant string to a non-`const` object and use the non-`const` object as destination argument of `strchr`.

```
#include <string.h>

char buffer[] = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

# CERT C: Rule STR31-C

Guarantee that storage for strings has sufficient space for character data and the null terminator

## Description

### Rule Definition

*Guarantee that storage for strings has sufficient space for character data and the null terminator.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of dangerous standard function**.
- **Missing null in string array**.
- **Buffer overflow from incorrect string format specifier**.
- **Destination buffer overflow in string manipulation**.
- **Insufficient destination buffer size**.

## Examples

### Use of dangerous standard function

#### Issue

The **Use of dangerous standard function** check highlights uses of functions that are inherently dangerous or potentially dangerous given certain circumstances. The following table lists possibly dangerous functions, the risks of using each function, and what function to use instead.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `cin` | Inherently dangerous — You cannot control the length of input from the console. | Avoid or prefaces calls to `cin` with `cin.width`. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Using `sprintf`

```
#include <stdio.h>
#include <string.h>
#include <iostream>
```

```
#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1) //Noncompliant
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

#### Correction — Use `snprintf` with Buffer Size

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Missing null in string array

#### Issue

**Missing null in string array** occurs when a string does not have enough space to terminate with a null character `'\0'`.

This defect applies only for projects in C.

#### Risk

A buffer overflow can occur if you copy a string to an array without assuming the implicit null terminator.

#### Fix

If you initialize a character array with a literal, avoid specifying the array bounds.

```
char three[]  = "THREE";
```

The compiler automatically allocates space for a null terminator. In the preceding example, the compiler allocates sufficient space for five characters and a null terminator.

If the issue occurs after initialization, you might have to increase the size of the array by one to account for the null terminator.

In certain circumstances, you might want to initialize the character array with a sequence of characters instead of a string. In this situation, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Array size is too small

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[5] = "THREE"; //Noncompliant
}
```

The character array `three` has a size of 5 and 5 characters `'T'`, `'H'`, `'R'`, `'E'`, and `'E'`. There is no room for the null character at the end because `three` is only five bytes large.

#### Correction — Increase Array Size

One possible correction is to change the array size to allow for the five characters plus a null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[6] = "THREE";
}
```

#### Correction — Change Initialization Method

One possible correction is to initialize the string by leaving the array size blank. This initialization method allocates enough memory for the five characters and a terminating-null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[]  = "THREE";
}
```

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf); //Noncompliant
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string); //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Insufficient destination buffer size

#### Issue

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(input, str); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

#### Risk

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if `argv[0]` contains 100 or more characters, the `strcpy` operation results in a buffer overflow.

#### Fix

Before calling the function `strcpy()`, allocate sufficient memory dynamically. For instance, use the function `strlen()` to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value `strlen(source) + 1`.

#### Example — Destination Buffer Too Small

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[128];
  strcpy(source, destination);//Noncompliant

  return 0;
}
```

#### Correction — Allocate Sufficient Memory for Destination Buffer

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char* destination = (char *)malloc(strlen(source)+ 1);
  if(destination!=NULL){
      strcpy(source, destination);//Compliant
  }else{
      /*Handle Error*/
  }
  //...
  free(destination);
  return 0;
}
```

# CERT C: Rule STR32-C

Do not pass a non-null-terminated character sequence to a library function that expects a string

## Description

### Rule Definition

*Do not pass a non-null-terminated character sequence to a library function that expects a string.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid use of standard library string routine**.
- **Tainted NULL or non-null-terminated string**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted NULL or non-null-terminated string** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source)
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
 #include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);  //Noncompliant
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Tainted NULL or non-null-terminated string

#### Issue

**Tainted NULL or non-null-terminated string** looks for strings from unsecure sources that are being used in string manipulation routines that implicitly dereference the string buffer. For example, `strcpy` or `sprintf`.

**Tainted NULL or non-null-terminated string** raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

**Note** If you reference a string using the form `ptr[i]`, `*ptr`, or pointer arithmetic, Bug Finder raises a **Use of tainted pointer** defect instead. The **Tainted NULL or non-null-terminated string** defect is raised only when the pointer is used as a string.

#### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

#### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

#### Example — Getting String from Input

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1)); //Noncompliant
    print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

#### Correction — Validate the Data

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
```

```
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // TAINTED_STRING only flagged here //Noncompliant
        // - string is not null
        // - string has a positive and limited size
        // - TAINTED_STRING on strlen used as a firewall
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

**Correction — Validate the Data**

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }
  return sensorValue;
}
```

Cast characters to unsigned char before converting to larger integer sizes

## Description

### Rule Definition

*Cast characters to unsigned char before converting to larger integer sizes.*

### Polyspace Implementation

The rule checker checks for **Misuse of sign-extended character value**.

## Examples

### Misuse of sign-extended character value

#### Issue

**Misuse of sign-extended character value** occurs when you convert a signed or plain `char` data type to a wider integer data type with sign extension. You then use the resulting sign-extended value as array index, for comparison with EOF or as argument to a character-handling function.

#### Risk

*Comparison with EOF*: Suppose, your compiler implements the plain `char` type as signed. In this implementation, the character with the decimal form of 255 (–1 in two's complement form) is stored as a signed value. When you convert a `char` variable to the wider data type `int` for instance, the sign bit is preserved (sign extension). This sign extension results in the character with the decimal form 255 being converted to the integer –1, which cannot be distinguished from EOF.

*Use as array index*: By similar reasoning, you cannot use sign-extended plain `char` variables as array index. If the sign bit is preserved, the conversion from `char` to `int` can result in negative integers. You must use positive integer values for array index.

*Argument to character-handling function*: By similar reasoning, you cannot use sign-extended plain `char` variables as arguments to character-handling functions declared in `ctype.h`, for instance, `isalpha()` or `isdigit()`. According to the C11 standard (Section 7.4), if you supply an integer argument that cannot be represented as `unsigned char` or EOF, the resulting behavior is undefined.

#### Fix

Before conversion to a wider integer data type, cast the signed or plain `char` value explicitly to `unsigned char`.

#### Example - Sign-Extended Character Value Compared with EOF

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];
```

```
static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = *buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {  //Noncompliant
        /* Handle error */
        fatal_error();
    }
}
```

In this example, the function `parser` can traverse a string input `buf`. If a character in the string has the decimal form 255, when converted to the `int` variable `c`, its value becomes –1, which is indistinguishable from `EOF`. The later comparison with `EOF` can lead to a false positive.

#### Correction — Cast to `unsigned char` Before Conversion

One possible correction is to cast the plain `char` value to `unsigned char` before conversion to the wider `int` type.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];

static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = (unsigned char)*buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

Arguments to character-handling functions must be representable as an unsigned char

## Description

### Rule Definition

*Arguments to character-handling functions must be representable as an unsigned char.*

### Polyspace Implementation

The rule checker checks for **Invalid arguments to character-handling functions**.

## Examples

### Invalid arguments to character-handling functions

#### Issue

**Invalid arguments to character-handling functions** occurs when you use a signed or plain `char` variable with a negative value as argument to a character-handling function declared in `ctype.h`, for instance, `isalpha()` or `isdigit()`.

#### Risk

You cannot use plain `char` variables as arguments to these character-handling functions. On certain platforms, plain `char` variables can have negative values that cannot be represented as `unsigned char` or EOF, resulting in undefined behavior.

#### Fix

To avoid unexpected results, explicitly cast plain `char` variables to unsigned `char` before passing to character-handling functions.

Do not confuse narrow and wide character strings and functions

## Description

### Rule Definition

*Do not confuse narrow and wide character strings and functions.*

### Polyspace Implementation

The rule checker checks for **Misuse of narrow or wide character string**.

## Examples

### Misuse of narrow or wide character string

#### Issue

**Misuse of narrow or wide character string** occurs when you pass a narrow character string to a wide string function, or a wide character string to a narrow string function.

**Misuse of narrow or wide character string** raises no defect on operating systems where narrow and wide character strings have the same size.

#### Risk

Using a narrow character string with a wide string function, or vice versa, can result in unexpected or undefined behavior.

If you pass a wide character string to a narrow string function, you can encounter these issues:

- Data truncation. If the string contains null bytes, a copy operation using `strncpy()` can terminate early.
- Incorrect string length. `strlen()` returns the number of characters of a string up to the first null byte. A wide string can have additional characters after its first null byte.

If you pass a narrow character string to a wide string function, you can encounter this issue:

- Buffer overflow. In a copy operation using `wcsncpy()`, the destination string might have insufficient memory to store the result of the copy.

#### Fix

Use the narrow string functions with narrow character strings. Use the wide string functions with wide character strings.

#### Example - Passing Wide Character Strings to `strncpy()`

```
#include <string.h>
#include <wchar.h>

void func(void)
```

```
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    strncpy(wide_str2, wide_str1, 10); //Noncompliant
}
```

In this example, `strncpy()` copies 10 wide characters from `wide_strt1` to `wide_str2`. If `wide_str1` contains null bytes, the copy operation can end prematurely and truncate the wide character string.

#### Correction — Use `wcsncpy()` to Copy Wide Character Strings

One possible correction is to use `wcsncpy()` to copy `wide_str1` to `wide_str2`.

```
#include <string.h>
#include <wchar.h>

void func(void)
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    wcsncpy(wide_str2, wide_str1, 10);
}
```

Do not access freed memory

## Description

### Rule Definition

*Do not access freed memory.*

### Polyspace Implementation

This checker checks for:

- **Accessing previously freed pointer**
- **Freeing previously freed pointer**

## Examples

### Accessing previously freed pointer

#### Issue

**Accessing previously freed pointer** occurs when you attempt to access a block of memory after freeing the block by using the `free` function.

#### Risk

When a pointer is allocated dynamic memory by using `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation and the pointer becomes a dangling pointer. Attempting to access this block of memory by dereferencing the dangling pointer can result in unpredictable behavior or a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. Determine if you intended to free the memory later or allocate another memory block to the pointer before access.

As a best practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

#### Example — Accessing Previously Freed Pointer Error

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   {
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);

    j = *pi + shift; //Noncompliant
    /* Defect: Reading a freed pointer */

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing `pi` after the `free` statement is not valid.

**Correction — Free Pointer After Last Use**

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

### Freeing previously freed pointer

**Issue**

**Freeing previously freed pointer** occurs when you attempt to free the memory allocated to a pointer after already freeing the pointer by using the `free` function.

**Risk**

Attempting to free the memory associated with a previously freed pointer might corrupt the memory management of the program and cause a memory leak. This defect might allow an attacker to access the memory and execute arbitrary code.

**Fix**

To avoid this defect, assign pointers to NULL after freeing them. Check the pointers for NULL value before attempting to access the memory associated with the pointer. In this way, you are protected against accessing a freed block.

**Example — Freeing Previously Freed Pointer**

```
#include <stdlib.h>
#include <stdio.h>
int getStatus();
void double_deallocation(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == 0) return;

    *pi = 2;
    /*...*/
    if(getStatus()==1)
    {
        /*...*/
        free(pi);
    }
    free(pi); //Noncompliant //Noncompliant
}
```

The second `free` statement attempts to release the block of memory that `pi` refers to, but the pointer `pi` might already be freed in the `if` block of code. This second `free` statement might cause a memory leak and security vulnerabilities in the code. Polyspace flags the second `free` statement.

**Correction — Check Pointers Before Calling `free`**

One possible correction is to assign freed pointers to NULL and to check pointers for NULL before freeing them.

```
#include <stdlib.h>
#include <stdio.h>
int getStatus();
void double_deallocation(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == 0) return;

    *pi = 2;
    /*...*/
    if(getStatus()==1)
    {
        /*...*/
        if(pi!=NULL)
        {
            free(pi);
            pi= NULL;
        }
    }
    /*...*/
    if(pi!=NULL)
    {
        free(pi);
        pi= NULL;
    } //Compliant
}
```

In this case, the memory allocated to pointer `pi` is freed only if it is not already freed.

**Example – Freeing Pointer Previously Reallocated With Possibly Zero Size**

```
#include <stdlib.h>

void reshape(char *buf, size_t size) {
  char *reshaped_buf = (char *)realloc(buf, size);
  if (reshaped_buf == NULL) {
    free(buf); //Noncompliant
  }
}
```

In this example, the argument `size` of the `reshape()` function can be zero and result in a zero-size reallocation with `realloc()`. In some implementations such as the GNU library, zero-size reallocations free the memory leading to a double free defect.

#### Correction – Guard Against Zero-Size Reallocations

One possible correction is to check size argument of `realloc()` for zero values before use. If the size argument is zero, you can simply free the memory instead of reallocating it.

```
#include <stdlib.h>

void reshape(char *buf, size_t size) {
  if (size != 0) {
    char *reshaped_buf = (char *)realloc(buf, size);
    if (reshaped_buf == NULL) {
      free(buf);
    }
  }
  else {
    free(buf);
  }

}
```

Free dynamically allocated memory when no longer needed

## Description

### Rule Definition

*Free dynamically allocated memory when no longer needed.*

### Polyspace Implementation

The rule checker checks for **Memory leak**.

## Examples

### Memory leak

#### Issue

**Memory leak** occurs when you do not free a block of memory allocated through `malloc`, `calloc`, `realloc`, or `new`. If the memory is allocated in a function, the defect does not occur if:

- Within the function, you free the memory using `free` or `delete`.
- The function returns the pointer assigned by `malloc`, `calloc`, `realloc`, or `new`.
- The function stores the pointer in a global variable or in a parameter.

#### Risk

Dynamic memory allocation functions such as `malloc` allocate memory on the heap. If you do not release the memory after use, you reduce the amount of memory available for another allocation. On embedded systems with limited memory, you might end up exhausting available heap memory even during program execution.

#### Fix

Determine the scope where the dynamically allocated memory is accessed. Free the memory block at the end of this scope.

To free a block of memory, use the `free` function on the pointer that was used during memory allocation. For instance:

```
ptr = (int*)malloc(sizeof(int));
//...
free(ptr);
```

It is a good practice to allocate and free memory in the same module at the same level of abstraction. For instance, in this example, `func` allocates and frees memory at the same level but `func2` does not.

```
void func() {
  ptr = (int*)malloc(sizeof(int));
  {
    //...
  }
  free(ptr);
}

void func2() {
  {
   ptr = (int*)malloc(sizeof(int));
   //...
  }
  free(ptr);
}
```

See CERT-C Rule MEM00-C.

**Example - Dynamic Memory Not Released Before End of Function**

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }

    *pi = 42;
    /* Defect: pi is not freed */
} //Noncompliant
```

In this example, `pi` is dynamically allocated by `malloc`. The function `assign_memory` does not free the memory, nor does it return `pi`.

**Correction — Free Memory**

One possible correction is to free the memory referenced by `pi` using the `free` function. The `free` function must be called before the function `assign_memory` terminates

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }
    *pi = 42;

    /* Fix: Free the pointer pi*/
    free(pi);
}
```

#### Correction — Return Pointer from Dynamic Allocation

Another possible correction is to return the pointer `pi`. Returning `pi` allows the function calling `assign_memory` to free the memory block using `pi`.

```
#include<stdlib.h>
#include<stdio.h>

int* assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) 
        {
            printf("Memory allocation failed");
            return(pi);
        }
    *pi = 42;

    /* Fix: Return the pointer pi*/
    return(pi);
}
```

Allocate and copy structures containing a flexible array member dynamically

## Description

### Rule Definition

*Allocate and copy structures containing a flexible array member dynamically.*

### Polyspace Implementation

The rule checker checks for **Misuse of structure with flexible array member**.

## Examples

### Misuse of structure with flexible array member

#### Issue

**Misuse of structure with flexible array member** occurs when:

- You define an object with a flexible array member of unknown size at compilation time.
- You make an assignment between structures with a flexible array member without using `memcpy()` or a similar function.
- You use a structure with a flexible array member as an argument to a function and pass the argument by value.
- Your function returns a structure with a flexible array member.

A flexible array member has no array size specified and is the last element of a structure with at least two named members.

#### Risk

If the size of the flexible array member is not defined, it is ignored when allocating memory for the containing structure. Accessing such a structure has undefined behavior.

#### Fix

- Use `malloc()` or a similar function to allocate memory for a structure with a flexible array member.
- Use `memcpy()` or a similar function to copy a structure with a flexible array member.
- Pass a structure with a flexible array member as a function argument by pointer.

#### Example - Structure Passed By Value to Function

```
#include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <unistd.h>
```

```
struct example_struct
{
    size_t num;
    int data[];
};

extern void arg_by_value(struct example_struct s);

void func(void)
{
    struct example_struct *flex_struct;
    size_t i;
    size_t array_size = 4;
    /* Dynamically allocate memory for the struct */
    flex_struct = (struct example_struct *)
        malloc(sizeof(struct example_struct) + sizeof(int) * array_size);
    if (flex_struct == NULL)
    {
        /* Handle error */
    }
    /* Initialize structure */
    flex_struct->num = array_size;
    for (i = 0; i < array_size; ++i)
    {
        flex_struct->data[i] = 0;
    }
    /* Handle structure */

    /* Argument passed by value. 'data' not
    copied to passed value. */
    arg_by_value(*flex_struct);  //Noncompliant

    /* Free dynamically allocated memory */
    free(flex_struct);
}
```

In this example, `flex_struct` is passed by value as an argument to `arg_by_value`. As a result, the flexible array member data is not copied to the passed argument.

**Correction — Pass Structure by Pointer to Function**

To ensure that all the members of the structure are copied to the passed argument, pass `flex_struct` to `arg_by_pointer` by pointer.

```
#include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <unistd.h>

struct example_struct
{
    size_t num;
    int data[];
};

extern void arg_by_pointer(struct example_struct *s);

void func(void)
{
    struct example_struct *flex_struct;
    size_t i;
    size_t array_size = 4;
    /* Dynamically allocate memory for the struct */
    flex_struct = (struct example_struct *)
        malloc(sizeof(struct example_struct) + sizeof(int) * array_size);
    if (flex_struct == NULL)
    {
        /* Handler error */
    }
    /* Initialize structure */
    flex_struct->num = array_size;
    for (i = 0; i < array_size; ++i)
    {
        flex_struct->data[i] = 0;
    }
    /* Handle structure */

    /* Structure passed by pointer */
    arg_by_pointer(flex_struct);

    /* Free dynamically allocated memory */
    free(flex_struct);
}
```

MEM33-C

# CERT C: Rule MEM34-C

Only free memory allocated dynamically

## Description

### Rule Definition

*Only free memory allocated dynamically.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid free of pointer**
- **Invalid reallocation of pointer**

## Examples

### Invalid free of pointer

#### Issue

**Invalid free of pointer** occurs when a block of memory released using the `free` function was not previously allocated using `malloc`, `calloc`, or `realloc`.

#### Risk

The `free` function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `free` function on a different pointer.

#### Fix

In most cases, you can fix the issue by removing the `free` statement. If a pointer is not allocated memory from the heap with `malloc` or `calloc`, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of `free` or `malloc` on the wrong pointer, correct the error.

If the issue occurs because you use the `free` function to free memory allocated with the `new` operator, replace the `free` function with the `delete` operator.

#### Example - Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
```

```
     *(p+i)=1;

  free(p);    //Noncompliant
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer p is deallocated using the free function. However, p points to a memory location that was not dynamically allocated.

#### Correction — Remove Pointer Deallocation

If the number of elements of the array p is known at compile time, one possible correction is to remove the deallocation of the pointer p.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

#### Correction — Introduce Pointer Allocation

If the number of elements of the array p is not known at compile time, one possible correction is to dynamically allocate memory to the array p.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

### Invalid reallocation of pointer

#### Issue

**Invalid reallocation of pointer** occurs when a block of memory reallocated using the realloc function was not previously allocated using malloc or calloc.

#### Risk

Reallocating a block of memory that was not allocated dynamically allocated can result in undefined behavior.

The issue can highlight coding errors. For instance, you perhaps wanted to use the realloc function on a different pointer.

**Fix**

If you want to reallocate a block of memory, make sure that it was dynamically allocated in the first place.

**Example – Reallocation of Memory Allocated Statically**

```
#include <stdlib.h>

#define SIZE 256

void reshape(int isSpaceAvailable) {
  char buf[SIZE];
  char *newBuf;
  newBuf = (char *)realloc(buf, 2 * SIZE); //Noncompliant

  if (newBuf == NULL) {
    /* Handle error */
  }
}
```

In this example, the buffer `buf` is not allocated dynamically. Therefore, the reallocation of `buf` results in undefined behavior.

**Example – Reallocation of Memory Allocated Statically**

Make sure that a buffer that you reallocate was previous allocated memory dynamically.

```
#include <stdlib.h>

#define SIZE 256

void reshape(void){
  char *buf;
  char *newBuf;
  buf = (char*)malloc(SIZE *sizeof(char));
  newBuf = (char *)realloc(buf, 2 * SIZE);

  if (newBuf == NULL) {
    /* Handle error */
  }
  free(newBuf);
}
```

MEM34-C

# CERT C: Rule MEM35-C

Allocate sufficient memory for an object

## Description

### Rule Definition

*Allocate sufficient memory for an object.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Pointer access out of bounds**.
- **Memory allocation with tainted size**.
- **Insufficient memory allocation**

### Extend Checker

A default Bug Finder analysis might not flag a **Memory allocation with tainted size** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Memory allocation with tainted size

#### Issue

**Memory allocation with tainted size** checks memory allocation functions, such as `calloc` or `malloc`, for size arguments from unsecured sources.

#### Risk

Uncontrolled memory allocation can cause your program to request too much system memory. This consequence can lead to a crash due to an out-of-memory condition, or assigning too many resources.

#### Fix

Before allocating memory, check the value of your arguments to check that they do not exceed the bounds.

#### Example — Allocate Memory Using Input From User

```
#include<stdio.h>
#include <stdlib.h>

int* bug_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = (int*)malloc(size); //Noncompliant
    return p;
}
```

In this example, `malloc` allocates `size` bytes of memory for the pointer `p`. The variable `size` comes from the user of the program. Its value is not checked, and it could be larger than the amount of available memory. If `size` is larger than the number of available bytes, your program could crash.

#### Correction — Check Size of Memory to be Allocated

One possible correction is to check the size of the memory that you want to allocate before performing the `malloc` operation. This example checks to see if `size` is positive and less than the maximum size.

```
#include<stdio.h>
#include <stdlib.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int* corrected_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = NULL;
    if (size>0 && size<SIZE128) {          /* Fix: Check entry range before use */
        p = (int*)malloc((unsigned int)size);
    }
    return p;
}
```

### Insufficient memory allocation

#### Issue

**Insufficient memory allocation** occurs when the allocated memory is not sufficient to hold the target object. Consider this code:

```
typedef struct S {
    int a;
    int b;
    int c;
}S;

void foo(){
    S* a;
    a = (S*)malloc(sizeof(S*)*2);//Noncompliant
}
void bar(){
    S* a;
    a = (S*)malloc(sizeof(S*)*3); //Compliant
}
```

Objects of type S must accommodate three integers, which typically requires 12 bytes of memory. In foo() the allocated memory size for the S type object is eight bytes. Because the allocated memory is insufficient to hold the target object, Polyspace reports a violation of this rule. In bar(), the allocated memory is 12 bytes, which is sufficient. Polyspace does not report a violation.

#### Risk

Insufficient memory allocation results in buffer overflow and unexpected termination of the program.

#### Fix

When allocating memory blocks, allocate sufficient memory.

#### Example — Allocate Memory for Objects by Calling malloc()

In this example, the function foo() allocates memory for pointers a and b:

- When allocating memory for a, the argument of sizeof() is S*, which is a pointer. In a 64 bit system, all pointer types are 8 bytes in size. The malloc() statement allocates 24 bytes, which is sufficient to accommodate an object of S type. Because the allocated memory can hold the a object, Polyspace does not report a violation. This statement causes a Wrong type used in sizeof defect.

  From the context of the malloc() statement, the object a is intended to be a three element array of S type objects. Clearly, the malloc() statement does not allocate sufficient memory for the entire array. In the for loop, when you access the elements of the array, the insufficient memory causes a violation of this rule. This way, the Wrong type used in sizeof defect in the malloc() statement causes a violation of this rule when you use a as an array. If you use a as an object instead of an array, this rule is not violated.
- When allocating memory for b, the malloc() statement allocates enough memory to accommodate two integers. Because objects of type S require enough memory to accommodate three integers, the allocated memory is insufficient. Polyspace reports a violation of this rule.

```
#include <stdlib.h>
```

```
typedef struct S
{
  int a;
  int b;
  int c;
} S;

void setS (S * a, int x, int y, int z)
{
  a->a = x;            //Noncompliant: pointer access out of bounds
  a->b = y;
  a->c = z;
}

void foo ()
{
  S *a, *b;
  a = (S *) malloc (3 * sizeof (S *));    //Compliant but causes PTR_SIZEOF_MISMATCH defect/
  setS(a,22,32,45); //Compliant
  for (int i = 1; i < 3; ++i)
    {
      setS (a + i, i, i * i, i * i * i);

    }
  b = (S *) malloc (2 * sizeof (int));    //Noncompliant

}
```

### Correction — Allocate Sufficient Memory

To fix this issue, allocate sufficient memory. The best practice is to use the `sizeof()` function with correct argument type and a correct multiplier to calculate how much memory is required.

```
#include <stdlib.h>

typedef struct S
{
  int a;
  int b;
  int c;
} S;

void setS (S * a, int x, int y, int z)
{
  a->a = x;            //Compliant: pointer access out of bounds
  a->b = y;
  a->c = z;
}

void foo ()
{
  S *a, *b;
  a = (S *) malloc (3 * sizeof (S));    //No violations of PTR_SIZEOF_MISMATCH*/
  setS(a,22,32,45); //Compliant
  for (int i = 1; i < 3; ++i)
    {
      setS (a + i, i, i * i, i * i * i);

    }
  b = (S *) malloc (1 * sizeof (S));    //Compliant
  //...
  free(a);
  free (b);
}
```

Do not modify the alignment of objects by calling realloc()

## Description

### Rule Definition

*Do not modify the alignment of objects by calling realloc().*

### Polyspace Implementation

The rule checker checks for **Alignment changed after memory reallocation**.

## Examples

### Alignment changed after memory reallocation

#### Issue

**Alignment changed after memory reallocation** occurs when you use `realloc()` to modify the size of objects with strict memory alignment requirements.

#### Risk

The pointer returned by `realloc()` can be suitably assigned to objects with less strict alignment requirements. A misaligned memory allocation can lead to buffer underflow or overflow, an illegally dereferenced pointer, or access to arbitrary memory locations. In processors that support misaligned memory, the allocation impacts the performance of the system.

#### Fix

To reallocate memory:

1. Resize the memory block.
   - In Windows, use `_aligned_realloc()` with the alignment argument used in `_aligned_malloc()` to allocate the original memory block.
   - In UNIX/Linux, use the same function with the same alignment argument used to allocate the original memory block.
2. Copy the original content to the new memory block.
3. Free the original memory block.

**Note** This fix has implementation-defined behavior. The implementation might not support the requested memory alignment and can have additional constraints for the size of the new memory.

#### Example - Memory Reallocated Without Preserving the Original Alignment

```
#include <stdio.h>
#include <stdlib.h>
```

```
#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;
    int *ptr1;

    /* Allocate memory with 4096 bytes alignment */

    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
      }

    /*Reallocate memory without using the original alignment.
    ptr1 may not be 4096 bytes aligned. */

    ptr1 = (int *)realloc(ptr, sizeof(int) * resize); //Noncompliant

    if (ptr1 == NULL)
    {
        /* Handle error */
    }

    /* Processing using ptr1 */

    /* Free before exit */
    free(ptr1);
}
```

In this example, the allocated memory is 4096-bytes aligned. `realloc()` then resizes the allocated memory. The new pointer `ptr1` might not be 4096-bytes aligned.

**Correction — Specify the Alignment for the Reallocated Memory**

When you reallocate the memory, use `posix_memalign()` and pass the alignment argument that you used to allocate the original memory.

```
#include <stdio.h>
#include <stdlib.h>

#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;

    /* Allocate memory with 4096 bytes alignment */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
    }

    /* Reallocate memory using the original alignment. */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int) * resize) != 0)
    {
        /* Handle error */
        free(ptr);
        ptr = NULL;
    }

    /* Processing using ptr */

    /* Free before exit */
    free(ptr);
}
```

Exclude user input from format strings

## Description

### Rule Definition

*Exclude user input from format strings.*

### Polyspace Implementation

The rule checker checks for **Tainted string format**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted string format** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted string format

#### Issue

**Tainted string format** detects string formatting with `printf`-style functions that contain elements from unsecure sources.

#### Risk

If you use externally controlled elements to format a string, you can cause buffer overflow or data-representation problems. An attacker can use these string formatting elements to view the contents of a stack using `%x` or write to a stack using `%n`.

#### Fix

Pass a static string to format string functions. This fix ensures that an external actor cannot control the string.

Another possible fix is to allow only the expected number of arguments. If possible, use functions that do not support the vulnerable `%n` operator in format strings.

#### Example - Get Elements from User Input

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf(userstr);    //Noncompliant
}
```

This example prints the input argument `userstr`. The string is unknown. If it contains elements such as `%`, `printf` can interpret `userstr` as a string format instead of a string, causing your program to crash.

#### Correction — Print as String

One possible correction is to print `userstr` explicitly as a string so that there is no ambiguity.

```
#include "stdio.h"
#include <unistd.h>
#define MAX 40

void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf("%.20s", userstr);
}
```

# CERT C: Rule FIO32-C

Do not perform operations on devices that are only appropriate for files

## Description

### Rule Definition

*Do not perform operations on devices that are only appropriate for files.*

### Polyspace Implementation

The rule checker checks for **Inappropriate I/O operation on device files**.

## Examples

### Inappropriate I/O operation on device files

#### Issue

**Inappropriate I/O operation on device files** occurs when you do not check whether a file name parameter refers to a device file before you pass it to these functions:

- `fopen()`
- `fopen_s()`
- `freopen()`
- `remove()`
- `rename()`
- `CreateFile()`
- `CreateFileA()`
- `CreateFileW()`
- `_wfopen()`
- `_wfopen_s()`

Device files are files in a file system that provide an interface to device drivers. You can use these files to interact with devices.

**Inappropriate I/O operation on device files** does not raise a defect when:

- You use `stat` or `lstat`-family functions to check the file name parameter before calling the previously listed functions.
- You use a string comparison function to compare the file name against a list of device file names.

#### Risk

Operations appropriate only for regular files but performed on device files can result in denial-of-service attacks, other security vulnerabilities, or system failures.

### Fix

Before you perform an I/O operation on a file:

- Use `stat()`, `lstat()`, or an equivalent function to check whether the file name parameter refers to a regular file.
- Use a string comparison function to compare the file name against a list of device file names.

#### Example - Using `fopen()` Without Checking `file_name`

```
#include <stdio.h>
#include <string.h>

#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";

    if ((f = fopen(file_name, "w")) == NULL) { //Noncompliant
        /*handle error */
    };
    /*operate on file */
}
```

In this example, `func()` operates on the file `file_name` without checking whether it is a regular file. If `file_name` is a device file, attempts to access it can result in a system failure.

#### Correction — Check File with `lstat()` Before Calling `fopen()`

One possible correction is to use `lstat()` and the `S_ISREG` macro to check whether the file is a regular file. This solution contains a `TOCTOU` race condition that can allow an attacker to modify the file after you check it but before the call to fopen(). To prevent this vulnerability, ensure that `file_name` refers to a file in a secure folder.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <sys/stat.h>

#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";
    struct stat orig_st;
    if ((lstat(file_name, &orig_st) != 0) ||
        (!S_ISREG(orig_st.st_mode))) {
        exit(0);
    }
    if ((f = fopen(file_name, "w")) == NULL) {
        /*handle error */
    };
    /*operate on file */
}
```

Distinguish between characters read from a file and EOF or WEOF

## Description

### Rule Definition

*Distinguish between characters read from a file and EOF or WEOF.*

### Polyspace Implementation

The rule checker checks for **Character value absorbed into EOF**.

## Examples

### Character value absorbed into EOF

#### Issue

**Character value absorbed into EOF** occurs when you perform a data type conversion that makes a valid character value indistinguishable from `EOF` (End-of-File). Bug Finder flags the defect in one of the following situations:

- *End-of-File*: You perform a data type conversion such as from `int` to `char` that converts a non-EOF character value into `EOF`.

  ```
  char ch = (char)getchar()
  ```

  You then compare the result with EOF.

  ```
  if((int)ch == EOF)
  ```

  The conversion can be explicit or implicit.
- *Wide End-of-File*: You perform a data type conversion that can convert a non-WEOF wide character value into WEOF, and then compare the result with WEOF.

#### Risk

The data type `char` cannot hold the value `EOF` that indicates the end of a file. Functions such as `getchar` have return type `int` to accommodate `EOF`. If you convert from `int` to `char`, the values `UCHAR_MAX` (a valid character value) and `EOF` get converted to the same value -1 and become indistinguishable from each other. When you compare the result of this conversion with `EOF`, the comparison can lead to false detection of `EOF`. This rationale also applies to wide character values and `WEOF`.

#### Fix

Perform the comparison with `EOF` or `WEOF` before conversion.

#### Example - Return Value of `getchar` Converted to `char`

```
#include <stdio.h>
#include <stdlib.h>
```

```
#define fatal_error() abort()

char func(void)
{
    char ch;
    ch = getchar();
    if (EOF == (int)ch) { //Noncompliant
        fatal_error();
    }
    return ch;
}
```

In this example, the return value of `getchar` is implicitly converted to `char`. If `getchar` returns `UCHAR_MAX`, it is converted to -1, which is indistinguishable from EOF. When you compare with EOF later, it can lead to a false positive.

#### Correction — Perform Comparison with EOF Before Conversion

One possible correction is to first perform the comparison with EOF, and then convert from `int` to `char`.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

char func(void)
{
    int i;
    i = getchar();
    if (EOF == i) {
        fatal_error();
    }
    else {
        return (char)i;
    }
}
```

Do not assume that fgets() or fgetws() returns a nonempty string when successful

## Description

### Rule Definition

*Do not assume that fgets() or fgetws() returns a nonempty string when successful.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate string**.

## Examples

### Use of indeterminate string

#### Issue

**Use of indeterminate string** occurs when you do not check the validity of the buffer returned from `fgets`-family functions. The checker raises a defect when such a buffer is used as:

- An argument in standard functions that print or manipulate strings or wide strings.
- A return value.
- An argument in external functions with parameter type `const char *` or `const wchar_t *`.

#### Risk

If an `fgets`-family function fails, the content of its output buffer is indeterminate. Use of such a buffer has undefined behavior and can result in a program that stops working or other security vulnerabilities.

#### Fix

Reset the output buffer of an `fgets`-family function to a known string value when the function fails.

#### Example - Output of `fgets()` Passed to External Function

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func(void) {
    char buf[SIZE20];

    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* 'buf' may contain an indeterminate string.  */
        ;
    }
    /* 'buf passed to external function */
    display_text(buf);  //Noncompliant
}
```

In this example, the output `buf` is passed to the external function `display_text()`, but its value is not reset if `fgets()` fails.

#### Correction — Reset `fgets()` Output on Failure

If `fgets()` fails, reset `buf` to a known value before you pass it to an external function.

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func1(void) {
    char buf[SIZE20];
    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* value of 'buf' reset after fgets() failure. */
        buf[0] = '\0';
    }
    /* 'buf' passed to external function */
    display_text(buf);
}
```

## Check Information

Do not copy a FILE object

## Description

### Rule Definition

*Do not copy a FILE object.*

### Polyspace Implementation

The rule checker checks for **Misuse of a FILE object**.

## Examples

### Misuse of a FILE object

#### Issue

**Misuse of a FILE object** occurs when:

- You dereference a pointer to a FILE object, including indirect dereference by using `memcmp()`.
- You modify an entire FILE object or one of its components through its pointer.
- You take the address of FILE object that was not returned from a call to an `fopen`-family function. No defect is raised if a macro defines the pointer as the address of a built-in FILE object, such as `#define ptr (&__stdout)`.

#### Risk

In some implementations, the address of the pointer to a FILE object used to control a stream is significant. A pointer to a copy of a FILE object is interpreted differently than a pointer to the original object, and can potentially result in operations on the wrong stream. Therefore, the use of a copy of a FILE object can cause the software to stop responding, which an attacker might exploit in denial-of-service attacks.

#### Fix

Do not make a copy of a FILE object. Do not use the address of a FILE object that was not returned from a successful call to an `fopen`-family function.

#### Example - Copy of FILE Object Used in `fputs()`

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /*'stdout' dereferenced and contents
        copied to 'my_stdout'. */
    FILE my_stdout = *stdout;   //Noncompliant

    /* Address of 'my_stdout' may not point to correct stream. */
    if (fputs("Hello, World!\n", &my_stdout) == EOF)   //Noncompliant
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

In this example, FILE object `stdout` is dereferenced and its contents are copied to `my_stdout`. The contents of `stdout` might not be significant. `fputs()` is then called with the address of `my_stdout` as an argument. Because no call to `fopen()` or a similar function was made, the address of `my_stdout` might not point to the correct stream.

**Correction — Copy the FILE Object Pointer**

Declare `my_stdout` to point to the same address as `stdout` to ensure that you write to the correct stream when you call `fputs()`.

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /* 'my_stdout' and 'stdout' point to the same object. */
    FILE *my_stdout = stdout;
    if (fputs("Hello, World!\n", my_stdout) == EOF)
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

# CERT C: Rule FIO39-C

Do not alternately input and output from a stream without an intervening flush or positioning call

## Description

### Rule Definition

*Do not alternately input and output from a stream without an intervening flush or positioning call.*

### Polyspace Implementation

The rule checker checks for **Alternating input and output from a stream without flush or positioning call**.

## Examples

### Alternating input and output from a stream without flush or positioning call

#### Issue

**Alternating input and output from a stream without flush or positioning call** occurs when:

- You do not perform a flush or function positioning call between an output operation and a following input operation on a file stream in update mode.
- You do not perform a function positioning call between an input operation and a following output operation on a file stream in update mode.

#### Risk

Alternating input and output operations on a stream without an intervening flush or positioning call is undefined behavior.

#### Fix

Call `fflush()` or a file positioning function such as `fseek()` or `fsetpos()` between output and input operations on an update stream.

Call a file positioning function between input and output operations on an update stream.

#### Example - Read After Write Without Intervening Flush

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;
    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Read operation after write without
    intervening flush. */
    if (fread(data, 1, SIZE20, file) < SIZE20)   //Noncompliant
      {
          (void)fclose(file);
          /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

In this example, the file `demo.txt` is opened for reading and appending. After the call to `fwrite()`, a call to `fread()` without an intervening flush operation is undefined behavior.

### Correction — Call `fflush()` Before the Read Operation

After writing data to the file, before calling `fread()`, perform a flush call.

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
```

```
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Buffer flush after write and before read */
    if (fflush(file) != 0)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

Reset strings on fgets() or fgetws() failure

## Description

### Rule Definition

*Reset strings on fgets() or fgetws() failure.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate string**.

## Examples

### Use of indeterminate string

#### Issue

**Use of indeterminate string** occurs when you do not check if a write operation using an `fgets`-family function such as:

```
char * fgets(char* buf, int n, FILE *stream);
```

succeeded and the buffer written has valid content, or you do not reset the buffer on failure. You then perform an operation that assumes a buffer with valid content. For instance, if the buffer with possibly indeterminate content is `buf` (as shown above), the checker raises a defect if:

- You pass `buf` as argument to standard functions that print or manipulate strings or wide strings.
- You return `buf` from a function.
- You pass `buf` as argument to external functions with parameter type `const char *` or `const wchar_t *`.
- You read `buf` as `buf[index]` or `*(buf + offset)`, where `index` or `offset` is a numerical value representing the distance from the beginning of the buffer.

#### Risk

If an `fgets`-family function fails, the content of its output buffer is indeterminate. Use of such a buffer has undefined behavior and can result in a program that stops working or other security vulnerabilities.

#### Fix

Reset the output buffer of an `fgets`-family function to a known string value when the function fails.

#### Example - Output of `fgets()` Passed to External Function

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>
```

```
#define SIZE20 20

extern void display_text(const char *txt);

void func(void) {
    char buf[SIZE20];

    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* 'buf' may contain an indeterminate string.  */
        ;
    }
    /* 'buf passed to external function */
    display_text(buf);  //Noncompliant
}
```

In this example, the output `buf` is passed to the external function `display_text()`, but its value is not reset if `fgets()` fails.

**Correction — Reset `fgets()` Output on Failure**

If `fgets()` fails, reset `buf` to a known value before you pass it to an external function.

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func1(void) {
    char buf[SIZE20];
    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* value of 'buf' reset after fgets() failure. */
        buf[0] = '\0';
    }
    /* 'buf' passed to external function */
    display_text(buf);
}
```

Do not call getc(), putc(), getwc(), or putwc() with a stream argument that has side effects

## Description

### Rule Definition

*Do not call getc(), putc(), getwc(), or putwc() with a stream argument that has side effects.*

### Polyspace Implementation

The rule checker checks for **Stream argument with possibly unintended side effects**.

## Examples

### Stream argument with possibly unintended side effects

#### Issue

**Stream argument with possibly unintended side effects** occurs when you call getc(), putc(), getwc(), or putwc() with a stream argument that has side effects.

**Stream argument with possibly unintended side effects** considers the following as stream side effects:

- Any assignment of a variable of a stream, such as FILE *, or any assignment of a variable of a deeper stream type, such as an array of FILE *.
- Any call to a function that manipulates a stream or a deeper stream type.

The number of defects raised corresponds to the number of side effects detected. When a stream argument is evaluated multiple times in a function implemented as a macro, a defect is raised for each evaluation that has a side effect.

A defect is also raised on functions that are not implemented as macros but that can be implemented as macros on another operating system.

#### Risk

If the function is implemented as an unsafe macro, the stream argument can be evaluated more than once, and the stream side effect happens multiple times. For instance, a stream argument calling fopen() might open the same file multiple times, which is unspecified behavior.

#### Fix

To ensure that the side effect of a stream happens only once, use a separate statement for the stream argument.

#### Example - Stream Argument of getc() Has Side Effect fopen()

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
```

```
#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;
    /* getc() has stream argument fptr with
    * 2 side effects: call to fopen(), and assignment
    * of fptr
    */
    c = getc(fptr = fopen(myfile, "r")); //Noncompliant
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

In this example, `getc()` is called with stream argument `fptr`. The stream argument has two side effects: the call to `fopen()` and the assignment of `fptr`. If `getc()` is implemented as an unsafe macro, the side effects happen multiple times.

#### Correction — Use Separate Statement for `fopen()`

One possible correction is to use a separate statement for `fopen()`. The call to `fopen()` and the assignment of `fptr` happen in this statement so there are no side effects when you pass `fptr` to `getc()`.

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;

    /* Separate statement for fopen()
    * before call to getc()
    */
    fptr = fopen(myfile, "r");
    if (fptr == NULL) {
        /* Handle error */
        fatal_error();
    }
    c = getc(fptr);
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

Close files when they are no longer needed

## Description

### Rule Definition

*Close files when they are no longer needed.*

### Polyspace Implementation

The rule checker checks for **Resource leak**.

## Examples

### Resource leak

#### Issue

**Resource leak** occurs when you open a file stream by using a FILE pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

#### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

#### Fix

Close a FILE pointer before the end of its scope, or before you assign the pointer to another stream.

#### Example - FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" ); //Noncompliant
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer fp1 is pointing to a file data1.txt. Before fp1 is explicitly dissociated from the file stream of data1.txt, it is used to access another file data2.txt.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate fp1 from the file stream of data1.txt.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

Only use values for fsetpos() that are returned from fgetpos()

## Description

### Rule Definition

*Only use values for fsetpos() that are returned from fgetpos().*

### Polyspace Implementation

The rule checker checks for **Invalid file position**.

## Examples

### Invalid file position

#### Issue

**Invalid file position** occurs when the file position argument of `fsetpos()` uses a value that is not obtained from `fgetpos()`.

#### Risk

The function `fgetpos(FILE *stream, fpos_t *pos)` gets the current file position of the stream. When you use any other value as the file position argument of `fsetpos(FILE *stream, const fpos_t *pos)`, you might access an unintended location in the stream.

#### Fix

Use the value returned from a successful call to `fgetpos()` as the file position argument of `fsetpos()`.

#### Example - `memset()` Sets File Position Argument

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset' */
    (void)memset(&offset, 0, sizeof(offset));

    /* Read data from file */

    /* Return to the initial position. offset was not
    returned from a call to fgetpos()    */
    if (fsetpos(file, &offset) != 0)           //Noncompliant
    {
        /* Handle error */
    }
    return file;
}
```

In this example, `fsetpos()` uses `offset` as its file position argument. However, the value of `offset` is set by `memset()`. The preceding code might access the wrong location in the stream.

**Correction — Use a File Position Returned From `fgetpos()`**

Call `fgetpos()`, and if it returns successfully, use the position argument in your call to `fsetpos()`.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset'
    using fgetpos() */
    if (fgetpos(file, &offset) != 0)
    {
        /* Handle error */
    }

    /* Read data from file */

    /* Back to the initial position */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

Avoid TOCTOU race conditions while accessing files

## Description

### Rule Definition

*Avoid TOCTOU race conditions while accessing files.*

### Polyspace Implementation

The rule checker checks for **File access between time of check and use (TOCTOU)**.

## Examples

### File access between time of check and use (TOCTOU)

#### Issue

**File access between time of check and use (TOCTOU)** detects race condition issues between checking the existence of a file or folder, and using a file or folder.

#### Risk

An attacker can access and manipulate your file between your check for the file and your use of a file. Symbolic links are particularly risky because an attacker can change where your symbolic link points.

#### Fix

Before using a file, do not check its status. Instead, use the file and check the results afterward.

If you want to justify this violation, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Check File Before Using

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    if (access(log_path, W_OK)==0) {
        FILE* f = fopen(log_path, "w"); //Noncompliant
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

In this example, before opening and using the file, the function checks if the file exists. However, an attacker can change the file between the first and second lines of the function.

#### Correction — Open Then Check

One possible correction is to open the file, and then check the existence and contents afterward.

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    int fd = open(log_path, O_WRONLY);
    if (fd!=-1) {
        FILE *f = fdopen(fd, "w");
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

Do not access a closed file

## Description

### Rule Definition

*Do not access a closed file.*

### Polyspace Implementation

The rule checker checks for **Use of previously closed resource**.

## Examples

### Use of previously closed resource

#### Issue

**Use of previously closed resource** occurs when a function operates on a stream that you closed earlier in your code.

#### Risk

The standard states that the value of a `FILE*` pointer is indeterminate after you close the stream associated with it. Operations using the `FILE*` pointer can produce unintended results.

#### Fix

One possible fix is to close the stream only at the end of operations. Another fix is to reopen the stream before using it again.

#### Example - Use of FILE* Pointer After Closing Stream

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fclose(fp);
        fprintf(fp,"text"); //Noncompliant
    }
}
```

In this example, `fclose` closes the stream associated with `fp`. When you use `fprintf` on `fp` after `fclose`, the **Use of previously closed resource** defect appears.

#### Correction — Close Stream After All Operations

One possible correction is to reverse the order of the `fprintf` and `fclose` operations.

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fprintf(fp,"text");
        fclose(fp);
    }
}
```

# CERT C: Rule FIO47-C

Use valid format strings

## Description

### Rule Definition

*Use valid format strings.*

### Polyspace Implementation

The rule checker checks for **Format string specifiers and arguments mismatch**.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
  const char *message = "License not available";
  int err_number = -4;
  printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {
    unsigned long fst = 1;

    printf("%d\n", fst); //Noncompliant
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

Do not modify the object referenced by the return value of certain functions

## Description

### Rule Definition

*Do not modify the object referenced by the return value of certain functions.*

### Polyspace Implementation

The rule checker checks for **Modification of internal buffer returned from nonreentrant standard function**.

## Examples

### Modification of internal buffer returned from nonreentrant standard function

#### Issue

**Modification of internal buffer returned from nonreentrant standard function** occurs when the following happens:

- A nonreentrant standard function returns a pointer.
- You attempt to write to the memory location that the pointer points to.

Nonreentrant standard functions that return a non `const`-qualified pointer to an internal buffer include `getenv`, `getlogin`, `crypt`, `setlocale`, `localeconv`, `strerror` and others.

#### Risk

Modifying the internal buffer that a nonreentrant standard function returns can cause the following issues:

- It is possible that the modification does not succeed or alters other internal data.

  For instance, `getenv` returns a pointer to an environment variable value. If you modify this value, you alter the environment of the process and corrupt other internal data.
- Even if the modification succeeds, it is possible that a subsequent call to the same standard function does not return your modified value.

  For instance, you modify the environment variable value that `getenv` returns. If another process, thread, or signal handler calls `setenv`, the modified value is overwritten. Therefore, a subsequent call to `getenv` does not return your modified value.

#### Fix

Avoid modifying the internal buffer using the pointer returned from the function.

#### Example - Modification of getenv Return Value

```
#include <stdlib.h>
#include <string.h>
```

```
void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        strncpy(env, "C", 1); //Noncompliant
        printstr(env);
    }
}
```

In this example, the first argument of `strncpy` is the return value from a nonreentrant standard function `getenv`. The behavior can be undefined because `strncpy` modifies this argument.

#### Correction - Copy Return Value of `getenv` and Modify Copy

One possible solution is to copy the return value of `getenv` and pass the copy to the `strncpy` function.

```
#include <stdlib.h>
#include <string.h>
enum {
    SIZE20 = 20
};

void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        char env_cp[SIZE20];
        strncpy(env_cp, env, SIZE20);
        strncpy(env_cp, "C", 1);
        printstr(env_cp);
    }
}
```

# CERT C: Rule ENV31-C

Do not rely on an environment pointer following an operation that may invalidate it

## Description

### Rule Definition

*Do not rely on an environment pointer following an operation that may invalidate it.*

### Polyspace Implementation

The rule checker checks for **Environment pointer invalidated by previous operation**.

## Examples

### Environment pointer invalidated by previous operation

#### Issue

**Environment pointer invalidated by previous operation** occurs when you use the third argument of *main()* in a hosted environment to access the environment after an operation modifies the environment. In a hosted environment, many C implementations support the nonstandard syntax:

```
main (int argc, char *argv[], char *envp[])
```

A call to a `setenv` or `putenv` family function modifies the environment pointed to by `*envp`.

#### Risk

When you modify the environment through a call to a `setenv` or `putenv` family function, the environment memory can potentially be reallocated. The hosted environment pointer is not updated and might point to an incorrect location. A call to this pointer can return unexpected results or cause an abnormal program termination.

#### Fix

Do not use the hosted environment pointer. Instead, use global external variable `environ` in Linux, `_environ` or `_wenviron` in Windows, or their equivalent. When you modify the environment, these variables are updated.

#### Example - Access Environment Through Pointer envp

```
#include <stdio.h>
#include <stdlib.h>

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

/* envp is from main function */
int func(char **envp)
{
    /* Call to setenv may cause environment
     *memory to be reallocated
     */
    if (setenv(("MY_NEW_VAR"),("new_value"),1) != 0)
    {
        /* Handle error */
        return -1;
    }
    /* envp not updated after call to setenv, and may
     *point to incorrect location.
     **/
    if (envp != ((void *)0)) {  //Noncompliant
        use_envp(envp);
/* No defect on second access to
*envp because defect already raised */
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func(envp);
    }
}
```

In this example, `envp` is accessed inside `func()` after a call to `setenv` that can reallocate the environment memory. `envp` can point to an incorrect location because it is not updated after `setenv` modifies the environment. No defect is raised when `use_envp()` is called because the defect is already raised on the previous line of code.

#### Correction — Use Global External Variable `environ`

One possible correction is to access the environment by using a variable that is always updated after a call to `setenv`. For instance, in the following code, the pointer `envp` is still available from `main()`, but the environment is accessed in `func()` through the global external variable `environ`.

```
#include <stdio.h>
#include <stdlib.h>
extern char **environ;

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

int func(void)
{
    if (setenv(("MY_NEW_VAR"), ("new_value"),1) != 0) {
        /* Handle error */
        return -1;
    }
  /* Use global external variable environ
   *which is always updated after a call to setenv */

    if (environ != NULL) {
        use_envp(environ);
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
```

```
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func();
    }
}
```

All exit handlers must return normally

## Description

### Rule Definition

*All exit handlers must return normally.*

### Polyspace Implementation

The rule checker checks for **Abnormal termination of exit handler**.

## Examples

### Abnormal termination of exit handler

#### Issue

**Abnormal termination of exit handler** looks for registered exit handlers. Exit handlers are registered with specific functions such as `atexit`, (WinAPI) `_onexit`, or `at_quick_exit()`. If the exit handler calls a function that interrupts the program's expected termination sequence, Polyspace raises a defect. Some functions that can cause abnormal exits are `exit`, `abort`, `longjmp`, or (WinAPI) `_onexit`.

#### Risk

If your exit handler terminates your program, you can have undefined behavior. Abnormal program termination means other exit handlers are not invoked. These additional exit handlers may do additional clean up or other required termination steps.

#### Fix

In inside exit handlers, remove calls to functions that prevent the exit handler from terminating normally.

#### Example - Exit Handler With Call to exit

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        exit(0); //Noncompliant
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() performs additional cleanup */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

In this example, demo_install_exitabnormalhandler registers two exit handlers, demo_exit1 and exitabnormalhandler. Exit handlers are invoked in the reverse order of which they are registered. When the program ends, exitabnormalhandler runs, then demo_exit1. However, exitabnormalhandler calls exit interrupting the program exit process. Having this exit inside an exit handler causes undefined behavior because the program is not finished cleaning up safely.

#### Correction — Remove exit from Exit Handler

One possible correction is to let your exit handlers terminate normally. For this example, exit is removed from exitabnormalhandler, allowing the exit termination process to complete as expected.

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        /* Return normally */
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() continues clean up */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

## Check Information

**Group:** Rule 10. Environment (ENV)

# Version History

**Introduced in R2019a**

Do not call system()

## Description

### Rule Definition

*Do not call system().*

### Polyspace Implementation

The rule checker checks for **Unsafe call to a system function**.

## Examples

### Unsafe call to a system function

#### Issue

**Unsafe call to a system function** occurs when you use a function that invokes an implementation-defined command processor. These functions include:

- The C standard `system()` function.
- The POSIX `popen()` function.
- The Windows `_popen()` and `_wpopen()` functions.

#### Risk

If the argument of a function that invokes a command processor is not sanitized, it can cause exploitable vulnerabilities. An attacker can execute arbitrary commands or read and modify data anywhere on the system.

#### Fix

Do not use a `system`-family function to invoke a command processor. Instead, use safer functions such as POSIX `execve()` and WinAPI `CreateProcess()`.

#### Example - `system()` Called

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
    char buf[SIZE512];
    int retval=sprintf(buf, "/usr/bin/any_cmd %s", arg);
    if (retval<=0 || retval>SIZE512){
        /* Handle error */
        abort();
    }
    /* Use of system() to pass any_cmd with
    unsanitized argument to command processor */

    if (system(buf) == -1) { //Noncompliant
    /* Handle error */
  }
}
```

In this example, `system()` passes its argument to the host environment for the command processor to execute. This code is vulnerable to an attack by command-injection.

**Correction — Sanitize Argument and Use execve()**

In the following code, the argument of `any_cmd` is sanitized, and then passed to `execve()` for execution. `exec`-family functions are not vulnerable to command-injection attacks.

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
  char *const args[SIZE3] = {"any_cmd", arg, NULL};
  char  *const env[] = {NULL};

  /* Sanitize argument */

  /* Use execve() to execute any_cmd. */

  if (execve("/usr/bin/time", args, env) == -1) {
    /* Handle error */
  }
}
```

# CERT C: Rule ENV34-C

Do not store pointers returned by certain functions

## Description

### Rule Definition

*Do not store pointers returned by certain functions.*

### Polyspace Implementation

The rule checker checks for **Misuse of return value from nonreentrant standard function**.

## Examples

### Misuse of return value from nonreentrant standard function

#### Issue

**Misuse of return value from nonreentrant standard function** occurs when these events happen in this sequence:

1. You point to the buffer returned from a nonreentrant standard function such as `getenv` or `setlocale`.

   ```
   user = getenv("USER");
   ```
2. You call that nonreentrant standard function again.

   ```
   user2 = getenv("USER2");
   ```
3. You use or dereference the pointer from the first step expecting the buffer to remain unmodified since that step. In the meantime, the call in the second step has modified the buffer.

   For instance:

   ```
   var=*user;
   ```

In some cases, the defect might appear even if you do not call the `getenv` function a second time but simply return the pointer. For instance:

```
char* func() {
     user=getenv("USER");
     .
     .
     return user;
}
```

For information on which functions are covered by this defect, see documentation on nonreentrant standard functions.

#### Risk

The C Standard allows nonreentrant functions such as `getenv` to return a pointer to a *static* buffer. Because the buffer is static, a second call to `getenv` modifies the buffer. If you continue to use the

pointer returned from the first call past the second call, you can see unexpected results. The buffer that it points to no longer has values from the first call.

The defect appears even if you do not call `getenv` a second time but simply return the pointer. The reason is that someone calling your function might use the returned pointer *after* a second call to `getenv`. By returning the pointer from your call to `getenv`, you make your function unsafe to use.

The same rationale is true for other nonreentrant functions covered by this defect.

**Fix**

After the first call to `getenv`, make a copy of the buffer that the returned pointer points to. After the second call to `getenv`, use this copy. Even if the second call modifies the buffer, your copy is untouched.

**Example - Return from `getenv` Used After Second Call to `getenv`**

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");   /* First call */
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');

        if (user_name_from_home != NULL) {
            user = getenv("USER");   /* Second call */
            if ((user != NULL) &&
                (strcmp(user, user_name_from_home) == 0))  //Noncompliant
            {
                result = 1;
            }
        }
    }
    return result;
}
```

In this example, the pointer `user_name_from_home` is derived from the pointer `home`. `home` points to the buffer returned from the first call to `getenv`. Therefore, `user_name_from_home` points to a location in the same buffer.

After the second call to `getenv`, the buffer is modified. If you continue to use `user_name_from_home`, you can get unexpected results.

**Correction — Make Copy of Buffer Before Second Call**

If you want to access the buffer from the first call to `getenv` past the second call, make a copy of the buffer after the first call. One possible correction is to use the `strdup` function to make the copy.

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');
        if (user_name_from_home != NULL) {
            /* Make copy before second call */
            char *saved_user_name_from_home = strdup(user_name_from_home);
            if (saved_user_name_from_home != NULL) {
                user = getenv("USER");
                if ((user != NULL) &&
                    (strcmp(user, saved_user_name_from_home) == 0))
                {
                    result = 1;
                }
                free(saved_user_name_from_home);
            }
        }
    }
    return result;
}
```

Call only asynchronous-safe functions within signal handlers

## Description

### Rule Definition

*Call only asynchronous-safe functions within signal handlers.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Function called from signal handler not asynchronous-safe**.
- **Function called from signal handler not asynchronous-safe (strict)**.

## Examples

### Function called from signal handler not asynchronous-safe

#### Issue

**Function called from signal handler not asynchronous-safe** occurs when a signal handler calls a function that is not asynchronous-safe according to the POSIX standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

#### Risk

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

#### Fix

The POSIX standard defines these functions as asynchronous-safe. You can call these functions from a signal handler.

| | | |
|---|---|---|
| `_exit()` | `getpgrp()` | `setsockopt()` |
| `_Exit()` | `getpid()` | `setuid()` |
| `abort()` | `getppid()` | `shutdown()` |
| `accept()` | `getsockname()` | `sigaction()` |
| `access()` | `getsockopt()` | `sigaddset()` |
| `aio_error()` | `getuid()` | `sigdelset()` |

| | | |
|---|---|---|
| aio_return() | kill() | sigemptyset() |
| aio_suspend() | link() | sigfillset() |
| alarm() | linkat() | sigismember() |
| bind() | listen() | signal() |
| cfgetispeed() | lseek() | sigpause() |
| cfgetospeed() | lstat() | sigpending() |
| cfsetispeed() | mkdir() | sigprocmask() |
| cfsetospeed() | mkdirat() | sigqueue() |
| chdir() | mkfifo() | sigset() |
| chmod() | mkfifoat() | sigsuspend() |
| chown() | mknod() | sleep() |
| clock_gettime() | mknodat() | sockatmark() |
| close() | open() | socket() |
| connect() | openat() | socketpair() |
| creat() | pathconf() | stat() |
| dup() | pause() | symlink() |
| dup2() | pipe() | symlinkat() |
| execl() | poll() | sysconf() |
| execle() | posix_trace_event() | tcdrain() |
| execv() | pselect() | tcflow() |
| execve() | pthread_kill() | tcflush() |
| faccessat() | pthread_self() | tcgetattr() |
| fchdir() | pthread_sigmask() | tcgetpgrp() |
| fchmod() | quick_exit() | tcsendbreak() |
| fchmodat() | raise() | tcsetattr() |
| fchown() | read() | tcsetpgrp() |
| fchownat() | readlink() | time() |
| fcntl() | readlinkat() | timer_getoverrun() |
| fdatasync() | recv() | timer_gettime() |
| fexecve() | recvfrom() | timer_settime() |
| fork() | recvmsg() | times() |
| fpathconf() | rename() | umask() |
| fstat() | renameat() | uname() |
| fstatat() | rmdir() | unlink() |
| fsync() | select() | unlinkat() |
| ftruncate() | sem_post() | utime() |
| futimens() | send() | utimensat() |

| | | |
|---|---|---|
| getegid() | sendmsg() | utimes() |
| geteuid() | sendto() | wait() |
| getgid() | setgid() | waitpid() |
| getgroups() | setpgid() | write() |
| getpeername() | setsid() | |

Functions not in the previous table are not asynchronous-safe, and should not be called from a signal hander.

### Example - Call to `printf()` Inside Signal Handler

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler(int signum)
{
    /* Call function printf() that is not
    asynchronous-safe */
    printf("signal %d received.", signum);  //Noncompliant
    e_flag = 1;
}

int main(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, sizeof(char));
    if (info == NULL)
    {
        /* Handle Error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

In this example, `sig_handler` calls `printf()` when catching a signal. If the handler catches another signal while `printf()` is executing, the behavior of the program is undefined.

**Correction — Set Flag Only in Signal Handler**

Use your signal handler to set only the value of a flag. `e_flag` is of type volatile `sig_atomic_t`. `sig_handler` can safely access it asynchronously.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler1(int signum)
{
    int s0 = signum;
    e_flag = 1;
}

int func(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler1) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, 1);
    if (info == NULL)
    {
        /* Handle error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

### Function called from signal handler not asynchronous-safe (strict)

#### Issue

**Function called from signal handler not asynchronous-safe (strict)** occurs when a signal handler calls a function that is not asynchronous-safe according to the C standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

When you select the checker **Function called from signal handler not asynchronous-safe**, the checker detects calls to functions that are not asynchronous-safe according to the POSIX standard. **Function called from signal handler not asynchronous-safe (strict)** does not raise a defect for these cases. **Function called from signal handler not asynchronous-safe (strict)** raises a defect for functions that are asynchronous-safe according to the POSIX standard but not according to the C standard.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

#### Risk

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

#### Fix

The C standard defines the following functions as asynchronous-safe. You can call these functions from a signal handler:

- `abort()`
- `_Exit()`
- `quick_exit()`
- `signal()`

#### Example - Call to `raise()` Inside Signal Handler

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
{
    int s0 = signum;
    /* SIGTERM specific handling */
}

void sig_handler(int signum)
{
    int s0 = signum;
    /* Call raise() */
    if (raise(SIGTERM) != 0) {  //Noncompliant
        /* Handle error */
    }
}

int finc(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` calls `raise()` when catching a signal. If the handler catches another signal while `raise()` is executing, the behavior of the program is undefined.

#### Correction — Remove Call to `raise()` in Signal Handler

According to the C standard, the only functions that you can safely call from a signal handler are `abort()`, `_Exit()`, `quick_exit()`, and `signal()`.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
{
    int s0 = signum;
    /* SIGTERM specific handling */
}
void sig_handler(int signum)
{
    int s0 = signum;
}

int func(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

Do not access shared objects in signal handlers

## Description

### Rule Definition

*Do not access shared objects in signal handlers.*

### Polyspace Implementation

The rule checker checks for **Shared data access within signal handler**.

## Examples

### Shared data access within signal handler

#### Issue

**Shared data access within signal handler** occurs when you access or modify a shared object inside a signal handler.

#### Risk

When you define a signal handler function to access or modify a shared object, the handler accesses or modifies the shared object when it receives a signal. If another function is already accessing the shared object, that function causes a race condition and can leave the data in an inconsistent state.

#### Fix

To access or modify shared objects inside a signal handler, check that the objects are lock-free atomic, or, if they are integers, declare them as `volatile sig_atomic_t`.

#### Example - `int` Variable Access in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* declare global variable. */
int e_flag;

void sig_handler(int signum)
{
    /* Signal handler accesses variable that is not
    of type volatile sig_atomic_t. */
    e_flag = signum;  //Noncompliant
}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` accesses `e_flag`, a variable of type `int`. A concurrent access by another function can leave `e_flag` in an inconsistent state.

### Correction — Declare Variable of Type `volatile sig_atomic_t`

Before you access a shared variable from a signal handler, declare the variable with type `volatile sig_atomic_t` instead of `int`. You can safely access variables of this type asynchronously.

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* Declare variable of type volatile sig_atomic_t. */
volatile sig_atomic_t e_flag;
void sig_handler(int signum)
{
    /* Use variable of proper type inside signal handler. */
    e_flag = signum;

}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

# CERT C: Rule SIG34-C

Do not call signal() from within interruptible signal handlers

## Description

### Rule Definition

*Do not call signal() from within interruptible signal handlers.*

### Polyspace Implementation

The rule checker checks for **Signal call from within signal handler**.

## Examples

### Signal call from within signal handler

#### Issue

**Signal call from within signal handler** occurs when you call the function `signal()` from a signal handler on Windows platforms.

The issue is detected only if you specify a Visual Studio compiler. See `Compiler (-compiler)`.

#### Risk

The function `signal()` associates a signal with a signal handler function. On platforms such as Windows, which removes this association after receiving the signal, you might call the function `signal()` again *within the signal handler* to re-establish the association.

However, this attempt to make a signal handler persistent is prone to race conditions. On Windows platforms, from the time the signal handler begins execution to when the `signal` function is called again, it is the default signal handling, `SIG_DFL`, that is active. If a second signal is received within this time window, you see the default signal handling and not the custom signal handler, but you might expect otherwise.

#### Fix

Do not call `signal()` from a signal handler on Windows platforms.

#### Example - `signal()` Called from Signal Handler

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;

    /* Call signal() to reestablish sig_handler
    upon receiving SIG_ERR. */

    if (signal(s0, sig_handler) == SIG_ERR)  //Noncompliant
    {
        /* Handle error */
    }
}

void func(void)
{
        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
  /* more code */
}
```

In this example, the definition of `sig_handler()` includes a call to `signal()` when the handler catches `SIG_ERR`. On Windows platforms, signal handlers are nonpersistent. This code can result in a race condition.

The issue is detected only if you specify a compiler such as `visual15.x` for the analysis.

**Correction — Do Not Call `signal()` from Signal Handler**

Avoid attempting to make a signal handler persistent on Windows. If your code requires the use of a persistent signal handler on a Windows platform, use a persistent signal handler after performing a thorough risk analysis.

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;
    /* No call to signal() */
}

int main(void)
{

        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }
}
```

SIG34-C

# CERT C: Rule SIG35-C

Do not return from a computational exception signal handler

## Description

### Rule Definition

*Do not return from a computational exception signal handler.*

### Polyspace Implementation

The rule checker checks for **Return from computational exception signal handler**.

## Examples

### Return from computational exception signal handler

#### Issue

**Return from computational exception signal handler** occurs when a signal handler returns after catching a computational exception signal SIGFPE, SIGILL, or SIGSEGV.

#### Risk

A signal handler that returns normally from a computational exception is undefined behavior. Even if the handler attempts to fix the error that triggered the signal, the program can behave unexpectedly.

#### Fix

Check the validity of the values of your variables before the computation to avoid using a signal handler to catch exceptions. If you cannot avoid a handler to catch computation exception signals, call abort(), quick_exit(), or _Exit() in the handler to stop the program.

#### Example - Signal Handler Return from Division by Zero

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */
void sig_handler(int s)
{
    int s0 = s;
    if (denom == 0)
    {
        denom = 1;
    }
    /* Normal return from computation exception
    signal */
    return;  //Noncompliant
}
```

```
long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

In this example, `sig_handler` is declared to handle a division by zero computation error. The handler changes the value of `denom` if it is zero and returns, which is undefined behavior.

#### Correction — Call `abort()` to Terminate Program

After catching a computational exception, call `abort()` from `sig_handler` to exit the program without further error.

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */

void sig_handler(int s)
{
    int s0 = s;
    /* call to abort() to exit the program */
    abort();
}

long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

Set errno to zero before calling a library function known to set errno, and check errno only after the function returns a value indicating failure

## Description

### Rule Definition

*Set errno to zero before calling a library function known to set errno, and check errno only after the function returns a value indicating failure.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Misuse of errno**.
- **Errno not reset**.

## Examples

### Misuse of errno

#### Issue

**Misuse of errno** occurs when you check `errno` for error conditions in situations where checking `errno` does not guarantee the absence of errors. In some cases, checking `errno` can lead to false positives.

For instance, you check `errno` following calls to the functions:

- `fopen`: If you follow the ISO Standard, the function might not set `errno` on errors.
- `atof`: If you follow the ISO Standard, the function does not set `errno`.
- `signal`: The `errno` value indicates an error only if the function returns the `SIG_ERR` error indicator.

#### Risk

The ISO C Standard does not enforce that these functions set `errno` on errors. Whether the functions set `errno` or not is implementation-dependent.

To detect errors, if you check `errno` alone, the validity of this check also becomes implementation-dependent.

In some cases, the `errno` value indicates an error only if the function returns a specific error indicator. If you check `errno` before checking the function return value, you can see false positives.

#### Fix

For information on how to detect errors, see the documentation for that specific function.

Typically, the functions return an out-of-band error indicator to indicate errors. For instance:

- fopen returns a null pointer if an error occurs.
- signal returns the SIG_ERR error indicator and sets errno to a positive value. Check errno only after you have checked the function return value.

### Example - Incorrectly Checking for errno After fopen Call

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    errno = 0;
    fileptr = fopen(temp_filename, "w+b");
    if (errno != 0) { //Noncompliant
        if (fileptr != NULL) {
            (void)fclose(fileptr);
        }
        /* Handle error */
        fatal_error();
    }
    return fileptr;
}
```

In this example, errno is the first variable that is checked after a call to fopen. You might expect that fopen changes errno to a nonzero value if an error occurs. If you run this code with an implementation of fopen that does not set errno on errors, you might miss an error condition. In this situation, fopen can return a null pointer that escapes detection.

### Correction — Check Return Value of fopen After Call

One possible correction is to only check the return value of fopen for a null pointer.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    fileptr = fopen(temp_filename, "w+b");
    if (fileptr == NULL) {
        fatal_error();
    }
    return fileptr;
}
```

## Errno not reset

### Issue

**Errno not reset** occurs when you do not reset errno before calling a function that sets errno to indicate error conditions. However, you check errno for those error conditions after the function call.

### Risk

The errno is not clean and can contain values from a previous call. Checking errno for errors can give the false impression that an error occurred.

errno is set to zero at program startup but subsequently, errno is not reset by a C standard library function. You must explicitly set errno to zero when required.

### Fix

Before calling a function that sets errno to indicate error conditions, reset errno to zero explicitly.

### Example - errno Not Reset Before Call to strtod

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    f1 = strtod (s1, NULL);
    if (0 == errno) {         //Noncompliant
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
                  {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

In this example, errno is not reset to 0 before the first call to strtod. Checking errno for 0 later can lead to a false positive.

### Correction — Reset errno Before Call

One possible correction is to reset errno to 0 before calling strtod.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>
```

```
#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    errno = 0;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
              {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

Do not rely on indeterminate values of errno

## Description

### Rule Definition

*Do not rely on indeterminate values of errno.*

### Polyspace Implementation

The rule checker checks for **Misuse of errno in a signal handler**.

## Examples

### Misuse of errno in a signal handler

#### Issue

**Misuse of errno in a signal handler** occurs when you call one of these functions in a signal handler:

- `signal`: You call the `signal` function in a signal handler and then read the value of `errno`.

  For instance, the signal handler function `handler` calls `signal` and then calls `perror`, which reads `errno`.

  ```
  typedef void (*pfv)(int);

  void handler(int signum) {
    pfv old_handler = signal(signum, SIG_DFL);
    if (old_handler == SIG_ERR) {
      perror("SIGINT handler");
    }
  }
  ```
- `errno`-setting POSIX function: You call an `errno`-setting POSIX function in a signal handler but do not restore `errno` when returning from the signal handler.

  For instance, the signal handler function `handler` calls `waitpid`, which changes `errno`, but does not restore `errno` before returning.

  ```
  #include <stddef.h>
  #include <errno.h>
  #include <sys/wait.h>

  void handler(int signum) {
    int rc = waitpid(-1, NULL, WNOHANG);
    if (ECHILD != errno) {
    }
  }
  ```

### Risk

In each case that the checker flags, you risk relying on an indeterminate value of errno.

- signal: If the call to signal in a signal handler fails, the value of errno is indeterminate (see C11 Standard, Sec. 7.14.1.1). If you rely on a specific value of errno, you can see unexpected results.
- errno-setting POSIX function: An errno-setting function sets errno on failure. If you read errno after a signal handler is called and the signal handler itself calls an errno-setting function, you can see unexpected results.

### Fix

Avoid situations where you risk relying on an indeterminate value of errno.

- signal: After calling the signal function in a signal handler, do not read errno or use a function that reads errno.
- errno-setting POSIX function: Before calling an errno-setting function in a signal handler, save errno to a temporary variable. Restore errno from this variable before returning from the signal handler.

### Example - Reading errno After signal Call in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()

void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        perror("SIGINT handler");
    }
} //Noncompliant

int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

In this example, the function handler is called to handle the SIGINT signal. In the body of handler, the signal function is called. Following this call, the value of errno is indeterminate. The checker raises a defect when the perror function is called because perror relies on the value of errno.

### Correction — Avoid Reading errno After signal Call

One possible correction is to not read errno after calling the signal function in a signal handler. The corrected code here calls the abort function via the fatal_error macro instead of the perror function.

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()

void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        fatal_error();
    }
}

int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

Detect and handle standard library errors

## Description

### Rule Definition

*Detect and handle standard library errors.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Errno not checked**.
- **Returned value of a sensitive standard function not checked**.
- **Unprotected dynamic memory allocation**.
- **Pointer overwritten during reallocation**.

## Examples

### Errno not checked

#### Issue

**Errno not checked** occurs when you call a function that sets `errno` to indicate error conditions, but do not check `errno` after the call. For these functions, checking `errno` is the only reliable way to determine if an error occurred.

Functions that set `errno` on errors include:

- `fgetwc`, `strtol`, and `wcstol`.

  For a comprehensive list of functions, see documentation about errno.
- POSIX `errno`-setting functions such as `encrypt` and `setkey`.

#### Risk

To see if the function call completed without errors, check `errno` for error values.

The return values of these `errno`-setting functions do not indicate errors. The return value can be one of the following:

- `void`
- Even if an error occurs, the return value can be the same as the value from a successful call. Such return values are called in-band error indicators.

You can determine if an error occurred only by checking `errno`.

For instance, `strtol` converts a string to a long integer and returns the integer. If the result of conversion overflows, the function returns `LONG_MAX` and sets `errno` to `ERANGE`. However, the function can also return LONG_MAX from a successful conversion. Only by checking errno can you distinguish between an error and a successful conversion.

#### Fix

Before calling the function, set errno to zero.

After the function call, to see if an error occurred, compare errno to zero. Alternatively, compare errno to known error indicator values. For instance, strtol sets errno to ERANGE to indicate errors.

The error message in the Polyspace result shows the error indicator value that you can compare to.

#### Example - errno Not Checked After Call to strtol

```
#include<stdio.h>
#include<stdlib.h>
#include<errno.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    long val = strtol(str, &endptr, base); //Noncompliant
    printf("Return value of strtol() = %ld\n", val);
}
```

You are using the return value of strtol without checking errno.

#### Correction — Check errno After Call

Before calling strtol, set errno to zero . After a call to strtol, check the return value for LONG_MIN or LONG_MAX and errno for ERANGE.

```
#include<stdlib.h>
#include<stdio.h>
#include<errno.h>
#include<limits.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    errno = 0;
    long val = strtol(str, &endptr, base);
    if((val == LONG_MIN || val == LONG_MAX) && errno == ERANGE) {
         printf("strtol error");
         exit(EXIT_FAILURE);
    }
    printf("Return value of strtol() = %ld\n", val);
}
```

### Returned value of a sensitive standard function not checked

#### Issue

**Returned value of a sensitive standard function not checked** occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `thrd_create`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example - Sensitive Function Return Ignored

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    scanf("%d",&n); //Noncompliant
    setlocale (LC_CTYPE, "en_US.UTF-8");   //Noncompliant
    *size = mbstowcs (wcs, utf8, n);
}
```

This example shows a call to the sensitive function `scanf()`. The return value of `scanf()` is ignored, causing a defect. Similarly, the pointer returned by `setlocale` is not checked. When `setlocal` returns a NULL pointer, the call to mbstowcs might fail or produce unexpected results. Polyspace flags these calls to sensitive functions when their returns are not checked.

#### Correction — Cast Function to (void)

One possible correction is to cast the functions to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of these sensitive functions.

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    (void)scanf("%d",&n); //Compliant
    (void)setlocale (LC_CTYPE, "en_US.UTF-8");   //Compliant
    *size = mbstowcs (wcs, utf8, n);
}
```

#### Correction — Test Return Value

One possible correction is to test the return value of scanf and setlocale to check for errors.

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    int flag = scanf("%d",&n);
    if(flag>0){ //Compliant
        // action
    }
    char* status = setlocale (LC_CTYPE, "en_US.UTF-8");
    if(status!=NULL){//Compliant
        *size = mbstowcs (wcs, utf8, n);
    }

}
```

#### Example - Critical Function Return Ignored

```
#include <threads.h>
int thrd_func(void);
void initialize() {
    thrd_t thr;
    int n = 1;

    (void) thrd_create(&thr,thrd_func,&n);  //Noncompliant
}
```

In this example, a critical function thrd_create is called and its return value is ignored by casting to void, but because thrd_create is a critical function, Polyspace does not ignore this defect.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <threads.h>
int thrd_func(void);
```

```
void initialize() {
    thrd_t thr;
    int n = 1;
    if( thrd_success!= thrd_create(&thr,thrd_func,&n) ){
        // handle error

    }
}
```

### Unprotected dynamic memory allocation

#### Issue

**Unprotected dynamic memory allocation** occurs when you do not check after dynamic memory allocation whether the memory allocation succeeded.

#### Risk

When memory is dynamically allocated using `malloc`, `calloc`, or `realloc`, it returns a value `NULL` if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this `NULL` value, this access is not protected from failures.

#### Fix

Check the return value of `malloc`, `calloc`, or `realloc` for NULL before accessing the allocated memory location.

```
#DEFINE SIZE 8;

int *ptr = malloc(SIZE * sizeof(int));

if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

#### Example - Unprotected Dynamic Memory Allocation Error

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));
  *p = 2;  //Noncompliant
  /* Defect: p is not checked for NULL value */
  free(p);
}
/*Defect: p is not checked for NULL before deallocating*/
```

If the memory allocation fails, the function such as `calloc` returns `NULL` to `p`. Before accessing the memory through `p` or freeing `p`, the code does not check whether `p` is `NULL`. These operations might result in memory leaks.

#### Correction — Check for NULL Value

One possible correction is to check whether `p` has value `NULL` before dereference.

```
#include <stdlib.h>
```

```
void Assign_Value(void)
 {
   int* p = (int*)calloc(5, sizeof(int));
   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;
   free(p);
 }
```

### Pointer overwritten during reallocation

#### Issue

**Pointer overwritten during reallocation** occurs when you overwrite the original pointer by the return value of `realloc()`. For instance:

```
p = realloc(p,SIZE);
```

#### Risk

The function `realloc()` returns a `NULL` value when memory allocation fails. In the preceding code, because you overwrite `p` by the return of `realloc()`, it becomes `NULL` when the reallocation operation fails. You lose the connection between the original memory block and `p`, resulting in a memory leak.

#### Fix

When reallocating pointers, preserve the original pointer. For instance, you might use a temporary variable to store the reallocated memory.

#### Example — Avoid Overwriting Original Pointer When Reallocating Memory

```
#include <stdlib.h>
//...
void foo (int* ptrI, size_t new_size)
{

  if (new_size == 0) {
    /* Handle error */
    return;
  }

  ptrI = (int*)realloc (ptrI, new_size);   //Noncompliant

  if (ptrI == NULL) {
    /* Handle error */
    return;
  }
}
```

Overwriting the pointer `ptrI` by the pointer returned by `realloc` destroys the association between `ptrI` and the original memory block. If `realloc` fails, such overwriting might cause a memory leak and data loss.

#### Correction — Store Reallocated Memory in Temporary Variable

When reallocating a pointer, use a temporary variable to hold the reallocated memory. Before assigning the temporary variable to `ptrI`, check it for `NULL` value to avoid memory leaks and data loss.

```
#include <stdlib.h>

void foo (int* ptrI, size_t new_size)
{
int* temp;
  if (new_size == 0) {
    /* Handle error */
    return;
  }

  temp = (int*)realloc (ptrI, new_size);

  if (temp == NULL) {
    /* Handle error */
    return;
  }else{
      ptrI = temp;
  }
}
```

Detect errors when converting a string to a number

## Description

### Rule Definition

*Detect errors when converting a string to a number.*

### Polyspace Implementation

The rule checker checks for **Unsafe conversion from string to numerical value**.

## Examples

### Unsafe conversion from string to numerical value

#### Issue

**Unsafe conversion from string to numerical value** detects conversions from strings to integer or floating-point values. If your conversion method does not include robust error handling, a defect is raised.

#### Risk

Converting a string to numerical value can cause data loss or misinterpretation. Without validation of the conversion or error handling, your program continues with invalid values.

#### Fix

- Add additional checks to validate the numerical value.
- Use a more robust string-to-numeric conversion function such as `strtol`, `strtoll`, `strtoul`, or `strtoull`.

#### Example - Conversion With `atoi`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char* argv1)
{
    int s = 0;
    if (demo_check_string_not_empty(argv1))
    {
        s = atoi(argv1);  //Noncompliant
    }
    return s;
}
```

In this example, `argv1` is converted to an integer with `atoi`. `atoi` does not provide errors for an invalid integer string. The conversion can fail unexpectedly.

**Correction — Use `strtol` instead**

One possible correction is to use `strtol` to validate the input string and the converted integer.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>
#include <errno.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char *argv1)
{
    char *c_str = argv1;
    char *end;
    long sl;

    if (demo_check_string_not_empty(c_str))
    {
        errno = 0; /* set errno for error check */
        sl = strtol(c_str, &end, 10);
        if (end == c_str)
        {
            (void)fprintf(stderr, "%s: not a decimal number\n", c_str);
        }
        else if ('\0' != *end)
        {
            (void)fprintf(stderr, "%s: extra characters: %s\n", c_str, end);
        }
        else if ((LONG_MIN == sl || LONG_MAX == sl) && ERANGE == errno)
        {
            (void)fprintf(stderr, "%s out of range of type long\n", c_str);
        }
        else if (sl > INT_MAX)
        {
            (void)fprintf(stderr, "%ld greater than INT_MAX\n", sl);
        }
        else if (sl < INT_MIN)
        {
            (void)fprintf(stderr, "%ld less than INT_MIN\n", sl);
        }
        else
        {
            return (int)sl;
        }
    }
    return 0;
}
```

Clean up thread-specific storage

## Description

### Rule Definition

*Clean up thread-specific storage.*

### Polyspace Implementation

The rule checker checks for **Thread-specific memory leak**.

## Examples

### Thread-specific memory leak

#### Issue

**Thread-specific memory leak** occurs when you do not free thread-specific dynamically allocated memory before the end of a thread.

To create thread-specific storage, you generally do these steps:

1. You create a key for thread-specific storage.
2. You create the threads.
3. In each thread, you allocate storage dynamically and then associate the key with this storage.

   After the association, you can read the stored data later using the key.
4. Before the end of the thread, you free the thread-specific memory using the key.

The checker flags execution paths in the thread where the last step is missing.

The checker works on these families of functions:

- `tss_get` and `tss_set` (C11)
- `pthread_getspecific` and `pthread_setspecific` (POSIX)

#### Risk

The data stored in the memory is available to other processes even after the threads end (memory leak). Besides security vulnerabilities, memory leaks can shrink the amount of available memory and reduce performance.

#### Fix

Free dynamically allocated memory before the end of a thread.

You can explicitly free dynamically allocated memory with functions such as `free`.

Alternatively, when you create a key, you can associate a destructor function with the key. The destructor function is called with the key value as argument at the end of a thread. In the body of the destructor function, you can free any memory associated with the key. If you use this method, Bug Finder still flags a defect. Ignore this defect with appropriate comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Memory Not Freed at End of Thread**

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;

  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */ //Noncompliant
  }
  print_data();
  return 0; //Noncompliant
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }
  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

In this example, the start function of each thread `func` calls two functions:

- `add_data`: This function allocates storage dynamically and associates the storage with a key using the `tss_set` function.
- `print_data`: This function reads the stored data using the `tss_get` function.

At the points where `func` returns, the dynamically allocated storage has not been freed.

**Correction — Free Dynamically Allocated Memory Explicitly**

One possible correction is to free dynamically allocated memory explicitly before leaving the start function of a thread. See the highlighted change in the corrected version.

In this corrected version, a defect still appears on the `return` statement in the error handling section of `func`. The defect cannot occur in practice because the error handling section is entered only if dynamic memory allocation fails. Ignore this remaining defect with appropriate comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;
  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */ //Noncompliant
  }
  print_data();
  free(tss_get(key));
  return 0;
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }

  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

Do not destroy a mutex while it is locked

## Description

### Rule Definition

*Do not destroy a mutex while it is locked.*

### Polyspace Implementation

The rule checker checks for **Destruction of locked mutex**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See "Multitasking".

## Examples

### Destruction of locked mutex

#### Issue

**Destruction of locked mutex** occurs when a task destroys a mutex after it is locked (and before it is unlocked). The locking and destruction can happen in the same task or different tasks.

#### Risk

A mutex is locked to protect shared variables from concurrent access. If a mutex is destroyed in the locked state, the protection does not apply.

#### Fix

To fix this defect, destroy the mutex only after you unlock it. It is a good design practice to:

- Initialize a mutex *before* creating the threads where you use the mutex.
- Destroy a mutex *after* joining the threads that you created.

On the **Result Details** pane, you see two events, the locking and destruction of the mutex, and the tasks that initiated the events. To navigate to the corresponding line in your source code, click the event.

#### Example - Locking and Destruction in Different Tasks

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
  pthread_mutex_unlock (&lock3);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_destroy (&lock3); //Noncompliant
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

In this example, after task `t0` locks the mutex `lock3`, task `t1` can destroy it. The destruction occurs if the following events happen in sequence:

1. `t0` acquires `lock3`.
2. `t0` releases `lock2`.
3. `t0` releases `lock1`.
4. `t1` acquires the lock `lock1` released by `t0`.
5. `t1` acquires the lock `lock2` released by `t0`.
6. `t1` destroys `lock3`.

For simplicity, this example uses a mix of automatic and manual concurrency detection. The tasks `t0` and `t1` are manually specified as entry points by using the option `Tasks (-entry-points)`. The critical sections are implemented through primitives `pthread_mutex_lock` and `pthread_mutex_unlock` that the software detects automatically. In practice, for entry point specification (thread creation), you will use primitives such as `pthread_create`. The next example shows how the defect can appear when you use `pthread_create`.

**Correction — Place Lock-Unlock Pair Together in Same Critical Section as Destruction**

The locking and destruction of `lock3` occurs inside the critical section imposed by `lock1` and `lock2`, but the unlocking occurs outside. One possible correction is to place the lock-unlock pair in the same critical section as the destruction of the mutex. Use one of these critical sections:

- Critical section imposed by `lock1` alone.
- Critical section imposed by `lock1` and `lock2`.

In this corrected code, the lock-unlock pair and the destruction is placed in the critical section imposed by `lock1` and `lock2`. When `t0` acquires `lock1` and `lock2`, `t1` has to wait for their release before it executes the instruction `pthread_mutex_destroy (&lock3);`. Therefore, `t1` cannot destroy mutex `lock3` in the locked state.

```
#include <pthread.h>
```

```
pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_destroy (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

**Example - Locking and Destruction in Start Routine of Thread**

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_destroy(&lock); //Noncompliant
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Thread that initializes mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use mutex for atomic operation*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   pthread_exit(NULL);
}
```

In this example, four threads are created. The threads are assigned different actions.

- The first thread `callThd[0]` initializes the mutex `lock`.
- The second and third threads, `callThd[1]` and `callThd[2]`, perform an atomic operation protected by the mutex `lock`.
- The fourth thread `callThd[3]` destroys the mutex `lock`.

The threads can interrupt each other. Therefore, immediately after the second or third thread locks the mutex, the fourth thread can destroy it.

**Correction — Initialize and Destroy Mutex Outside Start Routine**

One possible correction is to initialize and destroy the mutex in the `main` function outside the start routine of the threads. The threads perform only the atomic operation. You need two fewer threads because the mutex initialization and destruction threads are not required.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 2
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_work(void *arg) {
   pthread_mutex_lock (&lock);
   atomic_operation();
   pthread_mutex_unlock (&lock);
   pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize mutex */
   pthread_mutex_init(&lock, NULL);

   for(i=0; i<NUMTHREADS; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy mutex */
   pthread_mutex_destroy(&lock);

   pthread_exit(NULL);
}
```

#### Correction — Use A Second Mutex To Protect Lock-Unlock Pair and Destruction

Another possible correction is to use a second mutex and protect the lock-unlock pair from the destruction. This corrected code uses the mutex `lock2` to achieve this protection. The second mutex is initialized in the `main` function outside the start routine of the threads.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
pthread_mutex_t lock2;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_destroy(&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize second mutex */
   pthread_mutex_init(&lock2, NULL);

   /* Thread that initializes first mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use first mutex for atomic operation */
   /* The threads use second mutex to protect first from destruction in locked state*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys first mutex */
   /* The thread uses the second mutex to prevent destruction of locked mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy second mutex */
   pthread_mutex_destroy(&lock2);

   pthread_exit(NULL);
}
```

Prevent data races when accessing bit fields from multiple threads

## Description

### Rule Definition

*Prevent data races when accessing bit fields from multiple threads.*

### Polyspace Implementation

The rule checker checks for **Data race on adjacent bit fields**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

## Examples

### Data race on adjacent bit fields

#### Issue

Data race on adjacent bit fields occurs when both of these conditions are true:

- Multiple tasks perform unprotected operations on bit fields that are part of the same structure.

  For instance, a task operates on field `errorFlag1` and another task on field `errorFlag2` in a variable of this type:

  ```
  struct errorFlags {
     unsigned int errorFlag1 : 1;
     unsigned int errorFlag2 : 1;
     //...
  };
  ```

  Suppose that the operations are not atomic with respect to each other. In other words, you have not implemented protection mechanisms to ensure that one operation is completed before another operation begins.
- At least one of the unprotected operations is a write operation.

To find this defect, before analysis, you must specify the multitasking options. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

#### Risk

Adjacent bit fields that are part of the same structure might be stored in one byte in the same memory location. Read or write operations on all variables including bit fields occur one byte or word at a time. To modify only specific bits in a byte, steps similar to these steps occur in sequence:

1. The byte is loaded into RAM.
2. A mask is created so that only specific bits are modified to the intended value and the remaining bits remain unchanged.
3. A bitwise OR operation is performed between the copy of the byte in RAM and the mask.
4. The byte with specific bits modified is copied back from RAM.

When you access two different bit fields, these four steps have to be performed for each bit field. If the accesses are not protected, all four steps for one bit field might not be completed before the four steps for the other bit field begin. As a result, the modification of one bit field might undo the modification of an adjacent bit field. For instance, in the preceding example, the modification of `errorFlag1` and `errorFlag2` can occur in the following sequence.

Steps 1,2 and 5 relate to modification of `errorFlag1` and while steps 3,4 and 6 relate to that of `errorFlag2`.

1. The byte with both `errorFlag1` and `errorFlag2` unmodified is copied into RAM, for purposes of modifying `errorFlag1`.
2. A mask that modifies only `errorFlag1` is bitwise OR-ed with this copy.
3. The byte containing both `errorFlag1` and `errorFlag2` unmodified is copied into RAM a second time, for purposes of modifying `errorFlag2`.
4. A mask that modifies only `errorFlag2` is bitwise OR-ed with this second copy.
5. The version with `errorFlag1` modified is copied back. This version has `errorFlag2` unmodified.
6. The version with `errorFlag2` modified is copied back. This version has `errorFlag1` unmodified and overwrites the previous modification.

### Fix

To fix this defect, protect the operations on bit fields that are part of the same structure using critical sections, temporal exclusion, or another means. See "Protections for Shared Variables in Multitasking Code".

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon.

### Example - Unprotected Operation on Global Variable from Multiple Tasks

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12; //Noncompliant
```

```
void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

In this example, `task1` and `task2` access different bit fields `IOFlag` and `SetupFlag`, which belong to the same structured variable `InterruptConfigbitsProc12`.

To emulate multitasking behavior, specify the options listed in this table.

| Option | Specification |
|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ |
| **Tasks** on page 2-121 | `task1`<br>`task2` |

At the command-line, use:

```
 polyspace-bug-finder
   -entry-points task1,task2
```

#### Correction – Use Critical Sections

One possible correction is to wrap the bit field access in a critical section. A critical section lies between a call to a lock function and an unlock function. In this correction, the critical section lies between the calls to functions `begin_critical_section` and `end_critical_section`.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void begin_critical_section(void);
void end_critical_section(void);

void task1 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.IOFlag = 0;
    end_critical_section();
}
```

```
void task2 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.SetupFlag = 0;
    end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the options listed in this table.

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `task1`<br>`task2` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

At the command-line, use:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

#### Correction – Avoid Bit Fields

If you do not have memory constraints, use the `char` data type instead of bit fields. The `char` variables in a structure occupy at least one byte and do not have the thread-safety issues that come from bit manipulations in a byte-sized operation. Data races do not result from unprotected operations on different `char` variables that are part of the same structure.

```
typedef struct
{
   unsigned char IOFlag;
   unsigned char InterruptFlag;
   unsigned char Register1Flag;
   unsigned char SignFlag;
   unsigned char SetupFlag;
   unsigned char Register2Flag;
   unsigned char ProcessorFlag;
   unsigned char GeneralFlag;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

Though the checker does not flag this correction, do not use this correction for C99 or earlier. Only from C11 and later does the C Standard mandate that distinct `char` variables cannot be accessed using the same word.

#### Correction – Insert Bit Field of Size 0

You can enter a non-bit field member or an unnamed bit field member of size 0 between two adjacent bit fields that might be accessed concurrently. A non-bit field member or size 0 bit-field member ensures that the subsequent bit field starts from a new memory location. In this corrected example, the size 0 bit-field member ensures that `IOFlag` and `SetupFlag` are stored in distinct memory locations.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int : 0;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

Avoid race conditions when using library functions

## Description

### Rule Definition

*Avoid race conditions when using library functions.*

### Polyspace Implementation

The rule checker checks for **Data race through standard library function call**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

## Examples

### Data race through standard library function call

#### Issue

**Data race through standard library function call** occurs when:

- Multiple tasks call the same standard library function.

  For instance, multiple tasks call the `strerror` function.
- The calls are not protected using a common protection.

  For instance, the calls are not protected by the same critical section.

Functions flagged by this defect are not guaranteed to be reentrant. A function is reentrant if it can be interrupted and safely called again before its previous invocation completes execution. If a function is not reentrant, multiple tasks calling the function without protection can cause concurrency issues. For the list of functions that are flagged, see CON33-C: Avoid race conditions when using library functions.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

#### Risk

The functions flagged by this defect are nonreentrant because their implementations can use global or static variables. When multiple tasks call the function without protection, the function call from one task can interfere with the call from another task. The two invocations of the function can concurrently access the global or static variables and cause unpredictable results.

The calls can also cause more serious security vulnerabilities, such as abnormal termination, denial-of-service attack, and data integrity violations.

**Fix**

To fix this defect, do one of the following:

- Use a reentrant version of the standard library function if it exists.

  For instance, instead of `strerror()`, use `strerror_r()` or `strerror_s()`. For alternatives to functions flagged by this defect, see the documentation for CON33-C.
- Protect the function calls using common critical sections or temporal exclusion.

  See `Critical section details (-critical-section-begin -critical-section-end)` and `Temporally exclusive tasks (-temporal-exclusions-file)`.

  To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

**Example - Unprotected Call to Standard Library Function from Multiple Tasks**

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno); //Noncompliant
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
    end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| Configure multitasking manually | ☑ | |
| Tasks (-entry-points) | task1<br>task2<br>task3 | |
| Critical section details (-critical-section-begin -critical-section-end) | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

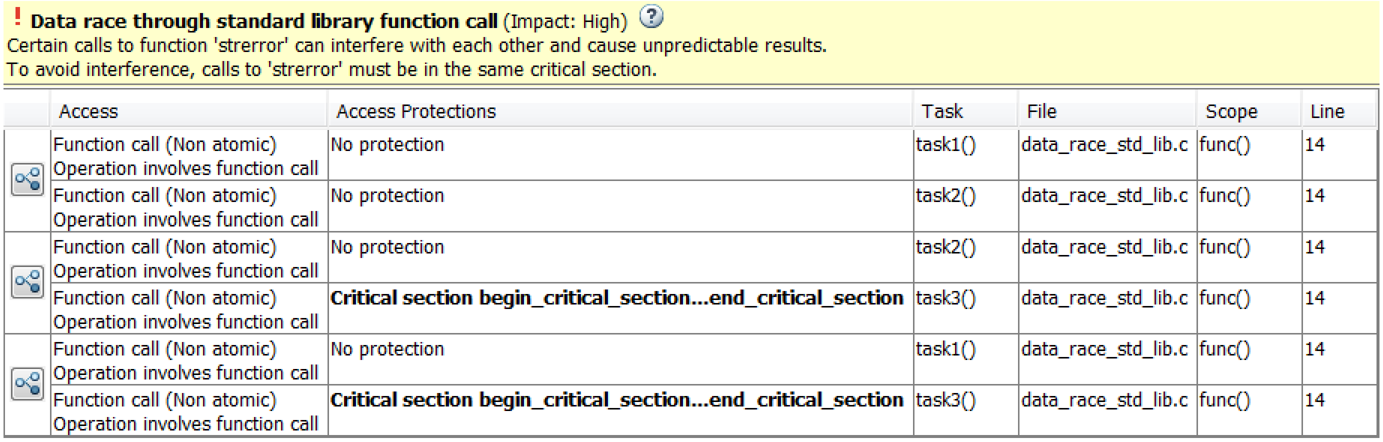
On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2,task3
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

In this example, the tasks, `task1`, `task2` and `task3`, call the function `func`. `func` calls the nonreentrant standard library function, `strerror`.

Though `task3` calls `func` inside a critical section, other tasks do not use the same critical section. Operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

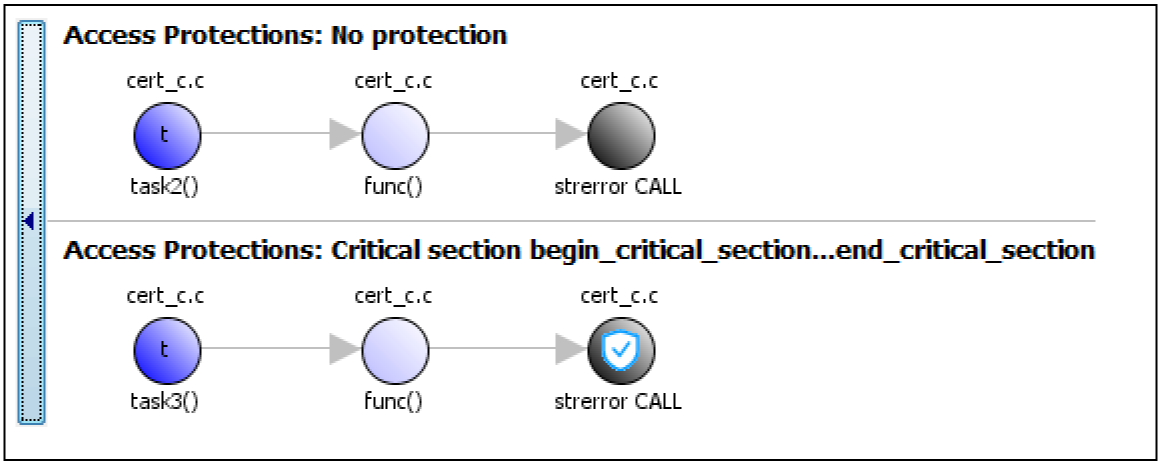
These three tasks are calling a nonreentrant standard library function without common protection. In your result details, you see each pair of conflicting function calls.



! **Data race through standard library function call** (Impact: High) ?
Certain calls to function 'strerror' can interfere with each other and cause unpredictable results.
To avoid interference, calls to 'strerror' must be in the same critical section.

| | Access | Access Protections | Task | File | Scope | Line |
|---|---|---|---|---|---|---|
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |

If you click the icon, you see the function call sequence starting from the entry point to the standard library function call. You also see that the call starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



Access Protections: No protection
cert_c.c
cert_c.c
cert_c.c
t
task2()
func()
strerror CALL
Access Protections: Critical section begin_critical_section...end_critical_section
cert_c.c
cert_c.c
cert_c.c
t
task3()
func()
strerror CALL

**Correction — Use Reentrant Version of Standard Library Function**

One possible correction is to use a reentrant version of the standard library function `strerror`. You can use the POSIX version `strerror_r` which has the same functionality but also guarantees thread-safety.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);
enum { BUFFERSIZE = 64 };

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char errmsg[BUFFERSIZE];
    if (strerror_r(errno, errmsg, BUFFERSIZE) != 0) {
      /* Handle error */
    }
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}
```

```
void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

**Correction — Place Function Call in Critical Section**

One possible correction is to place the call to `strerror` in critical section. You can implement the critical section in multiple ways.

For instance, you can place the call to the intermediate function `func` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `func` and therefore the calls to `strerror` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `func` between calls to `begin_critical_section` and `end_critical_section`.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno);
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    begin_critical_section();
    func(fptr1);
    end_critical_section();
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     begin_critical_section();
     func(fptr2);
     end_critical_section();
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| `Temporally exclusive tasks (-temporal-exclusions-file)` | `task1 task2 task3` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
     -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

Declare objects shared between threads with appropriate storage durations

## Description

### Rule Definition

*Declare objects shared between threads with appropriate storage durations.*

### Polyspace Implementation

The rule checker checks for **Automatic or thread local variable escaping from a C11 thread**.

## Examples

### Automatic or thread local variable escaping from a C11 thread

#### Issue

**Automatic or thread local variable escaping from a C11 thread** occurs when an automatic or thread local variable is passed by address from one C11 thread to another without ensuring that the variable stays alive through the duration of the latter thread.

#### Risk

An automatic or thread local variable is allocated on the stack at the beginning of a thread and its lifetime extends till the end of the thread. The variable is not guaranteed to be alive when a different thread accesses it.

For instance, consider the start function of a C11 thread with these lines:

```
int start_thread(thrd_t *tid) {
   int aVar = 0;
   if(thrd_success != thrd_create(tid, start_thread_child, &aVar) {
     //...
   }
}
```

The `thrd_create` function creates a child thread with start function `start_thread_child` and passes the address of the automatic variable `aVar`to this function. When this child thread accesses `aVar`, the parent thread might have completed execution and `aVar` is no longer on the stack. The access might result in reading unpredictable values.

#### Fix

When you pass a variable from one thread to another, make sure that the variable lifetime matches or exceeds the lifetime of both threads. You can achieve this synchronization in one of these ways:

- Declare the variable `static` so that it does not go out of stack when the current thread completes execution.
- Dynamically allocate the storage for the variable so that it is allocated on the heap instead of the stack and must be explicitly deallocated. Make sure that the deallocation happens after both threads complete execution.

These solutions require you to create a variable in nonlocal memory. Instead, you can use other solutions such as the `shared` keyword available with OpenMP's threading interface that allows you to safely share local variables across threads.

**Example – Automatic or Thread-Local Variable Escaping Thread**

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}

void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) { //Noncompliant
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  int parentVal = 1;

  create_parent_thread(&tid, &parentVal);

  if (thrd_success != thrd_join(tid, NULL)) {
    /* Handle error */
  }
  return 0;
}
```

In this example, the value `parentVal` is local to the parent thread that starts in `main` and continues into the function `create_parent_thread`. However, in the body of `create_parent_thread`, the address of this local variable is passed to a child thread (the thread with start routine `create_child_thread`). The parent thread might have completed execution and the variable `parentVal` might have gone out of scope when the child thread accesses this variable.

The same issue appears if the variable is declared as thread-local, for instance with the C11 keyword `_Thread_local` (or `thread_local`):

```
_Thread_local int parentVal = 1;
```

**Correction – Use Static Variables**

One possible correction is to declare the variable `parentVal` as `static` so that the variable is on the stack for the entire duration of the program.

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}
```

```
void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) {
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  static int parentVal = 1;

  create_parent_thread(&tid, &parentVal);

  if (thrd_success != thrd_join(tid, NULL)) {
    /* Handle error */
  }
  return 0;
}
```

**Correction – Use Dynamic Memory Allocation**

One possible correction is to dynamically allocate storage for variables to be shared across threads and explicitly free the storage after the variable is no longer required.

```
#include <threads.h>
#include <stdio.h>

int create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return 0;
}

void create_parent_thread(thrd_t *tid, int *parentPtr) {
   if (thrd_success != thrd_create(tid, create_child_thread, parentPtr)) {
    /* Handle error */
  }
}

int main(void) {
  thrd_t tid;
  int parentVal = 1;
  int parentPtr = (int*) malloc(sizeof(int));

  if(!parentPtr) {
      create_parent_thread(&tid, parentPtr);

      if (thrd_success != thrd_join(tid, NULL)) {
        /* Handle error */
      }
      free(parentPtr);
  }
  return 0;
}
```

Avoid deadlock by locking in a predefined order

## Description

### Rule Definition

*Avoid deadlock by locking in a predefined order.*

### Polyspace Implementation

The rule checker checks for **Deadlock**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

You can also extend this checker to detect synchronization issues by mapping your multithreading functions to their known POSIX equivalents. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Deadlock

#### Issue

**Deadlock** occurs when multiple tasks are stuck in their critical sections (CS) because:

- Each CS waits for another CS to end.
- The critical sections (CS) form a closed cycle. For example:
  - CS #1 waits for CS #2 to end, and CS #2 waits for CS #1 to end.
  - CS #1 waits for CS #2 to end, CS #2 waits for CS #3 to end and CS #3 waits for CS #1 to end.

Polyspace expects critical sections of code to follow a specific format. A critical section lies between a call to a lock function and a call to an unlock function. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

#### Risk

Each task waits for a critical section in another task to end and is unable to proceed. The program can freeze indefinitely.

#### Fix

The fix depends on the root cause of the defect. You can try to break the cyclic order between the tasks in one of these ways:

- Write down all critical sections involved in the deadlock in a certain sequence. Whenever you call the lock functions of the critical sections within a task, respect the order in that sequence. See an example below.
- If one of the critical sections involved in a deadlock occurs in an interrupt, try to disable all interrupts during critical sections in all tasks. See `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Reviewing this defect is an opportunity to check if all operations in your critical section are really meant to be executed as an atomic block. It is a good practice to keep critical sections at a bare minimum.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Deadlock with Two Tasks

```
void task1(void);
void task2(void);

int var;
void perform_task_cycle(void) {
 var++;
}

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2(); //Noncompliant
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_2();
    begin_critical_section_1();
    perform_task_cycle();
    end_critical_section_1();
    end_critical_section_2();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | task1<br>task2 | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | begin_critical_section_1 | end_critical_section_1 |
| | begin_critical_section_2 | end_critical_section_2 |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `begin_critical_section_1`.
2. `task2` calls `begin_critical_section_2`.
3. `task1` reaches the instruction `begin_critical_section_2();`. Since `task2` has already called `begin_critical_section_2`, `task1` waits for `task2` to call `end_critical_section_2`.
4. `task2` reaches the instruction `begin_critical_section_1();`. Since `task1` has already called `begin_critical_section_1`, `task2` waits for `task1` to call `end_critical_section_1`.

#### Correction-Follow Same Locking Sequence in Both Tasks

One possible correction is to follow the same sequence of calls to lock and unlock functions in both `task1` and `task2`.

```
void task1(void);
void task2(void);
void perform_task_cycle(void);

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}
```

**Example - Deadlock with More Than Two Tasks**

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2(); //Noncompliant
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock3();
    lock1();
    performTaskCycle();
    unlock1();
    unlock3();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | `task1`<br>`task2`<br>`task3` | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | `lock1` | `unlock1` |
| | `lock2` | `unlock2` |
| | `lock3` | `unlock3` |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `lock1`.
2. `task2` calls `lock2`.
3. `task3` calls `lock3`.
4. `task1` reaches the instruction `lock2();`. Since `task2` has already called `lock2`, `task1` waits for call to `unlock2`.
5. `task2` reaches the instruction `lock3();`. Since `task3` has already called `lock3`, `task2` waits for call to `unlock3`.
6. `task3` reaches the instruction `lock1();`. Since `task1` has already called `lock1`, `task3` waits for call to `unlock1`.

#### Correction — Break Cyclic Order

To break the cyclic order between critical sections, note every lock function in your code in a certain sequence, for example:

1. `lock1`
2. `lock2`
3. `lock3`

If you use more than one lock function in a task, use them in the order in which they appear in the sequence. For example, you can use `lock1` followed by `lock2` but not `lock2` followed by `lock1`.

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2();
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock1();
    lock3();
    performTaskCycle();
    unlock3();
    unlock1();
 }
}
```

Wrap functions that can spuriously wake up in a loop

## Description

### Rule Definition

*Wrap functions that can spuriously wake up in a loop.*

### Polyspace Implementation

The rule checker checks for **Function that can spuriously wake up not wrapped in loop**.

## Examples

### Function that can spuriously wake up not wrapped in loop

#### Issue

**Function that can spuriously wake up not wrapped in loop** occurs when the following wait-on-condition functions are called from outside a loop:

- C functions:
  - `cnd_wait()`
  - `cnd_timedwait()`
- POSIX functions:
  - `pthread_cond_wait()`
  - `pthread_cond_timedwait()`
- C++ `std::condition_variable` and `std::condition_variable_any` class member functions:
  - `wait()`
  - `wait_until()`
  - `wait_for()`

Wait-on-condition functions pause the execution of the calling thread when a specified condition is met. The thread wakes up and resumes once another thread notifies it with `cnd_broadcast()` or an equivalent function. The wake-up notification can be spurious or malicious.

#### Risk

If a thread receives a spurious wake-up notification and the condition of the wait-on-condition function is not checked, the thread can wake up prematurely. The wake-up can cause unexpected control flow, indefinite blocking of other threads, or denial of service.

#### Fix

Wrap wait-on-condition functions that can wake up spuriously in a loop. The loop checks the wake-up condition after a possible spurious wake-up notification.

**Example - `cnd_wait()` Not Wrapped in Loop**

```
#include <stdio.h>
#include <stddef.h>
#include <threads.h>

#define THRESHOLD 100

static mtx_t lock;
static cnd_t cond;

void func(int input)
{
    if (thrd_success != mtx_lock(&lock)) {
        /* Handle error */
    }
    /* test condition to pause thread */
    if (input > THRESHOLD) {
        if (thrd_success != cnd_wait(&cond, &lock)) { //Noncompliant
            /* Handle error */
        }
    }
    /* Proceed if condition to pause does not hold */

    if (thrd_success != mtx_unlock(&lock)) {
        /* Handle error */
    }
}
```

In this example, the thread uses `cnd_wait()` to pause execution when `input` is greater than `THRESHOLD`. The paused thread can resume if another thread uses `cnd_broadcast()`, which notifies all the threads. This notification causes the thread to wake up even if the pause condition is still true.

**Correction — Wrap `cnd_wait()` in a `while` Loop**

One possible correction is to wrap `cnd_wait()` in a `while` loop. The loop checks the pause condition after the thread receives a possible spurious wake-up notification.

```
#include <stdio.h>
#include <stddef.h>
#include <threads.h>

#define THRESHOLD 100

static mtx_t lock;
static cnd_t cond;

void func(int input)
{
    if (thrd_success != mtx_lock(&lock)) {
        /* Handle error */
    }
    /* test condition to pause thread */
    while (input > THRESHOLD) {
        if (thrd_success != cnd_wait(&cond, &lock)) {
            /* Handle error */
        }
    }
    /* Proceed if condition to pause does not hold */

    if (thrd_success != mtx_unlock(&lock)) {
        /* Handle error */
    }
}
```

## Description

### Rule Definition

*Do not call signal() in a multithreaded program.*

### Polyspace Implementation

The rule checker checks for **Signal call in multithreaded program**.

## Examples

### Signal call in multithreaded program

#### Issue

**Signal call in multithreaded program** occurs when you use the `signal()` function in a program with multiple threads.

#### Risk

According to the C11 standard (Section 7.14.1.1), use of the `signal()` function in a multithreaded program is undefined behavior.

#### Fix

Depending on your intent, use other ways to perform an asynchronous action on a specific thread.

#### Example - Use of `signal()` Function to Terminate Loop in Thread

```
#include <signal.h>
#include <stddef.h>
#include <threads.h>

volatile sig_atomic_t flag = 0;

void handler(int signum) {
  flag = 1;
}

/* Runs until user sends SIGUSR1 */
int func(void *data) {
  while (!flag) {
    /* ... */
  }
  return 0;
}

int main(void) {
  signal(SIGINT, handler); /* Undefined behavior */ //Noncompliant
  thrd_t tid;
  if (thrd_success != thrd_create(&tid, func, NULL)) {
    /* Handle error */
  }
  /* ... */
  return 0;
}
```

In this example, the `signal` function is used to terminate a `while` loop in the thread created with `thrd_create`.

### Correction — Use `atomic_bool` Variable to Terminate Loop

One possible correction is to use an `atomic_bool` variable that multiple threads can access. In the corrected example, the child thread evaluates this variable before every loop iteration. After completing the program, you can modify this variable so that the child thread exits the loop.

```
#include <stdatomic.h>
#include <stdbool.h>
#include <stddef.h>
#include <threads.h>

atomic_bool flag = ATOMIC_VAR_INIT(false);

int func(void *data) {
  while (!flag) {
    /* ... */
  }
  return 0;
}

int main(void) {
  thrd_t tid;

  if (thrd_success != thrd_create(&tid, func, NULL)) {
    /* Handle error */
  }
  /* ... */
  /* Set flag when done */
  flag = true;

  return 0;
}
```

Preserve thread safety and liveness when using condition variables

## Description

### Rule Definition

*Preserve thread safety and liveness when using condition variables.*

### Polyspace Implementation

The rule checker checks for **Multiple threads waiting on same condition variable**.

## Examples

### Multiple threads waiting on same condition variable

#### Issue

This issue occurs when you use `cnd_signal` family functions to wake up one of at least two threads that are concurrently waiting on the same condition variable. For threads with the same priority level, `cnd_signal` family functions cause the thread scheduler to arbitrarily wake up on of the threads waiting on the condition variable that you signal with the `cnd_signal` family function.

The checkers flags the `cnd_signal` family function call. See the **Event** column in the **Results Details** pane to view the threads waiting on the same condition variable.

#### Risk

The thread that is woken up with a `cnd_signal` family function usually tests for a condition predicate. While the condition predicate is false, the thread waits again on the condition variable until it is woken up by another thread that signals the condition variable. It is possible that the program ends up in a state where no thread is available to signal the condition variable, which results in indefinite blocking.

#### Fix

Use `cnd_broadcast` family functions instead to wake all threads waiting on the condition variable, or use a different condition variable for each thread.

#### Example - Use of `cnd_signal` to Wake Up One of Many Threads Waiting on Condition Variable

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <threads.h>

typedef int thrd_return_t;

static void fatal_error(void)
{
    exit(1);
}
```

```
enum { NTHREADS = 5 };

mtx_t mutex;
cnd_t cond;

thrd_return_t next_step(void* t)
{
    static size_t current_step = 0;
    size_t my_step = *(size_t*)t;

    if (thrd_success != mtx_lock(&mutex)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu has the lock\n", my_step);
    while (current_step != my_step) {
        printf("Thread %zu is sleeping...\n", my_step);
        if (thrd_success !=
            cnd_wait(&cond, &mutex)) {
            /* Handle error */
            fatal_error();
        }
        printf("Thread %zu woke up\n", my_step);
    }
    /* Do processing ... */
    printf("Thread %zu is processing...\n", my_step);
    current_step++;

    /* Signal a waiting task */
    if (thrd_success !=
        cnd_signal(&cond)) { //Noncompliant
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu is exiting...\n", my_step);

    if (thrd_success != mtx_unlock(&mutex)) {
        /* Handle error */
        fatal_error();
    }
    return (thrd_return_t)0;
}

int main(void)
{
    thrd_t threads[NTHREADS];
    size_t step[NTHREADS];

    if (thrd_success != mtx_init(&mutex, mtx_plain)) {
        /* Handle error */
        fatal_error();
    }
    if (thrd_success != cnd_init(&cond)) {
        /* Handle error */
        fatal_error();
    }
    /* Create threads */
    for (size_t i = 0; i < NTHREADS; ++i) {
        step[i] = i;
        if (thrd_success != thrd_create(&threads[i],
                                        next_step,
                                        &step[i])) {
            /* Handle error */
            fatal_error();
        }
    }
    /* Wait for all threads to complete */
    for (size_t i = NTHREADS; i != 0; --i) {
        if (thrd_success != thrd_join(threads[i - 1], NULL)) {
            /* Handle error */
            fatal_error();
        }
    }
    (void)mtx_destroy(&mutex);
    (void)cnd_destroy(&cond);
    return 0;
}
```

In this example, multiple threads are created and assigned step level. Each thread checks if its assigned step level matches the current step level (condition predicate). If the predicate is false, the thread goes back to waiting on the condition variable `cond`. The use of `cnd_signal` to signal the `cond` causes the thread scheduler to arbitrarily wake up one of the threads waiting on `cond`. This can result in indefinite blocking when the condition predicate of woken up thread is false and no other thread is available to signal `cond`.

**Correction — Use `cnd_broadcast` to Wake up All the Threads**

One possible correction is to use `cnd_broadcast` instead to signal `cond`. The function `cnd_signal` wakes up all the thread that are waiting on `cond`.

```
 #include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <threads.h>

typedef int thrd_return_t;

static void fatal_error(void)
{
    exit(1);
}

enum { NTHREADS = 5 };

mtx_t mutex;
cnd_t cond;

thrd_return_t next_step(void* t)
{
    static size_t current_step = 0;
    size_t my_step = *(size_t*)t;

    if (thrd_success != mtx_lock(&mutex)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu has the lock\n", my_step);
    while (current_step != my_step) {
        printf("Thread %zu is sleeping...\n", my_step);
        if (thrd_success !=
            cnd_wait(&cond, &mutex)) {
            /* Handle error */
            fatal_error();
        }
        printf("Thread %zu woke up\n", my_step);
    }
    /* Do processing ... */
    printf("Thread %zu is processing...\n", my_step);
    current_step++;

    /* Signal a waiting task */
    if (thrd_success !=
        cnd_broadcast(&cond)) {
        /* Handle error */
        fatal_error();
    }

    printf("Thread %zu is exiting...\n", my_step);

    if (thrd_success != mtx_unlock(&mutex)) {
        /* Handle error */
        fatal_error();
    }
    return (thrd_return_t)0;
}

int main_test_next_step(void)
{
    thrd_t threads[NTHREADS];
    size_t step[NTHREADS];

    if (thrd_success != mtx_init(&mutex, mtx_plain)) {
        /* Handle error */
        fatal_error();
    }
    if (thrd_success != cnd_init(&cond)) {
        /* Handle error */
        fatal_error();
    }
    /* Create threads */
    for (size_t i = 0; i < NTHREADS; ++i) {
        step[i] = i;
        if (thrd_success != thrd_create(&threads[i],
                                        next_step,
                                        &step[i])) {
            /* Handle error */
            fatal_error();
        }
    }
    /* Wait for all threads to complete */
    for (size_t i = NTHREADS; i != 0; --i) {
        if (thrd_success != thrd_join(threads[i - 1], NULL)) {
            /* Handle error */
            fatal_error();
        }
    }
    (void)mtx_destroy(&mutex);
    (void)cnd_destroy(&cond);
    return 0;
}
```

# CERT C: Rule CON39-C

Do not join or detach a thread that was previously joined or detached

## Description

### Rule Definition

*Do not perform operations that can block while holding a lock.*

### Polyspace Implementation

The rule checker checks for **Join or detach of a joined or detached thread**.

## Examples

### Join or detach of a joined or detached thread

#### Issue

**Join or detach of a joined or detached thread** occurs when:

- A thread that is joined was previously joined or detached
- A thread that is detached was previously joined or detached.

The **Result Details** pane describes if the thread was previously joined or detached and also shows previous related events.

For instance, the issue occurs when a thread joined with `thrd_join` is then detached with `pthread_detach`:

```
thrd_t id;
//...
thrd_join(id, NULL);
thrd_detach(id);
```

Note that a thread is considered as joined only if a previous thread joining is successful. For instance, the thread is not considered as joined in the `if` branch here:

```
thrd_t t;
//...
if (thrd_success != thrd_join(t, 0)) {
    /* Thread not considered joined */
}
```

The analysis cannot detect cases where a joined thread detaches itself using, for instance, the `thrd_current()` function.

#### Risk

The C11 standard (clauses 7.26.5.3 and 7.26.5.6) states that a thread shall not be joined or detached once it was previously joined or detached. Violating these clauses of the standard results in undefined behavior.

#### Fix

Avoid joining a thread that was already joined or detached previously. Likewise, avoid detaching a thread that was already joined or detached.

#### Example – Joining Followed by Detaching of Thread

```
#include <stddef.h>
#include <threads.h>
#include <stdlib.h>

extern int thread_func(void *arg);

int main (void)
{
  thrd_t t;

  if (thrd_success != thrd_create (&t, thread_func, NULL)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_join (t, 0)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_detach (t)) {    //Noncompliant
    /* Handle error */
    return 0;
  }

  return 0;
}
```

In this example, the use of `thrd_detach` on a thread that was previously joined with `thrd_join` leads to undefined behavior.

To avoid compilation errors with this example, specify the C11 standard with the option `C standard version (-c-version)`.

#### Correction – Avoid Detaching a Joined Thread

Remove the `thrd_join` or `thrd_detach` statement.

```
#include <stddef.h>
#include <threads.h>
#include <stdlib.h>

extern int thread_func(void *arg);

int main (void)
{
  thrd_t t;
  if (thrd_success != thrd_create (&t, thread_func, NULL)) {
    /* Handle error */
    return 0;
  }

  if (thrd_success != thrd_join (t, 0)) {
    /* Handle error */
    return 0;
  }

  return 0;
}
```

### Example – Joining Thread Created in Detached State

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success != pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_DETACHED)) {
        return 0;
    }

    if(thread_success != pthread_create(&id, &attr, thread_func, NULL)) {
            return 0;
    }

    if(thread_success != pthread_join(id, NULL)) { //Noncompliant
            return 0;
    }

    return 0;
}
```

In this example, the thread attribute is assigned the state `PTHREAD_CREATE_DETACHED`. A thread created using this attribute is then joined.

### Correction – Create Threads as Joinable

One possible correction is to create a thread with thread attribute assigned to the state `PTHREAD_CREATE_JOINABLE` and then join the thread.

```
#include <stddef.h>
#include <pthread.h>
#define thread_success 0

extern void *thread_func(void *arg);

int main() {
    pthread_t id;
    pthread_attr_t attr;

    if(thread_success != pthread_attr_init(&attr)) {
        return 0;
    }

    if(thread_success != pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE)) {
        return 0;
    }

    if(thread_success != pthread_create(&id, &attr, thread_func, NULL)) {
            return 0;
    }

    if(thread_success != pthread_join(id, NULL)) {
            return 0;
    }

    return 0;
}
```

Do not refer to an atomic variable twice in an expression

## Description

### Rule Definition

*Do not refer to an atomic variable twice in an expression.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Atomic variable accessed twice in an expression**.
- **Atomic load and store sequence not atomic**.

## Examples

### Atomic variable accessed twice in an expression

#### Issue

**Atomic variable accessed twice in an expression** occurs when C atomic types or C++ `std::atomic` class variables appear twice in an expression and there are:

- Two atomic read operations on the variable.
- An atomic read and a distinct atomic write operation on the variable.

The C standard defines certain operations on atomic variables that are thread safe and do not cause data race conditions. Unlike individual operations, a pair of operations on the same atomic variable in an expression is not thread safe.

#### Risk

A thread can modify the atomic variable between the pair of atomic operations, which can result in a data race condition.

#### Fix

Do not reference an atomic variable twice in the same expression.

#### Example - Referencing Atomic Variable Twice in an Expression

In this example, the global variable `n` is referenced twice in the return statement of `compute_sum()`. The value of `n` can change between the two distinct read operations. `compute_sum()` can return an incorrect value.

To see this violation, run Polyspace Bug Finder on this code and spcify `gnu4.9` as the compiler. See `Compiler (-compiler)`.

```
#include <stdatomic.h>

atomic_int n = ATOMIC_VAR_INIT(0);
```

```
int compute_sum(void)
{
    return n * (n + 1) / 2; //Noncompliant
}
```

#### Correction — Pass Variable as Function Argument

One possible correction is to pass the variable as a function argument `n`. The variable is copied to memory and the read operations on the copy guarantee that `compute_sum()` returns a correct result. If you pass a variable of type `int` instead of type `atomic_int`, the correction is still valid.

```
#include <stdatomic.h>

int compute_sum(atomic_int n)
{
    return n * (n + 1) / 2;
}
```

### Atomic load and store sequence not atomic

#### Issue

**Atomic load and store sequence not atomic** occurs when you use these functions to load, and then store an atomic variable.

- C functions:
  - `atomic_load()`
  - `atomic_load_explicit()`
  - `atomic_store()`
  - `atomic_store_explicit()`
- C++ functions:
  - `std::atomic_load()`
  - `std::atomic_load_explicit()`
  - `std::atomic_store()`
  - `std::atomic_store_explicit()`
  - `std::atomic::load()`
  - `std::atomic::store()`

A thread cannot interrupt an atomic load or an atomic store operation on a variable, but a thread can interrupt a store, and then load sequence.

#### Risk

A thread can modify a variable between the load and store operations, resulting in a data race condition.

#### Fix

To read, modify, and store a variable atomically, use a compound assignment operator such as `+=`, `atomic_compare_exchange()` or `atomic_fetch_*`-family functions.

#### Example - Loading Then Storing an Atomic Variable

In this example, variable `flag` of type `atomic_bool` is referenced twice inside the `toggle_flag()` function. The function loads the variable, negates its value, then stores the new value back to the variable. If two threads call `toggle_flag()`, the second thread can access `flag` between the load and store operations of the first thread. `flag` can end up in an incorrect state.

To see this violation, run Polyspace Bug Finder on this code and spcify `gnu4.9` as the compiler. See `Compiler (-compiler)`.

```
#include <stdatomic.h>
#include <stdbool.h>

static atomic_bool flag = ATOMIC_VAR_INIT(false);

void init_flag(void)
{
    atomic_init(&flag, false);
}

void toggle_flag(void)
{
    bool temp_flag = atomic_load(&flag);
    temp_flag = !temp_flag;
    atomic_store(&flag, temp_flag); //Noncompliant
}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

#### Correction — Use Compound Assignment to Modify Variable

One possible correction is to use a compound assignment operator to toggle the value of `flag`. The C standard defines the operation by using ^= as atomic.

```
#include <stdatomic.h>
#include <stdbool.h>

static atomic_bool flag = ATOMIC_VAR_INIT(false);

void toggle_flag(void)
{
    flag ^= 1;
}

bool get_flag(void)
{
    return flag;
}
```

Wrap functions that can fail spuriously in a loop

## Description

### Rule Definition

*Wrap functions that can fail spuriously in a loop.*

### Polyspace Implementation

The rule checker checks for **Function that can spuriously fail not wrapped in loop**.

## Examples

### Function that can spuriously fail not wrapped in loop

#### Issue

**Function that can spuriously fail not wrapped in loop** occurs when the following atomic compare and exchange functions that can fail spuriously are called from outside a loop.

- C atomic functions:
  - `atomic_compare_exchange_weak()`
  - `atomic_compare_exchange_weak_explicit()`
- C++ atomic functions:
  - `std::atomic<T>::compare_exchange_weak(T* expected, T desired)`
  - `std::atomic<T>::compare_exchange_weak_explicit(T* expected, T desired, std::memory_order succ, std::memory_order fail)`
  - `std::atomic_compare_exchange_weak(std::atomic<T>* obj, T* expected, T desired)`
  - `std::atomic_compare_exchange_weak_explicit(volatile std::atomic<T>* obj, T* expected, T desired, std::memory_order succ, std::memory_order fail)`

The functions compare the memory contents of the object representations pointed to by `obj` and `expected`. The comparison can spuriously return false even if the memory contents are equal. This spurious failure makes the functions faster on some platforms.

#### Risk

An atomic compare and exchange function that spuriously fails can cause unexpected results and unexpected control flow.

#### Fix

Wrap atomic compare and exchange functions that can spuriously fail in a loop. The loop checks the failure condition after a possible spurious failure.

### Example - `atomic_compare_exchange_weak()` Not Wrapped in Loop

```
#include <stdatomic.h>

extern void reset_count(void);
atomic_int count = ATOMIC_VAR_INIT(0);

void increment_count(void)
{
    int old_count = atomic_load(&count);
    int new_count;
    new_count = old_count + 1;
    if (!atomic_compare_exchange_weak(&count, &old_count, new_count)) //Noncompliant
        reset_count();

}
```

In this example, `increment_count()` uses `atomic_compare_exchange_weak()` to compare `count` and `old_count`. If the counts are equal, `count` is incremented to `new_count`. If they are not equal, the count is reset. When `atomic_compare_exchange_weak()` fails spuriously, the count is reset unnecessarily.

### Correction — Wrap `atomic_compare_exchange_weak()` in a `while` Loop

One possible correction is to wrap the call to `atomic_compare_exchange_weak()` in a `while` loop. The loop checks the failure condition after a possible spurious failure.

```
#include <stdatomic.h>

extern void reset_count(void);
atomic_int count = ATOMIC_VAR_INIT(0);

void increment_count(void)
{
    int old_count = atomic_load(&count);
    int new_count;
    new_count = old_count + 1;

    do {
        reset_count();

    } while (!atomic_compare_exchange_weak(&count, &old_count, new_count));

}
```

Do not allow data races in multithreaded code

## Description

### Rule Definition

*Do not allow data races in multithreaded code.*

### Polyspace Implementation

The rule checker checks for **Data race**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

You can also extend this checker in the following ways:

- Map your multithreading functions to their known POSIX equivalents. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.
- Detect all data races including ones involving atomic operations.

  Polyspace assumes that certain operations are atomic and excludes them from data race checks. See “Define Atomic Operations in Multitasking Code”. These assumptions might not apply to your environment. To extend the data race checkers to include these operations, use the option `-detect-atomic-data-race`. See “Extend Data Race Checkers to Atomic Operations”.

## Examples

### Data race

#### Issue

Data race occurs when:

- Multiple tasks perform unprotected operations on a shared variable.
- At least one task performs a write operation.
- At least one operation is nonatomic. To detect data race on both atomic and nonatomic operations, use the options `-detect-atomic-data-race`. See “Extend Data Race Checkers to Atomic Operations”.

  See also “Define Atomic Operations in Multitasking Code”.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

#### Risk

Data race can result in unpredictable values of the shared variable because you do not control the order of the operations in different tasks.

Data races between two write operations are more serious than data races between a write and read operation. Two write operations can interfere with each other and result in indeterminate values. To identify write-write conflicts, use the filters on the **Detail** column of the **Results List** pane. For these conflicts, the **Detail** column shows the additional line:

```
Variable value may be altered by write-write concurrent access.
```

See “Filter and Group Results in Polyspace Desktop User Interface” or “Filter and Sort Results in Polyspace Access Web Interface”.

#### Fix

To fix this defect, protect the operations on the shared variable using critical sections, temporal exclusion or another means. See “Protections for Shared Variables in Multitasking Code”.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

#### Example - Unprotected Operation on Global Variable from Multiple Tasks

```
int var; //Noncompliant
void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
    var++;
}

void task1(void)  {
      increment();
}

void task2(void)  {
      increment();
}

void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | task1<br>task2<br>task3 | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

On the command-line, you can use the following:

```
polyspace-bug-finder
  -entry-points task1,task2,task3
  -critical-section-begin begin_critical_section:cs1
  -critical-section-end end_critical_section:cs1
```

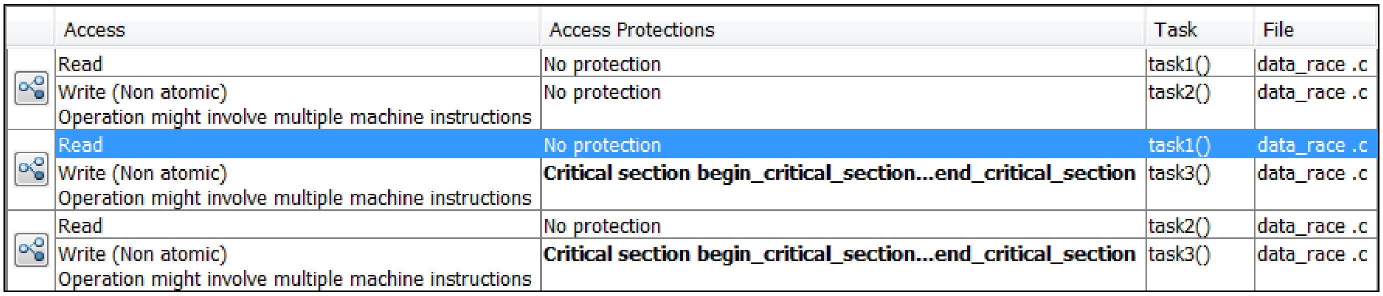
In this example, the tasks `task1`, `task2`, and `task3` call the function `increment`. `increment` contains the operation `var++` that can involve multiple machine instructions including:

- Reading `var`.
- Writing an increased value to `var`.

These machine instructions, when executed from `task1` and `task2`, can occur concurrently in an unpredictable sequence. For example, reading `var` from `task1` can occur either before or after writing to `var` from `task2`. Therefore the value of `var` can be unpredictable.

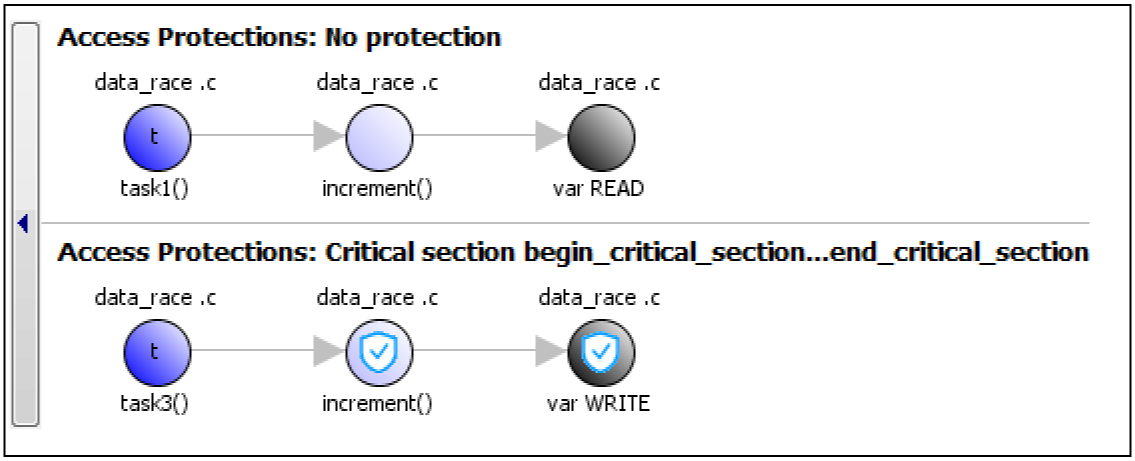
Though `task3` calls `increment` inside a critical section, other tasks do not use the same critical section. The operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

Therefore, the three tasks are operating on a shared variable without common protection. In your result details, you see each pair of conflicting function calls.



| | Access | Access Protections | Task | File |
|---|---|---|---|---|
| | Read | No protection | task1() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | No protection | task2() | data_race .c |
| | Read | No protection | task1() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | Critical section begin_critical_section...end_critical_section | task3() | data_race .c |
| | Read | No protection | task2() | data_race .c |
| | Write (Non atomic)<br>Operation might involve multiple machine instructions | Critical section begin_critical_section...end_critical_section | task3() | data_race .c |

If you click the icon, you see the function call sequence starting from the entry point to the read or write operation. You also see that the operation starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



**Correction — Place Operation in Critical Section**

One possible correction is to place the operation in critical section. You can implement the critical section in multiple ways. For instance:

- You can place `var++` in a critical section. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The operation `var++` from the three tasks cannot interfere with each other.

  To implement the critical section, in the function `increment`, place the operation `var++` between calls to `begin_critical_section` and `end_critical_section`.

```
int var;

void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
      begin_critical_section();
      var++;
      end_critical_section();
}

void task1(void)  {
      increment();
}

void task2(void)  {
      increment();
}

void task3(void)  {
      increment();
}
```

- You can place the call to `increment` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `increment` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `increment` between calls to `begin_critical_section` and `end_critical_section`.

```
int var;

void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
      var++;
}

void task1(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task2(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| **Temporally exclusive tasks** on page 2-136 | `task1 task2 task3` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
     -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

#### Example - Unprotected Operation in Threads Created with `pthread_create`

```
#include <pthread.h>

pthread_mutex_t count_mutex;
```

```
long long count; //Noncompliant

void* increment_count(void* args)
{
    count = count + 1;
    return NULL;
}

void* set_count(void *args)
{
    long long c;
    c = count;
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

In this example, Bug Finder detects the creation of separate threads with `pthread_create`. The **Data race** defect is raised because the operation `count = count + 1` in the thread with id `thread_increment` conflicts with the operation `c = count` in the thread with id `thread_get`. The variable `count` is accessed in multiple threads without a common protection.

The two conflicting operations are nonatomic. The operation `c = count` is nonatomic on 32-bit targets. See “Define Atomic Operations in Multitasking Code”.

**Correction — Protect Operations with `pthread_mutex_lock` and `pthread_mutex_unlock` Pair**

To prevent concurrent access on the variable `count`, protect operations on `count` with a critical section. Use the functions `pthread_mutex_lock` and `pthread_mutex_unlock` to implement the critical section.

```
#include <pthread.h>

pthread_mutex_t count_mutex;
long long count;

void* increment_count(void* args)
{
    pthread_mutex_lock(&count_mutex);
    count = count + 1;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}
```

```
void* set_count(void *args)
{
    long long c;
    pthread_mutex_lock(&count_mutex);
    c = count;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

Do not use the rand() function for generating pseudorandom numbers

## Description

### Rule Definition

*Do not use the rand() function for generating pseudorandom numbers.*

### Polyspace Implementation

The rule checker checks for **Use of `rand()` for Generating Pseudorandom Number**.

## Examples

### Use of `rand()` for Generating Pseudorandom Number

**Issue**

This issue occurs when you use the function `rand` for generating pseudorandom numbers.

**Risk**

The function `rand` is cryptographically weak. That is, the numbers generated by `rand` can be predictable. Do not use pseudorandom numbers generated from `rand` for security purposes. When a predictable random value controls the execution flow, your program is vulnerable to attacks.

**Fix**

Use more cryptographically sound pseudorandom number generators (PRNG), such as `CryptGenRandom` (Windows), `OpenSSL/RAND_bytes`(Linux/UNIX), or `random` (POSIX).

**Example - Random Loop Numbers**

```
#include <stdio.h>
#include <stdlib.h>

volatile int rd = 1;
int main(int argc, char *argv[])
{
    int j, r, nloops;
    struct random_data buf;
    int i = 0;

    nloops = rand(); //Noncompliant

    for (j = 0; j < nloops; j++) {
        i = rand(); //Noncompliant
        printf("random_r: %ld\n", (long)i);
    }
    return 0;
}
```

This example uses `rand` to generate random numbers `nloops` and `i`. The predictability of these variables makes these function vulnerable to attacks.

#### Correction — Use Stronger PRNG

One possible correction is to replace the vulnerable PRNG with a stronger random number generator. For instance, this code uses the PRNG `random()` from POSIX library. `random` is a much stronger PRNG because it can be seeded by a different number every time it is called.

```
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#define TIME_UTC 1
volatile int rd = 1;
int randomWrapper(){
    struct timespec ts;
  if (timespec_get(&ts, TIME_UTC) == 0) {
    /* Handle error */
  }
  srandom(ts.tv_nsec ^ ts.tv_sec);  /* Seed the PRNG */
    return random();
}
int main(int argc, char *argv[])
{
    int j, r, nloops;
    struct random_data buf;
    int i = 0;

    nloops = randomWrapper();

    for (j = 0; j < nloops; j++) {
        i = randomWrapper();
        printf("random_r: %ld\n", (long)i);
    }
    return 0;
}
```

# CERT C: Rule MSC32-C

Properly seed pseudorandom number generators

## Description

### Rule Definition

*Properly seed pseudorandom number generators.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Deterministic random output from constant seed**.
- **Predictable random output from predictable seed**.

## Examples

### Deterministic random output from constant seed

#### Issue

**Deterministic random output from constant seed** detects random standard functions that when given a constant seed, have deterministic output.

#### Risk

When some random functions, such as `srand`, `srandom`, and `initstate`, have constant seeds, the results produce the same output every time that your program is run. A hacker can disrupt your program if they know how your program behaves.

#### Fix

Use a different random standard function or use a nonconstant seed.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Random Number Generator Initialization

```
#include <stdlib.h>

void random_num(void)
{
    srand(12345U); //Noncompliant
    /* ... */
}
```

This example initializes a random number generator using `srand` with a constant seed. The random number generation is deterministic, making this function cryptographically weak.

#### Correction — Use Different Random Number Generator

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S
#include <stdlib.h>
#include <stdio.h>

unsigned int random_num_time(void)
{

    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

### Predictable random output from predictable seed

#### Issue

**Predictable random output from predictable seed** looks for random standard functions that use a nonconstant but predictable seed. Examples of predictable seed generators are `time`, `gettimeofday`, and `getpid`.

#### Risk

When you use predictable seed values for random number generation, your random numbers are also predictable. A hacker can disrupt your program if they know how your program behaves.

#### Fix

You can use a different function to generate less predictable seeds.

You can also use a different random number generator that does not require a seed. For example, the Windows API function `rand_s` seeds itself by default. It uses information from the entire system, for example, system time, thread ids, system counter, and memory clusters. This information is more random and a user cannot access this information.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Seed as an Argument

```
#include <stdlib.h>
#include <time.h>

void seed_rng(int seed)
```

```
{
    srand(seed); //Noncompliant
}

int generate_num(void)
{
    seed_rng(time(NULL) + 3);
    /* ... */
}
```

This example uses `srand` to start the random number generator with `seed` as the seed. However, `seed` is predictable because the function `time` generates it. So, an attacker can predict the random numbers generated by `srand`.

**Correction — Use Different Random Number Generator**

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S

#include <stdlib.h>
#include <stdio.h>
#include <errno.h>

int generate_num(void)
{
    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

Do not pass invalid data to the asctime() function

## Description

### Rule Definition

*Do not pass invalid data to the asctime() function.*

### Polyspace Implementation

The rule checker checks for **Use of obsolete standard function**.

## Examples

### Use of obsolete standard function

#### Issue

**Use of obsolete standard function** detects calls to standard function routines that are considered legacy, removed, deprecated, or obsolete by C/C++ coding standards.

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `asctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |
| `asctime_r` | Deprecated in POSIX.1-2008 | Implementation based on unsafe function `sprintf`. | `strftime` or `asctime_s` |
| `bcmp` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcmp` |
| `bcopy` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcpy` or `memmove` |
| `brk` and `sbrk` | Marked as legacy in SUSv2 and POSIX.1-2001. | | `malloc` |
| `bsd_signal` | Removed in POSIX.1-2008 | | `sigaction` |
| `bzero` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | `memset` |
| `ctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| ctime_r | Deprecated in POSIX.1-2008 | Implementation based on unsafe function sprintf. | strftime or asctime_s |
| cuserid | Removed in POSIX.1-2001. | Not reentrant. Precise functionality not standardized causing portability issues. | getpwuid |
| ecvt and fcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | Not reentrant | snprintf |
| ecvt_r and fcvt_r | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | | snprintf |
| ftime | Removed in POSIX.1-2008 | | time, gettimeofday, clock_gettime |
| gamma, gammaf, gammal | Function not specified in any standard because of historical variations | Portability issues. | tgamma, lgamma |
| gcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | snprintf |
| getcontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| getdtablesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_OPEN_MAX ) |
| gethostbyaddr | Removed in POSIX.1-2008 | Not reentrant | getaddrinfo |
| gethostbyname | Removed in POSIX.1-2008 | Not reentrant | getnameinfo |
| getpagesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_PAGESIZE ) |
| getpass | Removed in POSIX.1-2001. | Not reentrant. | getpwuid |
| getw | Not present in POSIX.1-2001. | | fread |
| getwd | Marked legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | getcwd |
| index | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strchr |
| makecontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| memalign | Appears in SunOS 4.1.3. Not in 4.4 BSD or POSIX.1-2001 | | posix_memalign |
| mktemp | Removed in POSIX.1-2008. | Generated names are predictable and can cause a race condition. | mkstemp removes race risk |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| pthread_attr_getstackaddr and pthread_attr_setstackaddr | | Ambiguities in the specification of the stackaddr attribute cause portability issues | pthread_attr_getstack and pthread_attr_setstack |
| putw | Not present in POSIX.1-2001. | Portability issues. | fwrite |
| qecvt and qfcvt | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| qecvt_r and qfcvt_r | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| rand_r | Marked as obsolete in POSIX.1-2008 | | |
| re_comp | BSD API function | Portability issues | regcomp |
| re_exes | BSD API function | Portability issues | regexec |
| rindex | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strrchr |
| scalb | Removed in POSIX.1-2008 | | scalbln, scalblnf, or scalblnl |
| sigblock | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigsetmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigstack | Interface is obsolete and not implemented on most platforms. | Portability issues. | sigaltstack |
| sigvec | 4.3BSD signal API whose origin is unclear | | sigaction |
| swapcontext | Removed in POSIX.1-2008 | Portability issues. | Use POSIX threads. |
| tmpnam and tmpnam_r | Marked as obsolete in POSIX.1-2008. | This function generates a different string each time it is called, up to TMP_MAX times. If it is called more than TMP_MAX times, the behavior is implementation-defined. | mkstemp, tmpfile |
| ttyslot | Removed in POSIX.1-2001. | | |
| ualarm | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | Errors are under-specified | setitimer or POSIX timer_create |
| usleep | Removed in POSIX.1-2008. | | nanosleep |
| utime | SVr4, POSIX.1-2001. POSIX.1-2008 marks as obsolete. | | |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `valloc` | Marked as obsolete in 4.3BSD.<br>Marked as legacy in SUSv2.<br>Removed from POSIX.1-2001 | | `posix_memalign` |
| `vfork` | Removed from POSIX.1-2008 | Under-specified in previous standards. | `fork` |
| `wcswcs` | This function was not included in the final ISO/IEC 9899:1990/ Amendment 1:1995 (E). | | `wcsstr` |
| `WinExec` | WinAPI provides this function only for 16-bit Windows compatibility. | | `CreateProcess` |
| `LoadModule` | WinAPI provides this function only for 16-bit Windows compatibility. | | `CreateProcess` |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing Out Time

```
#include <stdio.h>
#include <time.h>

void timecheck_bad(int argc, char *argv[])
{
    time_t ticks;

    ticks = time(NULL);
    printf("%.24s\r\n", ctime(&ticks)); //Noncompliant
}
```

In this example, the function `ctime` formats the current time and prints it out. However, `ctime` was removed after C99 because it does not work on multithreaded programs.

#### Correction — Different Time Function

One possible correction is to use `strftime` instead because this function uses a set buffer size.

```
#include <stdio.h>
#include <string.h>
#include <time.h>

void timecheck_good(int argc, char *argv[])
{
    char outBuff[1025];
    time_t ticks;
    struct tm * timeinfo;

    memset(outBuff, 0, sizeof(outBuff));

    ticks = time(NULL);
    timeinfo = localtime(&ticks);
    strftime(outBuff,sizeof(outBuff),"%I:%M%p.",timeinfo);
    fprintf(stdout, outBuff);
}
```

Ensure that control never reaches the end of a non-void function

## Description

### Rule Definition

*Ensure that control never reaches the end of a non-void function.*

### Polyspace Implementation

The rule checker checks for **Missing return statement**.

## Examples

### Missing return statement

#### Issue

**Missing return statement** occurs when a function does not return a value along at least one execution path. If the return type of the function is `void`, this error does not occur.

#### Risk

If a function has a non-`void` return value in its signature, it is expected to return a value. The return value of this function can be used in later computations. If the execution of the function body goes through a path where a `return` statement is missing, the function return value is indeterminate. Computations with this return value can lead to unpredictable results.

#### Fix

In most cases, you can fix this defect by placing the `return` statement at the end of the function body.

Alternatively, you can identify which execution paths through the function body do not have a `return` statement and add a `return` statement on those paths. Often the result details show a sequence of events that indicate this execution path. You can add a `return` statement at an appropriate point in the path. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Missing or invalid return statement error**

```
int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }
 }  //Noncompliant
/* Defect: No return value if n is not 0*/
```

If n is equal to 0, the code does not enter the if statement. Therefore, the function AddSquares does not return a value if n is 0.

**Correction — Place Return Statement on Every Execution Path**

One possible correction is to return a value in every branch of the if...else statement.

```
 int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }

   /*Fix: Place a return statement on branches of if-else */
   else
     return 0;
  }
```

# CERT C: Rule MSC38-C

Do not treat a predefined identifier as an object if it might only be implemented as a macro

## Description

### Rule Definition

*Do not treat a predefined identifier as an object if it might only be implemented as a macro.*

### Polyspace Implementation

The rule checker checks for **Predefined macro used as an object**.

## Examples

### Predefined macro used as an object

#### Issue

**Predefined macro used as an object** occurs when you use certain identifiers in a way that requires an underlying object to be present. These identifiers are defined as macros. The C Standard does not allow you to redefine them as objects. You use the identifiers in such a way that macro expansion of the identifiers cannot occur.

For instance, you refer to an external variable `errno`:

```
extern int errno;
```

However, `errno` does not occur as a variable but a macro.

The defect applies to these macros: `assert`, `errno`, `math_errhandling`, `setjmp`, `va_arg`, `va_copy`, `va_end`, and `va_start`. The checker looks for the defect only in source files (not header files).

#### Risk

The C11 Standard (Sec. 7.1.4) allows you to redefine most macros as objects. To access the object and not the macro in a source file, you do one of these:

- Redeclare the identifier as an external variable or function.
- For function-like macros, enclose the identifier name in parentheses.

If you try to use these strategies for macros that cannot be redefined as objects, an error occurs.

#### Fix

Do not use the identifiers in such a way that a macro expansion is suppressed.

- Do not redeclare the identifiers as external variables or functions.
- For function-like macros, do not enclose the macro name in parentheses.

#### Example - Use of `assert` as Function

```
#include<assert.h>
typedef void (*err_handler_func)(int);

extern void demo_handle_err(err_handler_func, int);

void func(int err_code) {
    extern void assert(int);    //Noncompliant
    demo_handle_err(&(assert), err_code); //Noncompliant
}
```

In this example, the `assert` macro is redefined as an external function. When passed as an argument to `demo_handle_err`, the identifier `assert` is enclosed in parentheses, which suppresses use of the `assert` macro.

#### Correction — Use `assert` as Macro

One possible correction is to directly use the `assert` macro from `assert.h`. A different implementation of the function `demo_handle_err` directly uses the `assert` macro instead of taking the address of an `assert` function.

```
#include<assert.h>
void demo_handle_err(int err_code) {
    assert(err_code == 0);
}

void func(int err_code) {
    demo_handle_err(err_code);
}
```

Do not call va_arg() on a va_list that has an indeterminate value

## Description

### Rule Definition

*Do not call va_arg() on a va_list that has an indeterminate value.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate va_list values**.

## Examples

### Use of indeterminate va_list values

#### Issue

This issue occurs when:

- You use a local `va_list` without initializing it first using `va_start` or `va_copy`.

  You might be using the local `va_list` in `va_arg` or a `vprintf`-like function (function that takes variable number of arguments).
- You use a `va_list` (variable argument list) from a function parameter directly instead of making a copy using `va_copy` and using the copy.

#### Risk

If you use a local `va_list` without initializing it first, the behavior is undefined.

If you pass a `va_list` to another function and use it there, the `va_list` has indeterminate values in the original calling function. Using the `va_list` in the calling function following the function call can produce unexpected results.

#### Fix

Initialize a local `va_list` with `va_start` or `va_copy` before using it.

Pass a `va_list` by reference. In the called function, make a copy of the passed `va_list` and use the copy. You can then continue to access the original `va_list` in the calling function.

#### Example - Direct Use of `va_list` From Another Function

```
#include <stdarg.h>
#include <stdio.h>

int contains_zero(size_t count, va_list ap) {
    for (size_t i = 1; i < count; ++i) {
        if (va_arg(ap, double) == 0.0) {//Noncompliant
            return 1;
        }
    }
    return 0;
}

int print_reciprocals(size_t count, ...) {
    va_list ap;
    va_start(ap, count);

    if (contains_zero(count, ap)) {
        va_end(ap);
        return 1;
    }

    for (size_t i = 0; i < count; ++i) {
        printf("%f ", 1.0 / va_arg(ap, double));
    }

    va_end(ap);
    return 0;
}
```

In this example, the function `print_reciprocals` prints out its variable arguments and uses a helper function `contains_zero` to check if the `va_list` named `ap` contains zero. After `ap` is passed to `contains_zero` by value, the value of `ap` is indeterminate. Attempts to read this indeterminate value in `print_reciprocals` results in unexpected behavior. Polyspace flags the direct of `ap` in th helper function.

#### Correction – Copy `va_list` Obtained from Another Function

To avoid the violation, pass the `va_list` by reference and make a copy of the variable in the `contains_zero` function. Perform further operations on the copy.

```
#include <stdarg.h>
#include <stdio.h>

int contains_zero(size_t count, va_list *ap) {
    va_list ap1;
    va_copy(ap1, *ap);
    for (size_t i = 1; i < count; ++i) {
        if (va_arg(ap1, double) == 0.0) {
            return 1;
        }
    }
    va_end(ap1);
    return 0;
}

int print_reciprocals(size_t count, ...) {
    int status;
    va_list ap;
    va_start(ap, count);

    if (contains_zero(count, &ap)) {
        printf("0 in arguments!\n");
        status = 1;
    } else {
        for (size_t i = 0; i < count; i++) {
            printf("%f ", 1.0 / va_arg(ap, double));
        }
        printf("\n");
        status = 0;
    }

    va_end(ap);
    return status;
}
```

Do not violate constraints

## Description

### Rule Definition

*Do not violate constraints.*

### Polyspace Implementation

The rule checker checks for **Inline constraint not respected**.

## Examples

### Inline constraint not respected

#### Issue

**Inline constraint not respected** occurs when you refer to a file scope modifiable static variable or define a local modifiable static variable in a nonstatic inlined function. The checker considers a variable as modifiable if it is not `const`-qualified.

For instance, `var` is a modifiable `static` variable defined in an `inline` function `func`. `g_step` is a file scope modifiable static variable referred to in the same inlined function.

```
static int g_step;
inline void func (void) {
   static int var = 0;
   var += g_step;
}
```

#### Risk

When you modify a static variable in multiple function calls, you expect to modify the same variable in each call. For instance, each time you call `func`, the same instance of `var1` is incremented but a separate instance of `var2` is incremented.

```
void func(void) {
   static var1 = 0;
   var2 = 0;
   var1++;
   var2++;
}
```

If a function has an inlined and non-inlined definition (in separate files), when you call the function, the C standard allows compilers to use either the inlined or the non-inlined form (see ISO/IEC 9899:2011, sec. 6.7.4). If your compiler uses an inlined definition in one call and the non-inlined definition in another, you are no longer modifying the same variable in both calls. This behavior defies the expectations from a static variable.

#### Fix

Use one of these fixes:

- If you do not intend to modify the variable, declare it as `const`.

  If you do not modify the variable, there is no question of unexpected modification.
- Make the variable non-`static`. Remove the `static` qualifier from the declaration.

  If the variable is defined in the function, it becomes a regular local variable. If defined at file scope, it becomes an extern variable. Make sure that this change in behavior is what you intend.
- Make the function `static`. Add a `static` qualifier to the function definition.

  If you make the function `static`, the file with the inlined definition always uses the inlined definition when the function is called. Other files use another definition of the function. The question of which function definition gets used is not left to the compiler.

#### Example - Static Variable Use in Inlined and External Definition

```
/* file1. c  : contains inline definition of get_random()*/

inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;  //Noncompliant
    static unsigned int m_w = 0xbaddecaf;  //Noncompliant

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}
```

```
/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

In this example, get_random() has an inline definition in file1.c and an external definition in file2.c. When get_random is called in file1.c, compilers are free to choose whether to use the inline or the external definition.

Depending on the definition used, you might or might not modify the version of m_z and m_w in the inlined version of get_random(). This behavior contradicts the usual expectations from a static variable. When you call get_random(), you expect to always modify the same m_z and m_w.

**Correction — Make Inlined Function Static**

One possible correction is to make the inlined get_random() static. Irrespective of your compiler, calls to get_random() in file1.c then use the inlined definition. Calls to get_random() in other files use the external definition. This fix removes the ambiguity about which definition is used and whether the static variables in that definition are modified.

```
/* file1. c  : contains inline definition of get_random()*/

static inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}

/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

Never hard code sensitive information

## Description

### Rule Definition

*Never hard code sensitive information.*

### Polyspace Implementation

The rule checker checks for **Hard coded sensitive data**.

## Examples

### Hard coded sensitive data

**Hard coded sensitive data** occurs when data that is potentially sensitive is directly exposed in the code, for instance, as string literals. The checker identifies data as sensitive from their use in certain functions such as password encryption functions.

Following data can be potentially sensitive.

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Host name | • `sethostname`, `setdomainname`, `gethostbyname`, `gethostbyname2`, `getaddrinfo`, `gethostbyname_r`, `gethostbyname2_r` (string argument)<br>• `inet_aton`, `inet_pton`, `inet_net_pton`, `inet_addr`, `inet_network` (string argument)<br>• `mysql_real_connect`, `mysql_real_connect_nonblocking`, `mysql_connect` (2nd argument) |
| Password | • `CreateProcessWithLogonW`, `LogonUser` (1st argument)<br>• `mysql_real_connect`, `mysql_real_connect_nonblocking`, `mysql_connect` (3rd argument) |

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Database | • MySQL: mysql_real_connect, mysql_real_connect_nonblocking, mysql_connect (4th argument)<br>• SQLite: sqlite3_open, sqlite3_open16, sqlite3_open_v2 (1st argument)<br>• PostgreSQL: PQconnectdb<br>• Microsoft SQL: SQLDriverConnect (3rd argument) |
| User name | • getpw, getpwnam, getpwnam_r, getpwuid, getpwuid_r |
| Salt | crypt, crypt_r (2nd argument) |
| Cryptography keys and initialization vectors | OpenSSL:<br>• EVP_CipherInit, EVP_EncryptInit, EVP_DecryptInit (3rd argument)<br>• EVP_CipherInit_ex, EVP_EncryptInit_ex, EVP_DecryptInit_ex (4th argument) |
| Seed | • srand, srandom, initstate (1st argument)<br>• OpenSSL: RAND_seed, RAND_add |

**Risk**

Information that is hardcoded can be queried from binaries generated from the code.

**Fix**

Avoid hard coding sensitive information.

**Example – Sensitive Data Exposed Through String Literals**

```
// Typically, you include the header "mysql.h" with function and type declarations.
// In this example, only the required lines from the header are quoted.

typedef struct _MYSQL MYSQL;

MYSQL *mysql_real_connect(MYSQL *mysql,
                          const char *host, const char *user, const char *passwd,
                          const char *db, unsigned int port, const char *unix_socket,
                          unsigned long client_flag);

typedef void * DbHandle;
extern MYSQL *sql;

// File that uses functions from "mysql.h"
const char *host = "localhost";
char *user = "guest";
char *passwd;

DbHandle connect_to_database_server(const char *db)
```

```
{
    passwd = (char*)"guest";
    return (DbHandle)
        mysql_real_connect (sql, host, user, passwd, db, 0, 0x0, 0); //Noncompliant
}
```

In this example, the `mysql_real_connect` arguments `host` (host name), `user` (user name), and `passwd` (password) are string literals and directly exposed in the code.

Querying the generated binary for ASCII strings can reveal this information.

**Correction – Read Sensitive Data from Secured Configuration Files**

One possible correction is to read the data from a configuration file. In the following corrected example, the call to function `connect_to_database_server_init` presumably reads the host name, user name, and password into its arguments from a secured configuration file.

```
// Typically, you include the header "mysql.h" with function and type declarations.
// In this example, only the required lines from the header are quoted.

typedef struct _MYSQL MYSQL;

MYSQL *mysql_real_connect(MYSQL *mysql,
                          const char *host, const char *user, const char *passwd,
                          const char *db, unsigned int port, const char *unix_socket,
                          unsigned long client_flag);

typedef void * DbHandle;
extern MYSQL *sql;

// File that uses functions from "mysql.h"

DbHandle connect_to_database_server(const char *db)
{
    const char *host_from_cfg;
    const char *user_from_cfg;
    const char *passwd_from_cfg;
    const char *db_from_cfg;
    if (connect_to_database_server_init(&host_from_cfg,
                                        &user_from_cfg,
                                        &passwd_from_cfg,
                                        &db_from_cfg))
    {
        return (DbHandle)
            mysql_real_connect (sql, host_from_cfg, user_from_cfg,
                          passwd_from_cfg, db_from_cfg,  0, 0x0, 0);
    }
    else
        return (DbHandle)0x0;
}
```

Use the readlink() function properly

## Description

### Rule Definition

*Use the readlink() function properly.*

### Polyspace Implementation

The rule checker checks for **Misuse of readlink()**.

## Examples

### Misuse of readlink()

#### Issue

**Misuse of readlink()** occurs when you pass a buffer size argument to `readlink()` that does not leave space for a null terminator in the buffer.

For instance:

```
size_t len = readlink("/usr/bin/perl", buf, sizeof(buf));
```

The third argument is exactly equal to the size of the second argument. For large enough symbolic links, this use of `readlink()` does not leave space to enter a null terminator.

#### Risk

The `readlink()` function copies the content of a symbolic link (first argument) to a buffer (second argument). However, the function does not append a null terminator to the copied content. After using `readlink()`, you must explicitly add a null terminator to the buffer.

If you fill the entire buffer when using `readlink`, you do not leave space for this null terminator.

#### Fix

When using the `readlink()` function, make sure that the third argument is one less than the buffer size.

Then, append a null terminator to the buffer. To determine where to add the null terminator, check the return value of `readlink()`. If the return value is -1, an error has occurred. Otherwise, the return value is the number of characters (bytes) copied.

#### Example - Incorrect Size Argument of `readlink`

```
#include <unistd.h>

#define SIZE1024 1024

extern void display_path(const char *);
```

```
void func() {
    char buf[SIZE1024];
    ssize_t len = readlink("/usr/bin/perl", buf, sizeof(buf)); //Noncompliant
    if (len > 0) {
        buf[len - 1] = '\0';
    }
    display_path(buf);
}
```

In this example, the third argument of `readlink` is exactly the size of the buffer (second argument). If the first argument is long enough, this use of `readlink` does not leave space for the null terminator.

Also, if no characters are copied, the return value of `readlink` is 0. The following statement leads to a buffer underflow when `len` is 0.

```
buf[len - 1] = '\0';
```

#### Correction — Make Sure Size Argument is One Less Than Buffer Size

One possible correction is to make sure that the third argument of `readlink` is one less than size of the second argument.

The following corrected code also accounts for `readlink` returning 0.

```
#include <stdlib.h>
#include <unistd.h>

#define fatal_error() abort()
#define SIZE1024 1024

extern void display_path(const char *);

void func() {
    char buf[SIZE1024];
    ssize_t len = readlink("/usr/bin/perl", buf, sizeof(buf) - 1);
    if (len != -1) {
        buf[len] = '\0';
        display_path(buf);
    }
    else {
        /* Handle error */
        fatal_error();
    }
}
```

Do not call putenv() with a pointer to an automatic variable as the argument

## Description

### Rule Definition

*Do not call putenv() with a pointer to an automatic variable as the argument.*

### Polyspace Implementation

The rule checker checks for **Use of automatic variable as putenv-family function argument**.

## Examples

### Use of automatic variable as putenv-family function argument

#### Issue

**Use of automatic variable as putenv-family function argument** occurs when the argument of a putenv-family function is a local variable with automatic duration.

#### Risk

The function putenv(char *string) inserts a pointer to its supplied argument into the environment array, instead of making a copy of the argument. If the argument is an automatic variable, its memory can be overwritten after the function containing the putenv() call returns. A subsequent call to getenv() from another function returns the address of an out-of-scope variable that cannot be dereferenced legally. This out-of-scope variable can cause environment variables to take on unexpected values, cause the program to stop responding, or allow arbitrary code execution vulnerabilities.

#### Fix

Use setenv()/unsetenv() to set and unset environment variables. Alternatively, use putenv-family function arguments with dynamically allocated memory, or, if your application has no reentrancy requirements, arguments with static duration. For example, a single thread execution with no recursion or interrupts does not require reentrancy. It cannot be called (reentered) during its execution.

#### Example - Automatic Variable as Argument of putenv()

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
{
    char env[SIZE1024];
    int retval = sprintf(env, "TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }
    /* Environment variable TEST is set using putenv().
    The argument passed to putenv is an automatic variable. */
    retval = putenv(env);    //Noncompliant
    if (retval != 0) {
        /* Handle error */
    }
}
```

In this example, `sprintf()` stores the character string `TEST=var` in `env`. The value of the environment variable `TEST` is then set to `var` by using `putenv()`. Because `env` is an automatic variable, the value of `TEST` can change once `func()` returns.

#### Correction — Use `static` Variable for Argument of `putenv()`

Declare `env` as a static-duration variable. The memory location of `env` is not overwritten for the duration of the program, even after `func()` returns.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024
void func(int var)
{
    /* static duration variable */
    static char env[SIZE1024];
    int retval = sprintf(env,"TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }

    /* Environment variable TEST is set using putenv() */
    retval=putenv(env);
    if (retval != 0) {
        /* Handle error */
    }
}
```

#### Correction — Use `setenv()` to Set Environment Variable Value

To set the value of `TEST` to `var`, use `setenv()`.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
{
    /* Environment variable TEST is set using setenv() */
    int retval = setenv("TEST", var ? "1" : "0", 1);

    if (retval != 0) {
        /* Handle error */
    }
}
```

Avoid race conditions while checking for the existence of a symbolic link

## Description

### Rule Definition

*Avoid race conditions while checking for the existence of a symbolic link.*

### Polyspace Implementation

The rule checker checks for **File access between time of check and use (TOCTOU)**.

## Examples

### File access between time of check and use (TOCTOU)

#### Issue

**File access between time of check and use (TOCTOU)** detects race condition issues between checking the existence of a file or folder, and using a file or folder.

#### Risk

An attacker can access and manipulate your file between your check for the file and your use of a file. Symbolic links are particularly risky because an attacker can change where your symbolic link points.

#### Fix

Before using a file, do not check its status. Instead, use the file and check the results afterward.

#### Example - Check File Before Using

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    if (access(log_path, W_OK)==0) {
        FILE* f = fopen(log_path, "w"); //Noncompliant
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

In this example, before opening and using the file, the function checks if the file exists. However, an attacker can change the file between the first and second lines of the function.

#### Correction — Open Then Check

One possible correction is to open the file, and then check the existence and contents afterward.

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    int fd = open(log_path, O_WRONLY);
    if (fd!=-1) {
        FILE *f = fdopen(fd, "w");
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

Observe correct revocation order while relinquishing privileges

## Description

### Rule Definition

*Observe correct revocation order while relinquishing privileges.*

### Polyspace Implementation

The rule checker checks for **Bad order of dropping privileges**.

## Examples

### Bad order of dropping privileges

#### Issue

**Bad order of dropping privileges** checks the order of privilege drops. If you drop higher elevated privileges before dropping lower elevated privileges, Polyspace raises a defect. For example dropping elevated primary group privileges before dropping elevated ancillary group privileges.

#### Risk

If you drop privileges in the wrong order, you can potentially drop higher privileges that you need to drop lower privileges. The incorrect order can mean, privileges are not dropped, compromising the security of your program.

#### Fix

Respect this order of dropping elevated privileges:

- Drop (elevated) ancillary group privileges, then drop (elevated) primary group privileges.
- Drop (elevated) primary group privileges, then drop (elevated) user privileges.

#### Example - Dropping User Privileges First

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()

static void sanitize_privilege_drop_check(uid_t olduid, gid_t oldgid)
{
    if (seteuid(olduid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
    if (setegid(oldgid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
}
void badprivilegedroporder(void) {
    uid_t
        newuid = getuid(),
        olduid = geteuid();
    gid_t
        newgid = getgid(),
        oldgid = getegid();

    if (setuid(newuid) == -1) {
        /* handle error condition */
        fatal_error();
    }
    if (setgid(newgid) == -1)  {  //Noncompliant
        /* handle error condition */
        fatal_error();
    }
    if (olduid == 0) {
        /* drop ancillary groups IDs only possible for root */
        if (setgroups(1, &newgid) == -1) { //Noncompliant
            /* handle error condition */
            fatal_error();
        }
    }

    sanitize_privilege_drop_check(olduid, oldgid);
}
```

In this example, there are two privilege drops made in the incorrect order. `setgid` attempts to drop group privileges. However, `setgid` requires the user privileges, which were dropped previously using `setuid`, to perform this function. After dropping group privileges, this function attempts to drop ancillary groups privileges by using `setgroups`. This task requires the higher primary group privileges that were dropped with `setgid`. At the end of this function, it is possible to regain group privileges because the order of dropping privileges was incorrect.

#### Correction — Reverse Privilege Drop Order

One possible correction is to drop the lowest level privileges first. In this correction, ancillary group privileges are dropped, then primary group privileges are dropped, and finally user privileges are dropped.

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()

static void sanitize_privilege_drop_check(uid_t olduid, gid_t oldgid)
{
    if (seteuid(olduid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
    if (setegid(oldgid) != -1)
    {
        /* Privileges can be restored, handle error */
        fatal_error();
    }
}
void badprivilegedroporder(void) {
    uid_t
        newuid = getuid(),
        olduid = geteuid();
    gid_t
        newgid = getgid(),
        oldgid = getegid();

    if (olduid == 0) {
        /* drop ancillary groups IDs only possible for root */
        if (setgroups(1, &newgid) == -1) {
            /* handle error condition */
            fatal_error();
        }
    }
    if (setgid(getgid()) == -1)  {
        /* handle error condition */
        fatal_error();
    }
    if (setuid(getuid()) == -1) {
        /* handle error condition */
        fatal_error();
    }

    sanitize_privilege_drop_check(olduid, oldgid);
}
```

Ensure that privilege relinquishment is successful

## Description

### Rule Definition

*Ensure that privilege relinquishment is successful.*

### Polyspace Implementation

The rule checker checks for **Privilege drop not verified**.

## Examples

### Privilege drop not verified

**Issue**

**Privilege drop not verified** detects calls to functions that relinquish privileges. If you do not verify that the privileges were dropped before the end of your function, a defect is raised.

**Risk**

If privilege relinquishment fails, an attacker can regain elevated privileges and have more access to your program than intended. This security hole can cause unexpected behavior in your code if left open.

**Fix**

Before the end of scope, verify that the privileges that you dropped were actually dropped.

**Example - Drop Privileges Within a Function**

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()
extern int need_more_privileges;

void missingprivilegedropcheck()
{
    /* Code intended to run with elevated privileges */

    /* Temporarily drop elevated privileges */
    if (seteuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges */
    if (need_more_privileges) {
        /* Restore elevated privileges */
        if (seteuid(0) != 0) {
            /* Handle error */
            fatal_error();
        }
        /* Code intended to run with elevated privileges */
    }

    /* ... */

    /* Permanently drop elevated privileges */
    if (setuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges */
} //Noncompliant
```

In this example, privileges are elevated and dropped to run code with the intended privilege level. When privileges are dropped, the privilege level before exiting the function body is not verified. A malicious attacker can regain their elevated privileges.

**Correction — Verify Privilege Drop**

One possible correction is to use `setuid` to verify that the privileges were dropped.

```
#define _BSD_SOURCE
#include <sys/types.h>
#include <unistd.h>
#include <grp.h>
#include <stdlib.h>
#define fatal_error() abort()
extern int need_more_privileges;

void missingprivilegedropcheck()
{
    /* Store the privileged ID for later verification */
    uid_t privid = geteuid();

    /* Code intended to run with elevated privileges   */

    /* Temporarily drop elevated privileges */
    if (seteuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges  */

    if (need_more_privileges) {
        /* Restore elevated Privileges */
        if (seteuid(privid) != 0) {
            /* Handle error */
            fatal_error();
        }
        /* Code intended to run with elevated privileges   */
    }

    /* ... */

    /* Restore privileges if needed */
    if (geteuid() != privid) {
        if (seteuid(privid) != 0) {
            /* Handle error */
            fatal_error();
        }
    }

    /* Permanently drop privileges */
    if (setuid(getuid()) != 0) {
        /* Handle error */
        fatal_error();
    }

    if (setuid(0) != -1) {
        /* Privileges can be restored, handle error */
        fatal_error();
    }

    /* Code intended to run with lower privileges; */
}
```

Beware of race conditions when using fork and file descriptors

## Description

### Rule Definition

*Beware of race conditions when using fork and file descriptors.*

### Polyspace Implementation

The rule checker checks for **File descriptor exposure to child process**.

## Examples

### File descriptor exposure to child process

#### Issue

**File descriptor exposure to child process** occurs when a process is forked and the child process uses file descriptors inherited from the parent process.

#### Risk

When you fork a child process, file descriptors are copied from the parent process, which means that you can have concurrent operations on the same file. Use of the same file descriptor in the parent and child processes can lead to race conditions that may not be caught during standard debugging. If you do not properly manage the file descriptor permissions and privileges, the file content is vulnerable to attacks targeting the child process.

#### Fix

Check that the file has not been modified before forking the process. Close all inherited file descriptors and reopen them with stricter permissions and privileges, such as read-only permission.

#### Example - File Descriptor Accessed from Forked Process

```
# include <stdio.h>
# include <stdlib.h>
# include <string.h>
# include <unistd.h>
# include <fcntl.h>
# include <sys/types.h>
# include <sys/stat.h>

const char *test_file="/home/user/test.txt";

void func(void)
{
    char c;
    pid_t pid;
    /* create file descriptor in read and write mode */
    int fd = open(test_file, O_RDWR);
    if (fd == -1)
    {
        /* Handle error */
        abort();
    }
    /* fork process */
    pid = fork();
    if (pid == -1)
    {
        /* Handle error */
        abort();
    }
    else if (pid == 0)
    {   /* Child process accesses file descriptor inherited
        from parent process */
        (void)read(fd, &c, 1); //Noncompliant
    }
    else
    {   /* Parent process access same file descriptor as
        child process */
        (void)read(fd, &c, 1);
    }
}
```

In this example, a file descriptor `fd` is created in read and write mode. The process is then forked. The child process inherits and accesses `fd` with the same permissions as the parent process. A race condition exists between the parent and child processes. The contents of the file is vulnerable to attacks through the child process.

**Correction — Close and Reopen Inherited File Descriptor**

After you create the file descriptor, check the file for tampering. Then, close the inherited file descriptor in the child process and reopen it in read-only mode.

```
# include <stdio.h>
# include <stdlib.h>
# include <string.h>
# include <unistd.h>
# include <fcntl.h>
# include <sys/types.h>
# include <sys/stat.h>

const char *test_file="/home/user/test.txt";

void func(void)
{
    char c;
    pid_t pid;

    /* Get the state of file for further file tampering checking */

    /* create file descriptor in read and write mode */
    int fd = open(test_file, O_RDWR);
    if (fd == -1)
    {
        /* Handle error */
        abort();
    }

    /* Be sure the file was not tampered with while opening */

    /* fork process */

    pid = fork();
    if (pid == -1)
    {
        /* Handle error */
        (void)close(fd);
        abort();
    }
    else if (pid == 0)
    {  /* Close file descriptor in child process and repoen
        it in read only mode */

        (void)close(fd);
        fd = open(test_file, O_RDONLY);
        if (fd == -1)
        {
            /* Handle error */
            abort();
        }

        (void)read(fd, &c, 1);
        (void)close(fd);
    }
    else
    {  /* Parent acceses original file descriptor */
        (void)read(fd, &c, 1);
        (void)close(fd);
    }
}
```

Use the correct byte ordering when transferring data between systems

## Description

### Rule Definition

*Use the correct byte ordering when transferring data between systems.*

### Polyspace Implementation

The rule checker checks for **Missing byte reordering when transferring data**.

## Examples

### Missing byte reordering when transferring data

#### Issue

**Missing byte reordering when transferring data** occurs when you do not use a byte ordering function:

- Before sending data to a network socket.
- After receiving data from a network socket.

#### Risk

Some system architectures implement little endian byte ordering (least significant byte first), and other systems implement big endian (most significant byte first). If the endianness of the sent data does not match the endianness of the receiving system, the value returned when reading the data is incorrect.

#### Fix

After receiving data from a socket, use a byte ordering function such as `ntohl()`. Before sending data to a socket, use a byte ordering function such as `htonl()` .

#### Example - Data Transferred Without Byte Reordering

```
#include <stdio.h>
#include <stdlib.h>
#include <stdint.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <byteswap.h>
#include <unistd.h>
#include <string.h>

unsigned int func(int sock, int server)
{
    unsigned int num;   /* assume int is 32-bits */
    if (server)
    {
        /* Server side */
        num = 0x17;
        /* Endianness of server host may not match endianness of network. */
        if (send(sock, (void *)&num, sizeof(num), 0) < (int)sizeof(num))  //Noncompliant
        {
            /* Handle error */
        }
        return 0;
    }
    else {
        /* Endianness of client host may not match endianness of network. */
        if (recv (sock, (void *)&num, sizeof(num), 0) < (int) sizeof(num))
        {
            /* Handle error */
        }

        /* Comparison may be inaccurate */
        if (num> 255)   //Noncompliant
        {
            return 255;
        }
        else
        {
            return num;
        }
    }
}
```

In this example, variable num is assigned hexadecimal value 0x17 and is sent over a network to the client from the server. If the server host is little endian and the network is big endian, num is transferred as 0x17000000. The client then reads an incorrect value for num and compares it to a local numeric value.

**Correction — Use Byte Ordering Function**

Before sending num from the server host, use htonl() to convert from host to network byte ordering. Similarly, before reading num on the client host, use ntohl() to convert from network to host byte ordering.

```
#include <stdio.h>
#include <stdlib.h>
#include <stdint.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <arpa/inet.h>
#include <byteswap.h>
#include <unistd.h>
#include <string.h>

unsigned int func(int sock, int server)
{
    unsigned int num;   /* assume int is 32-bits */
    if (server)
    {
        /* Server side */
        num = 0x17;

        /* Convert to network byte order. */
        num = htonl(num);
        if (send(sock, (void *)&num, sizeof(num), 0) < (int)sizeof(num))
        {
            /* Handle error */
        }
        return 0;
    }
    else {
        if (recv (sock, (void *)&num, sizeof(num), 0) < (int) sizeof(num))
        {
            /* Handle error */
        }

        /* Convert to host byte order. */
        num = ntohl(num);
        if (num > 255)
        {
            return 255;
        }
        else
        {
            return num;
        }
    }
}
```

Do not use signals to terminate threads

## Description

### Rule Definition

*Do not use signals to terminate threads.*

### Polyspace Implementation

The rule checker checks for **Use of signal to kill thread**.

## Examples

### Use of signal to kill thread

#### Issue

**Use of signal to kill thread** occurs when you use an uncaught signal to kill a thread. For instance, you use the POSIX function `pthread_kill` and send the signal `SIGTERM` to kill a thread.

#### Risk

Sending a signal kills the entire process instead of just the thread that you intend to kill.

For instance, the `pthread_kill` specifications state that if the disposition of a signal is to terminate, this action affects the entire process.

#### Fix

Use other mechanisms that are intended to kill specific threads.

For instance, use the POSIX function `pthread_cancel` to terminate a specific thread.

#### Example - Use of `pthread_kill` to Terminate Threads

```
#include <signal.h>
#include <pthread.h>

void* func(void *foo) {
  /* Execution of thread */
}

int main(void) {
  int result;
  pthread_t thread;

  if ((result = pthread_create(&thread, NULL, func, 0)) != 0) {
  }
  if ((result = pthread_kill(thread, SIGTERM)) != 0) { //Noncompliant
  }

  /* This point is not reached because the process terminates in pthread_kill() */
  return 0;
}
```

In this example, the `pthread_kill` function sends the signal `SIGTERM` to kill a thread. The signal kills the entire process instead of the thread previously created with `pthread_create`.

#### Correction — Use `pthread_cancel` to Terminate Threads

One possible correction is to use the `pthread_cancel` function. The `pthread_cancel` terminates a thread specified by its first argument at a specific cancellation point or immediately, depending on the thread's cancellation type.

```
#include <signal.h>
#include <pthread.h>

void* func(void *foo) {
  /* Execution of thread */
}

int main(void) {
  int result;
  pthread_t thread;

  if ((result = pthread_create(&thread, NULL, func, 0)) != 0) {
    /* Handle Error */
  }
  if ((result = pthread_cancel(thread)) != 0) {
    /* Handle Error */
  }

  /* Continue executing */

  return 0;
}
```

See also:

- `pthread_cancel` for more information on cancellation types.
- Pthreads for functions that are allowed to be cancellation points.

POS44-C

# CERT C: Rule POS47-C

Do not use threads that can be canceled asynchronously

## Description

### Rule Definition

*Do not use threads that can be canceled asynchronously.*

### Polyspace Implementation

The rule checker checks for **Asynchronously cancellable thread**.

## Examples

### Asynchronously cancellable thread

#### Issue

This issue occurs when you use `pthread_setcanceltype` with argument `PTHREAD_CANCEL_ASYNCHRONOUS` to set the cancellability type of a calling thread to asynchronous (or immediate) . An asynchronously cancellable thread can be cancelled at any time, usually immediately upon receiving a cancellation request.

#### Risk

The calling thread might be cancelled in an unsafe state that could result in a resources leak, a deadlock, a data race, data corruption, or unpredictable behavior.

#### Fix

Remove the call to `pthread_setcanceltype` with argument `PTHREAD_CANCEL_ASYNCHRONOUS` to use the default cancellability type `PTHREAD_CANCEL_DEFERRED` instead. With the default cancellability type, the thread defers cancellation requests until it calls a function that is a cancellation point.

#### Example - Cancellability Type of Thread Set to Asynchronous

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

static int fatal_error(void)
{
    exit(1);
}

volatile int a = 5;
volatile int b = 10;

pthread_mutex_t global_lock = PTHREAD_MUTEX_INITIALIZER;

void* swap_values_thread(void* dummy)
{
    int i;
    int c;
    int result;
    if ((result =
             pthread_setcanceltype(PTHREAD_CANCEL_ASYNCHRONOUS, &i)) != 0) { //Noncompliant
```

```
        /* handle error */
        fatal_error();
    }
    while (1) {
        if ((result = pthread_mutex_lock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
        c = b;
        b = a;
        a = c;
        if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
    }
    return NULL;
}

int main(void)
{
    int result;
    pthread_t worker;

    if ((result = pthread_create(&worker, NULL, swap_values_thread, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }

    /* Additional code */

    if ((result = pthread_cancel(worker)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_join(worker, 0)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_mutex_lock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }
    printf("a: %i | b: %i", a, b);
    if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }

    return 0;
}
```

In this example, the cancellability type of the `worker` thread is set to asynchronous. The mutex `global_lock` helps ensure that the `worker` and `main` threads do not access variables `a` and `b` at the same time. However, the `worker` thread might be cancelled while holding `global_lock`, and the `main` thread will never acquire `global_lock`, which results in a deadlock.

#### Correction — Use the Default Cancellability Type

One possible correction is to remove the call to `pthread_setcanceltype`. By default, the cancellability type of a new thread is set to `PTHREAD_CANCEL_DEFERRED`. The `worker` thread defers cancellation requests until it calls a function that is a cancellation point.

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>

static int fatal_error(void)
{
    exit(1);
}

volatile int a = 5;
volatile int b = 10;

pthread_mutex_t global_lock = PTHREAD_MUTEX_INITIALIZER;

void* swap_values_thread(void* dummy)
{
    int i;
    int c;
    int result;
    while (1) {
        if ((result = pthread_mutex_lock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
        c = b;
        b = a;
        a = c;
        if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
            /* handle error */
            fatal_error();
        }
    }
    return NULL;
}

int main(void)
{
    int result;
    pthread_t worker;

    if ((result = pthread_create(&worker, NULL, swap_values_thread, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }

    /* Additional code */

    if ((result = pthread_cancel(worker)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_join(worker, 0)) != 0) {
        /* handle error */
        fatal_error();
    }

    if ((result = pthread_mutex_lock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }
    printf("a: %i | b: %i", a, b);
    if ((result = pthread_mutex_unlock(&global_lock)) != 0) {
        /* handle error */
        fatal_error();
    }

    return 0;
}
```

Do not unlock or destroy another POSIX thread's mutex

## Description

### Rule Definition

*Do not unlock or destroy another POSIX thread's mutex.*

### Polyspace Implementation

The rule checker checks for **Destruction of locked mutex**.

## Examples

### Destruction of locked mutex

#### Issue

**Destruction of locked mutex** occurs when a task destroys a mutex after it is locked (and before it is unlocked). The locking and destruction can happen in the same task or different tasks.

#### Risk

A mutex is locked to protect shared variables from concurrent access. If a mutex is destroyed in the locked state, the protection does not apply.

#### Fix

To fix this defect, destroy the mutex only after you unlock it. It is a good design practice to:

- Initialize a mutex *before* creating the threads where you use the mutex.
- Destroy a mutex *after* joining the threads that you created.

On the **Result Details** pane, you see two events, the locking and destruction of the mutex, and the tasks that initiated the events. To navigate to the corresponding line in your source code, click the event.

#### Example - Locking and Destruction in Different Tasks

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
  pthread_mutex_unlock (&lock3);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_destroy (&lock3); //Noncompliant
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

In this example, after task `t0` locks the mutex `lock3`, task `t1` can destroy it. The destruction occurs if the following events happen in sequence:

1. `t0` acquires `lock3`.
2. `t0` releases `lock2`.
3. `t0` releases `lock1`.
4. `t1` acquires the lock `lock1` released by `t0`.
5. `t1` acquires the lock `lock2` released by `t0`.
6. `t1` destroys `lock3`.

For simplicity, this example uses a mix of automatic and manual concurrency detection. The tasks `t0` and `t1` are manually specified as entry points by using the option `Tasks (-entry-points)`. The critical sections are implemented through primitives `pthread_mutex_lock` and `pthread_mutex_unlock` that the software detects automatically. In practice, for entry point specification (thread creation), you will use primitives such as `pthread_create`. The next example shows how the defect can appear when you use `pthread_create`.

#### Correction — Place Lock-Unlock Pair Together in Same Critical Section as Destruction

The locking and destruction of `lock3` occurs inside the critical section imposed by `lock1` and `lock2`, but the unlocking occurs outside. One possible correction is to place the lock-unlock pair in the same critical section as the destruction of the mutex. Use one of these critical sections:

- Critical section imposed by `lock1` alone.
- Critical section imposed by `lock1` and `lock2`.

In this corrected code, the lock-unlock pair and the destruction is placed in the critical section imposed by `lock1` and `lock2`. When `t0` acquires `lock1` and `lock2`, `t1` has to wait for their release before it executes the instruction `pthread_mutex_destroy (&lock3);`. Therefore, `t1` cannot destroy mutex `lock3` in the locked state.

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_destroy (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

**Example - Locking and Destruction in Start Routine of Thread**

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_destroy(&lock); //Noncompliant
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Thread that initializes mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use mutex for atomic operation*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   pthread_exit(NULL);
}
```

In this example, four threads are created. The threads are assigned different actions.

- The first thread `callThd[0]` initializes the mutex `lock`.
- The second and third threads, `callThd[1]` and `callThd[2]`, perform an atomic operation protected by the mutex `lock`.
- The fourth thread `callThd[3]` destroys the mutex `lock`.

The threads can interrupt each other. Therefore, immediately after the second or third thread locks the mutex, the fourth thread can destroy it.

### Correction — Initialize and Destroy Mutex Outside Start Routine

One possible correction is to initialize and destroy the mutex in the `main` function outside the start routine of the threads. The threads perform only the atomic operation. You need two fewer threads because the mutex initialization and destruction threads are not required.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 2
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_work(void *arg) {
   pthread_mutex_lock (&lock);
   atomic_operation();
   pthread_mutex_unlock (&lock);
   pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize mutex */
   pthread_mutex_init(&lock, NULL);

   for(i=0; i<NUMTHREADS; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy mutex */
   pthread_mutex_destroy(&lock);

   pthread_exit(NULL);
}
```

#### Correction — Use A Second Mutex To Protect Lock-Unlock Pair and Destruction

Another possible correction is to use a second mutex and protect the lock-unlock pair from the destruction. This corrected code uses the mutex `lock2` to achieve this protection. The second mutex is initialized in the `main` function outside the start routine of the threads.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
pthread_mutex_t lock2;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}
```

```
void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_destroy(&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize second mutex */
   pthread_mutex_init(&lock2, NULL);

   /* Thread that initializes first mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use first mutex for atomic operation */
   /* The threads use second mutex to protect first from destruction in locked state*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys first mutex */
   /* The thread uses the second mutex to prevent destruction of locked mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy second mutex */
   pthread_mutex_destroy(&lock2);

   pthread_exit(NULL);
}
```

When data must be accessed by multiple threads, provide a mutex and guarantee no adjacent data is also accessed

## Description

### Rule Definition

*When data must be accessed by multiple threads, provide a mutex and guarantee no adjacent data is also accessed.*

### Polyspace Implementation

The rule checker checks for **Data race on adjacent bit fields**.

## Examples

### Data race on adjacent bit fields

#### Issue

Data race on adjacent bit fields occurs when:

- Multiple tasks perform unprotected operations on bit fields that are part of the same structure.

  For instance, a task operates on field `errorFlag1` and another task on field `errorFlag2` in a variable of this type:

  ```
  struct errorFlags {
     unsigned int errorFlag1 : 1;
     unsigned int errorFlag2 : 1;
     ...
  }
  ```

  Suppose that the operations are not atomic with respect to each other. In other words, you have not implemented protection mechanisms to ensure that one operation completes before another begins.
- At least one of the unprotected operations is a write operation.

#### Risk

Adjacent bit fields that are part of the same structure might be stored in one byte in the same memory location. Read or write operations on all variables including bit fields happen one byte or word at a time. To modify only specific bits in a byte, steps similar to this happen in sequence:

1. The byte is loaded into RAM.
2. A mask is created so that only specific bits would be modified to the intended value and the remaining bits remain unchanged.
3. A bitwise OR operation is performed between the copy of the byte in RAM and the mask.
4. The byte with specific bits modified is copied back from RAM.

If two different bit fields are accessed, these four steps have to be performed for each bit field. If the accesses are not protected, all four steps for one bit field might not complete before the four steps for the other begin. As a result, the modification of one bit field might undo the modification of an adjacent bit field. For instance, the modification of `errorFlag1` and `errorFlag2` can happen in the following sequence. Steps marked 1 relate to modification of `errorFlag1` and steps marked 2 relate to that of `errorFlag2`.

1a. The byte with both `errorFlag1` and `errorFlag2` unmodified is copied into RAM, for purposes of modifying `errorFlag1`.

1b. A mask that modifies only `errorFlag1` is bitwise OR-ed with this copy.

2a. The byte containing both `errorFlag1` and `errorFlag2` unmodified is copied into RAM a second time, for purposes of modifying `errorFlag2`.

2b. A mask that modifies only `errorFlag2` is bitwise OR-ed with this second copy.

1c. The version with `errorFlag1` modified is copied back. This version has `errorFlag2` unmodified.

2c The version with `errorFlag2` modified is copied back. This version has `errorFlag1` unmodified and overwrites the previous modification.

#### Fix

To fix this defect, protect the operations on bit fields that are part of the same structure using critical sections, temporal exclusion or another means. See “Protections for Shared Variables in Multitasking Code”.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

#### Example - Unprotected Operation on Global Variable from Multiple POSIX Threads

```
#include <stdlib.h>
#include <pthread.h>
#define thread_success 0

typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12; //Noncompliant

void* task1 (void* arg) {
    InterruptConfigbitsProc12.IOFlag = 0;
    //Additional code
}

void* task2 (void* arg) {
    InterruptConfigbitsProc12.SetupFlag = 0;
    //Additional code
}

void main() {
    pthread_t thread1, thread2;
    if(thread_success != pthread_create(&thread1, NULL, task1, NULL)){
        //Handle error
    }
    if(thread_success != pthread_create(&thread2, NULL, task2, NULL)){
        //Handle error
    }
}
```

In this example, the threads with id `thread1` and `thread2` access different bit fields `IOFlag` and `SetupFlag`, which belong to the same structured variable `InterruptConfigbitsProc12`.

#### Correction - Use Critical Sections

One possible correction is to wrap the bit field accesses in a critical section. A critical section lies between a call to a lock function and an unlock function. In this correction, the critical section lies between the calls to functions `pthread_mutex_lock` and `pthread_mutex_unlock`.

```
#include <stdlib.h>
#include <pthread.h>
#define thread_success 0
#define lock_success 0

pthread_mutex_t lock;

typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void* task1 (void* arg) {
    if( lock_success != pthread_mutex_lock(&lock)) {
        //Handle error
    }
    InterruptConfigbitsProc12.IOFlag = 0;
    if( lock_success != pthread_mutex_unlock(&lock)) {
        //Handle error
    }
    //Additional code
}
```

```
void* task2 (void* arg) {
    if( lock_success != pthread_mutex_lock(&lock)) {
        //Handle error
    }
    InterruptConfigbitsProc12.SetupFlag = 0;
    if( lock_success != pthread_mutex_unlock(&lock)) {
        //Handle error
    }
    //Additional code
}

void main() {
    pthread_t thread1, thread2;
    if(thread_success != pthread_create(&thread1, NULL, task1, NULL)){
        //Handle error
    }
    if(thread_success != pthread_create(&thread2, NULL, task2, NULL)){
        //Handle error
    }
}
```

**Correction – Insert Bit Field of Size 0**

You can enter a non bit field member or an unnamed bit field member of size 0 in between two adjacent bit fields that might be accessed concurrently. A non bit field member or size 0 bit field member ensures that the subsequent bit field starts from a new memory location. In this corrected example, the size 0 bit field member ensures that `IOFlag` and `SetupFlag` are stored in distinct memory locations.

```
#include <stdlib.h>
#include <pthread.h>
#define thread_success 0

typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int : 0;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void* task1 (void* arg) {
    InterruptConfigbitsProc12.IOFlag = 0;
    //Additional code
}

void* task2 (void* arg) {
    InterruptConfigbitsProc12.SetupFlag = 0;
    //Additional code
}
```

```
void main() {
    pthread_t thread1, thread2;
    if(thread_success != pthread_create(&thread1, NULL, task1, NULL)){
        //Handle error
    }
    if(thread_success != pthread_create(&thread2, NULL, task2, NULL)){
        //Handle error
    }
}
```

### Check Information

Declare objects shared between POSIX threads with appropriate storage durations

## Description

### Rule Definition

*Declare objects shared between POSIX threads with appropriate storage durations.*

## Examples

### Automatic or thread local variable escaping from a POSIX thread

#### Issue

**Automatic or thread local variable escaping from a POSIX thread** occurs when an automatic or thread local variable is passed by address from one POSIX thread to another without ensuring that the variable stays alive through the duration of the latter thread.

#### Risk

An automatic or thread local variable is allocated on the stack at the beginning of a thread and its lifetime extends till the end of the thread. The variable is not guaranteed to be alive when a different thread accesses it.

For instance, consider the start function of a POSIX thread with these lines:

```
int start_thread(pthread_t *tid) {
   int aVar = 0;
   if(thrd_success != pthread_create(tid, NULL, start_thread_child, &aVar) {
     //...
   }
}
```

The `pthread_create` function creates a child thread with start function `start_thread_child` and passes the address of the automatic variable `aVar`to this function. When this child thread accesses `aVar`, the parent thread might have completed execution and `aVar` is no longer on the stack. The access might result in reading unpredictable values.

#### Fix

When you pass a variable from one thread to another, make sure that the variable lifetime matches or exceeds the lifetime of both threads. You can achieve this synchronization in one of these ways:

- Declare the variable `static` so that it does not go out of stack when the current thread completes execution.
- Dynamically allocate the storage for the variable so that it is allocated on the heap instead of the stack and must be explicitly deallocated. Make sure that the deallocation happens after both threads complete execution.

These solutions require you to create a variable in nonlocal memory. Instead, you can use other solutions such as the `shared` keyword with OpenMP's threading interface that allows you to safely share local variables across threads.

### Example – Local Variable Escaping Thread

```
#include <pthread.h>
#include <stdio.h>

void* create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return NULL;
}

void create_parent_thread(pthread_t *tid) {
  int parentVal = 1;
  int thrd_success;
  if ((thrd_success = pthread_create(tid, NULL, create_child_thread, &parentVal)) != 0) { //Nonco
    /* Handle error */
  }
}

int main(void) {
  pthread_t tid;
  int thrd_success;
  create_parent_thread(&tid);

  if ((thrd_success = thrd_join(tid, NULL)) != 0) {
    /* Handle error */
  }
  return 0;
}
```

In this example, the value `parentVal` is local to the parent thread that starts in `main` and continues into the function `create_parent_thread`. However, in the body of `create_parent_thread`, the address of this local variable is passed to a child thread (the thread with start routine `create_child_thread`). The parent thread might have completed execution and the variable `parentVal` might have gone out of scope when the child thread accesses this variable.

### Correction – Use Static Variables

One possible correction is to declare the variable `parentVal` as `static` so that the variable is on the stack for the entire duration of the program.

```
#include <pthread.h>
#include <stdio.h>

void* create_child_thread(void *childVal) {
  int *res = (int *)childVal;
  printf("Result: %d\n", *res);
  return NULL;
}

void create_parent_thread(pthread_t *tid) {
  static int parentVal = 1;
  int thrd_success;
  if ((thrd_success = pthread_create(tid, NULL, create_child_thread, &parentVal)) != 0) {
    /* Handle error */
  }
}
```

```
int main(void) {
  pthread_t tid;
  int thrd_success;
  create_parent_thread(&tid);

  if ((thrd_success = thrd_join(tid, NULL)) != 0) {
    /* Handle error */
  }
  return 0;
}
```

### Correction – Use Dynamic Memory Allocation

One possible correction is to dynamically allocate storage for variables to be shared across threads and explicitly free the storage after the variable is no longer required.

```
#include <pthread.h>
#include <stlib.h>

void* create_child_thread(void *val) {
  int *res = (int *)val;
  printf("Result: %d\n", *res);
  free(res);
  return NULL;
}

void create_parent_thread(pthread_t *tid) {
  int *val;
  int thrd_success;

  val = malloc(sizeof(int));

  if(!val) {
      *val = 1;
      if ((thrd_success = pthread_create(tid, NULL, create_child_thread, val)) != 0) {
        /* Handle error */
      }
  }
}

int main(void) {
  pthread_t tid;
  int thrd_success;
  create_parent_thread(&tid);

  if ((thrd_success = thrd_join(tid, NULL)) != 0) {
    /* Handle error */
  }
  return 0;
}
```

Avoid deadlock with POSIX threads by locking in predefined order

## Description

### Rule Definition

*Avoid deadlock with POSIX threads by locking in predefined order.*

### Polyspace Implementation

The rule checker checks for **Deadlock**.

### Extend Checker

You might be using multithreading functions that are not supported by Polyspace. Extend this checker by mapping the functions of your multithreading functions to their known POSIX equivalent. See "Extend Concurrency Defect Checkers to Unsupported Multithreading Environments".

## Examples

### Deadlock

#### Issue

**Deadlock** occurs when multiple tasks are stuck in their critical sections (CS) because:

- Each CS waits for another CS to end.
- The critical sections (CS) form a closed cycle. For example:
  - CS #1 waits for CS #2 to end, and CS #2 waits for CS #1 to end.
  - CS #1 waits for CS #2 to end, CS #2 waits for CS #3 to end and CS #3 waits for CS #1 to end.

Polyspace expects critical sections of code to follow a specific format. A critical section lies between a call to a lock function and a call to an unlock function. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

#### Risk

Each task waits for a critical section in another task to end and is unable to proceed. The program can freeze indefinitely.

#### Fix

The fix depends on the root cause of the defect. You can try to break the cyclic order between the tasks in one of these ways:

- Write down all critical sections involved in the deadlock in a certain sequence. Whenever you call the lock functions of the critical sections within a task, respect the order in that sequence. See an example below.
- If one of the critical sections involved in a deadlock occurs in an interrupt, try to disable all interrupts during critical sections in all tasks. See `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Reviewing this defect is an opportunity to check if all operations in your critical section are really meant to be executed as an atomic block. It is a good practice to keep critical sections at a bare minimum.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Deadlock with Two Tasks**

```
void task1(void);
void task2(void);

int var;
void perform_task_cycle(void) {
 var++;
}

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2(); //Noncompliant
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_2();
    begin_critical_section_1();
    perform_task_cycle();
    end_critical_section_1();
    end_critical_section_2();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | task1<br>task2 | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | begin_critical_section_1 | end_critical_section_1 |
| | begin_critical_section_2 | end_critical_section_2 |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `begin_critical_section_1`.
2. `task2` calls `begin_critical_section_2`.
3. `task1` reaches the instruction `begin_critical_section_2();`. Since `task2` has already called `begin_critical_section_2`, `task1` waits for `task2` to call `end_critical_section_2`.
4. `task2` reaches the instruction `begin_critical_section_1();`. Since `task1` has already called `begin_critical_section_1`, `task2` waits for `task1` to call `end_critical_section_1`.

#### Correction-Follow Same Locking Sequence in Both Tasks

One possible correction is to follow the same sequence of calls to lock and unlock functions in both `task1` and `task2`.

```
void task1(void);
void task2(void);
void perform_task_cycle(void);

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}
```

**Example - Deadlock with More Than Two Tasks**

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2(); //Noncompliant
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock3();
    lock1();
    performTaskCycle();
    unlock1();
    unlock3();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | `task1`<br>`task2`<br>`task3` | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | `lock1` | `unlock1` |
| | `lock2` | `unlock2` |
| | `lock3` | `unlock3` |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `lock1`.
2. `task2` calls `lock2`.
3. `task3` calls `lock3`.
4. `task1` reaches the instruction `lock2();`. Since `task2` has already called `lock2`, `task1` waits for call to `unlock2`.
5. `task2` reaches the instruction `lock3();`. Since `task3` has already called `lock3`, `task2` waits for call to `unlock3`.
6. `task3` reaches the instruction `lock1();`. Since `task1` has already called `lock1`, `task3` waits for call to `unlock1`.

#### Correction — Break Cyclic Order

To break the cyclic order between critical sections, note every lock function in your code in a certain sequence, for example:

1. `lock1`
2. `lock2`
3. `lock3`

If you use more than one lock function in a task, use them in the order in which they appear in the sequence. For example, you can use `lock1` followed by `lock2` but not `lock2` followed by `lock1`.

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2();
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock1();
    lock3();
    performTaskCycle();
    unlock3();
    unlock1();
 }
}
```

Do not perform operations that can block while holding a POSIX lock

## Description

### Rule Definition

*Do not perform operations that can block while holding a POSIX lock.*

### Polyspace Implementation

The rule checker checks for **Blocking operation while holding lock**.

## Examples

### Blocking operation while holding lock

#### Issue

**Blocking operation while holding lock** occurs when a task (thread) performs a potentially lengthy operation while holding a lock.

The checker considers calls to these functions as potentially lengthy:

- Functions that access a network such as `recv`
- System call functions such as `fork`, `pipe` and `system`
- Functions for I/O operations such as `getchar` and `scanf`
- File handling functions such as `fopen`, `remove` and `lstat`
- Directory manipulation functions such as `mkdir` and `rmdir`

The checker automatically detects certain primitives that hold and release a lock, for instance, `pthread_mutex_lock` and `pthread_mutex_unlock`. For the full list of primitives that are automatically detected, see “Auto-Detection of Thread Creation and Critical Section in Polyspace”.

#### Risk

If a thread performs a lengthy operation when holding a lock, other threads that use the lock have to wait for the lock to be available. As a result, system performance can slow down or deadlocks can occur.

#### Fix

Perform the blocking operation before holding the lock or after releasing the lock.

Some functions detected by this checker can be called in a way that does not make them potentially lengthy. For instance, the function `recv` can be called with the parameter `O_NONBLOCK` which causes the call to fail if no message is available. When called with this parameter, `recv` does not wait for a message to become available.

#### Example - Network I/O Operations with `recv` While Holding Lock

```
#include <pthread.h>
#include <sys/socket.h>
```

```
pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) { //Noncompliant
    /* Handle Error */
  }

  /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }

  return 0;
}
```

In this example, in each thread created with `pthread_create`, the function `thread_foo` performs a network I/O operation with `recv` after acquiring a lock with `pthread_mutex_lock`. Other threads using the same lock variable mutex have to wait for the operation to complete and the lock to become available.

### Correction — Perform Blocking Operation Before Acquiring Lock

One possible correction is to call recv before acquiring the lock.

```
#include <pthread.h>
#include <sys/socket.h>

pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */
  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

    /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }
  return 0;
}
```

Do not use more than one mutex for concurrent waiting operations on a condition variable

## Description

### Rule Definition

*Do not use more than one mutex for concurrent waiting operations on a condition variable.*

### Polyspace Implementation

The rule checker checks for **Multiple mutexes used with same conditional variable**.

## Examples

### Multiple mutexes used with same conditional variable

#### Issue

This issue occurs when multiple threads use more than one mutex to concurrently wait on the same condition variable. A thread waits on a condition variable by calling the functions `pthread_cond_timedwait` or `pthread_cond_wait`. These functions take a condition variable and a locked mutex as arguments, and the condition variable is bound to that mutex when the thread waits on the condition variable.

The checkers flags the use of `pthread_cond_timedwait` or `pthread_cond_wait` in one of the threads. See the **Event** column in the **Results Details** pane to view the threads waiting on the same condition variable and using a different mutex.

#### Risk

When a thread waits on a condition variable using a mutex, the condition variable is bound to that mutex. Any other thread using a different mutex to wait on the same condition variable is undefined behavior according to the POSIX standard.

#### Fix

Use the same mutex argument for `pthread_cond_timedwait` or `pthread_cond_wait` when threads are concurrently waiting on the same condition variable, or use separate condition variables for each mutex.

#### Example - Concurrent Waiting on Condition Variable with Multiple Mutexes

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <pthread.h>
#define Thrd_return_t                    void *
#define __USE_XOPEN2K8

#define COUNT_LIMIT 5

static void fatal_error(void)
{
    exit(1);
}
```

```
pthread_mutex_t mutex1;
pthread_mutex_t mutex2;
pthread_mutex_t mutex3;
pthread_cond_t cv;

int count1 = 0, count2 = 0, count3 = 0;
#define DELAY 8

Thrd_return_t waiter1(void* arg)
{
    int ret;
    while (count1 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex1)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex1)) != 0) { //Noncompliant
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count1 = %d\n", ++count1);
        if ((ret = pthread_mutex_unlock(&mutex1)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter2(void* arg)
{
    int ret;
    while (count2 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex2)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex2)) != 0) { //Noncompliant
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count2 = %d\n", ++count2);
        if ((ret = pthread_mutex_unlock(&mutex2)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t signaler(void* arg)
{
    int ret;
    while ((count1 < COUNT_LIMIT) || (count2 < COUNT_LIMIT)) {
        sleep(1);
        printf("signaling\n");
        if ((ret = pthread_cond_broadcast(&cv)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter3(void* arg)
{
    int ret;
    while (count3 % COUNT_LIMIT != 0) {
        if ((ret = pthread_mutex_lock(&mutex3)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex3)) != 0) { //Noncompliant
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count3 = %d\n", ++count3);
        if ((ret = pthread_mutex_unlock(&mutex3)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

int main(void)
{
    int ret;
    pthread_t thread1, thread2, thread3;

    pthread_mutexattr_t attr;

    if ((ret = pthread_mutexattr_init(&attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutexattr_settype(&attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
        /* Handle error */
        fatal_error();
    }

    if ((ret = pthread_mutex_init(&mutex1, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex2, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex3, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_cond_init(&cv, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread1, NULL, &waiter1, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread2, NULL, &waiter2, NULL))) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread3, NULL, &signaler, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread1, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread2, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread3, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }

    while (1) { ; }

    return 0;
}
```

In this example, a different mutex is used to protect each `count` variable. Since all three `waiter` functions wait on the same condition variable `cv` with different mutexes, the call to `pthread_cond_wait` will succeed for one of the threads and the call will be undefined for the other two.

The checker raises a defect for function `waiter3` even though the function is not invoked directly or indirectly by a thread, entry-point, or interrupt. The analysis considers function `waiter3` called by the main program through its function address or an unidentified thread whose creation is the missing source code.

#### Correction — Use the Same Mutex for All Threads Waiting on Same Condition Variable

One possible correction is to pass the same mutex argument to all the call to `pthread_cond_wait` that are used to wait on the same condition variable.

```
 #include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <pthread.h>
#define Thrd_return_t                    void *
#define __USE_XOPEN2K8

#define COUNT_LIMIT 5

static void fatal_error(void)
{
    exit(1);
}

pthread_mutex_t mutex;

pthread_cond_t cv;

int count1 = 0, count2 = 0, count3 = 0;
#define DELAY 8

Thrd_return_t waiter1(void* arg)
{
    int ret;
    while (count1 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count1 = %d\n", ++count1);
        if ((ret = pthread_mutex_unlock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter2(void* arg)
{
    int ret;
    while (count2 < COUNT_LIMIT) {
        if ((ret = pthread_mutex_lock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count2 = %d\n", ++count2);
        if ((ret = pthread_mutex_unlock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
```

```
}

Thrd_return_t signaler(void* arg)
{
    int ret;
    while ((count1 < COUNT_LIMIT) || (count2 < COUNT_LIMIT)) {
        sleep(1);
        printf("signaling\n");
        if ((ret = pthread_cond_broadcast(&cv)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}

Thrd_return_t waiter3(void* arg)
{
    int ret;
    while (count3 % COUNT_LIMIT != 0) {
        if ((ret = pthread_mutex_lock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        if ((ret =
                 pthread_cond_wait(&cv, &mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
        sleep(random() % DELAY);
        printf("count3 = %d\n", ++count3);
        if ((ret = pthread_mutex_unlock(&mutex)) != 0) {
            /* Handle error */
            fatal_error();
        }
    }
    return (Thrd_return_t)0;
}
/*
void user_task(void)
{
    (void)waiter3(NULL);
} */

int main(void)
{
    int ret;
    pthread_t thread1, thread2, thread3;

    pthread_mutexattr_t attr;

    if ((ret = pthread_mutexattr_init(&attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutexattr_settype(&attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
        /* Handle error */
        fatal_error();
    }

    if ((ret = pthread_mutex_init(&mutex, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_mutex_init(&mutex, &attr)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_cond_init(&cv, NULL)) != 0) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread1, NULL, &waiter1, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread2, NULL, &waiter2, NULL))) {
        /* handle error */
        fatal_error();
    }
    if ((ret = pthread_create(&thread3, NULL, &signaler, NULL))) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread1, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread2, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }
    if ((ret = pthread_join(thread3, NULL)) != 0) {
        /* Handle error */
        fatal_error();
    }

    while (1) { ; }

    return 0;
}
```

Detect and handle POSIX library errors

## Description

### Rule Definition

*Detect and handle POSIX library errors.*

### Polyspace Implementation

The rule checker checks for **Returned value of a sensitive POSIX function not checked**.

## Examples

### Returned value of a sensitive POSIX function not checked

#### Issue

**Returned value of a sensitive POSIX function not checked** occurs when you call sensitive POSIX functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example - Sensitive Function Return Ignored

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    pthread_attr_init(&attr);//Noncompliant
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r");
  return 0;  //Noncompliant

}
```

This example shows calls to the sensitive POSIX functions `pthread_attr_init` and `fmemopen`. Their return values are ignored, causing defect.

#### Correction — Cast Function to (void)

One possible correction is to cast the function to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of the sensitive function.

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    (void)pthread_attr_init(&attr);//Compliant
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  (void)fmemopen (argv[1], strlen (argv[1]), "r"); //Compliant
  return 0;
}
```

**Correction — Test Return Value**

One possible correction is to test the return value of `pthread_attr_init` and `fmemopen` to check for errors.

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>

void initialize() {
    pthread_attr_t attr;

    int result = pthread_attr_init(&attr);//Compliant
    if(result != 0){
        //Handle fatal error
    }
}
int read_file(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r"); //Compliant
  if (in==NULL){
      // Handle error
  }
  return 0;
}
```

**Example - Critical Function Return Ignored**

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res);  //Noncompliant
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), Polyspace does not ignore this *Return value of a sensitive function not checked* defect. The other critical function, `pthread_join`, returns value that is ignored implicitly. `pthread_join` uses the return value of `pthread_create`, which was not checked.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

Properly pair allocation and deallocation functions

## Description

### Rule Definition

*Properly pair allocation and deallocation functions.*

### Polyspace Implementation

The rule checker checks for **Mismatched alloc/dealloc functions on Windows**.

## Examples

### Mismatched alloc/dealloc functions on Windows

#### Issue

**Mismatched alloc/dealloc functions on Windows** occurs when you use a Windows deallocation function that is not properly paired to its corresponding allocation function.

#### Risk

Deallocating memory with a function that does not match the allocation function can cause memory corruption or undefined behavior. If you are using an older version of Windows, the improper function can also cause compatibility issues with newer versions.

#### Fix

Properly pair your allocation and deallocation functions according to the functions listed in this table.

| Allocation Function | Deallocation Function |
|---|---|
| `malloc()` | `free()` |
| `realloc()` | `free()` |
| `calloc()` | `free()` |
| `_aligned_malloc()` | `_aligned_free()` |
| `_aligned_offset_malloc()` | `_aligned_free()` |
| `_aligned_realloc()` | `_aligned_free()` |
| `_aligned_offset_realloc()` | `_aligned_free()` |
| `_aligned_recalloc()` | `_aligned_free()` |
| `_aligned_offset_recalloc()` | `_aligned_free()` |
| `_malloca()` | `_freea()` |
| `LocalAlloc()` | `LocalFree()` |
| `LocalReAlloc()` | `LocalFree()` |
| `GlobalAlloc()` | `GlobalFree()` |

| Allocation Function | Deallocation Function |
|---|---|
| GlobalReAlloc() | GlobalFree() |
| VirtualAlloc() | VirtualFree() |
| VirtualAllocEx() | VirtualFreeEx() |
| VirtualAllocExNuma() | VirtualFreeEx() |
| HeapAlloc() | HeapFree() |
| HeapReAlloc() | HeapFree() |

**Example - Memory Deallocated with Incorrect Function**

```
#ifdef _WIN32_
#include <windows.h>
#else
#define _WIN32_
typedef void *HANDLE;
typedef HANDLE HGLOBAL;
typedef HANDLE HLOCAL;
typedef unsigned int UINT;
extern HLOCAL LocalAlloc(UINT uFlags, UINT uBytes);
extern HLOCAL LocalFree(HLOCAL hMem);
extern HGLOBAL GlobalFree(HGLOBAL hMem);
#endif

#define SIZE9 9

void func(void)
{
    /* Memory allocation */
    HLOCAL p = LocalAlloc(0x0000, SIZE9);

    if (p) {
        /* Memory deallocation. */
        GlobalFree(p); //Noncompliant

    }
}
```

In this example, memory is allocated with `LocallAlloc()`. The program then erroneously uses `GlobalFree()` to deallocate the memory.

**Correction — Properly Pair Windows Allocation and Deallocation Functions**

When you allocate memory with `LocalAllocate()`, use `LocalFree()` to deallocate the memory.

```
#ifdef _WIN32_
#include <windows.h>
#else
#define _WIN32_
typedef void *HANDLE;
typedef HANDLE HGLOBAL;
typedef HANDLE HLOCAL;
typedef unsigned int UINT;
```

```
extern HLOCAL LocalAlloc(UINT uFlags, UINT uBytes);
extern HLOCAL LocalFree(HLOCAL hMem);
extern HGLOBAL GlobalFree(HGLOBAL hMem);
#endif

#define SIZE9 9
void func(void)
{
    /* Memory allocation */
    HLOCAL p = LocalAlloc(0x0000, SIZE9);
    if (p) {
        /* Memory deallocation. */
        LocalFree(p);
    }
}
```

Prefer inline or static functions to function-like macros

## Description

### Rule Definition

*Prefer inline or static functions to function-like macros.*

### Polyspace Implementation

The rule checker checks for **Use of function-like macro instead of function**.

## Examples

### Use of function-like macro instead of function

#### Issue

The issue occurs when you use a function-like macro instead of a function when the two are interchangeable.

Polyspace considers all function-like macro definitions.

#### Risk

In most circumstances, use functions instead of macros. Functions perform argument type-checking and evaluate their arguments once, avoiding problems with potential multiple side effects.

Use parentheses within macros around parameter names

## Description

### Rule Definition

*Use parentheses within macros around parameter names.*

### Polyspace Implementation

The rule checker checks for **Macro parameters not enclosed in parentheses**.

## Examples

### Macro parameters not enclosed in parentheses

**Issue**

The issue occurs when a macro parameter contains an expression but you do not enclose the parameter in parentheses either in the macro definition or in the macro use.

If a macro parameter does not contain an expression, then the parentheses are not necessary.

**Risk**

If you do not enclose macro parameters containing expressions in parentheses, when parameter substitution occurs, operator precedence might not give the results that you want .

**Fix**

If a macro parameter contains an expression, enclose the parameter in parenthesis in the macro definition or macro use.

**Example - Macro Expressions**

```
#define mac1(x, y) (x * y)
#define mac2(x, y) ((x) * (y))

void foo(void){
    int r;

    r = mac1(1 + 2, 3 + 4);       /* Non-compliant */
    r = mac1((1 + 2), (3 + 4));   /* Compliant */

    r = mac2(1 + 2, 3 + 4);       /* Compliant */
}
```

In this example, `mac1` and `mac2` are macros that presumably implement the same definition.

- The definition of `mac1` does not enclose the macro parameters in parentheses. In the noncompliant expression, the macro expands to `r = (1 + 2 * 3 + 4);` The intended expression can be `(1 + (2 * 3) + 4)` or `(1 + 2) * (3 + 4)`. However, without parentheses, a developer or code reviewer might not know the intent of the expression. The subsequent compliant expression encloses the macro parameters in parentheses, so the intended macro expansion is clearly `(1 + 2) * (3 + 4)`.

- The definition of `mac2` encloses the parameters in parentheses. The expression involving `mac2` expands to `(1 + 2) * (3 + 4)` and complies with the rule.

Enclose header files in an inclusion guard

## Description

### Rule Definition

*Enclose header files in an inclusion guard.*

### Polyspace Implementation

The rule checker checks for **Contents of header file not guarded from multiple inclusions**.

## Examples

### Contents of header file not guarded from multiple inclusions

#### Issue

The issue occurs when you do not take precautions order to prevent the contents of a header file being included more than once.

If you include a header file whose contents are not guarded from multiple inclusion, the analysis raises a violation of this directive. The violation is shown at the beginning of the header file.

You can guard the contents of a header file from multiple inclusion by using one of the following methods:

```
//<start-of-file>
#ifndef <control macro>
#define <control macro>
    /* Contents of file */
#endif
//<end-of-file>
```

or

```
//<start-of-file>
#ifdef <control macro>
#error ...
#else
#define <control macro>
    /* Contents of file */
#endif
//<end-of-file>
```

Unless you use one of these methods, Polyspace flags the header file inclusion as noncompliant.

#### Risk

When a translation unit contains a complex hierarchy of nested header files, it is possible for a particular header file to be included more than once, leading to confusion. If this multiple inclusion produces multiple or conflicting definitions, then your program can have undefined or erroneous behavior.

For instance, suppose that a header file contains:

```
#ifdef _WIN64
   int env_var;
#elseif
   long int env_var;
#endif
```

If the header file is contained in two inclusion paths, one that defines the macro `_WIN64` and another that undefines it, you can have conflicting definitions of `env_var`.

### Example - Code After Macro Guard

```
#ifndef  __MY_MACRO__
#define __MY_MACRO__
    void func(void);
#endif
void func2(void);
```

If a header file contains this code, it is noncompliant because the macro guard does not cover the entire content of the header file. The line `void func2(void)` is outside the guard.

**Note** You can have comments outside the macro guard.

### Example - Code Before Macro Guard

```
void func(void);
#ifndef  __MY_MACRO__
#define __MY_MACRO__
    void func2(void);
#endif
```

If a header file contains this code, it is noncompliant because the macro guard does not cover the entire content of the header file. The line `void func(void)` is outside the guard.

**Note** You can have comments outside the macro guard.

### Example - Mismatch in Macro Guard

```
#ifndef  __MY_MACRO__
#define __MY_MARCO__
    void func(void);
    void func2(void);
#endif
```

If a header file contains this code, it is noncompliant because the macro name in the `#ifndef` statement is different from the name in the following `#define` statement.

Avoid using repeated question marks

## Description

### Rule Definition

*Avoid using repeated question marks.*

### Polyspace Implementation

The rule checker checks for **Use of trigraphs**.

## Examples

### Use of trigraphs

#### Issue

The issue occurs when you use trigraphs in your code.

The Polyspace analysis converts trigraphs to the equivalent character for the defect analysis. However, Polyspace also raises a MISRA violation.

The standard requires that trigraphs must be transformed *before* comments are removed during preprocessing. Therefore, Polyspace raises a violation of this rule even if a trigraph appears in code comments.

#### Risk

You denote trigraphs with two question marks followed by a specific third character (for instance,`'??-'` represents a `'~'` (tilde) character and `'??)'` represents a `']'`). These trigraphs can cause accidental confusion with other uses of two question marks.

**Note** Digraphs (`<:  :>`, `<%  %>`, `%:`, `%:%:`) are permitted because they are tokens.

Do not replace secure functions with deprecated or obsolescent functions

## Description

### Rule Definition

*Do not replace secure functions with deprecated or obsolescent functions.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of dangerous standard function**.
- **Insufficient destination buffer size**.

## Examples

### Use of dangerous standard function

#### Issue

The **Use of dangerous standard function** check highlights uses of functions that are inherently dangerous or potentially dangerous given certain circumstances. The following table lists possibly dangerous functions, the risks of using each function, and what function to use instead.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `cin` | Inherently dangerous — You cannot control the length of input from the console. | Avoid or prefaces calls to `cin` with `cin.width`. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Using `sprintf`

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
```

```
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1) //Noncompliant
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

**Correction — Use `snprintf` with Buffer Size**

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Insufficient destination buffer size

**Issue**

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(input, str); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

#### Risk

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if `argv[0]` contains 100 or more characters, the `strcpy` operation results in a buffer overflow.

#### Fix

Before calling the function `strcpy()`, allocate sufficient memory dynamically. For instance, use the function `strlen()` to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value `strlen(source) + 1`.

#### Example — Destination Buffer Too Small

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[128];
  strcpy(source, destination);//Noncompliant

  return 0;
}
```

#### Correction — Allocate Sufficient Memory for Destination Buffer

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char* destination = (char *)malloc(strlen(source)+ 1);
  if(destination!=NULL){
      strcpy(source, destination);//Compliant
  }else{
      /*Handle Error*/
  }
  //...
  free(destination);
  return 0;
}
```

Wrap multistatement macros in a do-while loop

## Description

### Rule Definition

*Wrap multistatement macros in a do-while loop.*

### Polyspace Implementation

The rule checker checks for **Macro with multiple statements**.

## Examples

### Macro with multiple statements

#### Issue

**Macro with multiple statements** occurs when a macro contains multiple semicolon-terminated statements, irrespective of whether the statements are enclosed in braces.

#### Risk

The macro expansion, in certain contexts such as an `if` condition or a loop, can lead to unintended program logic.

For instance, consider the macro:

```
#define RESET(x,y) \
   x=0; \
   y=0;
```

In an `if` statement such as:

```
if(checkSomeCondition)
   RESET(x,y);
```

the macro expands to:

```
if(checkSomething)
   x=0;
y=0;
```

which might be unexpected if you want both statements to be executed in an `if` block.

#### Fix

In a macro definition, wrap multiple statements in a `do...while(0)` loop.

For instance, in the preceding example, use the definition:

```
#define RESET(x,y) \
   do { \
     x=0; \
     y=0; \
   } while(0)
```

This macro is appropriate to expand in all contexts. The `while(0)` ensures that the statements are executed only once.

Alternatively, use inline functions in preference to function-like macros that involve multiple statements.

Note that the loop is required for the correct solution and wrapping the statements in braces alone does not fix the issue. The macro expansion can still lead to unintended code.

#### Example – Macro with Multiple Statements

```
#define RESET(x,y) \ //Noncompliant
   x=0; \
   y=0;

void func(int *x, int *y, int resetFlag){
    if(resetFlag)
        RESET(x,y);
}
```

In this example, the defect occurs because the macro `RESET` consists of multiple statements.

#### Correction – Wrap Multiple Statements of Macro in do-while Loop

Wrap the statements of the macro in a `do..while(0)` loop in the macro definition.

```
#define RESET(x,y) \
   do { \
     x=0; \
     y=0; \
   } while(0)

void func(int *x, int *y, int resetFlag){
    if(resetFlag)
        RESET(x,y);
}
```

Do not conclude macro definitions with a semicolon

## Description

### Rule Definition

*Do not conclude macro definitions with a semicolon.*

### Polyspace Implementation

The rule checker checks for **Macro terminated with a semicolon**.

## Examples

### Macro terminated with a semicolon

#### Issue

**Macro terminated with a semicolon** occurs when a macro that is invoked at least once has a definition ending with a semicolon.

#### Risk

If a macro definition ends with a semicolon, the macro expansion can lead to unintended program logic in certain contexts, such as within an expression.

For instance, consider the macro:

```
#define INC_BY_ONE(x) ++x;
```

If used in the expression:

```
res = INC_BY_ONE(x)%2;
```

the expression resolves to:

```
res = ++x; %2;
```

The value of `x+1` is assigned to `res`, which is probably unintended. The leftover standalone statement `%2;` is valid C code and can only be detected by enabling strict compiler warnings.

#### Fix

Do not end macro definitions with a semicolon. Leave it up to users of the macro to add a semicolon after the macro when needed.

Alternatively, use inline functions in preference to function-like macros that involve statements ending with semicolon.

#### Example – Spurious Semicolon in Macro Definition

```
#define WHILE_LOOP(n) while(n>0); //Noncompliant
```

```
void performAction(int timeStep);

void main() {
    int loopIter = 100;
    WHILE_LOOP(loopIter) {
        performAction(loopIter);
        loopIter--;
    }
}
```

In this example, the defect occurs because the definition of the macro `WHILE_LOOP(n)` ends with a semicolon. As a result of the semicolon, the `while` loop has an empty body and the following statements run only once. It was probably intended that the loop must run 100 times.

**Correction – Remove Semicolon from Macro Definition**

Remove the trailing semicolon from the macro definition. Users of the macro can add a semicolon after the macro when needed. In this example, a semicolon is not required.

```
#define WHILE_LOOP(n) while(n>0)

void performAction(int timeStep);

void main() {
    int loopIter = 100;
    WHILE_LOOP(loopIter) {
        performAction(loopIter);
        loopIter--;
    }
}
```

Const-qualify immutable objects

## Description

### Rule Definition

*Const-qualify immutable objects.*

### Polyspace Implementation

The rule checker checks for **Unmodified variable not const-qualified**.

## Examples

### Unmodified variable not const-qualified

#### Issue

**Unmodified variable not const-qualified** occurs when a local variable is not `const`-qualified and one of the following statements is true during the variable lifetime:

- You do not perform write operations on the variable after initialization.
- When you perform write operations, you reassign the same constant value to the variable.

The checker considers a variable as modified if its address is assigned to a pointer or reference (unless it is a pointer or reference to a `const` variable), passed to another function, or otherwise used. In these situations, the checker does not suggest adding a `const` qualifier.

The checker flags arrays as candidates for `const`-qualification only if you do not perform write operations on the array elements at all after initialization.

#### Risk

`const`-qualifying a variable avoids unintended modification of the variable during later code maintenance. The `const` qualifier also indicates to a developer that the variable retains its initial value in the remainder of the code.

#### Fix

If you do not expect to modify a variable value during its lifetime, add the `const` qualifier to the variable declaration and initialize the variable at declaration.

If you expect the variable to be modified, see if the absence of a modification indicates a programming omission and fix the issue.

#### Example - Missing `const` Qualification on Pointer

```
#include <string.h>

char returnNthCharacter (int n) {
    char* pwd = "aXeWdf10fg" ; //Noncompliant
    char nthCharacter;
    for(int i=0; i < strlen(pwd); i++) {
        if(i==n)
            nthCharacter = pwd[i];
    }
    return nthCharacter;
}
```

In this example, the pointer pwd is not const-qualified. However, beyond initialization with a constant, it is not reassigned anywhere in the returnNthCharacter function.

#### Correction – Add const at Variable Declaration

If the variable is not intended to be modified, add the const qualifier at declaration. In this example, both the pointer and the pointed variable are not modified. Add a const qualifier to both the pointer and the pointed variable. Later modifications cannot reassign the pointer pwd to point at a different variable nor modify the value at the pointed location.

```
#include <string.h>

char returnNthCharacter (int n) {
    const char* const pwd = "aXeWdf10fg" ; //Compliant
    char nthCharacter;

    for(int i=0; i < strlen(pwd); i++) {
        if(i==n)
            nthCharacter = pwd[i];
    }
    return nthCharacter;
}
```

Note that the checker only flags the missing const from the pointer declaration. The checker does not determine if the pointed location also merits a const qualifier.

Do not reuse variable names in subscopes

## Description

### Rule Definition

*Do not reuse variable names in subscopes.*

### Polyspace Implementation

The rule checker checks for **Variable shadowing**.

## Examples

### Variable shadowing

#### Issue

**Variable shadowing** occurs when a variable hides another variable of the same name in an outer scope.

For instance, if a local variable has the same name as a global variable, the local variable hides the global variable during its lifetime.

#### Risk

When two variables with the same name exist in an inner and outer scope, any reference to the variable name uses the variable in the inner scope. However, a developer or reviewer might incorrectly expect that the variable in the outer scope was used.

#### Fix

The fix depends on the root cause of the defect. For instance, suppose you refactor a function such that you use a local static variable in place of a global variable. In this case, the global variable is redundant and you can remove its declaration. Alternatively, if you are not sure if the global variable is used elsewhere, you can modify the name of the local static variable and all references within the function.

If the shadowing is intended and you do not want to fix the issue, add comments to your result or code to avoid another review. See

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Variable Shadowing Error

```
#include <stdio.h>
```

```
int fact[5]={1,2,6,24,120};

int factorial(int n)
 {
  int fact=1;  //Noncompliant
  /*Defect: Local variable hides global array with same name */

  for(int i=1;i<=n;i++)
    fact*=i;

  return(fact);
 }
```

Inside the `factorial` function, the integer variable `fact` hides the global integer array `fact`.

**Correction — Change Variable Name**

One possible correction is to change the name of one of the variables, preferably the one with more local scope.

```
#include <stdio.h>

int fact[5]={1,2,6,24,120};

int factorial(int n)
 {
  /* Fix: Change name of local variable */
  int f=1;

  for(int i=1;i<=n;i++)
    f*=i;

  return(f);
 }
```

Use visually distinct identifiers

## Description

### Rule Definition

*Use visually distinct identifiers.*

### Polyspace Implementation

The rule checker checks for **Use of typographically ambiguous identifiers**.

## Examples

### Use of typographically ambiguous identifiers

#### Issue

The issue occurs when you use identifiers in the same name space with overlapping visibility and the identifiers are not typographically unambiguous.

#### Risk

What “unambiguous” means depends on the alphabet and language in which source code is written. When you use identifiers that are typographically close, you can confuse between them.

For the Latin alphabet as used in English words, at a minimum, the identifiers should not differ by:

- The interchange of a lowercase letter with its uppercase equivalent.
- The presence or absence of the underscore character.
- The interchange of the letter O and the digit 0.
- The interchange of the letter I and the digit 1.
- The interchange of the letter I and the letter l.
- The interchange of the letter S and the digit 5.
- The interchange of the letter Z and the digit 2.
- The interchange of the letter n and the letter h.
- The interchange of the letter B and the digit 8.
- The interchange of the letters rn and the letter m.

#### Example - Typographically Ambiguous Identifiers

```
void func(void) {
    int id1_numval;
    int id1_num_val;  /* Non-compliant */

    int id2_numval;
    int id2_numVal;   /* Non-compliant */
    int id3_lvalue;
    int id3_Ivalue;   /* Non-compliant */

    int id4_xyZ;
    int id4_xy2;      /* Non-compliant */

    int id5_zerO;
    int id5_zer0;     /* Non-compliant */

    int id6_rn;
    int id6_m;        /* Non-compliant */
}
```

In this example, the rule is violated when identifiers that can be confused for each other are used.

Use meaningful symbolic constants to represent literal values

## Description

### Rule Definition

*Use meaningful symbolic constants to represent literal values.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Hard-coded buffer size**.
- **Hard-coded loop boundary**.

## Examples

### Hard-coded buffer size

#### Issue

**Hard-coded buffer size** occurs when you use a numerical value instead of a symbolic constant when declaring a memory buffer such as an array.

#### Risk

Hard-coded buffer size causes the following issues:

- Hard-coded buffer size increases the likelihood of mistakes and therefore maintenance costs. If a policy change requires developers to change the buffer size, they must change every occurrence of the buffer size in the code.
- Hard-constant constants can be exposed to attack if the code is disclosed.

#### Fix

Use a symbolic name instead of a hard-coded constant for buffer size. Symbolic names include `const`-qualified variables, `enum` constants, or macros.

`enum` constants are recommended.

- Macros are replaced by their constant values after preprocessing. Therefore, they can expose the loop boundary.
- `enum` constants are known at compilation time. Therefore, compilers can optimize the loops more efficiently.

  `const`-qualified variables are usually known at run time.

#### Example - Hard-Coded Buffer Size

```
int table[100]; //Noncompliant
```

```
void read(int);

void func(void) {
    for (int i=0; i<100; i++) //Noncompliant
        read(table[i]);
}
```

In this example, the size of the array `table` and the loop boundary in the `for` loop are hard-coded.

#### Correction — Use Symbolic Name

One possible correction is to replace the hard-coded size with a symbolic name.

```
const int MAX_1 = 100;
#define MAX_2 100
enum { MAX_3 = 100 };

int table_2[MAX_2];
int table_3[MAX_3];

void read(int);

void func(void) {
    int table_1[MAX_1];
    for (int i=0; i < MAX_1; i++)
        read(table_1[i]);
    for (int i=0; i < MAX_2; i++)
        read(table_2[i]);
    for (int i=0; i < MAX_3; i++)
        read(table_3[i]);
}
```

### Hard-coded loop boundary

#### Issue

**Hard-coded loop boundary** occurs when you use a numerical value instead of symbolic constant for the boundary of a `for`, `while` or `do-while` loop.

#### Risk

Hard-coded loop boundary causes the following issues:

- Hard-coded loop boundary makes the code vulnerable to denial of service attacks when the loop involves time-consuming computation or resource allocation.
- Hard-coded loop boundary increases the likelihood of mistakes and maintenance costs. If a policy change requires developers to change the loop boundary, they must change every occurrence of the boundary in the code.

  For instance, the loop boundary is 10000 and represents the maximum number of client connections supported in a network server application. If the server supports more clients, you must change all instances of the loop boundary in your code. Even if the loop boundary occurs once, you have to search for a numerical value of `10000` in your code. The numerical value can occur in places other than the loop boundary. You must browse through those places before you find the loop boundary.

#### Fix

Use a symbolic name instead of a hard-coded constant for loop boundary. Symbolic names include `const`-qualified variables, `enum` constants or macros.`enum` constants are recommended because:

- Macros are replaced by their constant values after preprocessing. Therefore, they can expose the buffer size.
- `enum` constants are known at compilation time. Therefore, compilers can allocate storage for them more efficiently.

  `const`-qualified variables are usually known at run time.

#### Example - Hard-Coded Loop Boundary

```
void performOperation(int);

void func(void) {
    for (int i=0; i<100; i++) //Noncompliant
        performOperation(i);
}
```

In this example, the boundary of the `for` loop is hard-coded.

#### Correction — Use Symbolic Name

One possible correction is to replace the hard-coded loop boundary with a symbolic name.

```
const int MAX_1 = 100;
#define MAX_2 100
enum { MAX_3 = 100 };

void performOperation_1(int);
void performOperation_2(int);
void performOperation_3(int);

void func(void) {
    for (int i=0; i<MAX_1; i++)
        performOperation_1(i);
    for (int i=0; i<MAX_2; i++)
        performOperation_2(i);
    for (int i=0; i<MAX_3; i++)
        performOperation_3(i);
}
```

Include the appropriate type information in function declarators

## Description

### Rule Definition

*Include the appropriate type information in function declarators.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Cast between function pointers with different types**.
- **Function declared implicitly**.

## Examples

### Cast between function pointers with different types

#### Issue

The issues occurs when you perform a conversion between a pointer to a function and any other type.

Polyspace considers both explicit and implicit casts when checking this rule. However, casts from `NULL` or `(void*)0` do not violate this rule.

#### Risk

The rule forbids the following two conversions:

- Conversion from a function pointer to any other type. This conversion causes undefined behavior.
- Conversion from a function pointer to another function pointer, if the function pointers have different argument and return types.

  The conversion is forbidden because calling a function through a pointer with incompatible type results in undefined behavior.

#### Example - Cast between two function pointers

```
typedef void (*fp16) (short n);
typedef void (*fp32) (int n);

#include <stdlib.h>                     /* To obtain macro  NULL */

void func(void) {   /* Exception 1 - Can convert a null pointer
                     * constant into a pointer to a function */
  fp16 fp1 = NULL;                 /* Compliant - exception  */
  fp16 fp2 = (fp16) fp1;           /* Compliant */
  fp32 fp3 = (fp32) fp1;           /* Non-compliant */
  if (fp2 != NULL) {}              /* Compliant - exception  */
  fp16 fp4 = (fp16) 0x8000;        /* Non-compliant - integer to
                                    * function pointer */}
```

In this example, the rule is violated when:

- The pointer `fp1` of type `fp16` is cast to type `fp32`. The function pointer types `fp16` and `fp32` have different argument types.
- An integer is cast to type `fp16`.

The rule is not violated when function pointers `fp1` and `fp2` are cast to `NULL`.

### Function declared implicitly

#### Issue

The issue occurs when you declare a function implicitly.

#### Risk

An implicit declaration occurs when you call a function before declaring or defining it. When you declare a function explicitly before calling it, the compiler can match the argument and return types with the parameter types in the declaration. If an implicit declaration occurs, the compiler makes assumptions about the argument and return types. For instance, it assumes a return type of `int`. The assumptions might not agree with what you expect and cause undesired type conversions.

#### Example - Function Not Declared Before Call

```
#include <math.h>

extern double power3 (double val, int exponent);
int getChoice(void);

double func() {
    double res;
    int ch = getChoice();
    if(ch == 0) {
        res = power(2.0, 10);    /* Non-compliant */
    }
    else if( ch==1) {
        res = power2(2.0, 10);   /* Non-compliant */
    }
    else {
        res = power3(2.0, 10);   /* Compliant */
        return res;
    }
}

double power2 (double val, int exponent) {
    return (pow(val, exponent));
}
```

In this example, the rule is violated when a function that is not declared is called in the code. Even if a function definition exists later in the code, the rule violation occurs.

The rule is not violated when the function is declared before it is called in the code. If the function definition exists in another file and is available only during the link phase, you can declare the function in one of the following ways:

- Declare the function with the `extern` keyword in the current file.
- Declare the function in a header file and include the header file in the current file.

Maintain the contract between the writer and caller of variadic functions

## Description

### Rule Definition

*Maintain the contract between the writer and caller of variadic functions.*

### Polyspace Implementation

The rule checker checks for **Format string specifiers and arguments mismatch**.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
const char *message = "License not available";
int err_number = -4;
printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {
    unsigned long fst = 1;

    printf("%d\n", fst); //Noncompliant
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

**Correction — Use an Unsigned Long Format Specifier**

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

**Correction — Use an Integer Argument**

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

Understand the type issues associated with variadic functions

## Description

### Rule Definition

*Understand the type issues associated with variadic functions.*

### Polyspace Implementation

The rule checker checks for **Format string specifiers and arguments mismatch**.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
const char *message = "License not available";
int err_number = -4;
printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {
    unsigned long fst = 1;

    printf("%d\n", fst); //Noncompliant
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

Implement abstract data types using opaque types

## Description

### Rule Definition

*Implement abstract data types using opaque types.*

### Polyspace Implementation

The rule checker checks for **Structure or union object implementation visible in file where pointer to this object is not dereferenced**.

## Examples

### Structure or union object implementation visible in file where pointer to this object is not dereferenced

#### Issue

The issue occurs when a pointer to a structure or union is never dereferenced within a translation unit, but the implementation of the object is not hidden.

If a structure or union is defined in a file or a header file included in the file, a pointer to this structure or union declared but the pointer never dereferenced in the file, the checker flags a coding rule violation. The structure or union definition should not be visible to this file.

If you see a violation of this rule on a structure definition, identify if you have defined a pointer to the structure in the same file or in a header file included in the file. Then check if you dereference the pointer anywhere in the file. If you do not dereference the pointer, the structure definition should be hidden from this file and included header files.

`file.h`: Contains structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct  {
  int a;
} myStruct;

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

myStruct* getObj(void);
void useObj(myStruct*);

void func() {
  myStruct *sPtr = getObj();
  useObj(sPtr);
}
```

In this example, the pointer to the type `myStruct` is not dereferenced. The pointer is simply obtained from the `getObj` function and passed to the `useObj` function.

The implementation of `myStruct` is visible in the translation unit consisting of `file.c` and `file.h`.

One possible correction is to define an opaque data type in the header file `file.h`. The opaque data type `ptrMyStruct` points to the `myStruct` structure without revealing what the structure contains. The structure `myStruct` itself can be defined in a separate translation unit, in this case, consisting of the file `file2.c`. The common header file `file.h` must be included in both `file.c` and `file2.c` for linking the structure definition to the opaque type definition.

`file.h`: Does not contain structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct myStruct *ptrMyStruct;

ptrMyStruct getObj(void);
void useObj(ptrMyStruct);

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

void func() {
  ptrMyStruct sPtr = getObj();
  useObj(sPtr);
}
```

`file2.c`: Includes `file.h` and dereferences structure.

```
#include "file.h"

struct myStruct {
  int a;
};

void useObj(ptrMyStruct ptr) {
    (ptr->a)++;
}
```

### Risk

If a pointer to a structure or union is not dereferenced in a file, the implementation details of the structure or union need not be available in the translation unit for the file. You can hide the implementation details such as structure members and protect them from unintentional changes.

Define an opaque type that can be referenced via pointers but whose contents cannot be accessed.

### Example - Object Implementation Revealed

`file.h`: Contains structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct  {
  int a;
} myStruct;

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

myStruct* getObj(void);
void useObj(myStruct*);

void func() {
  myStruct *sPtr = getObj();
  useObj(sPtr);
}
```

In this example, the pointer to the type `myStruct` is not dereferenced. The pointer is simply obtained from the `getObj` function and passed to the `useObj` function.

The implementation of `myStruct` is visible in the translation unit consisting of `file.c` and `file.h`.

**Correction — Define Opaque Type**

One possible correction is to define an opaque data type in the header file `file.h`. The opaque data type `ptrMyStruct` points to the `myStruct` structure without revealing what the structure contains. The structure `myStruct` itself can be defined in a separate translation unit, in this case, consisting of the file `file2.c`. The common header file `file.h` must be included in both `file.c` and `file2.c` for linking the structure definition to the opaque type definition.

`file.h`: Does not contain structure implementation.

```
#ifndef TYPE_GUARD
#define TYPE_GUARD

typedef struct myStruct *ptrMyStruct;

ptrMyStruct getObj(void);
void useObj(ptrMyStruct);

#endif
```

`file.c`: Includes `file.h` but does not dereference structure.

```
#include "file.h"

void func() {
  ptrMyStruct sPtr = getObj();
  useObj(sPtr);
}
```

`file2.c`: Includes `file.h` and dereferences structure.

```
#include "file.h"
```

```
struct myStruct {
  int a;
};

void useObj(ptrMyStruct ptr) {
    (ptr->a)++;
}
```

Declare function parameters that are pointers to values not changed by the function as const

## Description

### Rule Definition

*Declare function parameters that are pointers to values not changed by the function as const.*

### Polyspace Implementation

The rule checker checks for **Pointer to non-cont qualified function parameter**.

## Examples

### Pointer to non-cont qualified function parameter

#### Issue

The rule checker flags a pointer to a non-`const` function parameter if the pointer does not modify the addressed object. The assumption is that the pointer is not meant to modify the object and so must point to a `const`-qualified type.

#### Risk

This rule ensures that you do not inadvertently use pointers to modify objects.

#### Example - Pointer That Should Point to const-Qualified Types

```
#include <string.h>

typedef unsigned short uint16_t;

uint16_t ptr_ex(uint16_t *p) {      /* Non-compliant */
    return *p;
}

char last_char(char * const s){     /* Non-compliant */
    return s[strlen(s) - 1u];
}

uint16_t first(uint16_t a[5]){      /* Non-compliant */
    return a[0];
}
```

This example shows three different noncompliant pointer parameters.

- In the `ptr_ex` function, `p` does not modify an object. However, the type to which `p` points is not `const`-qualified, so it is noncompliant.
- In `last_char`, the pointer `s` is `const`-qualified but the type it points to is not. This parameter is noncompliant because `s` does not modify an object.
- The function `first` does not modify the elements of the array `a`. However, the element type is not `const`-qualified, so `a` is also noncompliant.

#### Correction — Use `const` Keywords

One possible correction is to add `const` qualifiers to the definitions.

```
#include <string.h>

typedef unsigned short uint16_t;

uint16_t ptr_ex(const uint16_t *p){     /* Compliant */
    return *p;
}

char last_char(const char * const s){   /* Compliant */
    return s[strlen( s ) - 1u];
}

uint16_t first(const uint16_t a[5]) {   /* Compliant */
    return a[0];
}
```

Declare file-scope objects or functions that do not need external linkage as static

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*Declare file-scope objects or functions that do not need external linkage as static.*

### Polyspace Implementation

The rule checker checks for **Function or object with external linkage referenced in only one translation unit**.

## Examples

### Function or object with external linkage referenced in only one translation unit

**Issue**

The rule checker flags:

- Objects that are defined at file scope without the `static` specifier but used only in one file.
- Functions that are defined without the `static` specifier but called only in one file.

If you intend to use the object or function in one file only, declare it static.

Objects that are defined at file scope without the `static` specifier but used only in one file.

Functions that are defined without the `static` specifier but called only in one file.

**Risk**

Compliance with this rule avoids confusion between your identifier and an identical identifier in another translation unit or library. If you restrict or reduce the visibility of an object by giving it internal linkage or no linkage, you or someone else is less likely to access the object inadvertently.

**Example - Variable with External Linkage Used in One File**

Header file:

```
/* file.h */
extern int var;
```

First source file:

```
/* file1.c */
#include "file.h"

int var;    /* Compliant */
int var2;   /* Non compliant */
static int var3; /* Compliant */

void reset(void);

void reset(void) {
    var = 0;
    var2 = 0;
    var3 = 0;
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment(int var2);

void increment(int var2) {
    var++;
    var2++;
}
```

In this example:

- The declaration of `var` is compliant because `var` is declared with external linkage and used in multiple files.
- The declaration of `var2` is noncompliant because `var2` is declared with external linkage but used in one file only.

  It might appear that `var2` is defined in both files. However, in the second file, `var2` is a parameter with no linkage and is not the same as the `var2` in the first file.
- The declaration of `var3` is compliant because `var3` is declared with internal linkage (with the `static` specifier) and used in one file only.

#### Example - Function with External Linkage Used in One File

Header file:

```
/* file.h */
extern int var;
extern void increment1 (void);
```

First source file:

```
/* file1.c */
#include "file.h"

int var;

void increment2(void);
static void increment3(void);
void func(void);

void increment2(void) { /* Non compliant */
    var+=2;
}
```

```
static void increment3(void) { /* Compliant */
    var+=3;
}

void func(void) {
    increment1();
    increment2();
    increment3();
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment1(void) { /* Compliant */
    var++;
}
```

In this example:

- The definition of `increment1` is compliant because `increment1` is defined with external linkage and called in a different file.
- The declaration of `increment2` is noncompliant because `increment2` is defined with external linkage but called in the same file and nowhere else.
- The declaration of `increment3` is compliant because `increment3` is defined with internal linkage (with the `static` specifier) and called in the same file and nowhere else.

Use 'L,' not 'l,' to indicate a long value

## Description

### Rule Definition

*Use 'L,' not 'l,' to indicate a long value.*

### Polyspace Implementation

The rule checker checks for **Use of lowercase "l" in literal suffix**.

## Examples

### Use of lowercase "l" in literal suffix

#### Issue

The issue occurs when you use the lowercase character “l” in a literal suffix.

#### Risk

The lowercase character “l” can be confused with the digit “1”. Use the uppercase “L” instead.

Do not begin integer constants with 0 when specifying a decimal value

## Description

### Rule Definition

*Do not begin integer constants with 0 when specifying a decimal value.*

### Polyspace Implementation

The rule checker checks for **Use of octal constants**.

## Examples

### Use of octal constants

#### Issue

If you use octal constants in a macro definition, the rule checker flags the issue even if the macro is not used.

#### Risk

Octal constants are denoted by a leading zero. Developers can mistake an octal constant as a decimal constant with a redundant leading zero.

#### Example - Use of octal constants

```
#define CST     021              /* Noncompliant */
#define VALUE   010              /* Noncompliant */
#if 010 == 01                    /* Noncompliant*/
#define CST 021                  /* Noncompliant */
#endif

extern short code[5];
static char* str2 = "abcd\0efg";  /* Compliant */

void main(void) {
    int value1 = 0;               /* Compliant */
    int value2 = 01;              /* Noncompliant*/
    int value3 = 1;               /* Compliant */
    int value4 = '\109';          /* Compliant */

    code[1] = 109;                /* Compliant     - decimal 109 */
    code[2] = 100;                /* Compliant     - decimal 100 */
    code[3] = 052;                /* Noncompliant */
    code[4] = 071;                /* Noncompliant */

    if (value1 != CST) {
        value1 = !(value1 != 0);  /* Compliant */
    }
}
```

In this example, Polyspace flags the use of octal constants.

Minimize the scope of variables and functions

## Description

### Rule Definition

*Minimize the scope of variables and functions.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Function or object declared without static specifier and referenced in only one file**.
- **Object defined beyond necessary scope**.

## Examples

### Function or object declared without `static` specifier and referenced in only one file

**Issue**

The rule checker flags:

- Objects that are defined at file scope without the `static` specifier but used only in one file.
- Functions that are defined without the `static` specifier but called only in one file.

If you intend to use the object or function in one file only, declare it static.

Objects that are defined at file scope without the `static` specifier but used only in one file.

Functions that are defined without the `static` specifier but called only in one file.

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

**Risk**

Compliance with this rule avoids confusion between your identifier and an identical identifier in another translation unit or library. If you restrict or reduce the visibility of an object by giving it internal linkage or no linkage, you or someone else is less likely to access the object inadvertently.

**Example - Variable with External Linkage Used in One File**

Header file:

```
/* file.h */
extern int var;
```

First source file:

```
/* file1.c */
#include "file.h"
```

```
int var;    /* Compliant */
int var2;   /* Non compliant */

void reset(void);

void reset(void) {

    static int var3=0; /* Compliant */
    var = 0;
    var2 = 0;
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment(int var2);

void increment(int var2) {
    var++;
    var2++;
}
```

In this example:

- The declaration of `var` is compliant because `var` is declared with external linkage and used in multiple files.
- The declaration of `var2` is noncompliant because `var2` is declared with external linkage but used in one file only.

  It might appear that `var2` is defined in both files. However, in the second file, `var2` is a parameter with no linkage and is not the same as the `var2` in the first file.
- The declaration of `var3` is compliant because `var3` is declared with internal linkage (with the `static` specifier) and used in one file only.

**Example - Function with External Linkage Used in One File**

Header file:

```
/* file.h */
extern int var;
extern void increment1 (void);
```

First source file:

```
/* file1.c */
#include "file.h"

int var;

void increment2(void);
static void increment3(void);
void func(void);

void increment2(void) { /* Non compliant */
```

```
    var+=2;
}

static void increment3(void) { /* Compliant */
    var+=3;
}

void func(void) {
    increment1();
    increment2();
    increment3();
}
```

Second source file:

```
/* file2.c */
#include "file.h"

void increment1(void) { /* Compliant */
    var++;
}
```

In this example:

- The definition of `increment1` is compliant because `increment1` is defined with external linkage and called in a different file.
- The declaration of `increment2` is noncompliant because `increment2` is defined with external linkage but called in the same file and nowhere else.
- The declaration of `increment3` is compliant because `increment3` is defined with internal linkage (with the `static` specifier) and called in the same file and nowhere else.

### Object defined beyond necessary scope

#### Issue

The issue occurs when the identifier of an object only appears in a single function but the object is defined beyond the block scope.

The rule checker flags `static` objects that are accessed in one function only but declared at file scope.

#### Risk

If you define an object at block scope, you or someone else is less likely to access the object inadvertently outside the block.

#### Example - Object Declared at File Scope but Used in One Function

```
static int ctr;   /* Non compliant */

int checkStatus(void);
void incrementCount(void);

void incrementCount(void) {
    ctr=0;
    while(1) {
        if(checkStatus())
            ctr++;
    }
}
```

In this example, the declaration of `ctr` is noncompliant because it is declared at file scope but used only in the function `incrementCount`. Declare `ctr` in the body of `incrementCount` to be MISRA C-compliant.

Use volatile for data that cannot be cached

## Description

### Rule Definition

*Use volatile for data that cannot be cached.*

### Polyspace Implementation

The rule checker checks for **Write without a further read**.

## Examples

### Write without a further read

#### Issue

**Write without a further read** occurs when a value assigned to a variable is never read.

For instance, you write a value to a variable and then write a second value before reading the previous value. The first write operation is redundant.

#### Risk

Redundant write operations often indicate programming errors. For instance, you forgot to read the variable between two successive write operations or unintentionally read a different variable.

#### Fix

Identify the reason why you write to the variable but do not read it later. Look for common programming errors such as accidentally reading a different variable with a similar name.

If you determine that the write operation is redundant, remove the operation.

#### Example - Write Without Further Read Error

```
void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();             //Noncompliant
    /* Defect: Useless write */
}
```

After the variable `level` gets assigned the value `4 * getsensor()`, it is not read.

#### Correction — Use Value After Assignment

One possible correction is to use the variable `level` after the assignment.

```
#include <stdio.h>

void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();

    /* Fix: Use level after assignment */
    printf("The value is %d", level);

}
```

The variable `level` is printed, reading the new value.

Guarantee that mutually visible identifiers are unique

## Description

### Rule Definition

*Guarantee that mutually visible identifiers are unique.*

### Polyspace Implementation

The rule checker checks for these issues:

- **External identifiers not distinct**.
- **Identifier in same scope and namespace not distinct**.
- **Macro identifier not distinct**.
- **Name for macros and identifiers not distinct**.

## Examples

### External identifiers not distinct

#### Issue

The issue occurs when external identifiers have the same first six characters for C90 or the same first 31 characters for C99.

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

#### Risk

External identifiers are ones declared with global scope or storage class `extern`.

Polyspace considers two names as distinct if there is a difference between their first 31 characters. If the difference between two names occurs only beyond the first 31 characters, they can be easily mistaken for each other. The readability of the code is reduced. For C90, the difference must occur between the first six characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`.

#### Example - C90: First Six Characters of Identifiers Not Unique

```
int engine_temperature_raw;
int engine_temperature_scaled;   /* Non-compliant */
int engin2_temperature;          /* Compliant */
```

In this example, the identifier `engine_temperature_scaled` has the same first six characters as a previous identifier, `engine_temperature_raw`.

#### Example - C99: First 31 Characters of Identifiers Not Unique

```
int engine_exhaust_gas_temperature_raw;
int engine_exhaust_gas_temperature_scaled; /* Non-compliant */
int eng_exhaust_gas_temp_raw;
int eng_exhaust_gas_temp_scaled;           /* Compliant */
```

In this example, the identifier `engine_exhaust_gas_temperature_scaled` has the same first 31 characters as a previous identifier, `engine_exhaust_gas_temperature_raw`.

#### Example - C90: First Six Characters Identifiers in Different Translation Units Differ in Case Alone

```
/* file1.c */
int abc = 0;

/* file2.c */
int ABC = 0; /* Non-compliant */
```

In this example, the implementation supports six significant case-insensitive characters in *external identifiers*. The identifiers in the two translations are different but are not distinct in their significant characters.

### Identifier in same scope and namespace not distinct

#### Issue

The issue occurs when you declare identifiers in the same scope and namespace and the identifiers have the same first 31 characters in C90 or the same first 63 characters in C99.

#### Risk

Polyspace considers two names as distinct if there is a difference between their first 63 characters. If the difference between two names occurs only beyond the first 63 characters, they can be easily mistaken for each other. The readability of the code is reduced. For C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`.

#### Example - C90: First 31 Characters of Identifiers Not Unique

```
extern int engine_exhaust_gas_temperature_raw;
static int engine_exhaust_gas_temperature_scaled;      /* Non-compliant */

extern double engine_exhaust_gas_temperature_raw;
static double engine_exhaust_gas_temperature2_scaled;  /* Compliant */

void func ( void )
{
  /* Not in the same scope */
  int engine_exhaust_gas_temperature_local;            /* Compliant */
}
```

In this example, the identifier `engine_exhaust_gas_temperature_scaled` has the same 31 characters as a previous identifier, `engine_exhaust_gas_temperature_raw`.

The rule does not apply if the two identifiers have the same 31 characters but have different scopes. For instance, `engine_exhaust_gas_temperature_local` has the same 31 characters as `engine_exhaust_gas_temperature_raw` but different scope.

#### Example - C99: First 63 Characters of Identifiers Not Unique

```
extern int engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_x_raw;
static int engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_x_scale;
```

```
    /* Non-compliant */

extern int engine_gas_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx__raw;
static int engine_gas_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx__scale;
    /* Compliant */

void func ( void )
{
/* Not in the same scope */
    int engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_x_local;
          /* Compliant */
}
```

In this example, the identifier `engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_x_scale` has the same 63 characters as a previous identifier, `engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_x_raw`.

### Macro identifier not distinct

#### Issue

The issue occurs when you use macro identifiers that have the same first 31 characters in C90 or the same first 63 characters in C99.

#### Risk

The names of macro identifiers must be distinct from both other macro identifiers and their parameters.

Polyspace considers two names as distinct if there is a difference between their first 63 characters. If the difference between two names occurs only beyond the first 63 characters, they can be easily mistaken for each other. The readability of the code is reduced. For C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`.

#### Example - C90: First 31 Characters of Macro Names Not Unique

```
#define engine_exhaust_gas_temperature_raw egt_r
#define engine_exhaust_gas_temperature_scaled egt_s   /* Non-compliant */

#define engine_exhaust_gas_temp_raw egt_r
#define engine_exhaust_gas_temp_scaled egt_s          /* Compliant */
```

In this example, the macro `engine_exhaust_gas_temperature_scaled egt_s` has the same first 31 characters as a previous macro `engine_exhaust_gas_temperature_scaled`.

#### Example - C99: First 63 Characters of Macro Names Not Unique

```
#define engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_raw egt_r
#define engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_raw_scaled egt_s
    /* Non-compliant */

/* 63 significant case-sensitive characters in macro identifiers */
#define new_engine_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_raw egt_r
#define new_engine_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_scaled egt_s
    /* Compliant */
```

In this example, the macro `engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx___gaz_scaled` has the same first 63 characters as a previous macro `engine_xxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx_xxxxxxxxx___raw`.

#### Name for macros and identifiers not distinct

##### Issue

The issue occurs when identifiers are not distinct from macro names.

##### Risk

The rule requires that macro names that exist only prior to processing must be different from identifier names that also exist after preprocessing. Keeping macro names and identifiers distinct help avoid confusion.

Polyspace considers two names as distinct if there is a difference between their first 63 characters. If the difference between two names occurs only beyond the first 63 characters, they can be easily mistaken for each other. The readability of the code is reduced. For C90, the difference must occur between the first 31 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`.

##### Example - Macro Names Same as Identifier Names

```
#define Sum_1(x, y) ( ( x ) + ( y ) )
short Sum_1;                    /* Non-compliant */

#define Sum_2(x, y) ( ( x ) + ( y ) )
short x = Sum_2 ( 1, 2 );       /* Compliant */
```

In this example, `Sum_1` is both the name of an identifier and a macro. `Sum_2` is used only as a macro.

##### Example - C90: First 31 Characters of Macro Name Same as Identifier Name

```
#define       low_pressure_turbine_temperature_1 lp_tb_temp_1
static int low_pressure_turbine_temperature_2;      /* Non-compliant  */
```

In this example, the identifier `low_pressure_turbine_temperature_2` has the same first 31 characters as a previous macro `low_pressure_turbine_temperature_1`.

Use parentheses for precedence of operation

## Description

### Rule Definition

*Use parentheses for precedence of operation.*

### Polyspace Implementation

The rule checker checks for **Possibly unintended evaluation of expression because of operator precedence rules**.

## Examples

### Possibly unintended evaluation of expression because of operator precedence rules

#### Issue

**Possibly unintended evaluation of expression because of operator precedence rules** occurs when an arithmetic expression result is possibly unintended because operator precedence rules dictate an evaluation order that you do not expect.

The defect highlights expressions of the form `x op_1 y op_2 z`. Here, *op_1* and *op_2* are operator combinations that commonly induce this error. For instance, `x == y | z`.

The checker does not flag all operator combinations. For instance, `x == y || z` is not flagged because you most likely intended to perform a logical OR between `x == y` and `z`. Specifically, the checker flags these combinations:

- && and ||: For instance, `x || y && z` or `x && y || z`.
- Assignment and bitwise operations: For instance, `x = y | z`.
- Assignment and comparison operations: For instance, `x = y != z` or `x = y > z`.
- Comparison operations: For instance, `x > y > z` (except when one of the comparisons is an equality `x == y > z`).
- Shift and numerical operation: For instance, `x << y + 2`.
- Pointer dereference and arithmetic: For instance, `*p++`.

#### Risk

The defect can cause the following issues:

- If you or another code reviewer reviews the code, the intended order of evaluation is not immediately clear.
- It is possible that the result of the evaluation does not meet your expectations. For instance:
  - In the operation `*p++`, it is possible that you expect the dereferenced value to be incremented. However, the pointer `p` is incremented before the dereference.

- In the operation `(x == y | z)`, it is possible that you expect `x` to be compared with `y | z`. However, the == operation happens before the | operation.

**Fix**

See if the order of evaluation is what you intend. If not, apply parentheses to implement the evaluation order that you want.

For better readability of your code, it is good practice to apply parenthesis to implement an evaluation order even when operator precedence rules impose that order.

**Example - Expressions with Possibly Unintended Evaluation Order**

```
int test(int a, int b, int c) {
    return(a & b == c); //Noncompliant
}
```

In this example, the == operation happens first, followed by the & operation. If you intended the reverse order of operations, the result is not what you expect.

**Correction — Parenthesis For Intended Order**

One possible correction is to apply parenthesis to implement the intended evaluation order.

```
int test(int a, int b, int c) {
    return((a & b) == c);
}
```

Do not cast away a const qualification

## Description

### Rule Definition

*Do not cast away a const qualification.*

### Polyspace Implementation

The rule checker checks for **Cast to pointer that removes const qualification**.

## Examples

### Cast to pointer that removes `const` qualification

#### Issue

Polyspace flags both implicit and explicit conversions that violate this rule.

#### Risk

This rule forbids casts from a pointer to a `const` object to a pointer that does not point to a `const` object.

Such casts violate type qualification. For example, the `const` qualifier indicates the read-only status of an object. If a cast removes the qualifier, the object is no longer read-only.

#### Example - Casts That Remove Qualifiers

```
void foo(void) {

    /* Cast on simple type */
    unsigned short           x;
    unsigned short * const   cpi = &x;  /* const pointer */
    unsigned short * const  *pcpi;   /* pointer to const pointer */
    unsigned short **ppi;
    const unsigned short    *pci;    /* pointer to const */
    unsigned short          *pi;

    pi = cpi;                        /* Compliant - no cast required */
    pi  = (unsigned short *)  pci;   /* Non-compliant */
    ppi = (unsigned short **)pcpi;   /* Non-compliant */
}
```

In this example, the variables `pci` and `pcpi` have the `const` qualifier in their type. The rule is violated when the variables are cast to types that do not have the `const` qualifier.

Even though `cpi` has a `const` qualifier in its type, the rule is not violated in the statement `p=cpi;`. The assignment does not cause a type conversion because both `p` and `cpi` have type `unsigned short`.

Ensure pointer arithmetic is used correctly

## Description

### Rule Definition

*Ensure pointer arithmetic is used correctly.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access out of bounds**
- **Pointer access out of bounds**.
- **Subtraction between pointers to different arrays**.
- **Incorrect pointer scaling**.

### Extend Checker

A default Bug Finder analysis might not flag an **Array access out of bounds** issue when the input values are unknown and only a subset of inputs cause the issue. To check for the **Array access out of bounds** issue caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Array access out of bounds

#### Issue

This issue occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example – Array Access Out of Bounds Error**

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);    //Noncompliant
    /* Defect: Value of i is greater than allowed value of 9 */
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

**Correction – Keep Array Index Within Array Bounds**

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];
```

```
    for (i = 0; i < 10; i++)
     {
         if (i < 2)
             fib[i] = 1;
         else
             fib[i] = fib[i-1] + fib[i-2];
     }

     /* Fix: Print fib[9] instead of fib[10] */
     printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Pointer access out of bounds

#### Issue

This issue occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example – Pointer access out of bounds error**

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

**Correction — Check Pointer Stays Within Bounds**

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Subtraction between pointers to different arrays

**Issue**

This rule is raised whenever the analysis detects a `Subtraction or comparison between pointers to different arrays`.

**Risk**

This rule applies to expressions of the form `pointer_expression1 - pointer_expression2`. The behavior is undefined if `pointer_expression1` and `pointer_expression2`:

- Do not point to elements of the same array,
- Or do not point to the element one beyond the end of the array.

**Example - Subtracting Pointers**

```
#include <stdint.h>
#include <stddef.h>

void f1 (int32_t *ptr)
{
    int32_t a1[10];
    int32_t a2[10];
    int32_t *p1 = &a1[ 1];
    int32_t *p2 = &a2[10];
    ptrdiff_t diff1, diff2, diff3;

    diff1 =  p1 - a1;   // Compliant
    diff2 =  p2 - a2;   // Compliant
    diff3 =  p1 - p2;   // Non-compliant
}
```

In this example, the three subtraction expressions show the difference between compliant and noncompliant pointer subtractions. The `diff1` and `diff2` subtractions are compliant because the pointers point to the same array. The `diff3` subtraction is not compliant because `p1` and `p2` point to different arrays.

## Incorrect pointer scaling

### Issue

**Incorrect pointer scaling** occurs when Polyspace Bug Finder considers that you are ignoring the implicit scaling in pointer arithmetic.

For instance, the defect can occur in the following situations.

| Situation | Risk | Possible Fix |
|---|---|---|
| You use the `sizeof` operator in arithmetic operations on a pointer. | The `sizeof` operator returns the size of a data type in number of bytes.<br>Pointer arithmetic is already implicitly scaled by the size of the data type of the pointed variable. Therefore, the use of `sizeof` in pointer arithmetic produces unintended results. | Do not use `sizeof` operator in pointer arithmetic. |
| You perform arithmetic operations on a pointer, and then apply a cast. | Pointer arithmetic is implicitly scaled. If you do not consider this implicit scaling, casting the result of a pointer arithmetic produces unintended results. | Apply the cast before the pointer arithmetic. |

### Fix

The fix depends on the root cause of the defect. See fixes in the table above and code examples with fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Example - Use of sizeof Operator

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;

    int value_in_position_2 = *(ptr + 2*(sizeof(int))); //Noncompliant
}
```

In this example, the operation `2*(sizeof(int))` returns twice the size of an `int` variable in bytes. However, because pointer arithmetic is implicitly scaled, the number of bytes by which `ptr` is offset is `2*(sizeof(int))*(sizeof(int))`.

In this example, the incorrect scaling shifts `ptr` outside the bounds of the array. Therefore, a **Pointer access out of bounds** error appears on the * operation.

### Correction — Remove sizeof Operator

One possible correction is to remove the `sizeof` operator.

```
void func(void) {
    int arr[5] = {1,2,3,4,5};
    int *ptr = arr;

    int value_in_position_2 = *(ptr + 2);
}
```

### Example - Cast Following Pointer Arithmetic

```
int func(void) {
    int x = 0;
    char r = *(char *)(&x + 1); //Noncompliant
    return r;
}
```

In this example, the operation `&x + 1` offsets `&x` by `sizeof(int)`. Following the operation, the resulting pointer points outside the allowed buffer. When you dereference the pointer, a **Pointer access out of bounds** error appears on the * operation.

### Correction — Apply Cast Before Pointer Arithmetic

If you want to access the second byte of `x`, first cast `&x` to a `char*` pointer and then perform the pointer arithmetic. The resulting pointer is offset by `sizeof(char)` bytes and still points within the allowed buffer, whose size is `sizeof(int)` bytes.

```
int func(void) {
    int x = 0;
    char r = *((char *)(&x )+ 1);
    return r;
}
```

Use sizeof to determine the size of a type or variable

## Description

### Rule Definition

*Use sizeof to determine the size of a type or variable.*

### Polyspace Implementation

The rule checker checks for **Hard-coded object size used to manipulate memory**.

## Examples

### Hard-coded object size used to manipulate memory

#### Issue

The issue **Hard-coded object size used to manipulate memory** occurs when you use hard-coded constants as memory size arguments for these memory functions:

- Dynamic memory allocation function such as `malloc` or `calloc`.
- Memory manipulation functions such as `memcpy`, `memmove`, `memcmp`, or `memset`.

When performing memory operations with a string literal, Polyspace does not report a violation of this rule if you hard code the memory size.

#### Risk

If you hard code object size, your code is not portable to architectures with different type sizes. If the constant value is not the same as the object size, the buffer might or might not overflow.

#### Fix

For the size argument of memory functions, use `sizeof(`*`object`*`)`.

#### Example - Assume 4-Byte Integer Pointers

```
#include <stddef.h>
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};
extern void fill_ints(int **matrix, size_t nb, size_t s);

void bug_hardcodedmemsize()
{
    size_t i, s;

    s = 4;
    int **matrix = (int **)calloc(SIZE20, s); //Noncompliant
    if (matrix == NULL) {
        return; /* Indicate calloc() failure */
    }
    fill_ints(matrix, SIZE20, s);
    free(matrix);
}
```

In this example, the memory allocation function `calloc` is called with a memory size of 4. The memory is allocated for an integer pointer, which can be a more or less than 4 bytes depending on your target. If the integer pointer is not 4 bytes, your program can fail.

**Correction — Use `sizeof(int *)`**

When calling `calloc`, replace the hard-coded size with a call to `sizeof`. This change makes your code more portable.

```
#include <stddef.h>
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};
extern void fill_ints(int **matrix, size_t nb, size_t s);

void corrected_hardcodedmemsize()
{
    size_t i, s;

    s = sizeof(int *);
    int **matrix = (int **)calloc(SIZE20, s);
    if (matrix == NULL) {
        return; /* Indicate calloc() failure */
    }
    fill_ints(matrix, SIZE20, s);
    free(matrix);
}
```

**Hard Coded Size in `memset`**

In this example, the function `clean_sensitive_memory` clears sensitive information from the memory. Here, the memory size argument of `memset` is hardcoded to be 64 bytes. If `s->data` cannot accommodate `64` bytes, the program fails and the sensitive information might remain in memory. Polyspace reports a violation of this rule on the memory operations.

```
#include<string.h>

struct sensitiveInfo
{
    unsigned char data[64];
    int length;
};

char key[64];

void clean_sensitive_memory (struct sensitiveInfo *s)
{
    memset (s->data, 0, 64);          //Defect
    memset ((void *) key, 0, 64);  //Defect
}
```

#### Correction — Use `sizeof()` for Size Argument

To fix this violation, replace the hardcoded memory sizes by calls to `sizeof()`.

```
#include<string.h>

struct sensitiveInfo
{
    unsigned char data[64];
    int length;
};

char key[64];

void clean_sensitive_memory (struct sensitiveInfo *s)
{
  memset (s->data, 0, sizeof (s->data));    //Fixed
  memset ((void *) key, 0, sizeof(key)); //Fixed
}
```

Do not depend on the order of evaluation of subexpressions or the order in which side effects take place

## Description

### Rule Definition

*Do not depend on the order of evaluation of subexpressions or the order in which side effects take place.*

### Polyspace Implementation

The rule checker checks for **Expression value depends on order of evaluation or of side effects**.

## Examples

### Expression value depends on order of evaluation or of side effects

#### Issue

The issue occurs when the value of an expression and its persistent side effects is not the same under all permitted evaluation orders.

An expression can have different values under the following conditions:

- The same variable is modified more than once in the expression, or is both read and written.
- The expression allows more than one order of evaluation.

Therefore, this rule forbids expressions where a variable is modified more than once and can cause different results under different orders of evaluation.

#### Risk

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

#### Example - Variable Modified More Than Once in Expression

```
int a[10], b[10];
#define COPY_ELEMENT(index) (a[(index)]=b[(index)])

void main () {
    int i=0, k=0;

    COPY_ELEMENT (k);         /* Compliant */
    COPY_ELEMENT (i++);       /* Noncompliant  */
}
```

In this example, the rule is violated by the statement `COPY_ELEMENT(i++)` because `i++` occurs twice and the order of evaluation of the two expressions is unspecified.

**Example - Variable Modified and Used in Multiple Function Arguments**

```
void f (unsigned int param1, unsigned int param2) {}

void main () {
    unsigned int i=0;
    f ( i++, i );                 /* Non-compliant */
}
```

In this example, the rule is violated because it is unspecified whether the operation `i++` occurs before or after the second argument is passed to `f`. The call `f(i++,i)` can translate to either `f(0,0)` or `f(0,1)`.

Do not ignore values returned by functions

## Description

### Rule Definition

*Do not ignore values returned by functions.*

### Polyspace Implementation

The rule checker checks for **Returned value of a sensitive function not checked**.

## Examples

### Returned value of a sensitive function not checked

#### Issue

**Returned value of a sensitive function not checked** occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example - Sensitive Function Return Ignored

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    pthread_attr_init(&attr);  //Noncompliant
}
```

This example shows a call to the sensitive function `pthread_attr_init`. The return value of `pthread_attr_init` is ignored, causing a defect.

#### Correction — Cast Function to (void)

One possible correction is to cast the function to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of the sensitive function.

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    (void)pthread_attr_init(&attr);
}
```

#### Correction — Test Return Value

One possible correction is to test the return value of `pthread_attr_init` to check for errors.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

void initialize() {
    pthread_attr_t attr;
    int result;

    result = pthread_attr_init(&attr);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

#### Example - Critical Function Return Ignored

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res);  //Noncompliant
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), Polyspace does not ignore this *Return value of a sensitive function not checked* defect. The other critical function, `pthread_join`, returns value that is ignored implicitly. `pthread_join` uses the return value of `pthread_create`, which was not checked.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

Treat relational and equality operators as if they were nonassociative

## Description

### Rule Definition

*Treat relational and equality operators as if they were nonassociative.*

### Polyspace Implementation

The rule checker checks for **Possibly unintended evaluation of expression because of operator precedence rules**.

## Examples

### Possibly unintended evaluation of expression because of operator precedence rules

#### Issue

**Possibly unintended evaluation of expression because of operator precedence rules** occurs when an arithmetic expression result is possibly unintended because operator precedence rules dictate an evaluation order that you do not expect.

The defect highlights expressions of the form `x` *op_1* `y` *op_2* `z`. Here, *op_1* and *op_2* are operator combinations that commonly induce this error. For instance, `x == y | z`.

The checker does not flag all operator combinations. For instance, `x == y || z` is not flagged because you most likely intended to perform a logical OR between `x == y` and `z`. Specifically, the checker flags these combinations:

- `&&` and `||`: For instance, `x || y && z` or `x && y || z`.
- Assignment and bitwise operations: For instance, `x = y | z`.
- Assignment and comparison operations: For instance, `x = y != z` or `x = y > z`.
- Comparison operations: For instance, `x > y > z` (except when one of the comparisons is an equality `x == y > z`).
- Shift and numerical operation: For instance, `x << y + 2`.
- Pointer dereference and arithmetic: For instance, `*p++`.

#### Risk

The defect can cause the following issues:

- If you or another code reviewer reviews the code, the intended order of evaluation is not immediately clear.
- It is possible that the result of the evaluation does not meet your expectations. For instance:
  - In the operation `*p++`, it is possible that you expect the dereferenced value to be incremented. However, the pointer `p` is incremented before the dereference.

- In the operation `(x == y | z)`, it is possible that you expect `x` to be compared with `y | z`. However, the == operation happens before the | operation.

**Fix**

See if the order of evaluation is what you intend. If not, apply parentheses to implement the evaluation order that you want.

For better readability of your code, it is good practice to apply parenthesis to implement an evaluation order even when operator precedence rules impose that order.

**Example - Expressions with Possibly Unintended Evaluation Order**

```
int test(int a, int b, int c) {
    return(a & b == c); //Noncompliant
}
```

In this example, the == operation happens first, followed by the & operation. If you intended the reverse order of operations, the result is not what you expect.

**Correction — Parenthesis For Intended Order**

One possible correction is to apply parenthesis to implement the intended evaluation order.

```
int test(int a, int b, int c) {
    return((a & b) == c);
}
```

Do not place a semicolon on the same line as an if, for, or while statement

## Description

### Rule Definition

*Do not place a semicolon on the same line as an if, for, or while statement.*

### Polyspace Implementation

The rule checker checks for **Semicolon on same line as if, for or while statement**.

## Examples

### Semicolon on same line as if, for or while statement

#### Issue

**Semicolon on same line as if, for or while statement** occurs when a semicolon on the same line as the last token of an `if`, `for` or `while` statement results in an empty body.

The checker makes an exception for the case where the `if` statement is immediately followed by an `else` statement:

```
if(condition);
else {
  //...
}
```

#### Risk

The semicolon following the `if`, `for` or `while` statement often indicates a programming error. The spurious semicolon changes the execution flow and leads to unintended results.

#### Fix

If you want an empty body for the `if`, `for` or `while` statement , wrap the semicolon in a block and place the block on a new line to explicitly indicate your intent:

```
if(condition)
   {;}
```

Otherwise, remove the spurious semicolon.

#### Example - Spurious Semicolon

```
int credentialsOK(void);

void login () {
    int loggedIn = 0;
    if(credentialsOK()); //Noncompliant
      loggedIn = 1;
}
```

In this example, the spurious semicolon results in an empty `if` body. The assignment `loggedIn=1` is always performed. However, the assignment was probably to be performed only under a condition.

#### Correction – Remove Spurious Semicolon

If the semicolon was unintended, remove the semicolon.

```
int credentialsOK(void);

void login () {
    int loggedIn = 0;
    if(credentialsOK())
      loggedIn = 1;
}
```

Use braces for the body of an if, for, or while statement

## Description

### Rule Definition

*Use braces for the body of an if, for, or while statement.*

### Polyspace Implementation

The rule checker checks for **Iteration or selection statement body not enclosed in braces**.

## Examples

### Iteration or selection statement body not enclosed in braces

#### Issue

The issue occurs when you do not enclose the body of an iteration-statement or a selection-statement in braces.

#### Risk

The rule applies to:

- Iteration statements such as `while`, `do ... while` or `for`.
- Selection statements such as `if ... else` or `switch`.

If the block of code associated with an iteration or selection statement is not contained in braces, you can make mistakes about the association. For example:

- You can wrongly associate a line of code with an iteration or selection statement because of its indentation.
- You can accidentally place a semicolon following the iteration or selection statement. Because of the semicolon, the line following the statement is no longer associated with the statement even though you intended otherwise.

#### Example - Iteration Block

```
int data_available = 1;
void f1(void) {
    while(data_available)                /* Non-compliant */
        process_data();

    while(data_available) {              /* Compliant */
        process_data();
    }
}
```

In this example, the second `while` block is enclosed in braces and does not violate the rule.

**Example - Nested Selection Statements**

```
#include <stdbool.h>

bool flag_1, flag_2;

void f1(void) {
    if(flag_1)                          /* Non-compliant */
        if(flag_2)                      /* Non-compliant */
            action_1();
    else                                /* Non-compliant */
            action_2();
}
```

In this example, the rule is violated because the `if` or `else` blocks are not enclosed in braces. Unless indented as above, it is easy to associate the `else` statement with the inner `if`.

**Correction — Place Selection Statement Block in Braces**

One possible correction is to enclose each block associated with an `if` or `else` statement in braces.

```
#include <stdbool.h>

bool flag_1, flag_2;

void f1(void) {
    if(flag_1) {                        /* Compliant */
        if(flag_2) {                      /* Compliant */
            action_1();
        }
    }
    else {                              /* Compliant */
        action_2();
    }
}
```

**Example - Spurious Semicolon After Iteration Statement**

```
#include <stdbool.h>

bool flag_1;

void f1(void) {
    while(flag_1);                      /* Non-compliant */
    {
        flag_1 = action_1();
    }
}
```

In this example, the rule is violated even though the `while` statement is followed by a block in braces. The semicolon following the `while` statement causes the block to dissociated from the `while` statement.

The rule helps detect such spurious semicolons.

Understand the data model used by your implementation(s)

## Description

### Rule Definition

*Understand the data model used by your implementation(s).*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of basic types declarations and definitions of variables or functions**.
- **Integer overflow**.
- **Integer constant overflow**.
- **Format string specifiers and arguments mismatch**.

### Extend Checker

A default Bug Finder analysis might not detect **Integer constant overflow** and **Integer constant overflow** when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Use of basic types declarations and definitions of variables or functions

#### Issue

The issue occurs when you use basic numerical types instead of `typedefs` that indicate size and signedness.

The rule checker flags use of basic data types in variable or function declarations and definitions. The rule enforces use of `typedefs` instead.

The rule checker does not flag the use of basic types in the `typedef` statements themselves.

#### Risk

When the amount of memory being allocated is important, using specific-length types makes it clear how much storage is being reserved for each object.

#### Example - Direct Use of Basic Types in Definitions

```
typedef unsigned int uint32_t;

int x = 0;       /* Non compliant */
uint32_t y = 0;  /* Compliant */
```

In this example, the declaration of `x` is noncompliant because it uses a basic type directly.

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>
typedef int int32;
int32 plusplus(void) {

    int32 var = INT_MAX;
    var++;   //Noncompliant           //Noncompliant
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>
typedef int int32;
typedef long long llint;
llint plusplus(void) {

    llint var = INT_MAX;
    var++;   //Compliant
    return var;
}
```

### Integer constant overflow

#### Issue

**Integer constant overflow** occurs when you assign a compile-time constant to a signed integer variable whose data type cannot accommodate the value. An `n`-bit signed integer holds values in the range $[-2^{n-1}, 2^{n-1}-1]$.

For instance, `c` is an 8-bit signed `char` variable that cannot hold the value 255.

```
signed char c = 255;
```

To determine the sizes of fundamental types, Bug Finder uses your specification for `Target processor type (-target)`.

#### Risk

The default behavior for constant overflows can vary between compilers and platforms. Retaining constant overflows can reduce the portability of your code.

Even if your compilers wraps around overflowing constants with a warning, the wrap-around behavior can be unintended and cause unexpected results.

#### Fix

Check if the constant value is what you intended. If the value is correct, use a different, possibly wider, data type for the variable.

#### Example - Overflowing Constant from Macro Expansion

```
#define MAX_UNSIGNED_CHAR 255  //Noncompliant
#define MAX_SIGNED_CHAR 127 //Noncompliant

void main() {
    char c1 = MAX_UNSIGNED_CHAR;
    char c2 = MAX_SIGNED_CHAR+1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow. To reproduce these defects, use a `Target processor type (-target)` where `char` is signed by default.

#### Correction — Use Different Data Type

One possible correction is to use a different data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127
typedef unsigned char uchar;
void main() {
    uchar c1 = MAX_UNSIGNED_CHAR;
    uchar c2 = MAX_SIGNED_CHAR+1;
}
```

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
  const char *message = "License not available";
  int err_number = ;-4
  printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>
typedef unsigned long UL;
void string_format(void) {

    UL fst = 1;
    printf("%d\n", fst); //Noncompliant //Noncompliant
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>
typedef unsigned long UL;
typedef int int32;
void string_format(void) {

    UL fst = 1;

    printf("%lu\n", fst); //Compliant
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>
typedef unsigned long UL;
typedef int int32;
void string_format(void) {

    UL fst = 1;

    printf("%d\n", (int32)fst); //Compliant
}
```

Understand integer conversion rules

## Description

### Rule Definition

*Understand integer conversion rules.*

### Polyspace Implementation

The rule checker checks for **Sign change integer conversion overflow**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Sign change integer conversion overflow

#### Issue

**Sign change integer conversion overflow** occurs when converting an unsigned integer to a signed integer. If the variable does not have enough bytes to represent both the original constant and the sign bit, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Convert from `unsigned char` to `char`

```
char sign_change(void) {
    unsigned char count = 255;

    return (char)count; //Noncompliant
}
```

In the return statement, the unsigned character variable `count` is converted to a signed character. However, `char` has 8 bits, 1 for the sign of the constant and 7 to represent the number. The conversion operation overflows because 255 uses 8 bits.

#### Correction — Change conversion types

One possible correction is using a larger integer type. By using an `int`, there are enough bits to represent the sign and the number value.

```
int sign_change(void) {
    unsigned char count = 255;

    return (int)count;
}
```

Enforce limits on integer values originating from tainted sources

## Description

### Rule Definition

*Enforce limits on integer values originating from tainted sources.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access with tainted index**.
- **Loop bounded with tainted value**.
- **Memory allocation with tainted size**.
- **Tainted size of variable length array**.

### Extend Checker

A default Bug Finder analysis might not flag this checker for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

#### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

#### Example - Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];   //Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The index `num` is obtained from an unsecure source and the function `taintedarrayindex` does not check to see if `num` is inside the range of `tab`.

#### Correction — Check Range Before Use

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

### Loop bounded with tainted value

#### Issue

**Loop bounded with tainted value** detects loops that are bounded by values from an unsecure source.

#### Risk

A tainted value can cause over looping or infinite loops. Attackers can use this vulnerability to crash your program or cause other unintended behavior.

#### Fix

Before starting the loop, validate unknown boundary and iterator values.

#### Example - Loop Boundary From Input Argument

```
#include<stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    for (int i=0 ; i < count; ++i) { //Noncompliant
        res += i;
    }
    return res;
}
```

In this example, the function uses the input argument to loop `count` times. `count` could be any number because the value is not checked before starting the `for` loop.

#### Correction: Clamp Tainted Loop Control

One possible correction is to clamp the tainted loop control. To validate the tainted loop variable `count`, this example limits `count` to a minimum value and a maximum value by using inline functions `min` and `max`. Regardless of the user input, the value of `count` remains within a known range.

```
#include<stdio.h>
#include<algorithm>
#define MIN 50
#define MAX 128
static  inline int max(int a, int b) { return a > b ? a : b;}
static inline int min(int a, int b) { return a < b ? a : b; }

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    count = max(MIN, min(count, MAX));
    for (int i=0 ; i<count ; ++i) {
        res += i;
    }
    return res;
}
```

#### Correction — Check Tainted Loop Control

Another possible correction is to check the low bound and the high bound of the tainted loop boundary variable before starting the `for` loop. This example checks the low and high bounds of `count` and executes the loop only when `count` is between 0 and 127.

```
#include<stdio.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;

    if (count>=0 && count<SIZE128) {
        for (int i=0 ; i<count ; ++i) {
            res += i;
        }
    }
    return res;
}
```

### Memory allocation with tainted size

#### Issue

**Memory allocation with tainted size** checks memory allocation functions, such as `calloc` or `malloc`, for size arguments from unsecured sources.

#### Risk

Uncontrolled memory allocation can cause your program to request too much system memory. This consequence can lead to a crash due to an out-of-memory condition, or assigning too many resources.

#### Fix

Before allocating memory, check the value of your arguments to check that they do not exceed the bounds.

#### Example - Allocate Memory Using Input From User

```
#include<stdio.h>
#include <stdlib.h>

int* bug_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = (int*)malloc(size); //Noncompliant
    return p;
}
```

In this example, `malloc` allocates `size` bytes of memory for the pointer `p`. The variable `size` comes from the user of the program. Its value is not checked, and it could be larger than the amount of available memory. If `size` is larger than the number of available bytes, your program could crash.

#### Correction — Check Size of Memory to be Allocated

One possible correction is to check the size of the memory that you want to allocate before performing the `malloc` operation. This example checks to see if `size` is positive and less than the maximum size.

```
#include<stdio.h>
#include <stdlib.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int* corrected_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = NULL;
    if (size>0 && size<SIZE128) {          /* Fix: Check entry range before use */
        p = (int*)malloc((unsigned int)size);
    }
    return p;
}
```

### Tainted size of variable length array

#### Issue

**Tainted size of variable length array** detects variable length arrays (VLA) whose size is from an unsecure source.

#### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

#### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

#### Example - Input Argument Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
#define LIM 40

long squaredSum(int size) {

    int tabvla[size]; //Noncompliant
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

#### Correction — Check VLA Size

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 0 and less than 40, before creating the VLA

```
#include <stdio.h>
#include <stdlib.h>
#define LIM 40

long squaredSum(int size) {
    long res = 0;
    if (size>0 && size<LIM){
        int tabvla[size];
        for (int i=0 ; i<size || i<LIM-1 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }else{
        res = -1;
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

Use only explicitly signed or unsigned char type for numeric values

## Description

### Rule Definition

*Use only explicitly signed or unsigned char type for numeric values.*

### Polyspace Implementation

The rule checker checks for **Use of plain char type for numerical value**.

## Examples

### Use of plain char type for numerical value

#### Issue

**Use of plain char type for numerical value** detects `char` variables without explicit signedness that are being used in these ways:

- To store non-char constants
- In an arithmetic operation when the `char` is:
  - A negative value.
  - The result of a sign changing overflow.
- As a buffer offset.

`char` variables without a `signed` or `unsigned` qualifier can be either signed or unsigned depending on your compiler.

#### Risk

Operations on a plain char can result in unexpected numerical values. If the char is used as an offset, the char can cause buffer overflow or underflow.

#### Fix

When initializing a char variable, to avoid implementation-defined confusion, explicitly state whether the char is signed or unsigned.

#### Example - Divide by `char` Variable

```
#include <stdio.h>

void badplaincharuse(void)
{
    char c = 200;
    int i = 1000;
    (void)printf("i/c = %d\n", i/c); //Noncompliant
}
```

In this example, the char variable `c` can be signed or unsigned depending on your compiler. Assuming 8-bit, two's complement character types, the result is either `i/c = 5` (unsigned char) or `i/c = -17` (signed char). The correct result is unknown without knowing the signedness of `char`.

#### Correction — Add `signed` Qualifier

One possible correction is to add a `signed` qualifier to `char`. This clarification makes the operation defined.

```
#include <stdio.h>

void badplaincharuse(void)
{
    signed char c = -56;
    int i = 1000;
    (void)printf("i/c = %d\n", i/c);
}
```

Verify that all integer values are in range

## Description

### Rule Definition

*Verify that all integer values are in range.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer overflow**.
- **Integer constant overflow**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.

- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++;             //Noncompliant
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

### Integer constant overflow

#### Issue

**Integer constant overflow** occurs when you assign a compile-time constant to a signed integer variable whose data type cannot accommodate the value. An `n`-bit signed integer holds values in the range $[-2^{n-1}, 2^{n-1}-1]$.

For instance, `c` is an 8-bit signed `char` variable that cannot hold the value 255.

```
signed char c = 255;
```

To determine the sizes of fundamental types, Bug Finder uses your specification for `Target processor type (-target)`.

#### Risk

The default behavior for constant overflows can vary between compilers and platforms. Retaining constant overflows can reduce the portability of your code.

Even if your compilers wraps around overflowing constants with a warning, the wrap-around behavior can be unintended and cause unexpected results.

#### Fix

Check if the constant value is what you intended. If the value is correct, use a different, possibly wider, data type for the variable.

#### Example - Overflowing Constant from Macro Expansion

```
#define MAX_UNSIGNED_CHAR 255  //Noncompliant
#define MAX_SIGNED_CHAR 127 //Noncompliant

void main() {
    char c1 = MAX_UNSIGNED_CHAR;
    char c2 = MAX_SIGNED_CHAR+1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow. To reproduce these defects, use a `Target processor type (-target)` where `char` is signed by default.

#### Correction — Use Different Data Type

One possible correction is to use a different data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR;
    unsigned char c2 = MAX_SIGNED_CHAR+1;
}
```

## Check Information

Ensure enumeration constants map to unique values

## Description

### Rule Definition

*Ensure enumeration constants map to unique values.*

### Polyspace Implementation

The rule checker checks for **Enumeration constants map to same value**.

## Examples

### Enumeration constants map to same value

#### Issue

The issue occurs when, within an enumerator list, the value of an implicitly-specified enumeration constants are not unique.

The rule checker flags an enumeration if it has an implicitly specified enumeration constant with the same value as another enumeration constant.

#### Risk

An implicitly specified enumeration constant has a value one greater than its predecessor. If the first enumeration constant is implicitly specified, then its value is 0. An explicitly specified enumeration constant has the specified value.

If implicitly and explicitly specified constants are mixed within an enumeration list, it is possible for your program to replicate values. Such replications can be unintentional and can cause unexpected behavior.

#### Example - Replication of Value in Implicitly Specified Enum Constants

```
enum color1 {red_1, blue_1, green_1};   /* Compliant */
enum color2 {red_2 = 1, blue_2 = 2, green_2 = 3};       /* Compliant */
enum color3 {red_3 = 1, blue_3, green_3};     /* Compliant */
enum color4 {red_4, blue_4, green_4 = 1};     /* Non Compliant */
enum color5 {red_5 = 2, blue_5, green_5 = 2};     /* Compliant */
enum color6 {red_6 = 2, blue_6, green_6 = 2, yellow_6};     /* Non Compliant */
```

Compliant situations:

- `color1`: All constants are implicitly specified.
- `color2`: All constants are explicitly specified.
- `color3`: Though there is a mix of implicit and explicit specification, all constants have unique values.
- `color5`: The implicitly specified constants have unique values.

Noncompliant situations:

- `color4`: The implicitly specified constant `blue_4` has the same value as `green_4`.
- `color6`: The implicitly specified constant `blue_6` has the same value as `yellow_6`.

Do not assume a positive remainder when using the % operator

## Description

### Rule Definition

*Do not assume a positive remainder when using the % operator.*

### Polyspace Implementation

The rule checker checks for **Tainted modulo operand**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted modulo operand** issue for certain inputs that originate outside of the current analysis boundary. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted modulo operand

#### Issue

**Tainted modulo operand** checks the operands of remainder `%` operations. Bug Finder flags modulo operations with one or more tainted operands.

#### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is `-1`, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

#### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of `0` and `-1`. Check both operands for negative values.

#### Example — Modulo with User Input

```
#include <stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem =  128%userden;  //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using a user input. The input is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

**Correction — Check Operand Values**

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem = 0;
    if (userden > 0 ) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

Do not make assumptions about the type of a plain int bit-field when used in an expression

## Description

### Rule Definition

*Do not make assumptions about the type of a plain int bit-field when used in an expression.*

### Polyspace Implementation

The rule checker checks for **Bit-field declared without appropriate type**.

## Examples

### Bit-field declared without appropriate type

#### Issue

The issue occurs when you declare a bit-filed without an appropriate type.

#### Risk

Using `int` is implementation-defined because bit-fields of type `int` can be either `signed` or `unsigned`.

The use of `enum`, `short char`, or any other type of bit-field is not permitted in C90 because the behavior is undefined.

In C99, the implementation can potentially define other integer types that are permitted in bit-field declarations.

Use bitwise operators only on unsigned operands

## Description

### Rule Definition

*Use bitwise operators only on unsigned operands.*

### Polyspace Implementation

The rule checker checks for **Bitwise operation on negative value**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Bitwise operation on negative value

**Issue**

**Bitwise operation on negative value** detects bitwise operators (>>, ^, `|`, ~, `but`, `not`, &) used on signed integer variables with negative values.

**Risk**

If the value of the signed integer is negative, bitwise operation results can be unexpected because:

- Bitwise operations on negative values are compiler-specific.
- Unexpected calculations can lead to additional vulnerabilities, such as buffer overflow.

**Fix**

When performing bitwise operations, use `unsigned` integers to avoid unexpected results.

**Example - Right-Shift of Negative Integer**

```
#include <stdio.h>
#include <stdarg.h>

static void demo_sprintf(const char *format, ...)
{
    int rc;
    va_list ap;
    char buf[sizeof("256")];

    va_start(ap, format);
    rc = vsprintf(buf, format, ap);
    if (rc == -1 || rc >= sizeof(buf)) {
        /* Handle error */
    }
    va_end(ap);
}

void bug_bitwiseneg()
{
    int stringify = 0x80000000;
    demo_sprintf("%u", stringify >> 24); //Noncompliant
}
```

In this example, the statement `demo_sprintf("%u", stringify >> 24)` stops the program unexpectedly. You expect the result of `stringify >> 24` to be `0x80`. However, the actual result is `0xffffff80` because `stringify` is signed and negative. The sign bit is also shifted.

#### Correction — Add `unsigned` Keyword

By adding the `unsigned` keyword, `stringify` is not negative and the right-shift operation gives the expected result of `0x80`.

```
#include <stdio.h>
#include <stdarg.h>

static void demo_sprintf(const char *format, ...)
{
    int rc;
    va_list ap;
    char buf[sizeof("256")];

    va_start(ap, format);
    rc = vsprintf(buf, format, ap);
    if (rc == -1 || rc >= sizeof(buf)) {
        /* Handle error */
    }
    va_end(ap);
}

void corrected_bitwiseneg()
{
    unsigned int stringify = 0x80000000;
    demo_sprintf("%u", stringify >> 24);
}
```

Avoid performing bitwise and arithmetic operations on the same data

## Description

### Rule Definition

*Avoid performing bitwise and arithmetic operations on the same data.*

### Polyspace Implementation

The rule checker checks for **Bitwise and arithmetic operation on the same data**.

## Examples

### Bitwise and arithmetic operation on the same data

#### Issue

**Bitwise and arithmetic operation on a same data** detects statements with bitwise and arithmetic operations on the same variable or expression.

#### Risk

Mixed bitwise and arithmetic operations *do* compile. However, the size of integer types affects the result of these mixed operations. Mixed operations also reduce readability and maintainability.

#### Fix

Separate bitwise and arithmetic operations, or use only one type of operation per statement.

#### Example - Shift and Addition

```
unsigned int bitwisearithmix()
{
    unsigned int var = 50;
    var += (var << 2) + 1; //Noncompliant
    return var;
}
```

This example shows bitwise and arithmetic operations on the variable `var`. `var` is shifted by two (bitwise), then increased by 1 and added to itself (arithmetic).

#### Correction — Arithmetic Operations Only

You can reduce this expression to arithmetic-only operations: `var + (var << 2)` is equivalent to `var * 5`.

```
unsigned int bitwisearithmix()
{
    unsigned int var = 50;
    var = var * 5 +1;
    return var;
}
```

Evaluate integer expressions in a larger size before comparing or assigning to that size

## Description

### Rule Definition

*Evaluate integer expressions in a larger size before comparing or assigning to that size.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer overflow**.
- **Unsigned integer overflow**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.

- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++;              //Noncompliant
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

### Unsigned integer overflow

#### Issue

**Unsigned integer overflow** occurs when an operation on unsigned integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

**Risk**

The C11 standard states that unsigned integer overflows result in wrap-around behavior. However, a wrap around behavior might not always be desirable. For instance, if the result of a computation is used as an array size and the computation overflows, the array size is much smaller than expected.

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling. In the error handling code, you can override the default wrap-around behavior for overflows and implement saturation behavior, for instance.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Add One to Maximum Unsigned Integer**

```
#include <limits.h>

unsigned int plusplus(void) {

    unsigned uvar = UINT_MAX;
    uvar++; //Noncompliant
    return uvar;
}
```

In the third statement of this function, the variable `uvar` is increased by 1. However, the value of `uvar` is the maximum unsigned integer value, so 1 plus the maximum integer value cannot be represented by an `unsigned int`. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `uvar` is reduced by modulo `UINT_MAX`. The result is `uvar = 1`.

**Correction — Different Storage Type**

One possible correction is to store the operation result in a larger data type. In this example, by returning an `unsigned long long` instead of an `unsigned int`, the overflow error is fixed.

```
#include <limits.h>
```

```
unsigned long long plusplus(void) {

    unsigned long long ullvar = UINT_MAX;
    ullvar++;
    return ullvar;
}
```

Understand the limitations of floating-point numbers

## Description

### Rule Definition

*Understand the limitations of floating-point numbers.*

### Polyspace Implementation

The rule checker checks for **Absorption of float operand**.

## Examples

### Absorption of float operand

#### Issue

**Absorption of float operand** occurs when one operand of an addition or subtraction operation is *always* negligibly small compared to the other operand. Therefore, the result of the operation is always equal to the value of the larger operand, making the operation redundant.

#### Risk

Redundant operations waste execution cycles of your processor.

The absorption of a float operand can indicate design issues elsewhere in the code. It is possible that the developer expected a different range for one of the operands and did not expect the redundancy of the operation. However, the operand range is different from what the developer expects because of issues elsewhere in the code.

#### Fix

See if the operand ranges are what you expect. To see the ranges, place your cursor on the operation.

- If the ranges are what you expect, justify why you have the redundant operation in place. For instance, the code is only partially written and you anticipate other values for one or both of the operands from future unwritten code.

  If you cannot justify the redundant operation, remove it.
- If the ranges are not what you expect, in your code, trace back to see where the ranges come from. To begin your traceback, search for instances of the operand in your code. Browse through previous instances of the operand and determine where the unexpected range originates.

To determine when one operand is negligible compared to the other operand, the defect uses rules based on IEEE 754 standards. To fix the defect, instead of using the actual rules, you can use this heuristic: the ratio of the larger to the smaller operand must be less than $2^{p-1}$ at least for some values. Here, `p` is equal to 24 for 32-bit precision and 53 for 64-bit precision. To determine the precision, the defect uses your specification for `Target processor type (-target)`.

### Example - One Addition Operand Negligibly Smaller Than The Other Operand

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);

float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-30)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

float input_signal2(void) {
    float temp = get_signal();
    if(temp > 1.)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    float signal2 = input_signal2();
    float super_signal = signal1 + signal2; //Noncompliant
    do_operation(super_signal);
}
```

In this example, the defect appears on the addition because the operand `signal1` is in the range `(0,1e-30)` but `signal2` is greater than `1`.

### Correction — Remove Redundant Operation

One possible correction is to remove the redundant addition operation. In the following corrected code, the operand `signal2` and its associated code is also removed from consideration.

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);

float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-30)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    do_operation(signal1);
}
```

#### Correction — Verify Operand Range

Another possible correction is to see if the operand ranges are what you expect. For instance, if one of the operand range is not supposed to be negligibly small, fix the issue causing the small range. In the following corrected code, the range `(0,1e-2)` is imposed on `signal2` so that it is not *always* negligibly small as compared to `signal1`.

```
#include <stdlib.h>

float get_signal(void);
void do_operation(float);

float input_signal1(void) {
    float temp = get_signal();
    if(temp > 0. && temp < 1e-2)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

float input_signal2(void) {
    float temp = get_signal();
    if(temp > 1.)
        return temp;
    else {
       /* Reject value */
       exit(EXIT_FAILURE);
    }
}

void main() {
    float signal1 = input_signal1();
    float signal2 = input_signal2();
    float super_signal = signal1 + signal2;
    do_operation(super_signal);
}
```

Avoid using floating-point numbers when precise computation is needed

## Description

### Rule Definition

*Avoid using floating-point numbers when precise computation is needed.*

### Polyspace Implementation

The rule checker checks for **Floating point comparison with equality operators**.

## Examples

### Floating point comparison with equality operators

#### Issue

**Floating point comparison with equality operators** occurs when you use an equality (==) or inequality (!=) operation with floating-point numbers.

Polyspace does not raise a defect for an equality or inequality operation with floating-point numbers when:

- The comparison is between two float constants.

  ```
      float flt = 1.0;
      if (flt == 1.1)
  ```
- The comparison is between a constant and a variable that can take a finite, reasonably small number of values.

  ```
  float x;

  int rand = random();
  switch(rand) {
  case 1: x = 0.0; break;
  case 2: x = 1.3; break;
  case 3: x = 1.7; break;
  case 4: x = 2.0; break;
  default: x = 3.5; break; }
  //…
  if (x==1.3)
  ```
- The comparison is between floating-point expressions that contain only integer values.

  ```
  float x = 0.0;
  for (x=0.0;x!=100.0;x+=1.0) {
  //…
  if (random) break;
  }

  if (3*x+4==2*x-1)
  ```

```
//…
if (3*x+4 == 1.3)
```

- One of the operands is `0.0`, unless you use the option flag `-detect-bad-float-op-on-zero`.

  ```
  /* Defect detected when
  you use the option flag */

  if (x==0.0f)
  ```

  If you are running an analysis through the user interface, you can enter this option in the **Other** field, under the **Advanced Settings** node on the **Configuration** pane. See `Other`.

  At the command line, add the flag to your analysis command.

  ```
  polyspace-bug-finder -sources filename ^
  -checkers BAD_FLOAT_OP -detect-bad-float-op-on-zero
  ```

#### Risk

Checking for equality or inequality of two floating-point values might return unexpected results because floating-point representations are inexact and involve rounding errors.

#### Fix

Instead of checking for equality of floating-point values:

```
if (val1 == val2)
```

check if their difference is less than a predefined tolerance value (for instance, the value `FLT_EPSILON` defined in `float.h`):

```
#include <float.h>
if(fabs(val1-val2) < FLT_EPSILON)
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Floats Inequality in `for`-loop

```
#include <stdio.h>
#include <math.h>
#include <float.h>

void func(void)
{
    float f;
    for (f = 1.0; f != 2.0; f = f + 0.1)     //Noncompliant
        (void)printf("Value: %f\n", f);
}
```

In this function, the `for`-loop tests the inequality of `f` and the number 2.0 as a stopping mechanism. The number of iterations is difficult to determine, or might be infinite, because of the imprecision in floating-point representation.

#### Correction — Change the Operator

One possible correction is to use a different operator that is not as strict. For example, an inequality like >= or <=.

```
#include <stdio.h>
#include <math.h>
#include <float.h>

void func(void)
{
    float f;
    for (f = 1.0; f <= 2.0; f = f + 0.1)
        (void)printf("Value: %f\n", f);
}
```

Detect and handle floating-point errors

## Description

### Rule Definition

*Detect and handle floating-point errors.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Float conversion overflow**.
- **Float overflow**.
- **Float division by zero**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Float conversion overflow

#### Issue

**Float conversion overflow** occurs when converting a floating point number to a smaller floating point data type. If the variable does not have enough memory to represent the original number, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing conversion in subsequent computations and do not account for the overflow, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being converted acquires its current value You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller floating point types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

#### Example - Converting from double to float

```
float convert(void) {

    double diam = 1e100;
    return (float)diam; //Noncompliant
}
```

In the return statement, the variable `diam` of type double (64 bits) is converted to a variable of type float (32 bits). However, the value 1^100 requires more than 32 bits to be precisely represented.

### Float overflow

#### Issue

**Float overflow** occurs when an operation on floating point variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing computation in subsequent computations and do not account for the overflow, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

#### Example - Multiplication of Floats

```
#include <float.h>

float square(void) {

   float val = FLT_MAX;
   return val * val;   //Noncompliant
}
```

In the return statement, the variable `val` is multiplied by itself. The square of the maximum float value cannot be represented by a float (the return type for this function) because the value of `val` is the maximum float value.

#### Correction — Different Storage Type

One possible correction is to store the result of the operation in a larger data type. In this example, by returning a `double` instead of a `float`, the overflow defect is fixed.

```
#include <float.h>

double square(void) {
    float val = FLT_MAX;

    return (double)val * (double)val;
}
```

### Float division by zero

#### Issue

**Float division by zero** occurs when the denominator of a division operation can be a zero-valued floating point number.

#### Risk

A division by zero can result in a program crash.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the denominator variable acquires a zero value. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaN`s. Operations that results in infinities and `NaN`s might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

#### Example - Dividing a Floating Point Number by Zero

```
float fraction(float num)
{
    float denom = 0.0;
    float result = 0.0;

    result = num/denom; //Noncompliant

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
float fraction(float num)
{
    float denom = 0.0;
    float result = 0.0;

    if( ((int)denom) != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If denom is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that denom is not zero.

```
float fraction(float num)
{
    float denom = 2.0;
    float result = 0.0;

    result = num/denom;

    return result;
}
```

Convert integers to floating point for floating-point operations

## Description

### Rule Definition

*Convert integers to floating point for floating-point operations.*

### Polyspace Implementation

The rule checker checks for **Float overflow**.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Float overflow

#### Issue

**Float overflow** occurs when an operation on floating point variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing computation in subsequent computations and do not account for the overflow, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and NaNs. Operations that results in infinities and NaNs might be flagged as defects. To handle infinities and NaN values in your code, use the option Consider non finite floats (-allow-non-finite-floats).

#### Example - Multiplication of Floats

```
#include <float.h>

float square(void) {

   float val = FLT_MAX;
   return val * val;   //Noncompliant
}
```

In the return statement, the variable val is multiplied by itself. The square of the maximum float value cannot be represented by a float (the return type for this function) because the value of val is the maximum float value.

#### Correction — Different Storage Type

One possible correction is to store the result of the operation in a larger data type. In this example, by returning a double instead of a float, the overflow defect is fixed.

```
#include <float.h>

double square(void) {
    float val = FLT_MAX;

    return (double)val * (double)val;
}
```

Do not apply the sizeof operator to a pointer when taking the size of an array

## Description

### Rule Definition

*Do not apply the sizeof operator to a pointer when taking the size of an array.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Wrong type used in sizeof**.
- **Possible misuse of sizeof**.

## Examples

### Wrong type used in sizeof

#### Issue

**Wrong type used in sizeof** occurs when both of the following conditions hold:

- You assign the address of a block of memory to a pointer, or transfer data between two blocks of memory. The assignment or copy uses the `sizeof` operator.

  For instance, you initialize a pointer using `malloc(sizeof(`*`type`*`))` or copy data between two addresses using `memcpy(`*`destination_ptr`*`, `*`source_ptr`*`, sizeof(`*`type`*`))`.
- You use an incorrect type as argument of the `sizeof` operator. You use the pointer type instead of the type that the pointer points to.

  For instance, to initialize a *`type`*`*` pointer, you use `malloc(sizeof(`*`type`*`*))` instead of `malloc(sizeof(`*`type`*`))`.

#### Risk

Irrespective of what *`type`* stands for, the expression `sizeof(`*`type`*`*)` always returns a fixed size. The size returned is the pointer size on your platform in bytes. The appearance of `sizeof(`*`type`*`*)` often indicates an unintended usage. The error can cause allocation of a memory block that is much smaller than what you need and lead to weaknesses such as buffer overflows.

For instance, assume that `structType` is a structure with ten `int` variables. If you initialize a `structType*` pointer using `malloc(sizeof(structType*))` on a 32-bit platform, the pointer is assigned a memory block of four bytes. However, to be allocated completely for one `structType` variable, the `structType*` pointer must point to a memory block of `sizeof(structType) = 10 * sizeof(int)` bytes. The required size is much greater than the actual allocated size of four bytes.

#### Fix

To initialize a *`type`*`*` pointer, replace `sizeof(`*`type`*`*)` in your pointer initialization expression with `sizeof(`*`type`*`)`.

#### Example - Allocate a Char Array With sizeof

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char*) * 5); //Noncompliant
    free(str);

}
```

In this example, memory is allocated for the character pointer `str` using a `malloc` of five char pointers. However, `str` is a pointer to a character, not a pointer to a character pointer. Therefore the `sizeof` argument, `char*`, is incorrect.

#### Correction — Match Pointer Type to sizeof Argument

One possible correction is to match the argument to the pointer type. In this example, `str` is a character pointer, therefore the argument must also be a character.

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char) * 5);
    free(str);

}
```

### Possible misuse of sizeof

#### Issue

**Possible misuse of sizeof** occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

#### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

**Fix**

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

  The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.
- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

**Example - `sizeof` Used Incorrectly to Determine Array Size**

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++)    { //Noncompliant
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

**Correction — Determine Array Size in Another Way**

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

Explicitly specify array bounds, even if implicitly defined by an initializer

## Description

### Rule Definition

*Explicitly specify array bounds, even if implicitly defined by an initializer.*

### Polyspace Implementation

The rule checker checks for the issue **Improper array initialization**.

## Examples

### Improper array initialization

#### Issue

**Improper array initialization** occurs when Polyspace Bug Finder considers that an array initialization using initializers is incorrect.

This defect applies to normal and designated initializers. In C99, with designated initializers, you can place the elements of an array initializer in any order and implicitly initialize some array elements. The designated initializers use the array index to establish correspondence between an array element and an array initializer element. For instance, the statement `int arr[6] = { [4] = 29, [2] = 15 }` is equivalent to `int arr[6] = { 0, 0, 15, 0, 29, 0 }`.

You can use initializers incorrectly in one of the following ways.

| Issue | Risk | Possible Fix |
|---|---|---|
| In your initializer for a one-dimensional array, you have more elements than the array size. | Unused array initializer elements indicate a possible coding error. | Increase the array size or remove excess elements. |
| You place the braces enclosing initializer values incorrectly. | Because of the incorrect placement of braces, some array initializer elements are not used.<br>Unused array initializer elements indicate a possible coding error. | Place braces correctly. |
| In your designated initializer, you do not initialize the first element of the array explicitly. | The implicit initialization of the first array element indicates a possible coding error. You possibly overlooked the fact that array indexing starts from 0. | Initialize all elements explicitly. |

| Issue | Risk | Possible Fix |
|---|---|---|
| In your designated initializer, you initialize an element twice. | The first initialization is overridden.<br>The redundant first initialization indicates a possible coding error. | Remove the redundant initialization. |
| You use designated and nondesignated initializers in the same initialization. | You or another reviewer of your code cannot determine the size of the array by inspection. | Use either designated or nondesignated initializers. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Incorrectly Placed Braces (C Only)

```
int arr[2][3]
= {{1, 2},
    {3, 4},
    {5, 6} //Noncompliant
};
```

In this example, the array `arr` is initialized as `{1,2,0,3,4,0}`. Because the initializer contains `{5,6}`, you might expect the array to be initialized `{1,2,3,4,5,6}`.

#### Correction — Place Braces Correctly

One possible correction is to place the braces correctly so that all elements are explicitly initialized.

```
int a1[2][3]
= {{1, 2, 3},
    {4, 5, 6}
};
```

#### Example - First Element Not Explicitly Initialized

```
int arr[5]
= {
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};               //Noncompliant
```

In this example, `arr[0]` is not explicitly initialized. It is possible that the programmer did not consider that the array indexing starts from 0.

#### Correction — Explicitly Initialize All Elements

One possible correction is to initialize all elements explicitly.

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};
```

#### Example - Element Initialized Twice

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [2] = 4, //Noncompliant
    [4] = 5
};
```

In this example, `arr[2]` is initialized twice. The first initialization is overridden. In this case, because `arr[3]` was not explicitly initialized, it is possible that the programmer intended to initialize `arr[3]` when `arr[2]` was initialized a second time.

#### Correction — Fix Redundant Initialization

One possible correction is to eliminate the redundant initialization.

```
int arr[5]
= {
    [0] = 1,
    [1] = 2,
    [2] = 3,
    [3] = 4,
    [4] = 5
};
```

#### Example - Mix of Designated and Nondesignated Initializers

```
int arr[]
= {
    [0] = 1,
    [3] = 3,
    4,
    [5] = 5,
    6
    };               //Noncompliant
```

In this example, because a mix of designated and nondesignated initializers are used, it is difficult to determine the size of `arr` by inspection.

#### Correction — Use Only Designated Initializers

One possible correction is to use only designated initializers for array initialization and to specify the size of the array explicitly.

```
int arr[7]
= {
    [0] = 1,
    [3] = 3,
    [4] = 4,
    [5] = 5,
    [6] = 6
};
```

Sanitize data passed to complex subsystems

## Description

### Rule Definition

*Sanitize data passed to complex subsystems.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Execution of externally controlled command**.
- **Command executed from externally controlled path**.
- **Library loaded from externally controlled path**.

### Extend Checker

A default Bug Finder analysis might not flag this checker for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Execution of externally controlled command

#### Issue

**Execution of externally controlled command** checks for commands that are fully or partially constructed from externally controlled input.

#### Risk

Attackers can use the externally controlled input as operating system commands, or arguments to the application. An attacker could read or modify sensitive data can be read or modified, execute unintended code, or gain access to other aspects of the program.

#### Fix

Validate the inputs to allow only intended input values. For example, create a list of acceptable inputs and compare the input against this list.

#### Example - Call External Command

```
#include "stdlib.h"
#include "stdio.h"
#include "string.h"
#include "unistd.h"
#include "dlfcn.h"
#include "limits.h"
#define MAX 128
```

```
void taintedexternalcmd(void)
{
    char* usercmd;
    fgets(usercmd,MAX,stdin);
    char cmd[MAX] = "/usr/bin/cat ";
    strcat(cmd, usercmd);
    system(cmd);  //Noncompliant
}
```

This example function calls a command from a user input without checking the command variable.

**Correction — Use a Predefined Command**

One possible correction is to use a `switch` statement to run a predefined command, using the user input as the switch variable.

```
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include "stdlib.h"
#include "stdio.h"
#include "string.h"
#include "unistd.h"
#include "dlfcn.h"
#include "limits.h"

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
enum { CMD0 = 1, CMD1, CMD2 };

void taintedexternalcmd(void)
{
    int usercmd = strtol(getenv("cmd"),NULL,10);
    char cmd[SIZE128] = "/usr/bin/cat ";

    switch(usercmd) {
        case CMD0:
            strcat(cmd, "*.c");
            break;
        case CMD1:
            strcat(cmd, "*.h");
            break;
        case CMD2:
            strcat(cmd, "*.cpp");
            break;
        default:
            strcat(cmd, "*.c");
    }
    system(cmd);
}
```

### Command executed from externally controlled path

#### Issue

**Command executed from externally controlled path** checks the path of commands that the application controls. If the path of a command is from or constructed from external sources, Bug Finder flags the command function.

#### Risk

An attacker can:

- Change the command that the program executes, possibly to a command that only the attack can control.
- Change the environment in which the command executes, by which the attacker controls what the command means and does.

#### Fix

Before calling the command, validate the path to make sure that it is the intended location.

#### Example - Executing Path from Environment Variable

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void bug_taintedpathcmd() {
    char cmd[SIZE128] = "";
    char* userpath = getenv("MYAPP_PATH");

    strncpy(cmd, userpath, SIZE100);
    strcat(cmd, "/ls *");
    /* Launching command */
    system(cmd);  //Noncompliant
}
```

This example obtains a path from an environment variable `MYAPP_PATH`. `system` runs a command from that path without checking the value of the path. If the path is not the intended path, your program executes in the wrong location.

#### Correction — Use Trusted Path

One possible correction is to use a list of allowed paths to match against the environment variable path.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

/* Function to sanitize a string */
int sanitize_str(char* s, size_t n) {
    int res = 0;
    /* String is ok if */
    if (s && n>0 && n<SIZE128) {
        /* - string is not null                     */
        /* - string has a positive and limited size */
        s[n-1] = '\0';  /* Add a security \0 char at end of string */
        /* Tainted pointer detected above, used as "firewall" */
        res = 1;
    }
    return res;
}

/* Authorized path ids */
enum { PATH0=1, PATH1, PATH2 };

void taintedpathcmd() {
    char cmd[SIZE128] = "";

    char* userpathid = getenv("MYAPP_PATH_ID");
    if (sanitize_str(userpathid, SIZE100)) {
        int pathid = atoi(userpathid);

        char path[SIZE128] = "";
        switch(pathid) {
            case PATH0:
                strcpy(path, "/usr/local/my_app0");
                break;
            case PATH1:
                strcpy(path, "/usr/local/my_app1");
                break;
            case PATH2:
                strcpy(path, "/usr/local/my_app2");
                break;
            default:
                /* do nothing */
        break;
        }
        if (strlen(path)>0) {
            strncpy(cmd, path, SIZE100);
            strcat(cmd, "/ls *");
            system(cmd);
        }
    }
}
```

### Library loaded from externally controlled path

#### Issue

**Library loaded from externally controlled path** looks for libraries loaded from fixed or controlled paths. If unintended actors can control one or more locations on this fixed path, Bug Finder raises a defect.

#### Risk

If an attacker knows or controls the path that you use to load a library, the attacker can change:

- The library that the program loads, replacing the intended library and commands.
- The environment in which the library executes, giving unintended permissions and capabilities to the attacker.

#### Fix

When possible, use hard-coded or fully qualified path names to load libraries. It is possible the hard-coded paths do not work on other systems. Use a centralized location for hard-coded paths, so that you can easily modify the path within the source code.

Another solution is to use functions that require explicit paths. For example, `system()` does not require a full path because it can use the `PATH` environment variable. However, `execl()` and `execv()` do require the full path.

#### Example - Call Custom Library

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void* taintedpathlib() {
    void* libhandle = NULL;
    char lib[SIZE128] = "";
    char* userpath = getenv("LD_LIBRARY_PATH");
    strncpy(lib, userpath, SIZE128);
    strcat(lib, "/libX.so");
    libhandle = dlopen(lib, 0x00001); //Noncompliant
    return libhandle;
}
```

This example loads the library `libX.so` from an environment variable `LD_LIBRARY_PATH`. An attacker can change the library path in this environment variable. The actual library you load could be a different library from the one that you intend.

#### Correction — Change and Check Path

One possible correction is to change how you get the library path and check the path of the library before opening the library. This example receives the path as an input argument. Then the path is checked to make sure the library is not under `/usr/`.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

/* Function to sanitize a string */
int sanitize_str(char* s, size_t n) {
    /* strlen is used here as a kind of firewall for tainted string errors */
    int res = (strlen(s) > 0 && strlen(s) < n);
    return res;
}
void* taintedpathlib(char* userpath) {
    void* libhandle = NULL;
    if (sanitize_str(userpath, SIZE128)) {
        char lib[SIZE128] = "";

        if (strncmp(userpath, "/usr", 4)!=0) {
            strncpy(lib, userpath, SIZE128);
            strcat(lib, "/libX.so");
            libhandle = dlopen(lib, RTLD_LAZY);
        }
    }
    return libhandle;
}
```

Do not inadvertently truncate a string

## Description

### Rule Definition

*Do not inadvertently truncate a string.*

### Polyspace Implementation

The rule checker checks for **Invalid use of standard library string routine**.

## Examples

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
#include <string.h>
#include <stdio.h>
```

```
 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);  //Noncompliant
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

**Correction — Use Valid Arguments**

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

Use the bounds-checking interfaces for string manipulation

## Description

### Rule Definition

*Use the bounds-checking interfaces for string manipulation.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of dangerous standard function**.
- **Destination buffer overflow in string manipulation**.
- **Insufficient destination buffer size**.

## Examples

### Use of dangerous standard function

#### Issue

This issue occurs when your code uses standard functions that write data to a buffer in a way that can result in buffer overflows.

The following table lists dangerous standard functions, the risks of using each function, and what function to use instead. The checker flags:

- Any use of an inherently dangerous function.
- An use of a possibly dangerous function only if the size of the buffer to which data is written can be determined at compile time. The checker does not flag an use of such a function with a dynamically allocated buffer.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `cin` | Inherently dangerous — You cannot control the length of input from the console. | Avoid or prefaces calls to `cin` with `cin.width`. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Using `sprintf`

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1) //Noncompliant
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

#### Correction — Use `snprintf` with Buffer Size

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string); //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Insufficient destination buffer size

#### Issue

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(input, str); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

**Risk**

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if `argv[0]` contains 100 or more characters, the `strcpy` operation results in a buffer overflow.

**Fix**

Before calling the function `strcpy()`, allocate sufficient memory dynamically. For instance, use the function `strlen()` to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value `strlen(source) + 1`.

**Example — Destination Buffer Too Small**

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[128];
  strcpy(source, destination);//Noncompliant

  return 0;
}
```

**Correction — Allocate Sufficient Memory for Destination Buffer**

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char* destination = (char *)malloc(strlen(source)+ 1);
  if(destination!=NULL){
      strcpy(source, destination);//Compliant
  }else{
      /*Handle Error*/
  }
  //...
  free(destination);
  return 0;
}
```

Do not specify the bound of a character array initialized with a string literal

## Description

### Rule Definition

*Do not specify the bound of a character array initialized with a string literal.*

### Polyspace Implementation

The rule checker checks for **Missing null in string array**.

## Examples

### Missing null in string array

#### Issue

**Missing null in string array** occurs when a string does not have enough space to terminate with a null character `'\0'`.

This defect applies only for projects in C.

#### Risk

A buffer overflow can occur if you copy a string to an array without assuming the implicit null terminator.

#### Fix

If you initialize a character array with a literal, avoid specifying the array bounds.

```
char three[]  = "THREE";
```

The compiler automatically allocates space for a null terminator. In the preceding example, the compiler allocates sufficient space for five characters and a null terminator.

If the issue occurs after initialization, you might have to increase the size of the array by one to account for the null terminator.

In certain circumstances, you might want to initialize the character array with a sequence of characters instead of a string. In this situation, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Array size is too small**

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[5] = "THREE"; //Noncompliant
}
```

The character array `three` has a size of 5 and 5 characters `'T'`, `'H'`, `'R'`, `'E'`, and `'E'`. There is no room for the null character at the end because `three` is only five bytes large.

**Correction — Increase Array Size**

One possible correction is to change the array size to allow for the five characters plus a null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[6] = "THREE";
}
```

**Correction — Change Initialization Method**

One possible correction is to initialize the string by leaving the array size blank. This initialization method allocates enough memory for the five characters and a terminating-null character.

```
void countdown(int i)
{
    static char one[5]   = "ONE";
    static char two[5]   = "TWO";
    static char three[]  = "THREE";
}
```

Allocate and free memory in the same module, at the same level of abstraction

## Description

### Rule Definition

*Allocate and free memory in the same module, at the same level of abstraction.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid free of pointer**.
- **Deallocation of previously deallocated pointer**.
- **Use of previously freed pointer**.

## Examples

### Invalid free of pointer

#### Issue

**Invalid free of pointer** occurs when a block of memory released using the `free` function was not previously allocated using `malloc`, `calloc`, or `realloc`.

#### Risk

The `free` function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `free` function or a previous `malloc` function on a different pointer.

#### Fix

In most cases, you can fix the issue by removing the `free` statement. If the pointer is not allocated memory from the heap with `malloc` or `calloc`, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of `free` or `malloc` on the wrong pointer, correct the error.

If the issue occurs because you use the `free` function to free memory allocated with the `new` operator, replace the `free` function with the `delete` operator.

#### Example - Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;

  free(p);    //Noncompliant
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer p is deallocated using the free function. However, p points to a memory location that was not dynamically allocated.

#### Correction — Remove Pointer Deallocation

If the number of elements of the array p is known at compile time, one possible correction is to remove the deallocation of the pointer p.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

#### Correction — Introduce Pointer Allocation

If the number of elements of the array p is not known at compile time, one possible correction is to dynamically allocate memory to the array p.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

### Deallocation of previously deallocated pointer

#### Issue

**Deallocation of previously deallocated pointer** occurs when a block of memory is freed more than once using the free function without an intermediate allocation.

#### Risk

When a pointer is allocated dynamic memory with malloc, calloc or realloc, it points to a memory location on the heap. When you use the free function on this pointer, the associated block of memory is freed for reallocation. Trying to free this block of memory can result in a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to allocate a memory block to the pointer between the first deallocation and the second. Otherwise, remove the second `free` statement.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before freeing pointers, check them for NULL values and handle the error. In this way, you are protected against freeing an already freed block.

#### Example - Deallocation of Previously Deallocated Pointer Error

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    free (pi);        //Noncompliant
    /* Defect: pi has already been freed */
}
```

The first `free` statement releases the block of memory that `pi` refers to. The second `free` statement on `pi` releases a block of memory that has been freed already.

#### Correction — Remove Duplicate Deallocation

One possible correction is to remove the second `free` statement.

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    /* Fix: remove second deallocation */
 }
```

### Use of previously freed pointer

#### Issue

**Use of previously freed pointer** occurs when you access a block of memory after freeing the block using the `free` function.

#### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to access this block of memory can result in unpredictable behavior or even a segmentation fault.

**Fix**

The fix depends on the root cause of the defect. See if you intended to free the memory later or allocate another memory block to the pointer before access.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

**Example - Use of Previously Freed Pointer Error**

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   {
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);

    j = *pi + shift; //Noncompliant
    /* Defect: Reading a freed pointer */

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing`pi` after the `free` statement is not valid.

**Correction — Free Pointer After Use**

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

Store a new value in pointers immediately after free()

## Description

### Rule Definition

*Store a new value in pointers immediately after free().*

### Polyspace Implementation

The rule checker checks for **Missing reset of a freed pointer**.

## Examples

### Missing reset of a freed pointer

#### Issue

**Missing reset of a freed pointer** detects pointers that have been freed and not reassigned another value. After freeing a pointer, the memory data is still accessible. To clear this data, the pointer must also be set to NULL or another value.

#### Risk

Not resetting pointers can cause dangling pointers. Dangling pointers can cause:

- Freeing already freed memory.
- Reading from or writing to already freed memory.
- Hackers executing code stored in freed pointers or with vulnerable permissions.

#### Fix

After freeing a pointer, if it is not immediately assigned to another valid address, set the pointer to NULL.

#### Example - Free Without Reset

```
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};

void missingfreedptrreset()
{
    static char *str = NULL;

    if (str == NULL)
        str = (char *)malloc(SIZE20);

    if (str != NULL)
```

```
        free(str); //Noncompliant
}
```

In this example, the pointer `str` is freed at the end of the program. The next call to `bug_missingfreedptrrese` can fail because `str` is not NULL and the initialization to NULL can be invalid.

#### Correction — Redefine `free` to Free and Reset

One possible correction is to customize `free` so that when you free a pointer, it is automatically reset.

```
#include <stdlib.h>
enum {
    SIZE3   = 3,
    SIZE20  = 20
};

static void sanitize_free(void **p)
{
    if ((p != NULL) && (*p != NULL))
    {
        free(*p);
        *p = NULL;
    }
}

#define free(X) sanitize_free((void **)&X)

void missingfreedptrreset()
{
    static char *str = NULL;

    if (str == NULL)
        str = (char *)malloc(SIZE20);

    if (str != ((void *)0))
    {
        free(str);
    }
}
```

Immediately cast the result of a memory allocation function call into a pointer to the allocated type

## Description

### Rule Definition

*Immediately cast the result of a memory allocation function call into a pointer to the allocated type.*

### Polyspace Implementation

The rule checker checks for **Wrong allocated object size for cast**.

## Examples

### Wrong allocated object size for cast

#### Issue

**Wrong allocated object size for cast** occurs during pointer conversion when the pointer's address is misaligned. If a pointer is converted to a different pointer type, the size of the allocated memory must be a multiple of the size of the destination pointer.

#### Risk

Dereferencing a misaligned pointer has undefined behavior and can cause your program to crash.

#### Fix

Suppose you convert a pointer `ptr1` to `ptr2`. If `ptr1` points to a buffer of `N` bytes and `ptr2` is a *`type`* * pointer where `sizeof(`*`type`*`)` is `n` bytes, make sure that `N` is an integer multiple of `n`.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Dynamic Allocation of Pointers

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(13);
    long *dest;

    dest = (long*)ptr; //defect //Noncompliant
}
```

In this example, the software raises a defect on the conversion of `ptr` to a `long*`. The dynamically allocated memory of `ptr`, 13 bytes, is not a multiple of the size of `dest`, 4 bytes. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the allocated memory to 12 instead of 13.

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(12);
    long *dest;

    dest = (long*)ptr;
}
```

#### Example - Static Allocation of Pointers

```
void static_non_align(void){
    char arr[13], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr; //defect //Noncompliant
}
```

In this example, the software raises a defect on the conversion of `ptr` to an `int*` in line 6. `ptr` has a memory size of 13 bytes because the array `arr` has a size of 13 bytes. The size of `dest` is 4 bytes, which is not a multiple of 13. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the size of the array `arr` to a multiple of 4.

```
void static_non_align(void){
    char arr[12], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr;
}
```

#### Example - Allocation with a Function

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;
    dest1 = (int*)my_alloc(13);  //defect //Noncompliant
    dest2 = (char*)my_alloc(13); //not a defect
}
```

In this example, the software raises a defect on the conversion of the pointer returned by `my_alloc(13)` to an `int*` in line 11. `my_alloc(13)` returns a pointer with a dynamically allocated size of 13 bytes. The size of `dest1` is 4 bytes, which is not a divisor of 13. This misalignment causes the **Wrong allocated object size for cast** defect. In line 12, the same function call, `my_alloc(13)`, does not call a defect for the conversion to `dest2` because the size of `char*`, 1 byte, a divisor of 13.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the argument for `my_alloc` to a multiple of 4.

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(12);
    dest2 = (char*)my_alloc(13);
}
```

Clear sensitive information stored in reusable resources

## Description

### Rule Definition

*Clear sensitive information stored in reusable resources.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Sensitive heap memory not cleared before release**.
- **Uncleared sensitive data in stack**.

## Examples

### Sensitive heap memory not cleared before release

#### Issue

**Sensitive heap memory not cleared before release** detects dynamically allocated memory containing sensitive data. If you do not clear the sensitive data when you free the memory, Bug Finder raises a defect on the `free` function.

#### Risk

If the memory zone is reallocated, an attacker can still inspect the sensitive data in the old memory zone.

#### Fix

Before calling `free`, clear out the sensitive data using `memset` or `SecureZeroMemory`.

#### Example - Sensitive Buffer Freed, Not Cleared

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>

void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    free(buf); //Noncompliant
}
```

In this example, the function uses a buffer of passwords and frees the memory before the end of the function. However, the data in the memory is not cleared by using the `free` command.

#### Correction — Nullify Data

One possible correction is to write over the data to clear out the sensitive information. This example uses `memset` to write over the data with zeros.

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0;i<(sizeof(arr)/sizeof(arr[0]));i++) assert(arr[i]==0)

void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);

    if (buf) {
        getpwnam_r(my_user, &pwd, buf, bufsize, &result);
        memset(buf, 0, (size_t)1024);
        isNull(buf);
        free(buf);
    }
}
```

### Uncleared sensitive data in stack

#### Issue

**Uncleared sensitive data in stack** detects static memory containing sensitive data. If you do not clear the sensitive data from your stack before exiting the function or program, Bug Finder raises a defect on the last curly brace.

#### Risk

Leaving sensitive information in your stack, such as passwords or user information, allows an attacker additional access to the information after your program has ended.

#### Fix

Before exiting a function or program, clear out the memory zones that contain sensitive data by using `memset` or `SecureZeroMemory`.

#### Example - Static Buffer of Password Information

```
#include <unistd.h>
#include <sys/types.h>
#include <pwd.h>

void bug_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
}  //Noncompliant
```

In this example, a static buffer is filled with password information. The program frees the stack memory at the end of the program. However, the data is still accessible from the memory.

#### Correction — Clear Memory

One possible correction is to write over the memory before exiting the function. This example uses `memset` to clear the data from the buffer memory.

```
#include <unistd.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0; i<(sizeof(arr)/sizeof(arr[0])); i++) assert(arr[i]==0)

void corrected_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    memset(buf, 0, (size_t)1024);
    isNull(buf);
}
```

Beware of zero-length allocations

## Description

### Rule Definition

*Beware of zero-length allocations.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Zero length memory allocation**
- **Variable length array with nonpositive size**.
- **Tainted size of variable length array**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted size of variable length array** issue for certain inputs that originate outside of the current analysis boundary. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Zero length memory allocation

#### Issue

**Zero length memory allocation** occurs when a memory allocation function such as `malloc` or `calloc` takes a size argument (or number of elements) that might contain the value zero.

#### Risk

According to the C Standard (C11, Subclause 7.22.3), if zero-sized memory is requested from a memory allocation function, the behavior is implementation-defined. In some implementations, the function might return NULL and your existing guards against NULL might suffice to protect against the zero length allocation. In other cases, the function might return a memory region that must not be accessed. Attempts to dereference this region results in undefined behavior.

#### Fix

Check the size to be passed to `malloc`, or the size and number of elements to be passed to `calloc`, for zero.

#### Example – Possibly Zero Size Argument to `malloc`

```
#include <stdlib.h>

void  func(unsigned int size) {
    int *list = (int *)malloc(size);//Noncompliant
    if (list == NULL) {
      /* Handle allocation error */
    }
    else {
    /* Continue processing list */
    }
}
```

In this example, the variable `size` might contain the value zero leading to a zero length memory allocation.

#### Correction – Check for Zero Before Using Variable as Size

Validate external inputs for zero values before using as size argument to the `malloc` function.

```
#include <stdlib.h>

void  func(unsigned int size) {
    if(size == 0) {
        /* Handle zero size error */
    }
    else {
        int *list = (int *)malloc(size);
        if (list == NULL) {
          /* Handle allocation error */
        }
        else {
          /* Continue processing list */
        }
    }
}
```

### Variable length array with nonpositive size

#### Issue

**Variable length array with non-positive size** occurs when size of a variable-length array is zero or negative.

#### Risk

If the size of a variable-length array is zero or negative, unexpected behavior can occur, such as stack overflow.

#### Fix

When you declare a variable-length array as a local variable in a function:

- If you use a function parameter as the array size, check that the parameter is positive.
- If you use the result of a computation on a function parameter as the array size, check that the result is positive.

You can place a test for positive value either before the function call or the array declaration in the function body.

#### Example - Nonpositive Array Size

```
int input(void);
```

```
void add_scalar(int n, int m) {
    int r=0;
    int arr[m][n]; //Noncompliant
    for (int i=0; i<m; i++) {
        for (int j=0; j<n; j++) {
            arr[i][j] = input();
            r += arr[i][j];
        }
    }
}

void main() {
    add_scalar(2,2);
    add_scalar(-1,2);
    add_scalar(2,0);
}
```

In this example, the second and third calls to `add_scalar` result in a negative and zero size of `arr`.

#### Correction — Make Array Size Positive

One possible correction is fix or remove calls that result in a nonpositive array size.

### Tainted size of variable length array

#### Issue

**Tainted size of variable length array** detects variable length arrays (VLA) whose size is from an unsecure source.

#### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

#### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

#### Example - User Input Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
#define LIM 40

long squaredSum(int size) {

    int tabvla[size]; //Noncompliant
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

**Correction — Check VLA Size**

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 0 and less than 40, before creating the VLA

```
#include <stdio.h>
#include <stdlib.h>
#define LIM 40

long squaredSum(int size) {
    long res = 0;
    if (size>0 && size<LIM){
        int tabvla[size];
        for (int i=0 ; i<size || i<LIM-1 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }else{
        res = -1;
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

Avoid large stack allocations

## Description

### Rule Definition

*Avoid large stack allocations.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Direct or indirect function call to itself**.
- **Variable length array with nonpositive size**.
- **Tainted size of variable length array**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted size of variable length array** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Direct or indirect function call to itself

#### Issue

The issue occurs when your code contains functions that call themselves directly or indirectly.

#### Risk

Variables local to a function are stored in the call stack. If a function calls itself directly or indirectly several times, the available stack space can be exceeded, causing serious failure. Unless the recursion is tightly controlled, it is difficult to determine the maximum stack space required.

#### Example - Direct and Indirect Recursion

```
void foo1( void ) {     /* Non-compliant */
          /*- Indirect recursion foo1->foo2->foo1... */
    foo2();
    foo1();   /* Non-compliant - Direct recursion */
}

void foo2( void ) {/*Noncompliant*/
         /* Indirect Recursion - Foo2->foo1->foo2*/
    foo1();
}
```

In this example, the rule is violated because of:

- Direct recursion `foo1` → `foo1`.
- Indirect recursion `foo1` → `foo2` → `foo1`.
- Indirect recursion `foo2` → `foo1` → `foo2`.

### Variable length array with nonpositive size

#### Issue

**Variable length array with non-positive size** occurs when size of a variable-length array is zero or negative.

#### Risk

If the size of a variable-length array is zero or negative, unexpected behavior can occur, such as stack overflow.

#### Fix

When you declare a variable-length array as a local variable in a function:

- If you use a function parameter as the array size, check that the parameter is positive.
- If you use the result of a computation on a function parameter as the array size, check that the result is positive.

You can place a test for positive value either before the function call or the array declaration in the function body.

#### Example - Nonpositive Array Size

```
int input(void);

void add_scalar(int n, int m) {
    int r=0;
    int arr[m][n]; //Noncompliant
    for (int i=0; i<m; i++) {
        for (int j=0; j<n; j++) {
            arr[i][j] = input();
            r += arr[i][j];
        }
    }
}

void main() {
    add_scalar(2,2);
    add_scalar(-1,2);
    add_scalar(2,0);
}
```

In this example, the second and third calls to `add_scalar` result in a negative and zero size of `arr`.

#### Correction — Make Array Size Positive

One possible correction is fix or remove calls that result in a nonpositive array size.

### Tainted size of variable length array

#### Issue

**Tainted size of variable length array** detects variable length arrays (VLA) whose size is from an unsecure source.

#### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

#### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

#### Example — User Input Argument Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
#define LIM 40

long squaredSum(int size) {

    int tabvla[size]; //Noncompliant
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

#### Correction — Check VLA Size

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 10 and less than 100, before creating the VLA

```
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
```

```
int taintedvlasize(int size) {
    int res = 0;
    if (size>SIZE10 && size<SIZE100) {
        int tabvla[size];
        for (int i=0 ; i<SIZE10 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }
    return res;
}
```

Ensure that sensitive data is not written out to disk

## Description

### Rule Definition

*Ensure that sensitive data is not written out to disk.*

### Polyspace Implementation

The rule checker checks for **Sensitive data printed out**.

## Examples

### Sensitive data printed out

#### Issue

**Sensitive data printed out** detects print functions, such as `stdout` or `stderr`, that print sensitive information.

The checker considers the following as sensitive information:

- Return values of password manipulation functions such as `getpw`, `getpwnam` or `getpwuid`.
- Input values of functions such as the Windows-specific function `LogonUser`.

#### Risk

Printing sensitive information, such as passwords or user information, allows an attacker additional access to the information.

#### Fix

One fix for this defect is to not print out sensitive information.

If you are saving your logfile to an external file, set the file permissions so that attackers cannot access the logfile information.

#### Example - Printing Passwords

```
#include <sys/types.h>
#include <pwd.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

extern void verify_null(const char* buf);
void bug_sensitivedataprint(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    puts("Name\n");
    puts(pwd.pw_name);
    puts("PassWord\n");
    puts(pwd.pw_passwd); //Noncompliant
    memset(buf, 0, sizeof(buf));
    verify_null(buf);
}
```

In this example, Bug Finder flags `puts` for printing out the password `pwd.pw_passwd`.

#### Correction — Obfuscate the Password

One possible correction is to obfuscate the password information so that the information is not visible.

```
#include <sys/types.h>
#include <pwd.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>

extern void verify_null(const char* buf);

void sensitivedataprint(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    puts("Name\n");
    puts(pwd.pw_name);
    puts("PassWord\n");
    puts("XXXXXXXX\n");
    memset(buf, 0, sizeof(buf));
    verify_null(buf);
}
```

Do not assume infinite heap space

## Description

### Rule Definition

*Do not assume infinite heap space.*

### Polyspace Implementation

The rule checker checks for **Unprotected dynamic memory allocation**.

## Examples

### Unprotected dynamic memory allocation

#### Issue

**Unprotected dynamic memory allocation** occurs when you do not check after dynamic memory allocation whether the memory allocation succeeded.

#### Risk

When memory is dynamically allocated using `malloc`, `calloc`, or `realloc`, it returns a value `NULL` if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this `NULL` value, this access is not protected from failures.

#### Fix

Check the return value of `malloc`, `calloc`, or `realloc` for NULL before accessing the allocated memory location.

```
int *ptr = malloc(size * sizeof(int));

if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

#### Example - Unprotected dynamic memory allocation error

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));

  *p = 2;   //Noncompliant
  /* Defect: p is not checked for NULL value */

  free(p);
}
```

If the memory allocation fails, the function `calloc` returns `NULL` to `p`. Before accessing the memory through `p`, the code does not check whether `p` is `NULL`

#### Correction — Check for NULL Value

One possible correction is to check whether `p` has value `NULL` before dereference.

```
#include <stdlib.h>

void Assign_Value(void)
 {
   int* p = (int*)calloc(5, sizeof(int));

   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;

   free(p);
 }
```

Consider using a goto chain when leaving a function on error when using and releasing resources

## Description

### Rule Definition

*Consider using a goto chain when leaving a function on error when using and releasing resources.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Memory leak**.
- **Resource leak**.

## Examples

### Memory leak

#### Issue

**Memory leak** occurs when you do not free a block of memory allocated through `malloc`, `calloc`, `realloc`, or `new`. If the memory is allocated in a function, the defect does not occur if:

- Within the function, you free the memory using `free` or `delete`.
- The function returns the pointer assigned by `malloc`, `calloc`, `realloc`, or `new`.
- The function stores the pointer in a global variable or in a parameter.

#### Risk

Dynamic memory allocation functions such as `malloc` allocate memory on the heap. If you do not release the memory after use, you reduce the amount of memory available for another allocation. On embedded systems with limited memory, you might end up exhausting available heap memory even during program execution.

#### Fix

Determine the scope where the dynamically allocated memory is accessed. Free the memory block at the end of this scope.

To free a block of memory, use the `free` function on the pointer that was used during memory allocation. For instance:

```
ptr = (int*)malloc(sizeof(int));
//...
free(ptr);
```

It is a good practice to allocate and free memory in the same module at the same level of abstraction. For instance, in this example, `func` allocates and frees memory at the same level but `func2` does not.

```
void func() {
  ptr = (int*)malloc(sizeof(int));
  {
    .//..
  }
  free(ptr);
}

void func2() {
  {
   ptr = (int*)malloc(sizeof(int));
   //...
  }
  free(ptr);
}
```

See CERT-C Rule MEM00-C.

#### Example - Dynamic Memory Not Released Before End of Function

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }

    *pi = 42;
    /* Defect: pi is not freed */
} //Noncompliant
```

In this example, `pi` is dynamically allocated by `malloc`. The function `assign_memory` does not free the memory, nor does it return `pi`.

#### Correction — Free Memory

One possible correction is to free the memory referenced by `pi` using the `free` function. The `free` function must be called before the function `assign_memory` terminates

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }
    *pi = 42;

    /* Fix: Free the pointer pi*/
    free(pi);
}
```

#### Correction — Return Pointer from Dynamic Allocation

Another possible correction is to return the pointer `pi`. Returning `pi` allows the function calling `assign_memory` to free the memory block using `pi`.

```
#include<stdlib.h>
#include<stdio.h>

int* assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
            printf("Memory allocation failed");
            return(pi);
        }
    *pi = 42;

    /* Fix: Return the pointer pi*/
    return(pi);
}
```

### Resource leak

#### Issue

**Resource leak** occurs when you open a file stream by using a `FILE` pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

#### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

#### Fix

Close a `FILE` pointer before the end of its scope, or before you assign the pointer to another stream.

#### Example - FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" ); //Noncompliant
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer `fp1` is pointing to a file `data1.txt`. Before `fp1` is explicitly dissociated from the file stream of `data1.txt`, it is used to access another file `data2.txt`.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate `fp1` from the file stream of `data1.txt`.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

Canonicalize path names originating from tainted sources

## Description

### Rule Definition

*Canonicalize path names originating from tainted sources.*

### Polyspace Implementation

The rule checker checks for **Vulnerable path manipulation**.

## Examples

### Vulnerable path manipulation

#### Issue

**Vulnerable path manipulation** detects relative or absolute path traversals. If the path traversal contains a tainted source, or you use the path to open/create files, Bug Finder raises a defect.

#### Risk

Relative path elements, such as `".."` can resolve to locations outside the intended folder. Absolute path elements, such as `"/abs/path"` can also resolve to locations outside the intended folder.

An attacker can use these types of path traversal elements to traverse to the rest of the file system and access other files or folders.

#### Fix

Avoid vulnerable path traversal elements such as `/../` and `/abs/path/`. Use fixed file names and locations wherever possible.

#### Example - Relative Path Traversal

```
# include <stdio.h>
# include <string.h>
# include <wchar.h>
# include <sys/types.h>
# include <sys/stat.h>
# include <fcntl.h>
# include <unistd.h>
# include <stdlib.h>
# define BASEPATH "/tmp/"
# define FILENAME_MAX 512

static void Relative_Path_Traversal(void)
{
    char * data;
    char data_buf[FILENAME_MAX] = BASEPATH;
    char sub_buf[FILENAME_MAX];
    if (fgets(sub_buf, FILENAME_MAX, stdin) == NULL) exit (1);
    data = data_buf;
    strcat(data, sub_buf);

    FILE *file = NULL;
    file = fopen(data, "wb+");  //Noncompliant
    if (file != NULL) fclose(file);
}

int path_call(void){
    Relative_Path_Traversal();
}
```

This example opens a file from `"/tmp/"`, but uses a relative path to the file. An external user can manipulate this relative path when `fopen` opens the file.

#### Correction — Use Fixed File Name

One possible correction is to use a fixed file name instead of a relative path. This example uses `file.txt`.

```
# include <stdio.h>
# include <string.h>
# include <wchar.h>
# include <sys/types.h>
# include <sys/stat.h>
# include <fcntl.h>
# include <unistd.h>
# include <stdlib.h>
# define BASEPATH "/tmp/"
# define FILENAME_MAX 512

static void Relative_Path_Traversal(void)
{
    char * data;
    char data_buf[FILENAME_MAX] = BASEPATH;
    data = data_buf;

    /* FIX: Use a fixed file name */
    strcat(data, "file.txt");
    FILE *file = NULL;
    file = fopen(data, "wb+");
    if (file != NULL) fclose(file);
}

int path_call(void){
    Relative_Path_Traversal();
}
```

Take care when specifying the mode parameter of fopen()

## Description

### Rule Definition

*Take care when specifying the mode parameter of fopen().*

### Polyspace Implementation

The rule checker checks for **Bad file access mode or status**.

## Examples

### Bad file access mode or status

#### Issue

**Bad file access mode or status** occurs when you use functions in the `fopen` or `open` group with invalid or incompatible file access modes, file creation flags, or file status flags as arguments. For instance, for the `open` function, examples of valid:

- Access modes include `O_RDONLY`, `O_WRONLY`, and `O_RDWR`
- File creation flags include `O_CREAT`, `O_EXCL`, `O_NOCTTY`, and `O_TRUNC`.
- File status flags include `O_APPEND`, `O_ASYNC`, `O_CLOEXEC`, `O_DIRECT`, `O_DIRECTORY`, `O_LARGEFILE`, `O_NOATIME`, `O_NOFOLLOW`, `O_NONBLOCK`, `O_NDELAY`, `O_SHLOCK`, `O_EXLOCK`, `O_FSYNC`, `O_SYNC` and so on.

The defect can occur in the following situations.

| Situation | Risk | Fix |
|---|---|---|
| You pass an empty or invalid access mode to the `fopen` function.<br>According to the ANSI C standard, the valid access modes for `fopen` are:<br>• `r`,`r+`<br>• `w`,`w+`<br>• `a`,`a+`<br>• `rb`, `wb`, `ab`<br>• `r+b`, `w+b`, `a+b`<br>• `rb+`, `wb+`, `ab+` | `fopen` has undefined behavior for invalid access modes.<br>Some implementations allow extension of the access mode such as:<br>• GNU: `rb+cmxe,ccs=utf`<br>• Visual C++: `a+t`, where `t` specifies a text mode.<br>However, your access mode string must begin with one of the valid sequences. | Pass a valid access mode to `fopen`. |

| Situation | Risk | Fix |
|---|---|---|
| You pass the status flag O_APPEND to the open function without combining it with either O_WRONLY or O_RDWR. | O_APPEND indicates that you intend to add new content at the end of a file. However, without O_WRONLY or O_RDWR, you cannot write to the file.<br>The open function does not return -1 for this logical error. | Pass either O_APPEND\|O_WRONLY or O_APPEND\|O_RDWR as access mode. |
| You pass the status flags O_APPEND and O_TRUNC together to the open function. | O_APPEND indicates that you intend to add new content at the end of a file. However, O_TRUNC indicates that you intend to truncate the file to zero. Therefore, the two modes cannot operate together.<br>The open function does not return -1 for this logical error. | Depending on what you intend to do, pass one of the two modes. |
| You pass the status flag O_ASYNC to the open function. | On certain implementations, the mode O_ASYNC does not enable signal-driven I/O operations. | Use the fcntl(pathname, F_SETFL, O_ASYNC); instead. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Invalid Access Mode with fopen

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "rw"); //Noncompliant
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

In this example, the access mode rw is invalid. Because r indicates that you open the file for reading and w indicates that you create a new file for writing, the two access modes are incompatible.

### Correction — Use Either `r` or `w` as Access Mode

One possible correction is to use the access mode corresponding to what you intend to do.

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "w");
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

Do not create temporary files in shared directories

## Description

### Rule Definition

*Do not create temporary files in shared directories.*

### Polyspace Implementation

The rule checker checks for **Use of non-secure temporary file**.

## Examples

### Use of non-secure temporary file

#### Issue

**Use of non-secure temporary file** looks for temporary file routines that are not secure.

#### Risk

If an attacker guesses the file name generated by a standard temporary file routine, the attacker can:

- Cause a race condition when you generate the file name.
- Precreate a file of the same name, filled with malicious content. If your program reads the file, the attacker's file can inject the malicious code.
- Create a symbolic link to a file storing sensitive data. When your program writes to the temporary file, the sensitive data is deleted.

#### Fix

To create temporary files, use a more secure standard temporary file routine, such as `mkstemp` from POSIX.1-2001.

Also, when creating temporary files with routines that allow flags, such as `mkostemp`, use the exclusion flag `O_EXCL` to avoid race conditions.

#### Example - Temp File Created With `tempnam`

```
#define _BSD_SOURCE
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

int test_temp()
```

```
{
    char tpl[] = "abcXXXXXX";
    char suff_tpl[] = "abcXXXXXXsuff";
    char *filename = NULL;
    int fd;

    filename = tempnam("/var/tmp", "foo_");

    if (filename != NULL)
    {
        printf("generated tmp name (%s) in (%s:%s:%s)\n",
               filename, getenv("TMPDIR") ? getenv("TMPDIR") : "$TMPDIR",
               "/var/tmp", P_tmpdir);

        fd = open(filename, O_CREAT, S_IRWXU|S_IRUSR); //Noncompliant
        if (fd != -1)
        {
            close(fd);
            unlink(filename);
            return 1;
        }
    }
    return 0;
}
```

In this example, Bug Finder flags open because it tries to use an unsecure temporary file. The file is opened without exclusive privileges. An attacker can access the file causing various risks on page 13-84.

**Correction — Add O_EXCL Flag**

One possible correction is to add the O_EXCL flag when you open the temporary file.

```
#define _BSD_SOURCE
#define _XOPEN_SOURCE
#define _GNU_SOURCE

#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>

int test_temp()
{
    char tpl[] = "abcXXXXXX";
    char suff_tpl[] = "abcXXXXXXsuff";
    char *filename = NULL;
    int fd;

    filename = tempnam("/var/tmp", "foo_");

    if (filename != NULL)
    {
        printf("generated tmp name (%s) in (%s:%s:%s)\n",
               filename, getenv("TMPDIR") ? getenv("TMPDIR") : "$TMPDIR",
               "/var/tmp", P_tmpdir);
        fd = open(filename, O_CREAT|O_EXCL, S_IRWXU|S_IRUSR);
        if (fd != -1)
        {
            close(fd);
            unlink(filename);
            return 1;
        }
    }
    return 0;
}
```

Do not open a file that is already open

## Description

### Rule Definition

*Do not open a file that is already open.*

### Polyspace Implementation

The rule checker checks for **Opening previously opened resource**.

## Examples

### Opening previously opened resource

#### Issue

**Opening previously opened resource** checks for file opening functions that are opening an already opened file.

#### Risk

If you open a resource multiple times, you can encounter:

- A race condition when accessing the file.
- Undefined or unexpected behavior for that file.
- Portability issues when you run your program on different targets.

#### Fix

Once a resource is open, close the resource before reopening.

#### Example - File Reopened With New Permissions

```
#include <stdio.h>
const char* logfile = "my_file.log";

void doubleresourceopen()
{
    FILE* fpa = fopen(logfile, "w");
    if (fpa == NULL) {
        return;
    }
    (void)fprintf(fpa, "Writing");
    FILE* fpb = fopen(logfile, "r"); //Noncompliant
    (void)fclose(fpa);
    (void)fclose(fpb);
}
```

In this example, a `logfile` is opened in the first line of this function with write privileges. Halfway through the function, the `logfile` is opened again with read privileges.

#### Correction — Close Before Reopening

One possible correction is to close the file before reopening the file with different privileges.

```
#include <stdio.h>
const char* logfile = "my_file.log";

void doubleresourceopen()
{
    FILE* fpa = fopen(logfile, "w");
    if (fpa == NULL) {
        return;
    }
    (void)fprintf(fpa, "Writing");
    (void)fclose(fpa);
    FILE* fpb = fopen(logfile, "r");
    (void)fclose(fpb);
}
```

Do not make assumptions about the size of an environment variable

## Description

### Rule Definition

*Do not make assumptions about the size of an environment variable.*

### Polyspace Implementation

The rule checker checks for **Tainted NULL or non-null-terminated string**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted NULL or non-null-terminated string** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted NULL or non-null-terminated string

#### Issue

**Tainted NULL or non-null-terminated string** looks for strings from unsecure sources that are being used in string manipulation routines that implicitly dereference the string buffer. For example, `strcpy` or `sprintf`.

**Tainted NULL or non-null-terminated string** raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

**Note** If you reference a string using the form `ptr[i]`, `*ptr`, or pointer arithmetic, Bug Finder raises a **Use of tainted pointer** defect instead. The **Tainted NULL or non-null-terminated string** defect is raised only when the pointer is used as a string.

#### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

#### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

**Example - Getting String from Input Argument**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1)); //Noncompliant
    print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

**Correction — Validate the Data**

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // TAINTED_STRING only flagged here //Noncompliant
        // - string is not null
        // - string has a positive and limited size
        // - TAINTED_STRING on strlen used as a firewall
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

#### Correction — Validate the Data

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }

  return sensorValue;
}
```

Adopt and implement a consistent and comprehensive error-handling policy

## Description

### Rule Definition

*Adopt and implement a consistent and comprehensive error-handling policy.*

### Polyspace Implementation

The rule checker checks for **Returned value of a sensitive function not checked**.

## Examples

### Returned value of a sensitive function not checked

#### Issue

This issue occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example – Sensitive Function Return Ignored

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    pthread_attr_init(&attr);  //Noncompliant
}
```

This example shows a call to the sensitive function `pthread_attr_init`. The return value of `pthread_attr_init` is ignored, causing a defect.

#### Correction 1 – Cast Function to (void)

One possible correction is to cast the function to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of the sensitive function.

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    (void)pthread_attr_init(&attr);
}
```

#### Correction 2 – Test Return Value

One possible correction is to test the return value of `pthread_attr_init` to check for errors.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

void initialize() {
    pthread_attr_t attr;
    int result;

    result = pthread_attr_init(&attr);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

#### Example – Critical Function Return Ignored

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res);  //Noncompliant
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), Polyspace does not ignore this *Return value of a sensitive function not checked* defect. The other critical function, `pthread_join`, returns value that is ignored implicitly. `pthread_join` uses the return value of `pthread_create`, which was not checked.

**Correction — Test the Return Value of Critical Functions**

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

Provide a consistent and usable error-checking mechanism

## Description

### Rule Definition

*Provide a consistent and usable error-checking mechanism.*

### Polyspace Implementation

The rule checker checks for **Returned value of a sensitive function not checked**.

## Examples

### Returned value of a sensitive function not checked

#### Issue

This issue occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `pthread_create`)
- Lock or unlock mutex (for example, `pthread_mutex_lock`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example – Sensitive Function Return Ignored

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    pthread_attr_init(&attr);  //Noncompliant
}
```

This example shows a call to the sensitive function `pthread_attr_init`. The return value of `pthread_attr_init` is ignored, causing a defect.

#### Correction 1 – Cast Function to (void)

One possible correction is to cast the function to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of the sensitive function.

```
#include <pthread.h>

void initialize() {
    pthread_attr_t attr;

    (void)pthread_attr_init(&attr);
}
```

#### Correction 2 – Test Return Value

One possible correction is to test the return value of `pthread_attr_init` to check for errors.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

void initialize() {
    pthread_attr_t attr;
    int result;

    result = pthread_attr_init(&attr);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

#### Example – Critical Function Return Ignored

```
#include <pthread.h>
extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res);  //Noncompliant
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), Polyspace does not ignore this *Return value of a sensitive function not checked* defect. The other critical function, `pthread_join`, returns value that is ignored implicitly. `pthread_join` uses the return value of `pthread_create`, which was not checked.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
#include <pthread.h>
#include <stdlib.h>
#define fatal_error() abort()

extern void *start_routine(void *);

void returnnotchecked() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res);
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

Acquire and release synchronization primitives in the same module, at the same level of abstraction

## Description

### Rule Definition

*Acquire and release synchronization primitives in the same module, at the same level of abstraction.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Missing lock**.
- **Missing unlock**.
- **Double lock**.
- **Double unlock**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

You can also extend this checker to detect synchronization issues by mapping your multithreading functions to their known POSIX equivalents. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Missing lock

#### Issue

**Missing lock** occurs when a task calls an unlock function before calling the corresponding lock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait till `my_task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

#### Risk

A call to an unlock function without a corresponding lock function can indicate a coding error. For instance, perhaps the unlock function does not correspond to the lock function that begins the critical section.

#### Fix

The fix depends on the root cause of the defect. For instance, if the defect occurs because of a mismatch between lock and unlock function, check the lock-unlock function pair in your Polyspace analysis configuration and fix the mismatch.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    // ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
   // ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Missing lock

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
  begin_critical_section();
  global_var = 0;
  end_critical_section();
}

void my_task(void)
{
  global_var += 1;
  end_critical_section(); //Noncompliant
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `my_task`, `reset` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`. `my_task` calls `end_critical_section` before calling `begin_critical_section`.

#### Correction — Provide Lock

One possible correction is to call the lock function `begin_critical_section` before the instructions in the critical section.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
  begin_critical_section();
  global_var = 0;
  end_critical_section();
}

void my_task(void)
{
    begin_critical_section();
    global_var += 1;
    end_critical_section();
}
```

#### Example - Lock in Condition

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;
```

```
void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      if(index%10==0) {
        begin_critical_section();
        global_var ++;
      }
      end_critical_section();  //Noncompliant
      index++;
    }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `my_task`, `reset` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`.

In the `while` loop, `my_task` leaves a critical section through the call `end_critical_section();`. In an iteration of the `while` loop:

- If `my_task` enters the `if` condition branch, the critical section begins through a call to `begin_critical_section`.
- If `my_task` does not enter the `if` condition branch and leaves the `while` loop, the critical section does not begin. Therefore, a **Missing lock** defect occurs.
- If `my_task` does not enter the `if` condition branch and continues to the next iteration of the `while` loop, the unlock function `end_critical_section` is called again. A **Double unlock** defect occurs.

Because `numCycles` is a `volatile` variable, it can take any value. Any of the cases above are possible. Therefore, a **Missing lock** defect and a **Double unlock** defect appear on the call `end_critical_section`.

### Missing unlock

#### Issue

**Missing unlock** occurs when:

- A task calls a lock function.
- The task ends without a call to an unlock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task, `my_task`, calls a lock function, `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, before analysis, you must specify the multitasking options. On the **Configuration** pane, select **Multitasking**.

#### Risk

An unlock function ends a critical section so that other waiting tasks can enter the critical section. A missing unlock function can result in tasks blocked for an unnecessary length of time.

#### Fix

Identify the critical section of code, that is, the section that you want to be executed as an atomic block. At the end of this section, call the unlock function that corresponds to the lock function used at the beginning of the section.

There can be other reasons and corresponding fixes for the defect. Perhaps you called the incorrect unlock function. Check the lock-unlock function pair in your Polyspace analysis configuration and fix the mismatch.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    // ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
   // ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.

- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Missing Unlock**

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset()
{
    begin_critical_section();
    global_var = 0;
    end_critical_section();
}

void my_task(void)
{
    begin_critical_section();  //Noncompliant
    global_var += 1;
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `my_task`, `reset` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`. `my_task` enters a critical section through the call `begin_critical_section();`. `my_task` ends without calling `end_critical_section`.

**Correction — Provide Unlock**

One possible correction is to call the unlock function `end_critical_section` after the instructions in the critical section.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset(void)
{
    begin_critical_section();
    global_var = 0;
    end_critical_section();
}

void my_task(void)
{
    begin_critical_section();
    global_var += 1;
    end_critical_section();
}
```

#### Example - Unlock in Condition

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      begin_critical_section(); //Noncompliant
      global_var ++;
      if(index%10==0) {
        global_var = 0;
        end_critical_section();
      }
      index++;
    }
}
```

In this example, to emulate multitasking behavior, specify the following options.

| Option | Specification |
|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ |
| **Tasks** on page 2-121 | `my_task`, `reset` |

| Option | Specification | |
|---|---|---|
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | begin_critical_section | end_critical_section |

On the command-line, you can use the following:

```
polyspace-bug-finder
   -entry-points my_task,reset
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

The example has two entry points, `my_task` and `reset`.

In the `while` loop, `my_task` enters a critical section through the call `begin_critical_section();`. In an iteration of the `while` loop:

- If `my_task` enters the `if` condition branch, the critical section ends through a call to `end_critical_section`.
- If `my_task` does not enter the `if` condition branch and leaves the `while` loop, the critical section does not end. Therefore, a **Missing unlock** defect occurs.
- If `my_task` does not enter the `if` condition branch and continues to the next iteration of the `while` loop, the lock function `begin_critical_section` is called again. A **Double lock** defect occurs.

Because `numCycles` is a `volatile` variable, it can take any value. Any of the cases above is possible. Therefore, a **Missing unlock** defect and a **Double lock** defect appear on the call `begin_critical_section`.

#### Correction — Place Unlock Outside Condition

One possible correction is to call the unlock function `end_critical_section` outside the `if` condition.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      begin_critical_section();
      global_var ++;
      if(index%10==0) {
        global_var=0;
      }
      end_critical_section();
      index++;
    }
}
```

#### Correction — Place Unlock in Every Conditional Branch

Another possible correction is to call the unlock function `end_critical_section` in every branches of the `if` condition.

```
void begin_critical_section(void);
void end_critical_section(void);

int global_var;

void reset() {
    begin_critical_section();
    global_var=0;
    end_critical_section();
}

void my_task(void) {
    int index=0;
    volatile int numCycles;

    while(numCycles) {
      begin_critical_section();
      global_var ++;
      if(index%10==0) {
        global_var=0;
        end_critical_section();
      }
      else
        end_critical_section();
      index++;
    }
}
```

### Double lock

#### Issue

**Double lock** occurs when:

- A task calls a lock function `my_lock`.
- The task calls `my_lock` again before calling the corresponding unlock function.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `task1` calls a lock function `lock`, other tasks calling `lock` must wait until `task` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

**Risk**

A call to a lock function begins a critical section so that other tasks have to wait to enter the same critical section. If the same lock function is called again within the critical section, the task blocks itself.

**Fix**

The fix depends on the root cause of the defect. A double lock defect often indicates a coding error. Perhaps you omitted the call to an unlock function to end a previous critical section and started the next critical section. Perhaps you wanted to use a different lock function for the second critical section.

Identify each critical section of code, that is, the section that you want to be executed as an atomic block. Call a lock function at the beginning of the section. Within the critical section, make sure that you do not call the lock function again. At the end of the section, call the unlock function that corresponds to the lock function.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    // ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
   // ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Double Lock**

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    lock();  //Noncompliant
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `my_task`, `reset` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `lock` | `unlock` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin lock:cs1
   -critical-section-end unlock:cs1
```

`task1` enters a critical section through the call `lock();`. `task1` calls `lock` again before it leaves the critical section through the call `unlock();`.

#### Correction — Remove First Lock

If you want the first `global_var+=1;` to be outside the critical section, one possible correction is to remove the first call to `lock`. However, if other tasks are using `global_var`, this code can produce a `Data race` error.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    global_var += 1;
    lock();
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

**Correction — Remove Second Lock**

If you want the first `global_var+=1;` to be inside the critical section, one possible correction is to remove the second call to `lock`.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

**Correction — Add Another Unlock**

If you want the second `global_var+=1;` to be inside a critical section, another possible correction is to add another call to `unlock`.

```
int global_var;

void lock(void);
void unlock(void);

void task1(void)
{
    lock();
    global_var += 1;
    unlock();
    lock();
    global_var += 1;
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

**Example - Double Lock with Function Call**

```
int global_var;

void lock(void);
void unlock(void);

void performOperation(void) {
  lock(); //Noncompliant
  global_var++;
}

void task1(void)
{
    lock();
    global_var += 1;
    performOperation();
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `my_task`, `reset` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `lock` | `unlock` |

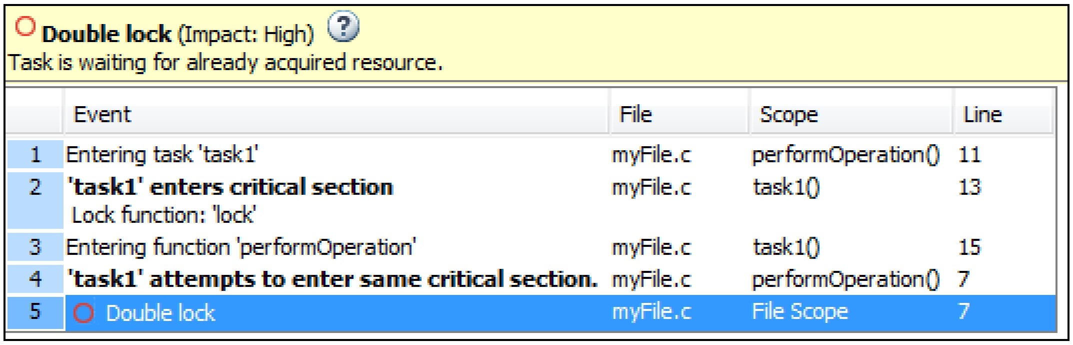
On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin lock:cs1
   -critical-section-end unlock:cs1
```

`task1` enters a critical section through the call `lock();`. `task1` calls the function `performOperation`. In `performOperation`, `lock` is called again even though `task1` has not left the critical section through the call `unlock();`.

In the result details for the defect, you see the sequence of instructions leading to the defect. For instance, you see that following the first entry into the critical section, the execution path:

- Enters function `performOperation`.
- Inside `performOperation`, attempts to enter the same critical section once again.



○ **Double lock** (Impact: High)

Task is waiting for already acquired resource.

| | Event | File | Scope | Line |
|---|---|---|---|---|
| 1 | Entering task 'task1' | myFile.c | performOperation() | 11 |
| 2 | **'task1' enters critical section**<br>Lock function: 'lock' | myFile.c | task1() | 13 |
| 3 | Entering function 'performOperation' | myFile.c | task1() | 15 |
| 4 | **'task1' attempts to enter same critical section.** | myFile.c | performOperation() | 7 |
| 5 | ○ Double lock | myFile.c | File Scope | 7 |

You can click each event to navigate to the corresponding line in the source code.

**Correction — Remove Second Lock**

One possible correction is to remove the call to `lock` in `task1`.

```
int global_var;

void lock(void);
void unlock(void);

void performOperation(void) {
  global_var++;
}

void task1(void)
{
    lock();
    global_var += 1;
    performOperation();
    unlock();
}

void task2(void)
{
    lock();
    global_var += 1;
    unlock();
}
```

### Double unlock

#### Issue

**Double unlock** occurs when:

- A task calls a lock function `my_lock`.
- The task calls the corresponding unlock function `my_unlock`.
- The task calls `my_unlock` again. The task does not call `my_lock` a second time between the two calls to `my_unlock`.

In multitasking code, a lock function begins a critical section of code and an unlock function ends it. When a task `task1` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `task1` calls the corresponding unlock function. Polyspace requires that both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

#### Risk

A double unlock defect can indicate a coding error. Perhaps you wanted to call a different unlock function to end a different critical section. Perhaps you called the unlock function prematurely the first time and only the second call indicates the end of the critical section.

#### Fix

The fix depends on the root cause of the defect.

Identify each critical section of code, that is, the section that you want to be executed as an atomic block. Call a lock function at the beginning of the section. Only at the end of the section, call the unlock function that corresponds to the lock function. Remove any other redundant call to the unlock function.

See examples of fixes below. To avoid the issue, you can follow the practice of calling the lock and unlock functions in the same module at the same level of abstraction. For instance, in this example, `func` calls the lock and unlock function at the same level but `func2` does not.

```
void func() {
  my_lock();
  {
    // ...
  }
  my_unlock();
}

void func2() {
  {
   my_lock();
   // ...
  }
  my_unlock();
}
```

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Double Unlock**

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION(); //Noncompliant
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Value | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `task1`<br>`task2` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `BEGIN_CRITICAL_SECTION` | `END_CRITICAL_SECTION` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin BEGIN_CRITICAL_SECTION:cs1
   -critical-section-end END_CRITICAL_SECTION:cs1
```

`task1` enters a critical section through the call `BEGIN_CRITICAL_SECTION();`. `task1` leaves the critical section through the call `END_CRITICAL_SECTION();`. `task1` calls `END_CRITICAL_SECTION` again without an intermediate call to `BEGIN_CRITICAL_SECTION`.

#### Correction — Remove Second Unlock

If you want the second `global_var+=1;` to be outside the critical section, one possible correction is to remove the second call to `END_CRITICAL_SECTION`. However, if other tasks are using `global_var`, this code can produce a `Data race` error.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    global_var += 1;
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

#### Correction — Remove First Unlock

If you want the second `global_var+=1;` to be inside the critical section, one possible correction is to remove the first call to `END_CRITICAL_SECTION`.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    global_var += 1;
    END_CRITICAL_SECTION();
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

#### Correction — Add Another Lock

If you want the second `global_var+=1;` to be inside a critical section, another possible correction is to add another call to `BEGIN_CRITICAL_SECTION`.

```
int global_var;

void BEGIN_CRITICAL_SECTION(void);
void END_CRITICAL_SECTION(void);

void task1(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}

void task2(void)
{
    BEGIN_CRITICAL_SECTION();
    global_var += 1;
    END_CRITICAL_SECTION();
}
```

Do not perform operations that can block while holding a lock

## Description

### Rule Definition

*Do not perform operations that can block while holding a lock.*

### Polyspace Implementation

The rule checker checks for **Blocking operation while holding lock**.

## Examples

### Blocking operation while holding lock

#### Issue

**Blocking operation while holding lock** occurs when a task (thread) performs a potentially lengthy operation while holding a lock.

The checker considers calls to these functions as potentially lengthy:

- Functions that access a network such as `recv`
- System call functions such as `fork`, `pipe` and `system`
- Functions for I/O operations such as `getchar` and `scanf`
- File handling functions such as `fopen`, `remove` and `lstat`
- Directory manipulation functions such as `mkdir` and `rmdir`

The checker automatically detects certain primitives that hold and release a lock, for instance, `pthread_mutex_lock` and `pthread_mutex_unlock`. For the full list of primitives that are automatically detected, see “Auto-Detection of Thread Creation and Critical Section in Polyspace”.

#### Risk

If a thread performs a lengthy operation when holding a lock, other threads that use the lock have to wait for the lock to be available. As a result, system performance can slow down or deadlocks can occur.

#### Fix

Perform the blocking operation before holding the lock or after releasing the lock.

Some functions detected by this checker can be called in a way that does not make them potentially lengthy. For instance, the function `recv` can be called with the parameter `O_NONBLOCK` which causes the call to fail if no message is available. When called with this parameter, `recv` does not wait for a message to become available.

#### Example - Network I/O Operations with `recv` While Holding Lock

```
#include <pthread.h>
#include <sys/socket.h>
```

```
pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) { //Noncompliant
    /* Handle Error */
  }

  /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }

  return 0;
}
```

In this example, in each thread created with `pthread_create`, the function `thread_foo` performs a network I/O operation with `recv` after acquiring a lock with `pthread_mutex_lock`. Other threads using the same lock variable mutex have to wait for the operation to complete and the lock to become available.

### Correction — Perform Blocking Operation Before Acquiring Lock

One possible correction is to call recv before acquiring the lock.

```
#include <pthread.h>
#include <sys/socket.h>

pthread_mutexattr_t attr;
pthread_mutex_t mutex;

void thread_foo(void *ptr) {
  unsigned int num;
  int result;
  int sock;

  /* sock is a connected TCP socket */
  if ((result = recv(sock, (void *)&num, sizeof(unsigned int), 0)) < 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_lock(&mutex)) != 0) {
    /* Handle Error */
  }

    /* ... */

  if ((result = pthread_mutex_unlock(&mutex)) != 0) {
    /* Handle Error */
  }
}

int main() {
  pthread_t thread;
  int result;

  if ((result = pthread_mutexattr_settype(
      &attr, PTHREAD_MUTEX_ERRORCHECK)) != 0) {
    /* Handle Error */
  }

  if ((result = pthread_mutex_init(&mutex, &attr)) != 0) {
    /* Handle Error */
  }

  if (pthread_create(&thread, NULL,(void*(*)(void*))& thread_foo, NULL) != 0) {
    /* Handle Error */
  }

  /* ... */

  pthread_join(thread, NULL);

  if ((result = pthread_mutex_destroy(&mutex)) != 0) {
    /* Handle Error */
  }
  return 0;
}
```

Strive for logical completeness

## Description

### Rule Definition

*Strive for logical completeness.*

### Polyspace Implementation

The rule checker checks for **Missing case for switch condition**.

## Examples

### Missing case for switch condition

#### Issue

**Missing case for switch condition** occurs when the `switch` variable can take values that are not covered by a `case` statement.

**Note** Bug Finder only raises a defect if the switch variable is not full range.

#### Risk

If the `switch` variable takes a value that is not covered by a `case` statement, your program can have unintended behavior.

A switch-statement that makes a security decision is particularly vulnerable when all possible values are not explicitly handled. An attacker can use this situation to deviate the normal execution flow.

#### Fix

It is good practice to use a `default` statement as a catch-all for values that are not covered by a `case` statement. Even if the `switch` variable takes an unintended value, the resulting behavior can be anticipated.

#### Example - Missing Default Condition

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}

int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )  //Noncompliant
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    }

    printf("Welcome!\n");
    return r;
}
```

In this example, the `enum` parameter `User` can take a value `UNKNOWN` that is not covered by a `case` statement.

**Correction — Add a Default Condition**

One possible correction is to add a default condition for possible values that are not covered by a `case` statement.

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}
```

```
int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    break;
    default:
        printf("Invalid login credentials!\n");
    }

    printf("Welcome!\n");
    return r;
}
```

Use comments consistently and in a readable fashion

## Description

### Rule Definition

*Use comments consistently and in a readable fashion.*

### Polyspace Implementation

The rule checker checks for **Use of /* and // within a comment**.

## Examples

### Use of /* and // within a comment

#### Issue

The issue occurs when you use the character sequences `/*` and `//` within a comment.

You cannot annotate this rule in the source code. For information on annotations, see “Annotate Code and Hide Known or Acceptable Results”.

#### Risk

These character sequences in code comments might indicate an unexpected error. For instance:

- If your code contains a `/*` or a `//` in a `/*  */` comment, it typically means that you have inadvertently commented out code.
- If your code contains a `/*` in a `//` comment, it typically means that you have inadvertently uncommented a `/*  */` comment.
- Your code contains nested comments. Such comments are confusing and might lead to developer confusion.

#### Example - /* Used in // Comments

```
int x,y,z,o;

void non_compliant_comments ( void )
{
    x = y //      /* Noncompliant
    + z
    //  */
    ;
    x = y//**/ z //Noncompliant
    +o;
    x = y //*divisor:*/z  //Noncompliant
    +o;

    z++;    //    Compliant with exception: // permitted within a // comment
}

void compliant_comments ( void )
{
    x = y /*      Compliant
    + z
    */
    ;
    x = y / /*divisor:*/ z //Compliant
    +o;
    z++;    //    Compliant with exception: // is permitted within a // comment
}
```

In this example, in the `non_compliant_comments` function, :

- In the first definition of `x`, the `/*` character occurs in what appears to be a `//` comment, violating the rule. Because of the comment structure, the operation that takes place is `x = y + z;`. However, without the two `//`-s, an entirely different operation `x=y;` takes place. It is not clear which operation is intended.
- In the second and third definition of `x`, the presence of the characters `/*` in what appears to be a `//` comment raises violations of this rule. Because of the confusing comment placement, `x` is defined as `y+o` in these statements, instead of `x = y/z + o`, as intended.

Use a comment format that makes your intention clear. For instance, in the `compliant_comments` function:

- In the first definition of x, it is clear that x is defined as `x = y` and the rest of the code is deliberately commented out;
- In the second definition of `x`, it is clear x is defined as `x = y/z+o`. The placement of the comment `/*divisor*/` is clear and does not hinder code understanding.

it is clear that the operation `x=y;` is intended.

# CERT C: Rec. MSC12-C

Detect and remove code that has no effect or is never executed

## Description

### Rule Definition

*Detect and remove code that has no effect or is never executed.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Unreachable code**.
- **Dead code**.
- **Useless if**.
- **Write without a further read**.

## Examples

### Unreachable code

#### Issue

The issue occurs when your project contains code that is unreachable.

#### Risk

Unless a program exhibits any undefined behavior, unreachable code cannot execute. The unreachable code cannot affect the program output. The presence of unreachable code can indicate an error in the program logic. Unreachable code that the compiler does not remove wastes resources, for example:

- It occupies space in the target machine memory.
- Its presence can cause a compiler to select longer, slower jump instructions when transferring control around the unreachable code.
- Within a loop, it can prevent the entire loop from residing in an instruction cache.

#### Example - Code Following `return` Statement

```
enum light { red, amber, red_amber, green };
void report_color(enum light);
enum light next_light ( enum light color )
{
    enum light res;

    switch ( color )
    {
    case red:
        res = red_amber;
        break;
    case red_amber:
        res = green;
        break;
    case green:
        res = amber;
        break;
    case amber:
        res = red;
        break;
    default:
    {
        error_handler ();
        break;
    }
    }

    report_color(res);
    return res;
    res = color;     /* Non-compliant */
}
```

In this example, the rule is violated because there is an unreachable operation following the `return` statement.

### Dead code

#### Issue

The issue occurs when the analysis detects a reachable operation that does not affect program behavior if the operation is removed.

Polyspace Bug Finder detects useless write operations during analysis.

#### Risk

If an operation is reachable but removing the operation does not affect program behavior, the operation constitutes dead code.

The presence of dead code can indicate an error in the program logic. Because a compiler can remove dead code, its presence can cause confusion for code reviewers.

Operations involving language extensions such as `__asm ( "NOP" );` are not considered dead code.

#### Example - Redundant Operations

```
extern volatile unsigned int v;
extern char *p;

void f ( void ) {
    unsigned int x;

    ( void ) v;      /* Compliant - Exception*/
    ( int ) v;       /* Non-compliant  */
    v >> 3;          /* Non-compliant  */
    x = 3;           /* Non-compliant - Detected in Bug Finder only */

    *p++;            /* Non-compliant  */
    ( *p )++;        /* Compliant  */
}
```

In this example, the rule is violated when an operation is performed on a variable, but the result of that operation is not used. For instance,

- The operations (int) and >> on the variable v are redundant because the results are not used.
- The operation = is redundant because the local variable x is not read after the operation.
- The operation * on p++ is redundant because the result is not used.

The rule is not violated when:

- A variable is cast to void. The cast indicates that you are intentionally not using the value.
- The result of an operation is used. For instance, the operation * on p is not redundant, because *p is incremented.

### Useless if

#### Issue

This issue occurs on if-statements where the condition is always true. This defect occurs only on if-statements that do not have an else-statement.

This defect shows unnecessary if-statements when there is no difference in code execution if the if-statement is removed.

#### Risk

Unnecessary if statements often indicate a coding error. Perhaps the if condition is coded incorrectly or the if statement is not required at all.

#### Fix

The fix depends on the root cause of the defect. For instance, the root cause can be an error condition that is checked twice on the same execution path, making the second check redundant.

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

See examples of fixes below.

If the redundant condition represents defensive coding practices and you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Example – if with Enumerated Type

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }

    if (card < 7) { //Noncompliant
        do_something(card);
    }
}
```

The type `suit` is enumerated with five options. However, the conditional expression `card < 7` always evaluates to true because `card` can be at most 5. The `if` statement is unnecessary.

### Correction 1 — Change Condition

One possible correction is to change the if-condition in the code. In this correction, the 7 is changed to `UNKNOWN_SUIT` to relate directly to the type of `card`.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }

    if (card > UNKNOWN_SUIT) {
        do_something(card);
    }
}
```

### Correction — Remove If

Another possible correction is to remove the if-condition in the code. Because the condition is always true, you can remove the condition to simplify your code.

```
typedef enum _suit {UNKNOWN_SUIT, SPADES, HEARTS, DIAMONDS, CLUBS} suit;
suit nextcard(void);
void do_something(suit s);

void bridge(void)
{
    suit card = nextcard();
    if ((card < SPADES) || (card > CLUBS)){
        card = UNKNOWN_SUIT;
    }
    do_something(card);
}
```

### Write without a further read

#### Issue

This issue occurs when a value assigned to a variable is never read.

For instance, you write a value to a variable and then write a second value before reading the previous value. The first write operation is redundant.

#### Risk

Redundant write operations often indicate programming errors. For instance, you forgot to read the variable between two successive write operations or unintentionally read a different variable.

#### Fix

Identify the reason why you write to the variable but do not read it later. Look for common programming errors such as accidentally reading a different variable with a similar name.

If you determine that the write operation is redundant, remove the operation.

#### Example – Write Without Further Read Error

```
void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();             //Noncompliant
    /* Defect: Useless write */
}
```

After the variable `level` gets assigned the value `4 * getsensor()`, it is not read.

#### Correction — Use Value After Assignment

One possible correction is to use the variable `level` after the assignment.

```
#include <stdio.h>

void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();

    /* Fix: Use level after assignment */
    printf("The value is %d", level);

}
```

The variable `level` is printed, reading the new value.

Detect and remove unused values

## Description

### Rule Definition

*Detect and remove unused values.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Unused parameter**.
- **Write without a further read**.

## Examples

### Unused parameter

#### Issue

**Unused parameter** occurs when a function parameter is neither read nor written in the function body.

#### Risk

Unused function parameters cause the following issues:

- Indicate that the code is possibly incomplete. The parameter is possibly intended for an operation that you forgot to code.
- If the copied objects are large, redundant copies can slow down performance.

#### Fix

Determine if you intend to use the parameters. Otherwise, remove parameters that you do not use in the function body.

You can intentionally have unused parameters. For instance, you have parameters that you intend to use later when you add enhancements to the function. Add a code comment indicating your intention for later use. The code comment helps you or a code reviewer understand why your function has unused parameters.

Alternatively, add a statement such as `(void)var;` in the function body. `var` is the unused parameter. You can define a macro that expands to this statement and add the macro to the function body.

#### Example - Unused Parameter

```
void func(int* xptr, int* yptr, int flag) { //Noncompliant
    if(flag==1) {
        *xptr=0;
    }
    else {
        *xptr=1;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

In this example, the parameter `yptr` is not used in the body of `func`.

#### Correction — Use Parameter

One possible correction is to check if you intended to use the parameter. Fix your code if you intended to use the parameter.

```
void func(int* xptr, int* yptr, int flag) {
    if(flag==1) {
        *xptr=0;
        *yptr=1;
    }
    else {
        *xptr=1;
        *yptr=0;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

#### Correction — Explicitly Indicate Unused Parameter

Another possible correction is to explicitly indicate that you are aware of the unused parameter.

```
#define UNUSED(x) (void)x

void func(int* xptr, int* yptr, int flag) {
    UNUSED(yptr);
    if(flag==1) {
        *xptr=0;
    }
    else {
        *xptr=1;
    }
}

int main() {
    int x,y;
    func(&x,&y,1);
    return 0;
}
```

### Write without a further read

#### Issue

**Write without a further read** occurs when a value assigned to a variable is never read.

For instance, you write a value to a variable and then write a second value before reading the previous value. The first write operation is redundant.

#### Risk

Redundant write operations often indicate programming errors. For instance, you forgot to read the variable between two successive write operations or unintentionally read a different variable.

#### Fix

Identify the reason why you write to the variable but do not read it later. Look for common programming errors such as accidentally reading a different variable with a similar name.

If you determine that the write operation is redundant, remove the operation.

#### Example - Write Without Further Read Error

```
void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();             //Noncompliant
    /* Defect: Useless write */
}
```

After the variable `level` gets assigned the value `4 * getsensor()`, it is not read.

#### Correction — Use Value After Assignment

One possible correction is to use the variable `level` after the assignment.

```
#include <stdio.h>

void sensor_amplification(void)
{
    extern int getsensor(void);
    int level;

    level = 4 * getsensor();

    /* Fix: Use level after assignment */
    printf("The value is %d", level);

}
```

The variable `level` is printed, reading the new value.

Do not depend on undefined behavior

## Description

### Rule Definition

*Do not depend on undefined behavior.*

### Polyspace Implementation

The rule checker checks for **Undefined behavior**.

## Examples

### Undefined behavior

#### Issue

The issue occurs when the analysis detects undefined or critical unspecified behaviour. Specifically, Polyspace flags these instances of undefined or critical undefined behavior:

- Use of `offsetof` on bit fields.
- Use of `offsetof` when the second argument is not a `struct` field of the first argument.
- Use of `defined` without an identifier.
- Use of an array of incomplete types.
- Use of a function like macros by using incorrect number of arguments.

#### Risk

C code that results in undefined or critical unspecified behavior might produce unexpected or incorrect results. Such code might behave differently in different implementations. Issues caused by undefined behavior in the code might be difficult to analyze because compilers might optimize the code assuming that undefined behavior does not occur.

#### Fix

Avoid code that might result in undefined or critically unspecified behavior.

#### Example — Avoid Undefined Behaviors

```
#include <stddef.h>     /* offsetof */

struct str {
  char a:8;
  char b[10];
  char c;
};
void foo() {

  offsetof(struct str, a);//Noncompliant
  offsetof(struct str, d);//Noncompliant
}
```

In this example, the function `foo` uses the macro `offsetof` on the bit field `str.a`. This behavior is undefined. Polyspace flags it. The function then calls `offsetof` on `str.d`. Because `d` is not a field of `str`, Polyspace flags it.

These issues might cause compilation errors with your compiler. Polyspace flags this issue as a rule violation while also showing a compilation failure.

Finish every set of statements associated with a case label with a break statement

## Description

### Rule Definition

*Finish every set of statements associated with a case label with a break statement.*

### Polyspace Implementation

The rule checker checks for **Missing break of switch case**.

## Examples

### Missing break of switch case

#### Issue

**Missing break of switch case** looks for switch cases that do not end in a `break` statement.

If the last entry in the case block is a code comment, for instance:

```
switch (wt)
    {
      case WE_W:
        do_something_for_WE_W();
        do_something_else_for_WE_W();
        /* fall through to WE_X*/
      case WE_X:
        ...
    }
```

Polyspace assumes that the missing break is intentional and does not raise a defect.

#### Risk

Switch cases without break statements fall through to the next switch case. If this fall-through is not intended, the switch case can unintentionally execute code and end the switch with unexpected results.

#### Fix

If you do not want a break for the highlighted switch case, add a comment to your code to document why this case falls through to the next case. This comment removes the defect from your results and makes your code more maintainable.

If you forgot the break, add it before the end of the switch case.

#### Example - Switch Without Break Statements

```
enum WidgetEnum { WE_W, WE_X, WE_Y, WE_Z } widget_type;

extern void demo_do_something_for_WE_W(void);
extern void demo_do_something_for_WE_X(void);
extern void demo_report_error(void);

void bug_missingswitchbreak(enum WidgetEnum wt)
{
    /*
      In this non-compliant code example, the case where widget_type is WE_W lacks a
      break statement. Consequently, statements that should be executed only when
      widget_type is WE_X are executed even when widget_type is WE_W.
    */
    switch (wt)
    {
      case WE_W:  //Noncompliant
        demo_do_something_for_WE_W();
      case WE_X:  //Noncompliant
        demo_do_something_for_WE_X();
      default:
        /* Handle error condition */
        demo_report_error();
    }
}
```

In this example, there are two cases without `break` statements. When `wt` is `WE_W`, the statements for `WE_W`, `WE_X`, and the `default` case execute because the program falls through the two cases without a break. No defect is raised on the `default` case or last case because it does not need a break statement.

**Correction — Add a Comment or break**

To fix this example, either add a comment to mark and document the acceptable fall-through or add a break statement to avoid fall-through. In this example, case `WE_W` is supposed to fall through, so a comment is added to explicitly state this action. For the second case, a break statement is added to avoid falling through to the `default` case.

```
enum WidgetEnum { WE_W, WE_X, WE_Y, WE_Z } widget_type;

extern void demo_do_something_for_WE_W(void);
extern void demo_do_something_for_WE_X(void);
extern void demo_report_error(void);

void corrected_missingswitchbreak(enum WidgetEnum wt)
{
    switch (wt)
    {
      case WE_W:
        demo_do_something_for_WE_W();
        /* fall through to WE_X*/
      case WE_X:
        demo_do_something_for_WE_X();
        break;
      default:
        /* Handle error condition */
        demo_report_error();
    }
}
```

Be careful while handling sensitive data, such as passwords, in program code

## Description

### Rule Definition

*Be careful while handling sensitive data, such as passwords, in program code.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Constant block cipher initialization vector**.
- **Constant cipher key**.
- **Predictable block cipher initialization vector**.
- **Predictable cipher key**.
- **Sensitive heap memory not cleared before release**.
- **Uncleared sensitive data in stack**.
- **Unsafe standard encryption function**.

## Examples

### Constant block cipher initialization vector

#### Issue

**Constant block cipher initialization vector** occurs when you use a constant for the initialization vector (IV) during encryption.

#### Risk

Using a constant IV is equivalent to not using an IV. Your encrypted data is vulnerable to dictionary attacks.

Block ciphers break your data into blocks of fixed size. Block cipher modes such as CBC (Cipher Block Chaining) protect against dictionary attacks by XOR-ing each block with the encrypted output from the previous block. To protect the first block, these modes use a random initialization vector (IV). If you use a constant IV to encrypt multiple data streams that have a common beginning, your data becomes vulnerable to dictionary attacks.

#### Fix

Produce a random IV by using a strong random number generator.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

#### Example - Constants Used for Initialization Vector

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

/* Using the cryptographic routines */

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16] = {'1', '2', '3', '4','5','6','b','8','9',
                                 '1','2','3','4','5','6','7'};
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);  //Noncompliant
}
```

In this example, the initialization vector `iv` has constants only. The constant initialization vector makes your cipher vulnerable to dictionary attacks.

#### Correction — Use Random Initialization Vector

One possible correction is to use a strong random number generator to produce the initialization vector. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

/* Using the cryptographic routines */

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

### Constant cipher key

#### Issue

**Constant cipher key** occurs when you use a constant for the encryption or decryption key.

#### Risk

If you use a constant for the encryption or decryption key, an attacker can retrieve your key easily.

You use a key to encrypt and later decrypt your data. If a key is easily retrieved, data encrypted using that key is not secure.

#### Fix

Produce a random key by using a strong random number generator.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

#### Example - Constants Used for Key

```
#include <openssl/evp.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16] = {'1', '2', '3', '4','5','6','b','8','9',
                                 '1','2','3','4','5','6','7'};
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);  //Noncompliant
}
```

In this example, the cipher key, `key`, has constants only. An attacker can easily retrieve a constant key.

#### Correction — Use Random Key

Use a strong random number generator to produce the cipher key. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

### Predictable block cipher initialization vector

#### Issue

**Predictable block cipher initialization vector** occurs when you use a weak random number generator for the block cipher initialization vector.

#### Risk

If you use a weak random number generator for the initiation vector, your data is vulnerable to dictionary attacks.

Block ciphers break your data into blocks of fixed size. Block cipher modes such as CBC (Cipher Block Chaining) protect against dictionary attacks by XOR-ing each block with the encrypted output from the previous block. To protect the first block, these modes use a random initialization vector (IV). If you use a weak random number generator for your IV, your data becomes vulnerable to dictionary attacks.

#### Fix

Use a strong pseudo-random number generator (PRNG) for the initialization vector. For instance, use:

- OS-level PRNG such as `/dev/random` on UNIX or `CryptGenRandom()` on Windows
- Application-level PRNG such as Advanced Encryption Standard (AES) in Counter (CTR) mode, HMAC-SHA1, etc.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

#### Example - Predictable Initialization Vector

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_pseudo_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);  //Noncompliant
}
```

In this example, the function `RAND_pseudo_bytes` declared in `openssl/rand.h` produces the initialization vector. The byte sequences that `RAND_pseudo_bytes` generates are not necessarily unpredictable.

#### Correction — Use Strong Random Number Generator

Use a strong random number generator to produce the initialization vector. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *key){
    unsigned char iv[SIZE16];
    RAND_bytes(iv, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

### Predictable cipher key

#### Issue

**Predictable cipher key** occurs when you use a weak random number generator for the encryption or decryption key.

#### Risk

If you use a weak random number generator for the encryption or decryption key, an attacker can retrieve your key easily.

You use a key to encrypt and later decrypt your data. If a key is easily retrieved, data encrypted using that key is not secure.

#### Fix

Use a strong pseudo-random number generator (PRNG) for the key. For instance:

- Use an OS-level PRNG such as `/dev/random` on UNIX or `CryptGenRandom()` on Windows
- Use an application-level PRNG such as Advanced Encryption Standard (AES) in Counter (CTR) mode, HMAC-SHA1, etc.

For a list of random number generators that are cryptographically weak, see `Vulnerable pseudo-random number generator`.

#### Example - Predictable Cipher Key

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_pseudo_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);  //Noncompliant
}
```

In this example, the function `RAND_pseudo_bytes` declared in `openssl/rand.h` produces the cipher key. However, the byte sequences that `RAND_pseudo_bytes` generates are not necessarily unpredictable.

#### Correction — Use Strong Random Number Generator

One possible correction is to use a strong random number generator to produce the cipher key. The corrected code here uses the function `RAND_bytes` declared in `openssl/rand.h`.

```
#include <openssl/evp.h>
#include <openssl/rand.h>
#include <stdlib.h>
#define SIZE16 16

int func(EVP_CIPHER_CTX *ctx, unsigned char *iv){
    unsigned char key[SIZE16];
    RAND_bytes(key, 16);
    return EVP_CipherInit_ex(ctx, EVP_aes_128_cbc(), NULL, key, iv, 1);
}
```

### Sensitive heap memory not cleared before release

#### Issue

**Sensitive heap memory not cleared before release** detects dynamically allocated memory containing sensitive data. If you do not clear the sensitive data when you free the memory, Bug Finder raises a defect on the `free` function.

#### Risk

If the memory zone is reallocated, an attacker can still inspect the sensitive data in the old memory zone.

#### Fix

Before calling `free`, clear out the sensitive data using `memset` or `SecureZeroMemory`.

#### Example - Sensitive Buffer Freed, Not Cleared

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>

void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    free(buf); //Noncompliant
}
```

In this example, the function uses a buffer of passwords and frees the memory before the end of the function. However, the data in the memory is not cleared by using the `free` command.

#### Correction — Nullify Data

One possible correction is to write over the data to clear out the sensitive information. This example uses `memset` to write over the data with zeros.

```
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0;i<(sizeof(arr)/sizeof(arr[0]));i++) assert(arr[i]==0)

void sensitiveheapnotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char* buf = (char*) malloc(1024);

    if (buf) {
        getpwnam_r(my_user, &pwd, buf, bufsize, &result);
        memset(buf, 0, (size_t)1024);
        isNull(buf);
        free(buf);
    }
}
```

### Uncleared sensitive data in stack

#### Issue

**Uncleared sensitive data in stack** detects static memory containing sensitive data. If you do not clear the sensitive data from your stack before exiting the function or program, Bug Finder raises a defect on the last curly brace.

#### Risk

Leaving sensitive information in your stack, such as passwords or user information, allows an attacker additional access to the information after your program has ended.

#### Fix

Before exiting a function or program, clear out the memory zones that contain sensitive data by using `memset` or `SecureZeroMemory`.

#### Example - Static Buffer of Password Information

```
#include <unistd.h>
#include <sys/types.h>
#include <pwd.h>

void bug_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
}  //Noncompliant
```

In this example, a static buffer is filled with password information. The program frees the stack memory at the end of the program. However, the data is still accessible from the memory.

#### Correction — Clear Memory

One possible correction is to write over the memory before exiting the function. This example uses `memset` to clear the data from the buffer memory.

```
#include <unistd.h>
#include <string.h>
#include <sys/types.h>
#include <pwd.h>
#include <assert.h>

#define isNull(arr) for(int i=0; i<(sizeof(arr)/sizeof(arr[0])); i++) assert(arr[i]==0)

void corrected_sensitivestacknotcleared(const char * my_user) {
    struct passwd* result, pwd;
    long bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    char buf[1024] = "";
    getpwnam_r(my_user, &pwd, buf, bufsize, &result);
    memset(buf, 0, (size_t)1024);
    isNull(buf);
}
```

### Unsafe standard encryption function

#### Issue

**Unsafe standard encryption function** detects use of functions with a broken or weak cryptographic algorithm. For example, `crypt` is not reentrant and is based on the risky Data Encryption Standard (DES).

#### Risk

The use of a broken, weak, or nonstandard algorithm can expose sensitive information to an attacker. A determined hacker can access the protected data using various techniques.

If the weak function is nonreentrant, when you use the function in concurrent programs, there is an additional race condition risk.

#### Fix

Avoid functions that use these encryption algorithms. Instead, use a reentrant function that uses a stronger encryption algorithm.

**Note** Some implementations of `crypt` support additional, possibly more secure, encryption algorithms.

#### Example - Decrypting Password Using `crypt`

```
#define _GNU_SOURCE
#include <pwd.h>
#include <string.h>
#include <crypt.h>

volatile int rd = 1;

const char *salt = NULL;
struct crypt_data input, output;

int verif_pwd(const char *pwd, const char *cipher_pwd, int safe)
{
    int r = 0;
    char *decrypted_pwd = NULL;

    switch(safe)
    {
      case 1:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      case 2:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      default:
        decrypted_pwd = crypt(pwd, cipher_pwd);  //Noncompliant
        break;
    }

    r = (strcmp(cipher_pwd, decrypted_pwd) == 0);

    return r;
}
```

In this example, `crypt_r` and `crypt` decrypt a password. However, `crypt` is nonreentrant and uses the unsafe Data Encryption Standard algorithm.

#### Correction — Use `crypt_r`

One possible correction is to replace `crypt` with `crypt_r`.

```
#define _GNU_SOURCE
#include <pwd.h>
```

```
#include <string.h>
#include <crypt.h>

volatile int rd = 1;

const char *salt = NULL;
struct crypt_data input, output;

int verif_pwd(const char *pwd, const char *cipher_pwd, int safe)
{
    int r = 0;
    char *decrypted_pwd = NULL;

    switch(safe)
    {
      case 1:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      case 2:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;

      default:
        decrypted_pwd = crypt_r(pwd, cipher_pwd, &output);
        break;
    }

    r = (strcmp(cipher_pwd, decrypted_pwd) == 0);

    return r;
}
```

Do not use a switch statement to transfer control into a complex block

## Description

### Rule Definition

*Do not use a switch statement to transfer control into a complex block.*

### Polyspace Implementation

The rule checker checks for **Switch label not at outermost level of body of switch statement**.

## Examples

### Switch label not at outermost level of body of switch statement

#### Issue

The issue occurs when you use a switch label and the most closely-enclosing compound statement is not the body of the switch statement. For instance a `case` label is enclosed inside a `for` loop that is enclosed inside the switch statement.

#### Risk

The C Standard permits placing a switch label (for instance, `case` or `default`) before any statement contained in the body of a switch statement. This flexibility can lead to unstructured code. To prevent unstructured code, make sure a switch label appears only at the outermost level of the body of a switch statement.

Use robust loop termination conditions

## Description

### Rule Definition

*Use robust loop termination conditions.*

### Polyspace Implementation

The rule checker checks for **Loop bounded with tainted value**.

### Extend Checker

A default Bug Finder analysis might not flag a **Loop bounded with tainted value** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Loop bounded with tainted value

#### Issue

**Loop bounded with tainted value** detects loops that are bounded by values from an unsecure source.

#### Risk

A tainted value can cause over looping or infinite loops. Attackers can use this vulnerability to crash your program or cause other unintended behavior.

#### Fix

Before starting the loop, validate unknown boundary and iterator values.

#### Example — Loop Boundary From User Input

```
#include<stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    for (int i=0 ; i < count; ++i) { //Noncompliant
        res += i;
    }
    return res;
}
```

In this example, the function uses a user input to loop `count` times. `count` could be any number because the value is not checked before starting the `for` loop.

#### Correction: Clamp Tainted Loop Control

One possible correction is to clamp the tainted loop control. To validate the tainted loop variable `count`, this example limits `count` to a minimum value and a maximum value by using inline functions `min` and `max`. Regardless of the user input, the value of `count` remains within a known range.

```
#include<stdio.h>
#include<algorithm>
#define MIN 50
#define MAX 128
static  inline int max(int a, int b) { return a > b ? a : b;}
static inline int min(int a, int b) { return a < b ? a : b; }

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;
    count = max(MIN, min(count, MAX));
    for (int i=0 ; i<count ; ++i) {
        res += i;
    }
    return res;
}
```

#### Correction — Check Tainted Loop Control

Another possible correction is to check the low bound and the high bound of the tainted loop boundary variable before starting the `for` loop. This example checks the low and high bounds of `count` and executes the loop only when `count` is between 0 and 127.

```
#include<stdio.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int taintedloopboundary(void) {
    int count;
    scanf("%d", &count);
    int res = 0;

    if (count>=0 && count<SIZE128) {
        for (int i=0 ; i<count ; ++i) {
            res += i;
        }
    }
    return res;
}
```

Use the setjmp(), longjmp() facility securely

## Description

### Rule Definition

*Use the setjmp(), longjmp() facility securely.*

### Polyspace Implementation

The rule checker checks for **Use of setjmp/longjmp**.

## Examples

### Use of setjmp/longjmp

#### Issue

**Use of setjmp/longjmp** occurs when you use a combination of `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` to deviate from normal control flow and perform non-local jumps in your code.

#### Risk

Using `setjmp` and `longjmp`, or `sigsetjmp` and `siglongjmp` has the following risks:

- Nonlocal jumps are vulnerable to attacks that exploit common errors such as buffer overflows. Attackers can redirect the control flow and potentially execute arbitrary code.
- Resources such as dynamically allocated memory and open files might not be closed, causing resource leaks.
- If you use `setjmp` and `longjmp` in combination with a signal handler, unexpected control flow can occur. POSIX does not specify whether `setjmp` saves the signal mask.
- Using `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` makes your program difficult to understand and maintain.

#### Fix

Perform nonlocal jumps in your code using `setjmp/longjmp` or `sigsetjmp/siglongjmp` only in contexts where such jumps can be performed securely. Alternatively, use POSIX threads if possible.

In C++, to simulate throwing and catching exceptions, use standard idioms such as `throw` expressions and `catch` statements.

#### Example - Use of `setjmp` and `longjmp`

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

static jmp_buf env;
```

```
void sighandler(int signum) {
    longjmp(env, signum); //Noncompliant
}
void func_main(int i) {
    signal(SIGINT, sighandler);
    if (setjmp(env)==0) { //Noncompliant
        while(1) {
            /* Main loop of program, iterates until SIGINT signal catch */
            i = update(i);
        }
    } else {
        /* Managing longjmp return */
        i = -update(i);
    }

    print_int(i);
    return;
}
```

In this example, the initial return value of `setjmp` is 0. The `update` function is called in an infinite `while` loop until the user interrupts it through a signal.

In the signal handling function, the `longjmp` statement causes a jump back to `main` and the return value of `setjmp` is now 1. Therefore, the `else` branch is executed.

**Correction — Use Alternative to `setjmp` and `longjmp`**

To emulate the same behavior more securely, use a `volatile` global variable instead of a combination of `setjmp` and `longjmp`.

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

volatile sig_atomic_t eflag = 0;

void sighandler(int signum) {
     eflag = signum;                   /* Fix: using global variable */
}

void func_main(int i) {
      /* Fix: Better design to avoid use of setjmp/longjmp */
    signal(SIGINT, sighandler);
    while(!eflag) {                   /* Fix: using global variable */
        /* Main loop of program, iterates until eflag is changed */
        i = update(i);
    }

    print_int(i);
    return;
}
```

Do not use deprecated or obsolescent functions

## Description

### Rule Definition

*Do not use deprecated or obsolescent functions.*

### Polyspace Implementation

The rule checker checks for **Use of obsolete standard function**.

## Examples

### Use of obsolete standard function

#### Issue

**Use of obsolete standard function** detects calls to standard function routines that are considered legacy, removed, deprecated, or obsolete by C/C++ coding standards.

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `asctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |
| `asctime_r` | Deprecated in POSIX.1-2008 | Implementation based on unsafe function `sprintf`. | `strftime` or `asctime_s` |
| `bcmp` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcmp` |
| `bcopy` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcpy` or `memmove` |
| `brk` and `sbrk` | Marked as legacy in SUSv2 and POSIX.1-2001. | | `malloc` |
| `bsd_signal` | Removed in POSIX.1-2008 | | `sigaction` |
| `bzero` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | `memset` |
| `ctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| ctime_r | Deprecated in POSIX.1-2008 | Implementation based on unsafe function sprintf. | strftime or asctime_s |
| cuserid | Removed in POSIX.1-2001. | Not reentrant. Precise functionality not standardized causing portability issues. | getpwuid |
| ecvt and fcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | Not reentrant | snprintf |
| ecvt_r and fcvt_r | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | | snprintf |
| ftime | Removed in POSIX.1-2008 | | time, gettimeofday, clock_gettime |
| gamma, gammaf, gammal | Function not specified in any standard because of historical variations | Portability issues. | tgamma, lgamma |
| gcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | snprintf |
| getcontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| getdtablesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_OPEN _MAX ) |
| gethostbyaddr | Removed in POSIX.1-2008 | Not reentrant | getaddrinfo |
| gethostbyname | Removed in POSIX.1-2008 | Not reentrant | getnameinfo |
| getpagesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_PAGE SIZE ) |
| getpass | Removed in POSIX.1-2001. | Not reentrant. | getpwuid |
| getw | Not present in POSIX.1-2001. | | fread |
| getwd | Marked legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | getcwd |
| index | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strchr |
| makecontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| memalign | Appears in SunOS 4.1.3. Not in 4.4 BSD or POSIX.1-2001 | | posix_memalign |
| mktemp | Removed in POSIX.1-2008. | Generated names are predictable and can cause a race condition. | mkstemp removes race risk |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| pthread_attr_ getstackaddr and pthread_attr_ setstackaddr | | Ambiguities in the specification of the stackaddr attribute cause portability issues | pthread_attr_ getstack and pthread_attr_ setstack |
| putw | Not present in POSIX.1-2001. | Portability issues. | fwrite |
| qecvt and qfcvt | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| qecvt_r and qfcvt_r | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | snprintf |
| rand_r | Marked as obsolete in POSIX.1-2008 | | |
| re_comp | BSD API function | Portability issues | regcomp |
| re_exes | BSD API function | Portability issues | regexec |
| rindex | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strrchr |
| scalb | Removed in POSIX.1-2008 | | scalbln, scalblnf, or scalblnl |
| sigblock | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigsetmask | 4.3BSD signal API whose origin is unclear | | sigprocmask |
| sigstack | Interface is obsolete and not implemented on most platforms. | Portability issues. | sigaltstack |
| sigvec | 4.3BSD signal API whose origin is unclear | | sigaction |
| swapcontext | Removed in POSIX.1-2008 | Portability issues. | Use POSIX threads. |
| tmpnam and tmpnam_r | Marked as obsolete in POSIX.1-2008. | This function generates a different string each time it is called, up to TMP_MAX times. If it is called more than TMP_MAX times, the behavior is implementation-defined. | mkstemp, tmpfile |
| ttyslot | Removed in POSIX.1-2001. | | |
| ualarm | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | Errors are under-specified | setitimer or POSIX timer_create |
| usleep | Removed in POSIX.1-2008. | | nanosleep |
| utime | SVr4, POSIX.1-2001. POSIX.1-2008 marks as obsolete. | | |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| valloc | Marked as obsolete in 4.3BSD.<br>Marked as legacy in SUSv2.<br>Removed from POSIX.1-2001 | | posix_memalign |
| vfork | Removed from POSIX.1-2008 | Under-specified in previous standards. | fork |
| wcswcs | This function was not included in the final ISO/IEC 9899:1990/ Amendment 1:1995 (E). | | wcsstr |
| WinExec | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |
| LoadModule | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Printing Out Time

```
#include <stdio.h>
#include <time.h>

void timecheck_bad(int argc, char *argv[])
{
    time_t ticks;

    ticks = time(NULL);
    printf("%.24s\r\n", ctime(&ticks)); //Noncompliant
}
```

In this example, the function ctime formats the current time and prints it out. However, ctime was removed after C99 because it does not work on multithreaded programs.

#### Correction — Different Time Function

One possible correction is to use strftime instead because this function uses a set buffer size.

```
#include <stdio.h>
#include <string.h>
#include <time.h>

void timecheck_good(int argc, char *argv[])
{
    char outBuff[1025];
    time_t ticks;
    struct tm * timeinfo;

    memset(outBuff, 0, sizeof(outBuff));

    ticks = time(NULL);
    timeinfo = localtime(&ticks);
    strftime(outBuff,sizeof(outBuff),"%I:%M%p.",timeinfo);
    fprintf(stdout, outBuff);
}
```

Limit access to files by creating a jail

## Description

### Rule Definition

*Limit access to files by creating a jail.*

### Polyspace Implementation

The rule checker checks for **File manipulation after chroot without chdir**.

## Examples

### File manipulation after chroot without chdir

#### Issue

**File manipulation after `chroot()` without `chdir("/")`** detects access to the file system outside of the jail created by `chroot`. By calling `chroot`, you create a file system jail that confines access to a specific file subsystem. However, this jail is ineffective if you do not call `chdir("/")`.

#### Risk

If you do not call `chdir("/")` after creating a `chroot` jail, file manipulation functions that takes a path as an argument can access files outside of the jail. An attacker can still manipulate files outside the subsystem that you specified, making the chroot jail ineffective.

#### Fix

After calling `chroot`, call `chdir("/")` to make your `chroot` jail more secure.

#### Example - Open File in `chroot`-jail

```
#include <unistd.h>
#include <stdio.h>

const char root_path[] = "/var/ftproot";
const char log_path[] = "file.log";
FILE* chrootmisuse() {
    FILE* res;
    chroot(root_path);
    chdir("base");  //Noncompliant
    res = fopen(log_path, "r");  //Noncompliant
    return res;
}
```

This example uses `chroot` to create a chroot-jail. However, to use the `chroot` jail securely, you must call `chdir("\")` afterward. This example calls `chdir("base")`, which is not equivalent. Bug Finder also flags `fopen` because `fopen` opens a file in the vulnerable `chroot`-jail.

#### Correction — Call `chdir("/")`

Before opening files, call `chdir("/")`.

```
#include <unistd.h>
#include <stdio.h>

const char root_path[] = "/var/ftproot";
const char log_path[] = "file.log";
FILE* chrootmisuse() {
    FILE* res;
    chroot(root_path);
    chdir("/");
    res = fopen(log_path, "r");
    return res;
}
```

Be specific when dynamically loading libraries

## Description

### Rule Definition

*Be specific when dynamically loading libraries.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Load of library from a relative path can be controlled by an external actor**.
- **Library loaded from externally controlled path**.

### Extend Checker

A default Bug Finder analysis might not flag a **Library loaded from externally controlled path** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Load of library from a relative path can be controlled by an external actor

#### Issue

**Load of library from a relative path can be controlled by an external actor** detects library loading routines that load an external library. If you load the library using a relative path or no path, Bug Finder flags the loading routine as a defect.

#### Risk

By using a relative path or no path to load an external library, your program uses an unsafe search process to find the library. An attacker can control the search process and replace the intended library with a library of their own.

#### Fix

When you load an external library, specify the full path.

#### Example - Open Library with Library Name

```
#include <dlfcn.h>
#include <stdlib.h>
#include <string.h>
#include <malloc.h>
#include <stdio.h>

void relative_path()
```

```
{
    dlopen("liberty.dll",RTLD_LAZY); //Noncompliant
}
```

In this example, `dlopen` opens the `liberty` library by calling only the name of the library. However, this call to the library uses a relative path to find the library, which is unsafe.

#### Correction — Use Full Path to Library

One possible correction is to use the full path to the library when you load it into your program.

```
#include <dlfcn.h>
#include <stdlib.h>
#include <string.h>
#include <malloc.h>
#include <stdio.h>

void relative_path()
{
    dlopen("/home/my_libs/library/liberty.dll",RTLD_LAZY);
}
```

### Library loaded from externally controlled path

#### Issue

**Library loaded from externally controlled path** looks for libraries loaded from fixed or controlled paths. If unintended actors can control one or more locations on this fixed path, Bug Finder raises a defect.

#### Risk

If an attacker knows or controls the path that you use to load a library, the attacker can change:

- The library that the program loads, replacing the intended library and commands.
- The environment in which the library executes, giving unintended permissions and capabilities to the attacker.

#### Fix

When possible, use hard-coded or fully qualified path names to load libraries. It is possible the hard-coded paths do not work on other systems. Use a centralized location for hard-coded paths, so that you can easily modify the path within the source code.

Another solution is to use functions that require explicit paths. For example, `system()` does not require a full path because it can use the `PATH` environment variable. However, `execl()` and `execv()` do require the full path.

#### Example - Call Custom Library

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void* taintedpathlib() {
    void* libhandle = NULL;
    char lib[SIZE128] = "";
    char* userpath = getenv("LD_LIBRARY_PATH");
    strncpy(lib, userpath, SIZE128);
    strcat(lib, "/libX.so");
    libhandle = dlopen(lib, 0x00001); //Noncompliant
    return libhandle;
}
```

This example loads the library `libX.so` from an environment variable `LD_LIBRARY_PATH`. An attacker can change the library path in this environment variable. The actual library you load could be a different library from the one that you intend.

**Correction — Change and Check Path**

One possible correction is to change how you get the library path and check the path of the library before opening the library. This example receives the path as an input argument. Then the path is checked to make sure the library is not under `/usr/`.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <dlfcn.h>
#include <limits.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

/* Function to sanitize a string */
int sanitize_str(char* s, size_t n) {
    /* strlen is used here as a kind of firewall for tainted string errors */
    int res = (strlen(s) > 0 && strlen(s) < n);
    return res;
}
void* taintedpathlib(char* userpath) {
    void* libhandle = NULL;
    if (sanitize_str(userpath, SIZE128)) {
        char lib[SIZE128] = "";

        if (strncmp(userpath, "/usr", 4)!=0) {
            strncpy(lib, userpath, SIZE128);
            strcat(lib, "/libX.so");
            libhandle = dlopen(lib, RTLD_LAZY);
        }
    }
    return libhandle;
}
```

Accessing freed memory

## Description

### Rule Definition

*Accessing freed memory.*

### Polyspace Implementation

This checker checks for these issues:

- **Use of previously freed pointer**.
- **Invalid use of standard library string routine**.

## Examples

### Use of previously freed pointer

#### Issue

**Use of previously freed pointer** occurs when you access a block of memory after freeing the block using the `free` function.

#### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to access this block of memory can result in unpredictable behavior or even a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to free the memory later or allocate another memory block to the pointer before access.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

#### Example - Use of Previously Freed Pointer Error

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   { 
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);
    j = *pi + shift;
    /* Defect: Reading a freed pointer */

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing`pi` after the `free` statement is not valid.

**Correction — Free Pointer After Use**

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

### Invalid use of standard library string routine

**Issue**

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

**Risk**

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

**Fix**

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Invalid Use of Standard Library String Routine Error**

```
 #include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

**Correction — Use Valid Arguments**

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

Accessing shared objects in signal handlers

## Description

### Rule Definition

*Accessing shared objects in signal handlers.*

### Polyspace Implementation

This checker checks for **Shared data access within signal handler**.

## Examples

### Shared data access within signal handler

#### Issue

**Shared data access within signal handler** occurs when you access or modify a shared object inside a signal handler.

#### Risk

When you define a signal handler function to access or modify a shared object, the handler accesses or modifies the shared object when it receives a signal. If another function is already accessing the shared object, that function causes a race condition and can leave the data in an inconsistent state.

#### Fix

To access or modify shared objects inside a signal handler, check that the objects are lock-free atomic, or, if they are integers, declare them as `volatile sig_atomic_t`.

#### Example - `int` Variable Access in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* declare global variable. */
int e_flag;

void sig_handler(int signum)
{
    /* Signal handler accesses variable that is not
    of type volatile sig_atomic_t. */
    e_flag = signum;
}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` accesses `e_flag`, a variable of type `int`. A concurrent access by another function can leave `e_flag` in an inconsistent state.

### Correction — Declare Variable of Type `volatile sig_atomic_t`

Before you access a shared variable from a signal handler, declare the variable with type `volatile sig_atomic_t` instead of `int`. You can safely access variables of this type asynchronously.

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* Declare variable of type volatile sig_atomic_t. */
volatile sig_atomic_t e_flag;
void sig_handler(int signum)
{
    /* Use variable of proper type inside signal handler. */
    e_flag = signum;

}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

# ISO/IEC TS 17961 [addrescape]

Escaping of the address of an automatic object

## Description

### Rule Definition

*Escaping of the address of an automatic object.*

### Polyspace Implementation

This checker checks for these issues:

- **Pointer or reference to stack variable leaving scope**.
- **Use of automatic variable as putenv-family function argument**.

## Examples

### Pointer or reference to stack variable leaving scope

#### Issue

**Pointer or reference to stack variable leaving scope** occurs when a pointer or reference to a local variable leaves the scope of the variable. For instance:

- A function returns a pointer to a local variable.
- A function performs the assignment `globPtr = &locVar`. `globPtr` is a global pointer variable and `locVar` is a local variable.
- A function performs the assignment `*paramPtr = &locVar`. `paramPtr` is a function parameter that is, for instance, an `int**` pointer and `locVar` is a local `int` variable.
- A C++ method performs the assignment `memPtr = &locVar`. `memPtr` is a pointer data member of the class the method belongs to. `locVar` is a variable local to the method.

The defect also applies to memory allocated using the `alloca` function. The defect does not apply to static, local variables. Polyspace assumes that the local objects within a function definition are in the same scope.

#### Risk

Local variables are allocated an address on the stack. Once the scope of a local variable ends, this address is available for reuse. Using this address to access the local variable value outside the variable scope can cause unexpected behavior.

If a pointer to a local variable leaves the scope of the variable, Polyspace Bug Finder highlights the defect. The defect appears even if you do not use the address stored in the pointer. For maintainable code, it is a good practice to not allow the pointer to leave the variable scope. Even if you do not use the address in the pointer now, someone else using your function can use the address, causing undefined behavior.

#### Fix

Do not allow a pointer or reference to a local variable to leave the variable scope.

#### Example - Pointer to Local Variable Returned from Function

```
void func2(int *ptr) {
    *ptr = 0;
}

int* func1(void) {
    int ret = 0;
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

In this example, `func1` returns a pointer to local variable `ret`.

In `main`, `ptr` points to the address of the local variable. When `ptr` is accessed in `func2`, the access is illegal because the scope of `ret` is limited to `func1`,

### Use of automatic variable as putenv-family function argument

#### Issue

**Use of automatic variable as `putenv`-family function argument** occurs when the argument of a `putenv`-family function is a local variable with automatic duration.

#### Risk

The function `putenv(char *string)` inserts a pointer to its supplied argument into the environment array, instead of making a copy of the argument. If the argument is an automatic variable, its memory can be overwritten after the function containing the `putenv()` call returns. A subsequent call to `getenv()` from another function returns the address of an out-of-scope variable that cannot be dereferenced legally. This out-of-scope variable can cause environment variables to take on unexpected values, cause the program to stop responding, or allow arbitrary code execution vulnerabilities.

#### Fix

Use `setenv()`/`unsetenv()` to set and unset environment variables. Alternatively, use `putenv`-family function arguments with dynamically allocated memory, or, if your application has no reentrancy requirements, arguments with static duration. For example, a single thread execution with no recursion or interrupts does not require reentrancy. It cannot be called (reentered) during its execution.

#### Example - Automatic Variable as Argument of `putenv()`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
```

```
{
    char env[SIZE1024];
    int retval = sprintf(env, "TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }
    /* Environment variable TEST is set using putenv().
    The argument passed to putenv is an automatic variable. */
    retval = putenv(env);
    if (retval != 0) {
        /* Handle error */
    }
}
```

In this example, `sprintf()` stores the character string `TEST=var` in `env`. The value of the environment variable `TEST` is then set to `var` by using `putenv()`. Because `env` is an automatic variable, the value of `TEST` can change once `func()` returns.

**Correction — Use `static` Variable for Argument of `putenv()`**

Declare `env` as a static-duration variable. The memory location of `env` is not overwritten for the duration of the program, even after `func()` returns.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024
void func(int var)
{
    /* static duration variable */
    static char env[SIZE1024];
    int retval = sprintf(env,"TEST=%s", var ? "1" : "0");
    if (retval <= 0) {
        /* Handle error */
    }

    /* Environment variable TEST is set using putenv() */
    retval=putenv(env);
    if (retval != 0) {
        /* Handle error */
    }
}
```

**Correction — Use `setenv()` to Set Environment Variable Value**

To set the value of `TEST` to `var`, use `setenv()`.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE1024 1024

void func(int var)
{
    /* Environment variable TEST is set using setenv() */
    int retval = setenv("TEST", var ? "1" : "0", 1);

    if (retval != 0) {
        /* Handle error */
    }
}
```

Converting pointer values to more strictly aligned pointer types

## Description

### Rule Definition

*Converting pointer values to more strictly aligned pointer types.*

### Polyspace Implementation

This checker checks for **Wrong allocated object size for cast**.

## Examples

### Wrong allocated object size for cast

#### Issue

**Wrong allocated object size for cast** occurs during pointer conversion when the pointer's address is misaligned. If a pointer is converted to a different pointer type, the size of the allocated memory must be a multiple of the size of the destination pointer.

#### Risk

Dereferencing a misaligned pointer has undefined behavior and can cause your program to crash.

#### Fix

Suppose you convert a pointer `ptr1` to `ptr2`. If `ptr1` points to a buffer of `N` bytes and `ptr2` is a *`type`* `*` pointer where `sizeof(`*`type`*`)` is `n` bytes, make sure that `N` is an integer multiple of `n`.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Dynamic Allocation of Pointers

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(13);
    long *dest;

    dest = (long*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to a `long*`. The dynamically allocated memory of `ptr`, 13 bytes, is not a multiple of the size of `dest`, 4 bytes. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the allocated memory to 12 instead of 13.

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(12);
    long *dest;

    dest = (long*)ptr;
}
```

#### Example - Static Allocation of Pointers

```
void static_non_align(void){
    char arr[13], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to an `int*` in line 6. `ptr` has a memory size of 13 bytes because the array `arr` has a size of 13 bytes. The size of `dest` is 4 bytes, which is not a multiple of 13. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the size of the array `arr` to a multiple of 4.

```
void static_non_align(void){
    char arr[12], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr;
}
```

#### Example - Allocation with a Function

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;
    dest1 = (int*)my_alloc(13);  //defect
    dest2 = (char*)my_alloc(13); //not a defect
}
```

In this example, the software raises a defect on the conversion of the pointer returned by `my_alloc(13)` to an `int*` in line 11. `my_alloc(13)` returns a pointer with a dynamically allocated size of 13 bytes. The size of `dest1` is 4 bytes, which is not a divisor of 13. This misalignment causes the **Wrong allocated object size for cast** defect. In line 12, the same function call, `my_alloc(13)`, does not call a defect for the conversion to `dest2` because the size of `char*`, 1 byte, a divisor of 13.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the argument for `my_alloc` to a multiple of 4.

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(12);
    dest2 = (char*)my_alloc(13);
}
```

Calling functions with incorrect arguments

## Description

### Rule Definition

*Calling functions with incorrect arguments.*

### Polyspace Implementation

This checker checks for these issues:

- **Conflicting declarations or conflicting declaration and definition**.
- **Unreliable cast of function pointer**.

## Examples

### Conflicting declarations or conflicting declaration and definition

#### Issue

The issue occurs when all declarations of an object or function do not use the same names and type qualifiers.

The rule checker detects situations where parameter names or data types are different between multiple declarations or the declaration and the definition. The checker considers declarations in all translation units and flags issues that are not likely to be detected by a compiler.

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis"*.

#### Risk

Consistently using parameter names and types across declarations of the same object or function encourages stronger typing. It is easier to check that the same function interface is used across all declarations.

#### Example - Mismatch in Parameter Names

```
extern int div (int num, int den);

int div(int den, int num) { /* Non compliant */
    return(num/den);
}
```

In this example, the rule is violated because the parameter names in the declaration and definition are switched.

#### Example - Mismatch in Parameter Data Types

```
typedef unsigned short width;
typedef unsigned short height;
typedef unsigned int area;

extern area calculate(width w, height h);

area calculate(width w, width h) { /* Noncompliant */
    return w*h;
}
```

In this example, the rule is violated because the second argument of the `calculate` function has data type:

- `height` in the declaration.
- `width` in the definition.

The rule is violated even though the underlying type of `height` and `width` are identical.

### Unreliable cast of function pointer

#### Issue

**Unreliable cast of function pointer** occurs when a function pointer is cast to another function pointer that has different argument or return type.

This defect applies only if the code language for the project is C.

#### Risk

If you cast a function pointer to another function pointer with different argument or return type and then use the latter function pointer to call a function, the behavior is undefined.

#### Fix

Avoid a cast between two function pointers with mismatch in argument or return types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Unreliable cast of function pointer error

```
#include <stdio.h>
#include <math.h>
#include <stdio.h>
#define PI 3.142

double Calculate_Sum(int (*fptr)(double))
{
    double  sum = 0.0;
    double  y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);
    /* Defect: fp implicitly cast to int(*) (double) */

    printf("sum(sin): %f\n", sum);
    return 0;
}
```

The function pointer `fp` is declared as `double (*)(double)`. However in passing it to function `Calculate_Sum`, `fp` is implicitly cast to `int (*)(double)`.

#### Correction — Avoid Function Pointer Cast

One possible correction is to check that the function pointer in the definition of `Calculate_Sum` has the same argument and return type as `fp`. This step makes sure that `fp` is not implicitly cast to a different argument or return type.

```
#include <stdio.h>
#include <math.h>
#include <stdio.h>
# define PI 3.142

/*Fix: fptr has same argument and return type everywhere*/
double Calculate_Sum(double (*fptr)(double))
{
    double  sum = 0.0;
    double y;

    for (int i = 0;  i <= 100;  i++)
    {
        y = (*fptr)(i*PI/100);
        sum += y;
    }
    return sum / 100;
}

int main(void)
{
    double  (*fp)(double);
    double  sum;

    fp = sin;
    sum = Calculate_Sum(fp);
    printf("sum(sin): %f\n", sum);
    return 0;
}
```

Calling functions in the C Standard Library other than abort, _Exit, and signal from within a signal handler

## Description

### Rule Definition

*Calling functions in the C Standard Library other than abort, _Exit, and signal from within a signal handler.*

### Polyspace Implementation

This checker checks for these issues:

- **Function called from signal handler not asynchronous-safe (strict)**.
- **Function called from signal handler not asynchronous-safe**.

## Examples

### Function called from signal handler not asynchronous-safe (strict)

#### Issue

**Function called from signal handler not asynchronous-safe (strict)** occurs when a signal handler calls a function that is not asynchronous-safe according to the C standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

When you select the checker **Function called from signal handler not asynchronous-safe**, the checker detects calls to functions that are not asynchronous-safe according to the POSIX standard. **Function called from signal handler not asynchronous-safe (strict)** does not raise a defect for these cases. **Function called from signal handler not asynchronous-safe (strict)** raises a defect for functions that are asynchronous-safe according to the POSIX standard but not according to the C standard.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

#### Risk

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

#### Fix

The C standard defines the following functions as asynchronous-safe. You can call these functions from a signal handler:

- abort()
- _Exit()
- quick_exit()
- signal()

**Example - Call to raise() Inside Signal Handler**

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
{
    int s0 = signum;
    /* SIGTERM specific handling */
}

void sig_handler(int signum)
{
    int s0 = signum;
    /* Call raise() */
    if (raise(SIGTERM) != 0) {
        /* Handle error */
    }
}

int finc(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` calls `raise()` when catching a signal. If the handler catches another signal while `raise()` is executing, the behavior of the program is undefined.

#### Correction — Remove Call to raise() in Signal Handler

According to the C standard, the only functions that you can safely call from a signal handler are `abort()`, `_Exit()`, `quick_exit()`, and `signal()`.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

void SIG_ERR_handler(int signum)
{
    int s0 = signum;
    /* SIGTERM specific handling */
}
void sig_handler(int signum)
{
    int s0 = signum;

}

int func(void)
{
    if (signal(SIGTERM, SIG_ERR_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
    }
    /* More code */
    return 0;
}
```

### Function called from signal handler not asynchronous-safe

#### Issue

**Function called from signal handler not asynchronous-safe** occurs when a signal handler calls a function that is not asynchronous-safe according to the POSIX standard. An asynchronous-safe function can be interrupted at any point in its execution, then called again without causing an inconsistent state. It can also correctly handle global data that might be in an inconsistent state.

If a signal handler calls another function that calls an asynchronous-unsafe function, the defect appears on the function call in the signal handler. The defect traceback shows the full path from the signal handler to the asynchronous-unsafe function.

**Risk**

When a signal handler is invoked, the execution of the program is interrupted. After the handler is finished, program execution resumes at the point of interruption. If a function is executing at the time of the interruption, calling it from within the signal handler is undefined behavior, unless it is asynchronous-safe.

**Fix**

The POSIX standard defines these functions as asynchronous-safe. You can call these functions from a signal handler.

| | | |
|---|---|---|
| `_exit()` | `getpgrp()` | `setsockopt()` |
| `_Exit()` | `getpid()` | `setuid()` |

| getgroups() | setpgid() | write() |
| getpeername() | setsid() | |

Functions not in the previous table are not asynchronous-safe, and should not be called from a signal hander.

**Example - Call to `printf()` Inside Signal Handler**

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler(int signum)
{
    /* Call function printf() that is not
    asynchronous-safe */
    printf("signal %d received.", signum);
    e_flag = 1;
}

int main(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, sizeof(char));
    if (info == NULL)
    {
        /* Handle Error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

In this example, `sig_handler` calls `printf()` when catching a signal. If the handler catches another signal while `printf()` is executing, the behavior of the program is undefined.

**Correction — Set Flag Only in Signal Handler**

Use your signal handler to set only the value of a flag. `e_flag` is of type volatile `sig_atomic_t`. `sig_handler` can safely access it asynchronously.

```
#include <signal.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <setjmp.h>
#include <syslog.h>
#include <unistd.h>

#define SIZE20 20

extern volatile sig_atomic_t e_flag;

void display_info(const char *info)
{
    if (info)
    {
        (void)fputs(info, stderr);
    }
}

void sig_handler1(int signum)
{
    int s0 = signum;
    e_flag = 1;
}

int func(void)
{
    e_flag = 0;
    if (signal(SIGINT, sig_handler1) == SIG_ERR)
    {
        /* Handle error */
    }
    char *info = (char *)calloc(SIZE20, 1);
    if (info == NULL)
    {
        /* Handle error */
    }
    while (!e_flag)
    {
        /* Main loop program code */
        display_info(info);
        /* More program code */
    }
    free(info);
    info = NULL;
    return 0;
}
```

No assignment in conditional expressions

## Description

### Rule Definition

*No assignment in conditional expressions.*

### Polyspace Implementation

This checker checks for **Invalid use of = (assignment) operator**.

## Examples

### Invalid use of = (assignment) operator

#### Issue

**Invalid use of = operator** occurs when an assignment is made inside the predicate of a conditional, such as `if` or `while`.

In C and C++, a single equal sign is an assignment not a comparison. Using a single equal sign in a conditional statement can indicate a typo or a mistake.

#### Risk

- Conditional statement tests the wrong values— The single equal sign operation assigns the value of the right operand to the left operand. Then, because this assignment is inside the predicate of a conditional, the program checks whether the new value of the left operand is nonzero or not NULL.
- Maintenance and readability issues — Even if the assignment is intended, someone reading or updating the code can misinterpret the assignment as an equality comparison instead of an assignment.

#### Fix

- If the assignment is a bug, to check for equality, add a second equal sign (==).
- If the assignment inside the conditional statement was intentional, to improve readability, separate the assignment and the test. Move the assignment outside the control statement. In the control statement, simply test the result of the assignment.

  If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

  - “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
  - “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
  - “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Single Equal Sign Inside an `if` Condition

```
#include <stdio.h>

void bad_equals_ex(int alpha, int beta)
{
    if(alpha = beta)
    {
        printf("Equal\n");
    }
}
```

The equal sign is flagged as a defect because the assignment operator is used within the predicate of the if-statement. The predicate assigns the value `beta` to `alpha`, then implicitly tests whether `alpha` is true or false.

#### Correction — Change Expression to Comparison

One possible correction is adding an additional equal sign. This correction changes the assignment to a comparison. The if condition compares whether `alpha` and `beta` are equal.

```
#include <stdio.h>

void equality_test(int alpha, int beta)
{
    if(alpha == beta)
    {
        printf("Equal\n");
    }
}
```

#### Correction — Assignment and Comparison Inside the `if` Condition

If an assignment must be made inside the predicate, a possible correction is adding an explicit comparison. This correction assigns the value of `beta` to `alpha`, then explicitly checks whether `alpha` is nonzero. The code is clearer.

```
#include <stdio.h>

int assignment_not_zero(int alpha, int beta)
{
    if((alpha = beta) != 0)
    {
        return alpha;
    }
    else
    {
        return 0;
    }
}
```

#### Correction — Move Assignment Outside the `if` Statement

If the assignment can be made outside the control statement, one possible correction is to separate the assignment and comparison. This correction assigns the value of `beta` to `alpha` before the if. Inside the if-condition, only `alpha` is given to test if `alpha` is nonzero or not NULL.

```
#include <stdio.h>
```

```
void assign_and_print(int alpha, int beta)
{
    alpha = beta;
    if(alpha)
    {
        printf("%d", alpha);
    }
}
```

Using character values that are indistinguishable from EOF

## Description

### Rule Definition

*Using character values that are indistinguishable from EOF.*

### Polyspace Implementation

This checker checks for **Character value absorbed into EOF**.

## Examples

### Character value absorbed into EOF

#### Issue

**Character value absorbed into EOF** occurs when you perform a data type conversion that makes a valid character value indistinguishable from `EOF` (End-of-File). Bug Finder flags the defect in one of the following situations:

- *End-of-File*: You perform a data type conversion such as from `int` to `char` that converts a non-EOF character value into `EOF`.

  ```
  char ch = (char)getchar();
  ```

  You then compare the result with EOF.

  ```
  if((int)ch == EOF){//...}
  ```

  The conversion can be explicit or implicit.
- *Wide End-of-File*: You perform a data type conversion that can convert a non-WEOF wide character value into WEOF, and then compare the result with WEOF.

#### Risk

The data type `char` cannot hold the value `EOF` that indicates the end of a file. Functions such as `getchar` have return type `int` to accommodate `EOF`. If you convert from `int` to `char`, the values `UCHAR_MAX` (a valid character value) and `EOF` get converted to the same value -1 and become indistinguishable from each other. When you compare the result of this conversion with `EOF`, the comparison can lead to false detection of `EOF`. This rationale also applies to wide character values and `WEOF`.

#### Fix

Perform the comparison with `EOF` or `WEOF` before conversion.

#### Example - Return Value of `getchar` Converted to `char`

```
#include <stdio.h>
#include <stdlib.h>
```

```
#define fatal_error() abort()

char func(void)
{
    char ch;
    ch = getchar();
    if (EOF == (int)ch) {
        fatal_error();
    }
    return ch;
}
```

In this example, the return value of `getchar` is implicitly converted to `char`. If `getchar` returns `UCHAR_MAX`, it is converted to -1, which is indistinguishable from EOF. When you compare with EOF later, it can lead to a false positive.

#### Correction — Perform Comparison with EOF Before Conversion

One possible correction is to first perform the comparison with EOF, and then convert from `int` to `char`.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

char func(void)
{
    int i;
    i = getchar();
    if (EOF == i) {
        fatal_error();
    }
    else {
        return (char)i;
    }
}
```

Passing arguments to character handling functions that are not representable as unsigned char

## Description

### Rule Definition

*Passing arguments to character handling functions that are not representable as unsigned char.*

### Polyspace Implementation

This checker checks for **Invalid use of standard library integer routine**.

## Examples

### Invalid use of standard library integer routine

#### Issue

**Invalid use of standard library integer routine** occurs when you use invalid arguments with an integer function from the standard library. This defect picks up:

- Character Conversion

  `toupper, tolower`
- Character Checks

  `isalnum, isalpha, iscntrl, isdigit, isgraph, islower, isprint, ispunct, isspace, isupper, isxdigit`
- Integer Division

  `div, ldiv`
- Absolute Values

  `abs, labs`

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Absolute Value of Large Negative

```
#include <limits.h>
#include <stdlib.h>

int absoluteValue(void) {

    int neg = INT_MIN;
    return abs(neg);
}
```

The input value to `abs` is `INT_MIN`. The absolute value of `INT_MIN` is `INT_MAX+1`. This number cannot be represented by the type `int`.

#### Correction — Change Input Argument

One possible correction is to change the input value to fit returned data type. In this example, change the input value to `INT_MIN+1`.

```
#include <limits.h>
#include <stdlib.h>

int absoluteValue(void) {

    int neg = INT_MIN+1;
    return abs(neg);
}
```

# ISO/IEC TS 17961 [dblfree]

Freeing memory multiple times

## Description

### Rule Definition

*Freeing memory multiple times.*

### Polyspace Implementation

This checker checks for **Deallocation of previously deallocated pointer**.

## Examples

### Deallocation of previously deallocated pointer

#### Issue

**Deallocation of previously deallocated pointer** occurs when a block of memory is freed more than once using the `free` function without an intermediate allocation.

#### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to free this block of memory can result in a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to allocate a memory block to the pointer between the first deallocation and the second. Otherwise, remove the second `free` statement.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before freeing pointers, check them for NULL values and handle the error. In this way, you are protected against freeing an already freed block.

#### Example - Deallocation of Previously Deallocated Pointer Error

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    free (pi);
    /* Defect: pi has already been freed */
}
```

The first `free` statement releases the block of memory that `pi` refers to. The second `free` statement on `pi` releases a block of memory that has been freed already.

#### Correction — Remove Duplicate Deallocation

One possible correction is to remove the second `free` statement.

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    /* Fix: remove second deallocation */
 }
```

Integer division errors

## Description

### Rule Definition

*Integer division errors.*

### Polyspace Implementation

This checker checks for **Integer division by zero**.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect an **Integer division by zero**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Integer division by zero

#### Issue

**Integer division by zero** occurs when the denominator of a division or modulo operation can be a zero-valued integer.

#### Risk

A division by zero can result in a program crash.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the denominator variable acquires a zero value. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Dividing an Integer by Zero

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    result = num/denom;

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    if (denom != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
int fraction(int num)
{
    int denom = 2;
    int result = 0;

    result = num/denom;

    return result;
}
```

#### Example - Modulo Operation with Zero

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        arr[i] = input % i;
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

In this example, Polyspace flags the modulo operation as a division by zero. Because modulo is inherently a division operation, the divisor (right hand argument) cannot be zero. The modulo operation uses the `for` loop index as the divisor. However, the `for` loop starts at zero, which cannot be an iterator.

#### Correction — Check Divisor Before Operation

One possible correction is checking the divisor before the modulo operation. In this example, see if the index `i` is zero before the modulo operation.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        if(i != 0)
        {
             arr[i] = input % i;
        }
        else
        {
             arr[i] = input;
        }
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

#### Correction — Change Divisor

Another possible correction is changing the divisor to a nonzero integer. In this example, add one to the index before the `%` operation to avoid dividing by zero.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
         arr[i] = input % (i+1);
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

Failing to close files or free dynamic memory when they are no longer needed

## Description

### Rule Definition

*Failing to close files or free dynamic memory when they are no longer needed.*

### Polyspace Implementation

This checker checks for these issues:

- **Memory leak**.
- **Resource leak**.
- **Thread-specific memory leak**.

## Examples

### Memory leak

#### Issue

**Memory leak** occurs when you do not free a block of memory allocated through `malloc`, `calloc`, `realloc`, or `new`. If the memory is allocated in a function, the defect does not occur if:

- Within the function, you free the memory using `free` or `delete`.
- The function returns the pointer assigned by `malloc`, `calloc`, `realloc`, or `new`.
- The function stores the pointer in a global variable or in a parameter.

#### Risk

Dynamic memory allocation functions such as `malloc` allocate memory on the heap. If you do not release the memory after use, you reduce the amount of memory available for another allocation. On embedded systems with limited memory, you might end up exhausting available heap memory even during program execution.

#### Fix

Determine the scope where the dynamically allocated memory is accessed. Free the memory block at the end of this scope.

To free a block of memory, use the `free` function on the pointer that was used during memory allocation. For instance:

```
ptr = (int*)malloc(sizeof(int));
//...
free(ptr);
```

It is a good practice to allocate and free memory in the same module at the same level of abstraction. For instance, in this example, `func` allocates and frees memory at the same level but `func2` does not.

```
void func() {
  ptr = (int*)malloc(sizeof(int));
  {
    ...
  }
  free(ptr);
}

void func2() {
  {
   ptr = (int*)malloc(sizeof(int));
   ...
  }
  free(ptr);
}
```

See CERT-C Rule MEM00-C.

**Example - Dynamic Memory Not Released Before End of Function**

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }

    *pi = 42;
    /* Defect: pi is not freed */
}
```

In this example, `pi` is dynamically allocated by `malloc`. The function `assign_memory` does not free the memory, nor does it return `pi`.

**Correction — Free Memory**

One possible correction is to free the memory referenced by `pi` using the `free` function. The `free` function must be called before the function `assign_memory` terminates

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }
    *pi = 42;

    /* Fix: Free the pointer pi*/
    free(pi);
}
```

#### Correction — Return Pointer from Dynamic Allocation

Another possible correction is to return the pointer `pi`. Returning `pi` allows the function calling `assign_memory` to free the memory block using `pi`.

```
#include<stdlib.h>
#include<stdio.h>

int* assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
            printf("Memory allocation failed");
            return(pi);
        }
    *pi = 42;

    /* Fix: Return the pointer pi*/
    return(pi);
}
```

### Resource leak

#### Issue

**Resource leak** occurs when you open a file stream by using a `FILE` pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

#### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

#### Fix

Close a `FILE` pointer before the end of its scope, or before you assign the pointer to another stream.

#### Example - FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer `fp1` is pointing to a file `data1.txt`. Before `fp1` is explicitly dissociated from the file stream of `data1.txt`, it is used to access another file `data2.txt`.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate `fp1` from the file stream of `data1.txt`.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

### Thread-specific memory leak

#### Issue

**Thread-specific memory leak** occurs when you do not free thread-specific dynamically allocated memory before the end of a thread.

To create thread-specific storage, you generally do these steps:

1. You create a key for thread-specific storage.
2. You create the threads.
3. In each thread, you allocate storage dynamically and then associate the key with this storage.

   After the association, you can read the stored data later using the key.
4. Before the end of the thread, you free the thread-specific memory using the key.

The checker flags execution paths in the thread where the last step is missing.

The checker works on these families of functions:

- `tss_get` and `tss_set` (C11)
- `pthread_getspecific` and `pthread_setspecific` (POSIX)

#### Risk

The data stored in the memory is available to other processes even after the threads end (memory leak). Besides security vulnerabilities, memory leaks can shrink the amount of available memory and reduce performance.

#### Fix

Free dynamically allocated memory before the end of a thread.

You can explicitly free dynamically allocated memory with functions such as `free`.

Alternatively, when you create a key, you can associate a destructor function with the key. The destructor function is called with the key value as argument at the end of a thread. In the body of the destructor function, you can free any memory associated with the key. If you use this method, Bug Finder still flags a defect. Ignore this defect with appropriate comments. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Memory Not Freed at End of Thread**

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;

  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */
  }
  print_data();
  return 0;
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }
  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

In this example, the start function of each thread `func` calls two functions:

- `add_data`: This function allocates storage dynamically and associates the storage with a key using the `tss_set` function.
- `print_data`: This function reads the stored data using the `tss_get` function.

At the points where `func` returns, the dynamically allocated storage has not been freed.

**Correction — Free Dynamically Allocated Memory Explicitly**

One possible correction is to free dynamically allocated memory explicitly before leaving the start function of a thread. See the highlighted change in the corrected version.

In this corrected version, a defect still appears on the `return` statement in the error handling section of `func`. The defect cannot occur in practice because the error handling section is entered only if dynamic memory allocation fails. Ignore this remaining defect with appropriate comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

```
#include <threads.h>
#include <stdlib.h>

/* Global key to the thread-specific storage */
tss_t key;
enum { MAX_THREADS = 3 };

int add_data(void) {
  int *data = (int *)malloc(2 * sizeof(int));
  if (data == NULL) {
    return -1;  /* Report error  */
  }
  data[0] = 0;
  data[1] = 1;
  if (thrd_success != tss_set(key, (void *)data)) {
    /* Handle error */
  }
  return 0;
}

void print_data(void) {
  /* Get this thread's global data from key */
  int *data = tss_get(key);

  if (data != NULL) {
    /* Print data */
  }
}

int func(void *dummy) {
  if (add_data() != 0) {
    return -1;  /* Report error */
  }
  print_data();
  free(tss_get(key));
  return 0;
}

int main(void) {
  thrd_t thread_id[MAX_THREADS];

  /* Create the key before creating the threads */
  if (thrd_success != tss_create(&key, NULL)) {
    /* Handle error */
  }

  /* Create threads that would store specific storage */
  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_create(&thread_id[i], func, NULL)) {
      /* Handle error */
    }
  }

  for (size_t i = 0; i < MAX_THREADS; i++) {
    if (thrd_success != thrd_join(thread_id[i], NULL)) {
      /* Handle error */
    }
  }

  tss_delete(key);
  return 0;
}
```

Copying a FILE object

## Description

### Rule Definition

*Copying a FILE object.*

### Polyspace Implementation

This checker checks for **Dereferencing a FILE* pointer**.

## Examples

### Dereferencing a FILE* pointer

#### Issue

The issue occurs when a pointer to a FILE object is dereferenced.

#### Risk

The Standard states that the address of a FILE object used to control a stream can be significant. Copying that object might not give the same behavior. This rule ensures that you cannot perform such a copy.

Directly manipulating a FILE object might be incompatible with its use as a stream designator.

#### Example - FILE* Pointer Dereferenced

```
#include <stdio.h>

void func(void) {
    FILE *pf1;
    FILE *pf2;
    FILE f3;

    pf2 = pf1;        /* Compliant */
    f3 = *pf2;        /* Non-compliant */
    pf2->_flags=0;    /* Non-compliant */
 }
```

In this example, the rule is violated when the FILE* pointer pf2 is dereferenced.

Declaring the same function or object in incompatible ways

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*Declaring the same function or object in incompatible ways.*

### Polyspace Implementation

This checker checks for these issues:

- **Indistinguishable external identifier names**.
- **Declaration mismatch**.

## Examples

### Indistinguishable external identifier names

#### Issue

The issue occurs when external identifiers are not distinct.

#### Risk

External identifiers are ones declared with global scope or storage class `extern`.

Polyspace considers two names as distinct if there is a difference between their first 31 characters. If the difference between two names occurs only beyond the first 31 characters, they can be easily mistaken for each other. The readability of the code is reduced. For C90, the difference must occur between the first 6 characters. To use the C90 rules checking, use the value `c90` for the option `C standard version (-c-version)`.

#### Example - C90: First Six Characters of Identifiers Not Unique

```
int engine_temperature_raw;
int engine_temperature_scaled;   /* Non-compliant */
int engin2_temperature;          /* Compliant */
```

In this example, the identifier `engine_temperature_scaled` has the same first six characters as a previous identifier, `engine_temperature_raw`.

#### Example - C99: First 31 Characters of Identifiers Not Unique

```
int engine_exhaust_gas_temperature_raw;
int engine_exhaust_gas_temperature_scaled; /* Non-compliant */

int eng_exhaust_gas_temp_raw;
int eng_exhaust_gas_temp_scaled;           /* Compliant */
```

In this example, the identifier `engine_exhaust_gas_temperature_scaled` has the same first 31 characters as a previous identifier, `engine_exhaust_gas_temperature_raw`.

#### Example - C90: First Six Characters Identifiers in Different Translation Units Differ in Case Alone

```
/* file1.c */
int abc = 0;

/* file2.c */
int ABC = 0; /* Non-compliant */
```

In this example, the implementation supports 6 significant case-insensitive characters in *external identifiers*. The identifiers in the two translation are different but are not distinct in their significant characters.

### Declaration mismatch

#### Issue

**Declaration mismatch** occurs when a function or variable declaration does not match other instances of the function or variable.

#### Risk

When a mismatch occurs between two variable declarations in different compilation units, a typical linker follows an algorithm to pick one declaration for the variable. If you expect a variable declaration that is different from the one chosen by the linker, you can see unexpected results when the variable is used.

A similar issue can occur with mismatch in function declarations.

#### Fix

The fix depends on the type of declaration mismatch. If both declarations indeed refer to the same object, use the same declaration. If the declarations refer to different objects, change the names of the one of the variables. If you change a variable name, remember to make the change in all places that use the variable.

Sometimes, declaration mismatches can occur because the declarations are affected by previous preprocessing directives. For instance, a declaration occurs in a macro, and the macro is defined on one inclusion path but undefined in another. These declaration mismatches can be tricky to debug. Identify the divergence between the two inclusion paths and fix the conflicting macro definitions.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Inconsistent Declarations in Two Files

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
double foo(void);

int bar(void) {
    return (int)foo();
}
```

In this example, *file1.c* declares `foo()` as returning an integer. In *file2.c*, `foo()` is declared as returning a double. This difference raises a defect on the second instance of `foo` in *file2*.

**Correction — Align the Function Return Values**

One possible correction is to change the function declarations so that they match. In this example, by changing the declaration of `foo` in *file2.c* to match *file1.c*, the defect is fixed.

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
int foo(void);

int bar(void) {
    return foo();
}
```

**Example - Inconsistent Structure Alignment**

| | |
|---|---|
| *test1.c*<br><br>`#include "square.h"`<br>`#include "circle.h"`<br>`struct aCircle circle;`<br>`struct aSquare square;`<br><br>`int main(){`<br>`    square.side=1;`<br>`    circle.radius=1;`<br>`    return 0;`<br>`}` | *test2.c*<br><br>`#include "circle.h"`<br>`#include "square.h"`<br>`struct aCircle circle;`<br>`struct aSquare square;`<br><br>`int main(){`<br>`    square.side=1;`<br>`    circle.radius=1;`<br>`    return 0;`<br>`}` |
| *circle.h*<br><br>`#pragma pack(1)`<br><br>`extern struct aCircle{`<br>`    int radius;`<br>`} circle;` | *square.h*<br><br>`extern struct aSquare {`<br>`    unsigned int side:1;`<br>`} square;` |

In this example, a declaration mismatch defect is raised on `square` in *square.h* because Polyspace infers that `square` in *square.h* does not have the same alignment as `square` in *test2.c*. This error occurs because the `#pragma pack(1)` statement in *circle.h* declares specific alignment. In *test2.c*, *circle.h* is included before *square.h*. Therefore, the `#pragma pack(1)` statement from *circle.h* is not reset to the default alignment after the `aCircle` structure. Because of this omission, *test2.c* infers that the `aSquare square` structure also has an alignment of 1 byte.

**Correction — Close Packing Statements**

One possible correction is to reset the structure alignment after the `aCircle` struct declaration. For the GNU or Microsoft Visual compilers, fix the defect by adding a `#pragma pack()` statement at the end of *circle.h*.

*test1.c*

```
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*test2.c*

```
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;

#pragma pack()
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

Other compilers require different `#pragma pack` syntax. For your syntax, see the documentation for your compiler.

**Correction — Use the `Ignore pragma pack directives` Option**

One possible correction is to add the `Ignore pragma pack directives` option to your Bug Finder analysis. If you want the structure alignment to change for each structure, and you do not want to see this **Declaration mismatch** defect, use this correction.

1. On the Configuration pane, select the **Advanced Settings** pane.
2. In the **Other** box, enter `-ignore-pragma-pack`.
3. Rerun your analysis.

   The **Declaration mismatch** defect is resolved.

Allocating insufficient memory

## Description

### Rule Definition

*Allocating insufficient memory.*

### Polyspace Implementation

This checker checks for these issues:

- **Wrong allocated object size for cast**.
- **Pointer access out of bounds**.
- **Wrong type used in sizeof**.
- **Possible misuse of sizeof**.

## Examples

### Wrong allocated object size for cast

#### Issue

**Wrong allocated object size for cast** occurs during pointer conversion when the pointer's address is misaligned. If a pointer is converted to a different pointer type, the size of the allocated memory must be a multiple of the size of the destination pointer.

#### Risk

Dereferencing a misaligned pointer has undefined behavior and can cause your program to crash.

#### Fix

Suppose you convert a pointer `ptr1` to `ptr2`. If `ptr1` points to a buffer of `N` bytes and `ptr2` is a *`type`* `*` pointer where `sizeof(`*`type`*`)` is `n` bytes, make sure that `N` is an integer multiple of `n`.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Dynamic Allocation of Pointers

```
#include <stdlib.h>
```

```
void dyn_non_align(void){
    void *ptr = malloc(13);
    long *dest;

    dest = (long*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to a `long*`. The dynamically allocated memory of `ptr`, 13 bytes, is not a multiple of the size of `dest`, 4 bytes. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the allocated memory to 12 instead of 13.

```
#include <stdlib.h>

void dyn_non_align(void){
    void *ptr = malloc(12);
    long *dest;

    dest = (long*)ptr;
}
```

#### Example - Static Allocation of Pointers

```
void static_non_align(void){
    char arr[13], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr; //defect
}
```

In this example, the software raises a defect on the conversion of `ptr` to an `int*` in line 6. `ptr` has a memory size of 13 bytes because the array `arr` has a size of 13 bytes. The size of `dest` is 4 bytes, which is not a multiple of 13. This misalignment causes the **Wrong allocated object size for cast** defect.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the size of the array `arr` to a multiple of 4.

```
void static_non_align(void){
    char arr[12], *ptr;
    int *dest;

    ptr = &arr[0];
    dest = (int*)ptr;
}
```

#### Example - Allocation with a Function

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(13);  //defect
    dest2 = (char*)my_alloc(13); //not a defect
}
```

In this example, the software raises a defect on the conversion of the pointer returned by `my_alloc(13)` to an `int*` in line 11. `my_alloc(13)` returns a pointer with a dynamically allocated size of 13 bytes. The size of `dest1` is 4 bytes, which is not a divisor of 13. This misalignment causes the **Wrong allocated object size for cast** defect. In line 12, the same function call, `my_alloc(13)`, does not call a defect for the conversion to `dest2` because the size of `char*`, 1 byte, a divisor of 13.

#### Correction — Change the Size of the Pointer

One possible correction is to use a pointer size that is a multiple of the destination size. In this example, resolve the defect by changing the argument for `my_alloc` to a multiple of 4.

```
#include <stdlib.h>

void *my_alloc(int size) {
    void *ptr_func = malloc(size);
    if(ptr_func == NULL) exit(-1);
    return ptr_func;
}

void fun_non_align(void){
    int *dest1;
    char *dest2;

    dest1 = (int*)my_alloc(12);
    dest2 = (char*)my_alloc(13);
}
```

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i;
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
```

```
        }

  return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Wrong type used in sizeof

#### Issue

**Wrong type used in sizeof** occurs when both of the following conditions hold:

- You assign the address of a block of memory to a pointer, or transfer data between two blocks of memory. The assignment or copy uses the `sizeof` operator.

  For instance, you initialize a pointer using `malloc(sizeof(`*`type`*`))` or copy data between two addresses using `memcpy(`*`destination_ptr`*`, `*`source_ptr`*`, sizeof(`*`type`*`))`.
- You use an incorrect type as argument of the `sizeof` operator. You use the pointer type instead of the type that the pointer points to.

  For instance, to initialize a *`type*`* pointer, you use `malloc(sizeof(`*`type*`*`))` instead of `malloc(sizeof(`*`type`*`))`.

#### Risk

Irrespective of what *`type`* stands for, the expression `sizeof(`*`type*`*`)` always returns a fixed size. The size returned is the pointer size on your platform in bytes. The appearance of `sizeof(`*`type*`*`)` often indicates an unintended usage. The error can cause allocation of a memory block that is much smaller than what you need and lead to weaknesses such as buffer overflows.

For instance, assume that `structType` is a structure with ten `int` variables. If you initialize a `structType*` pointer using `malloc(sizeof(structType*))` on a 32-bit platform, the pointer is assigned a memory block of four bytes. However, to be allocated completely for one `structType` variable, the `structType*` pointer must point to a memory block of `sizeof(structType) = 10 * sizeof(int)` bytes. The required size is much greater than the actual allocated size of four bytes.

#### Fix

To initialize a *`type*`* pointer, replace `sizeof(`*`type*`*`)` in your pointer initialization expression with `sizeof(`*`type`*`)`.

#### Example - Allocate a Char Array With `sizeof`

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char*) * 5);
    free(str);

}
```

In this example, memory is allocated for the character pointer `str` using a `malloc` of five char pointers. However, `str` is a pointer to a character, not a pointer to a character pointer. Therefore the `sizeof` argument, `char*`, is incorrect.

#### Correction — Match Pointer Type to sizeof Argument

One possible correction is to match the argument to the pointer type. In this example, `str` is a character pointer, therefore the argument must also be a character.

```
#include <stdlib.h>

void test_case_1(void) {
    char* str;

    str = (char*)malloc(sizeof(char) * 5);
    free(str);

}
```

### Possible misuse of sizeof

#### Issue

**Possible misuse of sizeof** occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

#### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

#### Fix

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.

- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

#### Example - `sizeof` Used Incorrectly to Determine Array Size

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++)    {
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

#### Correction — Determine Array Size in Another Way

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

Overflowing signed integers

## Description

### Rule Definition

*Overflowing signed integers.*

### Polyspace Implementation

This checker checks for these issues:

- **Integer overflow**.
- **Integer constant overflow**.

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect an **Integer overflow** or **Integer constant overflow**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different integer types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++;
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

### Integer constant overflow

#### Issue

**Integer constant overflow** occurs when you assign a compile-time constant to a signed integer variable whose data type cannot accommodate the value. An n-bit signed integer holds values in the range [-$2^{n-1}$, $2^{n-1}$-1].

For instance, c is an 8-bit signed char variable that cannot hold the value 255.

```
signed char c = 255;
```

To determine the sizes of fundamental types, Bug Finder uses your specification for Target processor type (-target).

#### Risk

The default behavior for constant overflows can vary between compilers and platforms. Retaining constant overflows can reduce the portability of your code.

Even if your compilers wraps around overflowing constants with a warning, the wrap-around behavior can be unintended and cause unexpected results.

#### Fix

Check if the constant value is what you intended. If the value is correct, use a different, possibly wider, data type for the variable.

#### Example - Overflowing Constant from Macro Expansion

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127

void main() {
    char c1 = MAX_UNSIGNED_CHAR;
    char c2 = MAX_SIGNED_CHAR+1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow. To reproduce these defects, use analysis option Target processor type (-target) where char is signed by default.

#### Correction — Use Different Data Type

One possible correction is to use a different data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_SIGNED_CHAR 127

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR;
    unsigned char c2 = MAX_SIGNED_CHAR+1;
}
```

Converting a pointer to integer or integer to pointer

## Description

### Rule Definition

*Converting a pointer to integer or integer to pointer.*

### Polyspace Implementation

This checker checks for **Conversion between pointers and integers**.

## Examples

### Conversion between pointers and integers

#### Issue

The issue occurs when a conversion is performed between a pointer to object and an integer type.

Casts or implicit conversions from NULL or (void*)0 do not generate a warning.

#### Risk

Conversion between integers and pointers can cause errors or undefined behavior.

- If an integer is cast to a pointer, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.
- If a pointer is cast to an integer, the resulting value can be outside the allowed range for the integer type.

#### Example - Casts between pointer and integer

```
#include <stdbool.h>

typedef unsigned char      uint8_t;
typedef          char      char_t;
typedef unsigned short     uint16_t;
typedef signed   int       int32_t;

typedef _Bool bool_t;
uint8_t *PORTA = (uint8_t *) 0x0002;            /* Non-compliant */

void foo(void) {

    char_t c = 1;
    char_t *pc = &c;                              /* Compliant */

    uint16_t ui16   = 7U;
    uint16_t *pui16 = &ui16;                      /* Compliant */
    pui16 = (uint16_t *) ui16;                    /* Non-compliant */
    uint16_t *p;
    int32_t addr = (int32_t) p;                  /* Non-compliant */
    bool_t b = (bool_t) p;                       /* Non-compliant */
    enum etag { A, B } e = ( enum etag ) p;      /* Non-compliant */
}
```

In this example, the rule is violated when:

- The integer `0x0002` is cast to a pointer.

  If the integer defines an absolute address, it is more common to assign the address to a pointer in a header file. To avoid the assignment being flagged, you can then exclude headers files from coding rules checking. For more information, see `Do not generate results for (-do-not-generate-results-for)`.
- The pointer `p` is cast to integer types such as `int32_t`, `bool_t` or `enum etag`.

The rule is not violated when the address `&ui16` is assigned to a pointer.

Incorrectly setting and using errno

## Description

### Rule Definition

*Incorrectly setting and using errno.*

### Polyspace Implementation

This checker checks for these issues:

- **Misuse of errno**.
- **Errno not checked**.
- **Errno not reset**.

## Examples

### Misuse of errno

#### Issue

**Misuse of errno** occurs when you check `errno` for error conditions in situations where checking `errno` does not guarantee the absence of errors. In some cases, checking `errno` can lead to false positives.

For instance, you check `errno` following calls to the functions:

- `fopen`: If you follow the ISO Standard, the function might not set `errno` on errors.
- `atof`: If you follow the ISO Standard, the function does not set `errno`.
- `signal`: The `errno` value indicates an error only if the function returns the `SIG_ERR` error indicator.

#### Risk

The ISO C Standard does not enforce that these functions set `errno` on errors. Whether the functions set `errno` or not is implementation-dependent.

To detect errors, if you check `errno` alone, the validity of this check also becomes implementation-dependent.

In some cases, the `errno` value indicates an error only if the function returns a specific error indicator. If you check `errno` before checking the function return value, you can see false positives.

#### Fix

For information on how to detect errors, see the documentation for that specific function.

Typically, the functions return an out-of-band error indicator to indicate errors. For instance:

- fopen returns a null pointer if an error occurs.
- signal returns the SIG_ERR error indicator and sets errno to a positive value. Check errno only after you have checked the function return value.

**Example - Incorrectly Checking for errno After fopen Call**

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    errno = 0;
    fileptr = fopen(temp_filename, "w+b");
    if (errno != 0) {
        if (fileptr != NULL) {
            (void)fclose(fileptr);
        }
        /* Handle error */
        fatal_error();
    }
    return fileptr;
}
```

In this example, errno is the first variable that is checked after a call to fopen. You might expect that fopen changes errno to a nonzero value if an error occurs. If you run this code with an implementation of fopen that does not set errno on errors, you might miss an error condition. In this situation, fopen can return a null pointer that escapes detection.

**Correction — Check Return Value of fopen After Call**

One possible correction is to only check the return value of fopen for a null pointer.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    fileptr = fopen(temp_filename, "w+b");
    if (fileptr == NULL) {
        fatal_error();
    }
    return fileptr;
}
```

### Errno not checked

#### Issue

**Errno not checked** occurs when you call a function that sets `errno` to indicate error conditions, but do not check `errno` after the call. For these functions, checking `errno` is the only reliable way to determine if an error occurred.

Functions that set `errno` on errors include:

- `fgetwc`, `strtol`, and `wcstol`.

  For a comprehensive list of functions, see documentation about errno.
- POSIX `errno`-setting functions such as `encrypt` and `setkey`.

#### Risk

To see if the function call completed without errors, check `errno` for error values.

The return values of these `errno`-setting functions do not indicate errors. The return value can be one of the following:

- `void`
- Even if an error occurs, the return value can be the same as the value from a successful call. Such return values are called in-band error indicators.

You can determine if an error occurred only by checking `errno`.

For instance, `strtol` converts a string to a long integer and returns the integer. If the result of conversion overflows, the function returns `LONG_MAX` and sets `errno` to `ERANGE`. However, the function can also return `LONG_MAX` from a successful conversion. Only by checking `errno` can you distinguish between an error and a successful conversion.

#### Fix

Before calling the function, set `errno` to zero.

After the function call, to see if an error occurred, compare `errno` to zero. Alternatively, compare `errno` to known error indicator values. For instance, `strtol` sets `errno` to `ERANGE` to indicate errors.

The error message in the Polyspace result shows the error indicator value that you can compare to.

#### Example - `errno` Not Checked After Call to `strtol`

```
#include<stdio.h>
#include<stdlib.h>
#include<errno.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    long val = strtol(str, &endptr, base);
    printf("Return value of strtol() = %ld\n", val);
}
```

You are using the return value of `strtol` without checking `errno`.

#### Correction — Check `errno` After Call

Before calling `strtol`, set `errno` to zero . After a call to `strtol`, check the return value for `LONG_MIN` or `LONG_MAX` and `errno` for `ERANGE`.

```
#include<stdlib.h>
#include<stdio.h>
#include<errno.h>
#include<limits.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    errno = 0;
    long val = strtol(str, &endptr, base);
    if((val == LONG_MIN || val == LONG_MAX) && errno == ERANGE) {
         printf("strtol error");
         exit(EXIT_FAILURE);
    }
    printf("Return value of strtol() = %ld\n", val);
}
```

### Errno not reset

#### Issue

**Errno not reset** occurs when you do not reset `errno` before calling a function that sets `errno` to indicate error conditions. However, you check `errno` for those error conditions after the function call.

#### Risk

The `errno` is not clean and can contain values from a previous call. Checking `errno` for errors can give the false impression that an error occurred.

`errno` is set to zero at program startup but subsequently, `errno` is not reset by a C standard library function. You must explicitly set `errno` to zero when required.

#### Fix

Before calling a function that sets `errno` to indicate error conditions, reset `errno` to zero explicitly.

#### Example - `errno` Not Reset Before Call to `strtod`

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()
```

```
double func(const char *s1, const char *s2)
{
    double f1;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
                  {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

In this example, `errno` is not reset to 0 before the first call to `strtod`. Checking `errno` for 0 later can lead to a false positive.

**Correction — Reset `errno` Before Call**

One possible correction is to reset `errno` to 0 before calling `strtod`.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    errno = 0;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
              {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

Using invalid format strings

## Description

### Rule Definition

*Using invalid format strings.*

### Polyspace Implementation

This checker checks for **Format string specifiers and arguments mismatch**.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
const char *message = "License not available";
int err_number = ;-4
printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {
    unsigned long fst = 1;

    printf("%d\n", fst);
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

Forming or using out-of-bounds pointers or array subscripts

## Description

### Rule Definition

*Forming or using out-of-bounds pointers or array subscripts.*

### Polyspace Implementation

This checker checks for these issues:

- **Array access out of bounds**.
- **Pointer access out of bounds**.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect an **Array access out of bounds**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Array access out of bounds

#### Issue

**Array access out of bounds** occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Array Access Out of Bounds Error**

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);
    /* Defect: Value of i is greater than allowed value of 9 */
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

**Correction — Keep Array Index Within Array Bounds**

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];

   for (i = 0; i < 10; i++)
    {
        if (i < 2)
            fib[i] = 1;
        else
            fib[i] = fib[i-1] + fib[i-2];
    }

    /* Fix: Print fib[9] instead of fib[10] */
    printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i;
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

Interleaving stream inputs and outputs without a flush or positioning call

## Description

### Rule Definition

*Interleaving stream inputs and outputs without a flush or positioning call.*

### Polyspace Implementation

This checker checks for **Alternating input and output from a stream without flush or positioning call**.

## Examples

### Alternating input and output from a stream without flush or positioning call

#### Issue

**Alternating input and output from a stream without flush or positioning call** occurs when:

- You do not perform a flush or function positioning call between an output operation and a following input operation on a file stream in update mode.
- You do not perform a function positioning call between an input operation and a following output operation on a file stream in update mode.

#### Risk

Alternating input and output operations on a stream without an intervening flush or positioning call is undefined behavior.

#### Fix

Call `fflush()` or a file positioning function such as `fseek()` or `fsetpos()` between output and input operations on an update stream.

Call a file positioning function between input and output operations on an update stream.

#### Example - Read After Write Without Intervening Flush

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;
    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Read operation after write without
    intervening flush. */
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
          (void)fclose(file);
          /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

In this example, the file `demo.txt` is opened for reading and appending. After the call to `fwrite()`, a call to `fread()` without an intervening flush operation is undefined behavior.

**Correction — Call `fflush()` Before the Read Operation**

After writing data to the file, before calling `fread()`, perform a flush call.

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
```

```
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Buffer flush after write and before read */
    if (fflush(file) != 0)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

Failing to detect and handle standard library errors

## Description

#### Rule Definition

*Failing to detect and handle standard library errors.*

#### Polyspace Implementation

This checker checks for these issues:

- **Returned value of a sensitive function not checked**.
- **Unprotected dynamic memory allocation**.

## Examples

### Returned value of a sensitive function not checked

#### Issue

**Returned value of a sensitive function not checked** occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `thrd_create`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example - Sensitive Function Return Ignored

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    scanf("%d",&n); //Noncompliant
    setlocale (LC_CTYPE, "en_US.UTF-8");   //Noncompliant
    *size = mbstowcs (wcs, utf8, n);
}
```

This example shows a call to the sensitive function `scanf()`. The return value of `scanf()` is ignored, causing a defect. Similarly, the pointer returned by `setlocale` is not checked. When `setlocal` returns a `NULL` pointer, the call to `mbstowcs` might fail or produce unexpected results. Polyspace flags these calls to sensitive functions when their returns are not checked.

#### Correction — Cast Function to (void)

One possible correction is to cast the functions to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of these sensitive functions.

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    (void)scanf("%d",&n); //Compliant
    (void)setlocale (LC_CTYPE, "en_US.UTF-8");   //Compliant
    *size = mbstowcs (wcs, utf8, n);
}
```

#### Correction — Test Return Value

One possible correction is to test the return value of `scanf` and `setlocale` to check for errors.

```
#include<stdio.h>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    int flag = scanf("%d",&n);
    if(flag>0){ //Compliant
        // action
    }
    char* status = setlocale (LC_CTYPE, "en_US.UTF-8");
    if(status!=NULL){//Compliant
        *size = mbstowcs (wcs, utf8, n);
    }

}
```

#### Example - Critical Function Return Ignored

```
#include <threads.h>
int thrd_func(void);
void initialize() {
    thrd_t thr;
    int n = 1;

    (void) thrd_create(&thr,thrd_func,&n);
}
```

In this example, a critical function `thrd_create` is called and its return value is ignored by casting to void, but because `thrd_create` is a critical function, Polyspace does not ignore this *Return value of a sensitive function not checked* defect.

#### Correction — Test the Return Value of Critical Functions

The correction for this defect is to check the return value of these critical functions to verify the function performed as expected.

```
 #include <threads.h>
int thrd_func(void);
void initialize() {
    thrd_t thr;
    int n = 1;
    if( thrd_success!= thrd_create(&thr,thrd_func,&n) ){
        // handle error

    }
}
```

### Unprotected dynamic memory allocation

#### Issue

**Unprotected dynamic memory allocation** occurs when you do not check after dynamic memory allocation whether the memory allocation succeeded.

#### Risk

When memory is dynamically allocated using `malloc`, `calloc`, or `realloc`, it returns a value `NULL` if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this `NULL` value, this access is not protected from failures.

#### Fix

Check the return value of `malloc`, `calloc`, or `realloc` for NULL before accessing the allocated memory location.

```
#define SIZE 10
//...
int *ptr = malloc(SIZE * sizeof(int));
```

```
if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

**Example - Unprotected dynamic memory allocation error**

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));

  *p = 2;
  /* Defect: p is not checked for NULL value */

  free(p);
}
```

If the memory allocation fails, the function `calloc` returns `NULL` to `p`. Before accessing the memory through `p`, the code does not check whether `p` is `NULL`

**Correction — Check for NULL Value**

One possible correction is to check whether `p` has value `NULL` before dereference.

```
#include <stdlib.h>

void Assign_Value(void)
 {
   int* p = (int*)calloc(5, sizeof(int));

   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;

   free(p);
 }
```

Modifying the string returned by getenv, localeconv, setlocale, and strerror

## Description

### Rule Definition

*Modifying the string returned by getenv, localeconv, setlocale, and strerror.*

### Polyspace Implementation

This checker checks for **Modification of internal buffer returned from nonreentrant standard function**.

## Examples

### Modification of internal buffer returned from nonreentrant standard function

#### Issue

**Modification of internal buffer returned from nonreentrant standard function** occurs when the following happens:

- A nonreentrant standard function returns a pointer.
- You attempt to write to the memory location that the pointer points to.

Nonreentrant standard functions that return a non `const`-qualified pointer to an internal buffer include `getenv`, `getlogin`, `crypt`, `setlocale`, `localeconv`, `strerror` and others.

#### Risk

Modifying the internal buffer that a nonreentrant standard function returns can cause the following issues:

- It is possible that the modification does not succeed or alters other internal data.

  For instance, `getenv` returns a pointer to an environment variable value. If you modify this value, you alter the environment of the process and corrupt other internal data.
- Even if the modification succeeds, it is possible that a subsequent call to the same standard function does not return your modified value.

  For instance, you modify the environment variable value that `getenv` returns. If another process, thread, or signal handler calls `setenv`, the modified value is overwritten. Therefore, a subsequent call to `getenv` does not return your modified value.

#### Fix

Avoid modifying the internal buffer using the pointer returned from the function.

#### Example - Modification of getenv Return Value

```
#include <stdlib.h>
#include <string.h>
```

```
void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        strncpy(env, "C", 1);
        printstr(env);
    }
}
```

In this example, the first argument of `strncpy` is the return value from a nonreentrant standard function `getenv`. The behavior can be undefined because `strncpy` modifies this argument.

**Correction - Copy Return Value of `getenv` and Modify Copy**

One possible solution is to copy the return value of `getenv` and pass the copy to the `strncpy` function.

```
#include <stdlib.h>
#include <string.h>
enum {
    SIZE20 = 20
};

void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        char env_cp[SIZE20];
        strncpy(env_cp, env, SIZE20);
        strncpy(env_cp, "C", 1);
        printstr(env_cp);
    }
}
```

# ISO/IEC TS 17961 [libptr]

Forming invalid pointers by library function

## Description

### Rule Definition

*Forming invalid pointers by library function.*

### Polyspace Implementation

This checker checks for these issues:

- **Use of path manipulation function without maximum sized buffer checking**.
- **Invalid use of standard library memory routine**.
- **Invalid use of standard library string routine**.
- **Destination buffer overflow in string manipulation**.

## Examples

### Use of path manipulation function without maximum sized buffer checking

#### Issue

**Use of path manipulation function without maximum-sized buffer checking** occurs when the destination argument of a path manipulation function such as `realpath` or `getwd` has a buffer size less than `PATH_MAX` bytes.

#### Risk

A buffer smaller than `PATH_MAX` bytes can overflow but you cannot test the function return value to determine if an overflow occurred. If an overflow occurs, following the function call, the content of the buffer is undefined.

For instance, `char *getwd(char *buf)` copies an absolute path name of the current folder to its argument. If the length of the absolute path name is greater than `PATH_MAX` bytes, `getwd` returns `NULL` and the content of `*buf` is undefined. You can test the return value of `getwd` for `NULL` to see if the function call succeeded.

However, if the allowed buffer for `buf` is less than `PATH_MAX` bytes, a failure can occur for a smaller absolute path name. In this case, `getwd` does not return `NULL` even though a failure occurred. Therefore, the allowed buffer for `buf` must be `PATH_MAX` bytes long.

#### Fix

Possible fixes are:

- Use a buffer size of `PATH_MAX` bytes. If you obtain the buffer from an unknown source, before using the buffer as argument of `getwd` or `realpath` function, make sure that the size is less than `PATH_MAX` bytes.

- Use a path manipulation function that allows you to specify a buffer size.

  For instance, if you are using `getwd` to get the absolute path name of the current folder, use `char *getcwd(char *buf, size_t size);` instead. The additional argument `size` allows you to specify a size greater than or equal to `PATH_MAX`.
- Allow the function to allocate additional memory dynamically, if possible.

  For instance, `char *realpath(const char *path, char *resolved_path);` dynamically allocates memory if `resolved_path` is `NULL`. However, you have to deallocate this memory later using the `free` function.

#### Example - Possible Buffer Overflow in Use of `getwd` Function

```
#include <unistd.h>
#include <linux/limits.h>
#include <stdio.h>

void func(void) {
    char buf[PATH_MAX];
    if (getwd(buf+1)!= NULL)         {
        printf("cwd is %s\n", buf);
    }
}
```

In this example, although the array `buf` has `PATH_MAX` bytes, the argument of `getwd` is `buf + 1`, whose allowed buffer is less than `PATH_MAX` bytes.

#### Correction — Use Array of Size `PATH_MAX` Bytes

One possible correction is to use an array argument with size equal to `PATH_MAX` bytes.

```
#include <unistd.h>
#include <linux/limits.h>
#include <stdio.h>

void func(void) {
    char buf[PATH_MAX];
    if (getwd(buf)!= NULL)         {
        printf("cwd is %s\n", buf);
    }
}
```

### Invalid use of standard library memory routine

#### Issue

**Invalid use of standard library memory routine** occurs when a memory library function is called with invalid arguments. For instance, the `memcpy` function copies to an array that cannot accommodate the number of bytes copied.

#### Risk

Use of a memory library function with invalid arguments can result in issues such as buffer overflow.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do

not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library Memory Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  char str1[10],str2[5];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  /* Defect: Arguments of memcpy invalid: str2 has size < 6 */

  return str2;
 }
```

The size of string `str2` is 5, but six characters of string `str1` are copied into `str2` using the `memcpy` function.

#### Correction — Call Function with Valid Arguments

One possible correction is to adjust the size of `str2` so that it accommodates the characters copied with the `memcpy` function.

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  /* Fix: Declare str2 with size 6 */
  char str1[10],str2[6];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  return str2;
 }
```

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_String(void)
{
 char *res;
 char gbuffer[5],text[20]="ABCDEFGHIJKL";

 res=strcpy(gbuffer,text);
 /* Error: Size of text is less than gbuffer */

 return(res);
}
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string);
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

Using an object overwritten by getenv, localeconv, setlocale, and strerror

## Description

### Rule Definition

*Using an object overwritten by getenv, localeconv, setlocale, and strerror.*

### Polyspace Implementation

This checker checks for **Misuse of return value from nonreentrant standard function**.

## Examples

### Misuse of return value from nonreentrant standard function

#### Issue

**Misuse of return value from nonreentrant standard function** occurs when these events happen in this sequence:

1. You point to the buffer returned from a nonreentrant standard function such as `getenv` or `setlocale`.

   ```
   user = getenv("USER");
   ```
2. You call that nonreentrant standard function again.

   ```
   user2 = getenv("USER2");
   ```
3. You use or dereference the pointer from the first step expecting the buffer to remain unmodified since that step. In the meantime, the call in the second step has modified the buffer.

   For instance:

   ```
   var=*user;
   ```

In some cases, the defect might appear even if you do not call the `getenv` function a second time but simply return the pointer. For instance:

```
char* func() {
     user=getenv("USER");
     .
     .
     return user;
}
```

For information on which functions are covered by this defect, see documentation on nonreentrant standard functions.

#### Risk

The C Standard allows nonreentrant functions such as `getenv` to return a pointer to a *static* buffer. Because the buffer is static, a second call to `getenv` modifies the buffer. If you continue to use the

pointer returned from the first call past the second call, you can see unexpected results. The buffer that it points to no longer has values from the first call.

The defect appears even if you do not call `getenv` a second time but simply return the pointer. The reason is that someone calling your function might use the returned pointer *after* a second call to `getenv`. By returning the pointer from your call to `getenv`, you make your function unsafe to use.

The same rationale is true for other nonreentrant functions covered by this defect.

**Fix**

After the first call to `getenv`, make a copy of the buffer that the returned pointer points to. After the second call to `getenv`, use this copy. Even if the second call modifies the buffer, your copy is untouched.

**Example - Return from getenv Used After Second Call to getenv**

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");   /* First call */
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');

        if (user_name_from_home != NULL) {
            user = getenv("USER");   /* Second call */
            if ((user != NULL) &&
                (strcmp(user, user_name_from_home) == 0))
            {
                result = 1;
            }
        }
    }
    return result;
}
```

In this example, the pointer `user_name_from_home` is derived from the pointer `home`. `home` points to the buffer returned from the first call to `getenv`. Therefore, `user_name_from_home` points to a location in the same buffer.

After the second call to `getenv`, the buffer is modified. If you continue to use `user_name_from_home`, you can get unexpected results.

**Correction — Make Copy of Buffer Before Second Call**

If you want to access the buffer from the first call to `getenv` past the second call, make a copy of the buffer after the first call. One possible correction is to use the `strdup` function to make the copy.

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');
        if (user_name_from_home != NULL) {
            /* Make copy before second call */
            char *saved_user_name_from_home = strdup(user_name_from_home);
            if (saved_user_name_from_home != NULL) {
                user = getenv("USER");
                if ((user != NULL) &&
                    (strcmp(user, saved_user_name_from_home) == 0))
                {
                    result = 1;
                }
                free(saved_user_name_from_home);
            }
        }
    }
    return result;
}
```

Passing a non-null-terminated character sequence to a library function

## Description

### Rule Definition

*Passing a non-null-terminated character sequence to a library function.*

### Polyspace Implementation

This checker checks for **Invalid use of standard library string routine**.

## Examples

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
#include <string.h>
#include <stdio.h>
```

```
 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

**Correction — Use Valid Arguments**

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

Dereferencing an out-of-domain pointer

## Description

### Rule Definition

*Dereferencing an out-of-domain pointer.*

### Polyspace Implementation

This checker checks for these issues:

- **Unsafe pointer arithmetic**.
- **Invalid use of standard library memory routine**.
- **Null pointer**.
- **Arithmetic operation with NULL pointer**.
- **Invalid use of standard library string routine**.

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect a **Null pointer**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Unsafe pointer arithmetic

#### Issue

The issue occurs when a pointer resulting from arithmetic on a pointer operand does not address an element of the same array as that pointer operand.

Polyspace reports violations of this rule when your code has these issues:

- `Array access out of bounds`
- `Pointer access out of bounds`

#### Risk

Using an invalid array subscript can lead to erroneous behavior of the program. Run-time derived array subscripts are especially troublesome because they cannot be easily checked by manual review or static analysis.

The C Standard defines the creation of a pointer to one beyond the end of the array. The rule permits the C Standard. Dereferencing a pointer to one beyond the end of an array causes undefined behavior and is noncompliant.

### Invalid use of standard library memory routine

#### Issue

**Invalid use of standard library memory routine** occurs when a memory library function is called with invalid arguments. For instance, the memcpy function copies to an array that cannot accommodate the number of bytes copied.

#### Risk

Use of a memory library function with invalid arguments can result in issues such as buffer overflow.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library Memory Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  char str1[10],str2[5];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  /* Defect: Arguments of memcpy invalid: str2 has size < 6 */

  return str2;
 }
```

The size of string str2 is 5, but six characters of string str1 are copied into str2 using the memcpy function.

#### Correction — Call Function with Valid Arguments

One possible correction is to adjust the size of str2 so that it accommodates the characters copied with the memcpy function.

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  /* Fix: Declare str2 with size 6 */
  char str1[10],str2[6];

  printf("Enter string:\n");
  scanf("%s",str1);

  memcpy(str2,str1,6);
  return str2;
 }
```

### Null pointer

#### Issue

**Null pointer** occurs when you use a pointer with a value of `NULL` as if it points to a valid memory location.

#### Risk

Dereferencing a null pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

#### Fix

Check a pointer for `NULL` before dereference.

If the issue occurs despite an earlier check for `NULL`, look for intermediate events between the check and the subsequent dereference. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

#### Example - Null pointer error

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 int* p=NULL;

 *p=arr[0];
 /* Defect: Null pointer dereference */

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

The pointer p is initialized with value of NULL. However, when the value arr[0] is written to *p, p is assumed to point to a valid memory location.

#### Correction — Assign Address to Null Pointer Before Dereference

One possible correction is to initialize p with a valid memory address before dereference.

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 /* Fix: Assign address to null pointer */
 int* p=&arr[0];

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

### Arithmetic operation with NULL pointer

#### Issue

**Arithmetic operation with NULL pointer** occurs when an arithmetic operation involves a pointer whose value is NULL.

#### Risk

Performing pointer arithmetic on a null pointer and dereferencing the resulting pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

#### Fix

Check a pointer for NULL before arithmetic operations on the pointer.

If the issue occurs despite an earlier check for NULL, look for intermediate events between the check and the subsequent dereference. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

#### Example - Arithmetic Operation with NULL Pointer Error

```
#include<stdlib.h>

int Check_Next_Value(int *loc, int val)
 {
  int *ptr = loc, found = 0;

  if (ptr==NULL)
   {
      ptr++;
      /* Defect: NULL pointer shifted */
      if (*ptr==val) found=1;
   }

  return(found);
 }
```

When ptr is a NULL pointer, the code enters the if statement body. Therefore, a NULL pointer is shifted in the statement ptr++.

#### Correction — Avoid NULL Pointer Arithmetic

One possible correction is to perform the arithmetic operation when ptr is not NULL.

```
#include<stdlib.h>

int Check_Next_Value(int *loc, int val)
 {
  int *ptr = loc, found = 0;

  /* Fix: Perform operation when ptr is not NULL */
  if (ptr!=NULL)
   {
      ptr++;

      if (*ptr==val) found=1;
   }

  return(found);
 }
```

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the strcpy function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the strcpy function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to strcpy. In some cases, you can use an alternative function to avoid the error. For instance, instead of strcpy, you can use strncpy to control the number of bytes copied.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Invalid Use of Standard Library String Routine Error**

```
#include <string.h>
#include <stdio.h>

char* Copy_String(void)
{
 char *res;
 char gbuffer[5],text[20]="ABCDEFGHIJKL";

 res=strcpy(gbuffer,text);
 /* Error: Size of text is less than gbuffer */

 return(res);
}
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

**Correction — Use Valid Arguments**

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

# ISO/IEC TS 17961 [padcomp]

Comparison of padding data

## Description

### Rule Definition

*Comparison of padding data.*

### Polyspace Implementation

This checker checks for **Memory comparison of padding data**.

## Examples

### Memory comparison of padding data

#### Issue

**Memory comparison of padding data** occurs when you use the memcmp function to compare two structures as a whole. In the process, you compare meaningless data stored in the structure padding.

For instance:

```
typedef struct structType {
    char member1;
    int member2;
    //...
}myStruct;

myStruct var1;
myStruct var2;
//...
if(memcmp(&var1,&var2,sizeof(var1)))//Noncompliant
{
//...
}
```

#### Risk

If members of a structure have different data types, your compiler introduces additional padding for data alignment in memory. For an example of padding, see Higher Estimate of Size of Local Variables.

The content of these extra padding bytes is meaningless. The C Standard allows the content of these bytes to be indeterminate, giving different compilers latitude to implement their own padding. If you perform a byte-by-byte comparison of structures with memcmp, you compare even the meaningless data stored in the padding. You might reach the false conclusion that two data structures are not equal, even if their corresponding members have the same value.

#### Fix

Instead of comparing two structures in one attempt, compare the structures member by member.

For efficient code, write a function that does the comparison member by member. Use this function for comparing two structures.

You can use memcmp for byte-by-byte comparison of structures only if you know that the structures do not contain padding. Typically, to prevent padding, you use specific attributes or pragmas such as #pragma pack. However, these attributes or pragmas are not supported by all compilers and make your code implementation-dependent. If your structures contain bit-fields, using these attributes or pragmas cannot prevent padding.

#### Example - Structures Compared with memcmp

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{

    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    if (0 == memcmp(left, right, sizeof(S_Padding)))
    {
        return 1;
    }
    else
        return 0;
}
```
