In this example, memcmp compares byte-by-byte the two structures that left and right point to. Even if the values stored in the structure members are the same, the comparison can show an inequality if the meaningless values in the padding bytes are not the same.

#### Correction — Compare Structures Member by Member

One possible correction is to compare individual structure members.

**Note** You can compare entire arrays by using memcmp. All members of an array have the same data type. Padding bytes are not required to store arrays.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{
    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    return ((left->c == right->c) &&
            (left->i == right->i) &&
            (left->bf1 == right->bf1) &&
            (left->bf2 == right->bf2) &&
            (memcmp(left->buffer, right->buffer, 20) == 0));
}
```

Accessing an object through a pointer to an incompatible type

## Description

### Rule Definition

*Accessing an object through a pointer to an incompatible type.*

### Polyspace Implementation

This checker checks for **Conversion between pointers to different objects**.

## Examples

### Conversion between pointers to different objects

#### Issue

The issue occurs when a cast is performed between a pointer to object type and a pointer to a different object type.

#### Risk

If a pointer to an object is cast into a pointer to a different object, the resulting pointer can be incorrectly aligned. The incorrect alignment causes undefined behavior.

Even if the conversion produces a pointer that is correctly aligned, the behavior can be undefined if the pointer is used to access an object.

Exception: You can convert a pointer to object type into a pointer to one of the following types:

- `char`
- `signed char`
- `unsigned char`

#### Example - Noncompliant: Cast to Pointer Pointing to Object of Wider Type

```
signed   char *p1;
unsigned int *p2;

void foo(void){
  p2 = ( unsigned int * ) p1;     /* Non-compliant */
}
```

In this example, `p1` can point to a `signed char` object. However, `p1` is cast to a pointer that points to an object of wider type, `unsigned int`.

#### Example - Noncompliant: Cast to Pointer Pointing to Object of Narrower Type

```
extern unsigned int read_value ( void );
extern void display ( unsigned int n );
```

```
void foo ( void ){
  unsigned int u = read_value ( );
  unsigned short *hi_p = ( unsigned short * ) &u;    /* Non-compliant  */
  *hi_p = 0;
  display ( u );
}
```

In this example, u is an unsigned int variable. &u is cast to a pointer that points to an object of narrower type, unsigned short.

On a big-endian machine, the statement *hi_p = 0 attempts to clear the high bits of the memory location that &u points to. But, from the result of display(u), you might find that the high bits have not been cleared.

**Example - Compliant: Cast Adding a Type Qualifier**

```
const short *p;
const volatile short *q;
void foo (void){
  q = ( const volatile short * ) p;  /* Compliant */
}
```

In this example, both p and q can point to short objects. The cast between them adds a volatile qualifier only and is therefore compliant.

Subtracting or comparing two pointers that do not refer to the same array

## Description

### Rule Definition

*Subtracting or comparing two pointers that do not refer to the same array.*

### Polyspace Implementation

This checker checks for **Subtraction or comparison between pointers to different arrays**.

## Examples

### Subtraction or comparison between pointers to different arrays

#### Issue

**Subtraction or comparison between pointers to different arrays** occurs when you subtract or compare pointers that are null or that point to elements in different arrays. The relational operators for the comparison are >, <, >=, and <=.

#### Risk

When you subtract two pointers to elements in the same array, the result is the difference between the subscripts of the two array elements. Similarly, when you compare two pointers to array elements, the result is the positions of the pointers relative to each other. If the pointers are null or point to different arrays, a subtraction or comparison operation is undefined. If you use the subtraction result as a buffer index, it can cause a buffer overflow.

#### Fix

Before you subtract or use relational operators to compare pointers to array elements, check that they are non-null and that they point to the same array.

#### Example - Subtraction Between Pointers to Elements in Different Arrays

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int end;
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation is undefined unless array nums
    is adjacent to variable end in memory. */
    free_elements = &end - next_num_ptr;
    return free_elements;
}
```

In this example, the array `nums` is incrementally filled. Pointer subtraction is then used to determine how many free elements remain. Unless `end` points to a memory location one past the last element of `nums`, the subtraction operation is undefined.

**Correction — Subtract Pointers to the Same Array**

Subtract the pointer to the last element that was filled from the pointer to the last element in the array.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define SIZE20 20

size_t func(void)
{
    int nums[SIZE20];
    int *next_num_ptr = nums;
    size_t free_elements;
    /* Increment next_num_ptr as array fills */

    /* Subtraction operation involves pointers to the same array. */
    free_elements = &(nums[SIZE20 - 1]) - next_num_ptr;

    return free_elements + 1;
}
```

Using identifiers that are reserved for the implementation

## Description

### Rule Definition

*Using identifiers that are reserved for the implementation.*

### Polyspace Implementation

This checker checks for **Declaration of reserved identifiers or macro names**.

## Examples

### Declaration of reserved identifiers or macro names

#### Issue

The issue occurs when a reserved identifier or macro name is declared.

If you define a macro name that corresponds to a standard library macro, object, or function, rule 21.1 is violated.

The rule considers tentative definitions as definitions.

#### Risk

The Standard allows implementations to treat reserved identifiers specially. If you reuse reserved identifiers, you can cause undefined behavior.

# ISO/IEC TS 17961 [restrict]

Passing pointers into the same object as arguments to different restrict-qualified parameters

## Description

### Rule Definition

*Passing pointers into the same object as arguments to different restrict-qualified parameters.*

### Polyspace Implementation

This checker checks for **Copy of overlapping memory**.

## Examples

### Copy of overlapping memory

#### Issue

**Copy of overlapping memory** occurs when there is a memory overlap between the source and destination argument of a copy function such as `memcpy` or `strcpy`. For instance, the source and destination arguments of `strcpy` are pointers to different elements in the same string.

#### Risk

If there is memory overlap between the source and destination arguments of copy functions, according to C standards, the behavior is undefined.

#### Fix

Determine if the memory overlap is what you want. If so, find an alternative function. For instance:

- If you are using `memcpy` to copy values from one memory location to another, use `memmove` instead of `memcpy`.
- If you are using `strcpy` to copy one string to another, use `memmove` instead of `strcpy`, as follows:

  ```
  s = strlen(source);
  memmove(destination, source, s + 1);
  ```

  `strlen` determines the string length without the null terminator. Therefore, you must move `s+1` bytes instead of `s` bytes.

#### Example - Overlapping Copy

```
#include <string.h>

char str[] = {"ABCDEFGH"};

void my_copy() {
    strcpy(&str[0],(const char*)&str[2]);
}
```

In this example, because the source and destination argument are pointers to the same string `str`, there is memory overlap between their allowed buffers.

# ISO/IEC TS 17961 [sigcall]

Calling signal from interruptible signal handlers

## Description

### Rule Definition

*Calling signal from interruptible signal handlers.*

### Polyspace Implementation

This checker checks for **Signal call from within signal handler**.

## Examples

### Signal call from within signal handler

#### Issue

**Signal call from within signal handler** occurs when you call `signal()` from a nonpersistent signal handler on a Windows platform.

#### Risk

A nonpersistent signal handler is reset after catching a signal. The handler does not catch subsequent signals unless the handler is reestablished by calling `signal()`. A nonpersistent signal handler on a Windows platform is reset to `SIG_DFL`. If another signal interrupts the execution of the handler, that signal can cause a race condition between `SIG_DFL` and the existing signal handler. A call to `signal()` can also result in an infinite loop inside the handler.

#### Fix

Do not call `signal()` from a signal handler on Windows platforms.

#### Example - `signal()` Called from Signal Handler

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;

    /* Call signal() to reestablish sig_handler
    upon receiving SIG_ERR. */

    if (signal(s0, sig_handler) == SIG_ERR)
    {
        /* Handle error */
    }
}

void func(void)
{
        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
  /* more code */
}
```

In this example, the definition of `sig_handler()` includes a call to `signal()` when the handler catches `SIG_ERR`. On Windows platforms, signal handlers are nonpersistent. This code can result in a race condition.

#### Correction — Do Not Call `signal()` from Signal Handler

If your code requires the use of a persistent signal handler on a Windows platform, use a persistent signal handler after performing a thorough risk analysis.

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;
    /* No call to signal() */
}

int main(void)
{

        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
}
```

Conversion of signed characters to wider integer types before a check for EOF

## Description

### Rule Definition

*Conversion of signed characters to wider integer types before a check for EOF.*

### Polyspace Implementation

This checker checks for **Misuse of sign-extended character value**.

## Examples

### Misuse of sign-extended character value

#### Issue

**Misuse of sign-extended character value** occurs when you convert a signed or plain `char` data type to a wider integer data type with sign extension. You then use the resulting sign-extended value as array index, for comparison with EOF or as argument to a character-handling function.

#### Risk

*Comparison with EOF*: Suppose, your compiler implements the plain `char` type as signed. In this implementation, the character with the decimal form of 255 (–1 in two's complement form) is stored as a signed value. When you convert a `char` variable to the wider data type `int` for instance, the sign bit is preserved (sign extension). This sign extension results in the character with the decimal form 255 being converted to the integer –1, which cannot be distinguished from EOF.

*Use as array index*: By similar reasoning, you cannot use sign-extended plain `char` variables as array index. If the sign bit is preserved, the conversion from `char` to `int` can result in negative integers. You must use positive integer values for array index.

*Argument to character-handling function*: By similar reasoning, you cannot use sign-extended plain `char` variables as arguments to character-handling functions declared in `ctype.h`, for instance, `isalpha()` or `isdigit()`. According to the C11 standard (Section 7.4), if you supply an integer argument that cannot be represented as `unsigned char` or EOF, the resulting behavior is undefined.

#### Fix

Before conversion to a wider integer data type, cast the signed or plain `char` value explicitly to `unsigned char`.

#### Example - Sign-Extended Character Value Compared with EOF

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];
```

```
static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = *buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

In this example, the function `parser` can traverse a string input `buf`. If a character in the string has the decimal form 255, when converted to the `int` variable `c`, its value becomes –1, which is indistinguishable from `EOF`. The later comparison with `EOF` can lead to a false positive.

#### Correction — Cast to `unsigned char` Before Conversion

One possible correction is to cast the plain `char` value to `unsigned char` before conversion to the wider `int` type.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];

static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = (unsigned char)*buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

## Check Information

"Check for and Review Coding Standard Violations"

# ISO/IEC TS 17961 [sizeofptr]

Taking the size of a pointer to determine the size of the pointed-to type

## Description

### Rule Definition

*Taking the size of a pointer to determine the size of the pointed-to type.*

### Polyspace Implementation

This checker checks for **Possible misuse of sizeof**.

## Examples

### Possible misuse of sizeof

#### Issue

**Possible misuse of sizeof** occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

#### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

#### Fix

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

  The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.
- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

#### Example - `sizeof` Used Incorrectly to Determine Array Size

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++)    {
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

#### Correction — Determine Array Size in Another Way

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

Modifying string literals

## Description

### Rule Definition

*Modifying string literals.*

### Polyspace Implementation

This checker checks for **Writing to const qualified object**.

## Examples

### Writing to const qualified object

#### Issue

**Writing to `const` qualified object** occurs when you do one of the following:

- Use a `const`-qualified object as the destination of an assignment.
- Pass a `const`-qualified object to a function that modifies the argument.

For instance, the defect can occur in the following situations:

- You pass a `const`-qualified object as first argument of one of the following functions:
  - `mkstemp`
  - `mkostemp`
  - `mkostemps`
  - `mkdtemp`
- You pass a `const`-qualified object as the destination argument of one of the following functions:
  - `strcpy`
  - `strncpy`
  - `strcat`
  - `memset`
- You perform a write operation on a `const`-qualified object.

#### Risk

The risk depends upon the modifications made to the `const`-qualified object.

| Situation | Risk |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | These functions replace the last six characters of their first argument with a string. Therefore, they expect a modifiable `char` array as their first argument. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | These functions modify their destination argument. Therefore, they expect a modifiable `char` array as their destination argument. |
| Writing to the object | The `const` qualifier implies an agreement that the value of the object will not be modified. By writing to a `const`-qualified object, you break the agreement. The result of the operation is undefined. |

#### Fix

The fix depends on the modification made to the `const`-qualified object.

| Situation | Fix |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | Pass a non-`const` object as first argument of the function. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | Pass a non-`const` object as destination argument of the function. |
| Writing to the object | Perform the write operation on a non-`const` object. |

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Writing to `const`-Qualified Object

```
#include <string.h>

const char* buffer = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

In this example, because `buffer` is `const`-qualified, `strchr(buffer,'X')` returns a `const`-qualified `char*` pointer. When this `char*` pointer is used as the destination argument of `strcpy`, a **Writing to const qualified object** error appears.

#### Correction — Copy const-Qualified Object to Non-const Object

One possible correction is to assign the constant string to a non-const object and use the non-const object as destination argument of strchr.

```
#include <string.h>

char buffer[] = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

Use of an implied default in a switch statement

## Description

### Rule Definition

*Use of an implied default in a switch statement.*

### Polyspace Implementation

This checker checks for **Missing case for switch condition**.

## Examples

### Missing case for switch condition

#### Issue

**Missing case for switch condition** occurs when the `switch` variable can take values that are not covered by a `case` statement.

**Note** Bug Finder only raises a defect if the switch variable is not full range.

#### Risk

If the `switch` variable takes a value that is not covered by a `case` statement, your program can have unintended behavior.

A switch-statement that makes a security decision is particularly vulnerable when all possible values are not explicitly handled. An attacker can use this situation to deviate the normal execution flow.

#### Fix

It is good practice to use a `default` statement as a catch-all for values that are not covered by a `case` statement. Even if the `switch` variable takes an unintended value, the resulting behavior can be anticipated.

#### Example - Missing Default Condition

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}

int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    }

    printf("Welcome!\n");
    return r;
}
```

In this example, the `enum` parameter `User` can take a value `UNKNOWN` that is not covered by a `case` statement.

**Correction — Add a Default Condition**

One possible correction is to add a default condition for possible values that are not covered by a `case` statement.

```
#include <stdio.h>
#include <string.h>

typedef enum E
{
    ADMIN=1,
    GUEST,
    UNKNOWN = 0
} LOGIN;

static LOGIN system_access(const char *username) {
  LOGIN user = UNKNOWN;

  if ( strcmp(username, "root") == 0 )
    user = ADMIN;

  if ( strcmp(username, "friend") == 0 )
    user = GUEST;

  return user;
}
```

```
int identify_bad_user(const char * username)
{
    int r=0;

    switch( system_access(username) )
    {
    case ADMIN:
        r = 1;
        break;
    case GUEST:
        r = 2;
    break;
    default:
        printf("Invalid login credentials!\n");
    }

    printf("Welcome!\n");
    return r;
}
```

Calling system

## Description

### Rule Definition

*Calling system.*

### Polyspace Implementation

This checker checks for **Unsafe call to a system function**.

## Examples

### Unsafe call to a system function

#### Issue

**Unsafe call to a system function** occurs when you use a function that invokes an implementation-defined command processor. These functions include:

- The C standard `system()` function.
- The POSIX `popen()` function.
- The Windows `_popen()` and `_wpopen()` functions.

#### Risk

If the argument of a function that invokes a command processor is not sanitized, it can cause exploitable vulnerabilities. An attacker can execute arbitrary commands or read and modify data anywhere on the system.

#### Fix

Do not use a `system`-family function to invoke a command processor. Instead, use safer functions such as POSIX `execve()` and WinAPI `CreateProcess()`.

#### Example - `system()` Called

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
    char buf[SIZE512];
    int retval=sprintf(buf, "/usr/bin/any_cmd %s", arg);
    if (retval<=0 || retval>SIZE512){
        /* Handle error */
        abort();
    }
    /* Use of system() to pass any_cmd with
    unsanitized argument to command processor */

    if (system(buf) == -1) {
    /* Handle error */
  }
}
```

In this example, `system()` passes its argument to the host environment for the command processor to execute. This code is vulnerable to an attack by command-injection.

#### Correction — Sanitize Argument and Use execve()

In the following code, the argument of `any_cmd` is sanitized, and then passed to `execve()` for execution. `exec`-family functions are not vulnerable to command-injection attacks.

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
  char *const args[SIZE3] = {"any_cmd", arg, NULL};
  char  *const env[] = {NULL};

  /* Sanitize argument */

  /* Use execve() to execute any_cmd. */

  if (execve("/usr/bin/time", args, env) == -1) {
    /* Handle error */
  }
}
```

Using a tainted value to write to an object using a formatted input or output function

## Description

### Rule Definition

*Using a tainted value to write to an object using a formatted input or output function.*

### Polyspace Implementation

This checker checks for these issues:

- **Buffer overflow from incorrect string format specifier**.
- **Destination buffer overflow in string manipulation**.
- **Invalid use of standard library routine**.
- **Invalid use of standard library string routine**.
- **Tainted NULL or non-null-terminated string**.
- **Tainted string format specifier**.
- **Invalid use of standard library string routine**.
- **Use of dangerous standard function**.
- **Insufficient destination buffer size**

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted NULL or non-null-terminated string** or **Tainted string format specifier** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf);
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string);
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Invalid use of standard library routine

#### Issue

This issue occurs when you use invalid arguments with a function from the standard library. This defect picks up errors related to other functions not covered by float, integer, memory, or string standard library routines.

#### Risk

Invalid arguments to a standard library function result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. For instance, the argument to a `printf` function can be `NULL` because a pointer was initialized with `NULL` and the initialization value was not overwritten along a specific execution path.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example – Calling `printf` Without a String

```
#include <stdio.h>
#include <stdlib.h>

void print_null(void) {

  printf(NULL);
}
```

The function `printf` takes only string input arguments or format specifiers. In this function, the input value is NULL, which is not a valid string.

#### Correction — Use Compatible Input Arguments

One possible correction is to change the input arguments to fit the requirements of the standard library routine. In this example, the input argument was changed to a character.

```
#include <stdio.h>

void print_null(void) {
    char zero_val = '0';
    printf((const char*)zero_val);
}
```

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
 #include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";
  res=strcpy(gbuffer,text);
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Tainted NULL or non-null-terminated string

#### Issue

This issue occurs when strings from nonsecure sources are used in string manipulation routines that implicitly dereference the string buffer, for instance, `strcpy` or `sprintf`.

The checker raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

#### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

#### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

**Example – Getting String from Input Argument**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Error: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

**Correction 1 — Validate the Data**

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // Defect only raised here
        // - string is not null
        // - string has a positive and limited size
        // - TAINTED_STRING on strlen used as a firewall
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

**Correction 2 — Validate the Data**

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }

  return sensorValue;
}
```

### Tainted string format specifier

**Issue**

This issue occurs when `printf`-style functions use a format specifier constructed from nonsecure sources.

**Risk**

If you use externally controlled elements to format a string, you can cause buffer overflow or data-representation problems. An attacker can use these string formatting elements to view the contents of a stack using `%x` or write to a stack using `%n`.

#### Fix

Pass a static string to format string functions. This fix ensures that an external actor cannot control the string.

Another possible fix is to allow only the expected number of arguments. If possible, use functions that do not support the vulnerable `%n` operator in format strings.

#### Example – Get Elements from User Input

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf(userstr);
}
```

This example prints the input argument `userstr`. The string is unknown. If it contains elements such as `%`, `printf` can interpret `userstr` as a string format instead of a string, causing your program to crash.

#### Correction — Print as String

One possible correction is to print `userstr` explicitly as a string so that there is no ambiguity.

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf("%.20s", userstr);;
}
```

### Use of dangerous standard function

#### Issue

The **Use of dangerous standard function** check highlights uses of functions that are inherently dangerous or potentially dangerous given certain circumstances. The following table lists possibly dangerous functions, the risks of using each function, and what function to use instead.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `cin` | Inherently dangerous — You cannot control the length of input from the console. | Avoid or prefaces calls to `cin` with `cin.width`. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Using `sprintf`

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

#### Correction — Use `snprintf` with Buffer Size

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Insufficient destination buffer size

#### Issue

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(str, input); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

#### Risk

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if `argv[0]` contains 100 or more characters, the `strcpy` operation results in a buffer overflow.

#### Fix

Before calling the function `strcpy()`, allocate sufficient memory dynamically. For instance, use the function `strlen()` to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value `strlen(source) + 1`.

Alternatively, use the function `strncpy()` instead of `strcpy()`. The function `strncpy()` copies a known number of characters from the source buffer to the destination buffer. Because the function `strncpy()` copies a known number of characters, it is a safer alternative to `strcpy()`.

#### Example — Destination Buffer Too Small

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <string.h>

int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[128];
  strcpy(destination,source);//Noncompliant

  return 0;
}
```

#### Correction — Use `strncpy` instead of `strcpy`

To fix this issue, use `strncpy()` to copy a known number of characters from the `source` buffer to the `destination` buffer.

```
#include <string.h>
#define MAX_ARGS  128
```

```
int main(int argc, char *argv[]) {
  const char *const source = (argc && argv[0]) ? argv[0] : "";
  char destination[MAX_ARGS];
  int num = (strlen(source)+1>MAX_ARGS)?MAX_ARGS:strlen(source)+1;
  strncpy(destination,source,num);//Compliant

  return 0;
}
```

**Correction — Allocate Sufficient Memory for Destination Buffer**

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <string.h>

int main(int argc, char *argv[]) {
    const char *const source = (argc && argv[0]) ? argv[0] : "";
    char* destination = (char *)malloc(strlen(source)+ 1);
    if(destination!=NULL){
        strcpy(destination, source);//Compliant
    }else{
        /*Handle Error*/
    }
    //...
    free(destination);
    return 0;
}
```

Using a tainted value as an argument to an unprototyped function pointer

## Description

### Rule Definition

*Using a tainted value as an argument to an unprototyped function pointer.*

### Polyspace Implementation

This checker checks for **Call through non-prototyped function pointer**.

## Examples

### Call through non-prototyped function pointer

#### Issue

**Call through non-prototyped function pointer** detects a call to a function through a pointer without a prototype. A function prototype specifies the type and number of parameters.

#### Risk

Arguments passed to a function without a prototype might not match the number and type of parameters of the function definition, which can cause undefined behavior. If the parameters are restricted to a subset of their type domain, arguments from untrusted sources can trigger vulnerabilities in the called function.

#### Fix

Before calling the function through a pointer, provide a function prototype.

#### Example - Argument Does Not Match Parameter Restriction

```
#include <stdio.h>
#include <limits.h>
#define SIZE2 2

typedef void (*func_ptr)();
extern int getchar_wrapper(void);
extern void restricted_int_sink(int i);
/* Integer value restricted to
range [-1, 255] */
extern void restricted_float_sink(double i);
/* Double value restricted to > 0.0 */

func_ptr generic_callback[SIZE2] =
{
    (func_ptr)restricted_int_sink,
    (func_ptr)restricted_float_sink
};
```

```
void func(void)
{
    int ic;
    ic = getchar_wrapper();
    /* Wrong index used for generic_callback.
    Negative 'int' passed to restricted_float_sink. */
    (*generic_callback[1])(ic);
}
```

In this example, a call through `func_ptr` passes `ic` as an argument to function `generic_callback[1]`. The type of `ic` can have negative values, while the parameter of `generic_callback[1]` is restricted to float values greater than `0.0`. Typically, compilers and static analysis tools cannot perform type checking when you do not provide a pointer prototype.

#### Correction — Provide Prototype of Pointer to Function

Pass the argument `ic` to a function with a parameter of type `int`, by using a properly prototyped pointer.

```
#include <stdio.h>
#include <limits.h>
#define SIZE2 2

typedef void (*func_ptr_proto)(int);
extern int getchar_wrapper(void);
extern void restricted_int_sink(int i);
/* Integer value restricted to
range [-1, 255] */
extern void restricted_float_sink(double i);
/* Double value restricted to > 0.0 */

func_ptr_proto generic_callback[SIZE2] =
{
    (func_ptr_proto)restricted_int_sink,
    (func_ptr_proto)restricted_float_sink
};

void func(void)
{
    int ic;
    ic = getchar_wrapper();
    /* ic passed to function through
properly prototyped pointer. */
    (*generic_callback[0])(ic);
}
```

Tainted, potentially mutilated, or out-of-domain integer values are used in a restricted sink

## Description

### Rule Definition

*Tainted, potentially mutilated, or out-of-domain integer values are used in a restricted sink.*

### Polyspace Implementation

This checker checks for these issues:

- **Tainted size of variable length array**.
- **Pointer dereference with tainted offset**.
- **Array access with tainted index**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted size of variable length array**, **Pointer dereference with tainted offset**, or **Array access with tainted index** issue for certain inputs that originate outside of the current analysis boundary. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted size of variable length array

#### Issue

**Tainted size of variable length array** detects variable length arrays (VLA) whose size is from an unsecure source.

#### Risk

If an attacker changed the size of your VLA to an unexpected value, it can cause your program to crash or behave unexpectedly.

If the size is non-positive, the behavior of the VLA is undefined. Your program does not perform as expected.

If the size is unbounded, the VLA can cause memory exhaustion or stack overflow.

#### Fix

Validate your VLA size to make sure that it is positive and less than a maximum value.

#### Example - Input Argument Used as Size of VLA

```
#include<stdio.h>
#inclule<stdlib.h>
```

```
#define LIM 40

long squaredSum(int size) {

    int tabvla[size];
    long res = 0;
    for (int i=0 ; i<LIM-1 ; ++i) {
        tabvla[i] = i*i;
        res += tabvla[i];
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

In this example, a variable length array size is based on an input argument. Because this input argument value is not checked, the size may be negative or too large.

#### Correction — Check VLA Size

One possible correction is to check the size variable before creating the variable length array. This example checks if the size is larger than 0 and less than 40, before creating the VLA

```
#include <stdio.h>
#include <stdlib.h>
#define LIM 40

long squaredSum(int size) {
    long res = 0;
    if (size>0 && size<LIM){
        int tabvla[size];
        for (int i=0 ; i<size || i<LIM-1 ; ++i) {
            tabvla[i] = i*i;
            res += tabvla[i];
        }
    }else{
        res = -1;
    }
    return res;
}
int main(){
    int size;
    scanf("%d",&size);
    //...
    long result = squaredSum(size);
    //...
    return 0;
}
```

### Pointer dereference with tainted offset

#### Issue

**Pointer dereference with tainted offset** detects pointer dereferencing, either reading or writing, using an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

#### Fix

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

#### Example - Dereference Pointer Array

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset];
        free(pint);
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `offset`. The value of `offset` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of the index. If the index is inside the valid range, continue with the pointer dereferencing.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

#### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

#### Example - Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
```

```
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];
}
```

In this example, the index `num` accesses the array `tab`. The function does not check to see if `num` is inside the range of `tab`.

**Correction — Check Range Before Use**

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

Tainted strings are passed to a string copying function

## Description

### Rule Definition

*Tainted strings are passed to a string copying function.*

### Polyspace Implementation

This checker checks for **Tainted NULL or non-null-terminated string**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted NULL or non-null-terminated string** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted NULL or non-null-terminated string

#### Issue

**Tainted NULL or non-null-terminated string** looks for strings from unsecure sources that are being used in string manipulation routines that implicitly dereference the string buffer. For example, `strcpy` or `sprintf`.

**Tainted NULL or non-null-terminated string** raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

**Note** If you reference a string using the form `ptr[i]`, `*ptr`, or pointer arithmetic, Bug Finder raises a **Use of tainted pointer** defect instead. The **Tainted NULL or non-null-terminated string** defect is raised only when the pointer is used as a string.

#### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

#### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

**Example - Getting String from Input Argument**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

**Correction — Validate the Data**

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // Defect only flagged here
        // - string is not null
        // - string has a positive and limited size
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

#### Correction — Validate the Data

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }

  return sensorValue;
}
```

Referencing uninitialized memory

## Description

### Rule Definition

*Referencing uninitialized memory.*

### Polyspace Implementation

This checker checks for these issues:

- **Non-initialized pointer**.
- **Pointer to non-initialized value converted to const pointer**.
- **Non-initialized variable**.

### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See "Extend Checkers for Initialization to Check Function Arguments Passed by Pointers".
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Non-initialized pointer

#### Issue

**Non-initialized pointer** occurs when a pointer is not assigned an address before dereference.

#### Risk

Unless a pointer is explicitly assigned an address, it points to an unpredictable location.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned an address to the pointer but the assignment is unreachable.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below. It is a good practice to initialize a pointer to NULL when declaring the pointer.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Example - Non-initialized pointer error

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL) 
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j;                    
    /* Defect: Writing to uninitialized pointer */

    return pi;
}
```

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not.

### Correction — Initialize Pointer on Every Execution Path

One possible correction is to assign an address to `pi` when `prev` is not `NULL`.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL) 
       {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
       } 
    /* Fix: Initialize pi in branches of if statement  */
    else 
        pi = prev;              

    *pi = j;
    return pi;
}
```

### Pointer to non-initialized value converted to const pointer

#### Issue

**Pointer to non initialized value converted to const pointer** occurs when a pointer to a constant (`const int*`, `const char*`, etc.) is assigned an address that does not yet contain a value.

#### Risk

A pointer to a constant stores a value that must not be changed later in the program. If you assign the address of a non-initialized variable to the pointer, it now points to an address with garbage values for the remainder of the program.

#### Fix

Initialize a variable before assigning its address to a pointer to a constant.

#### Example - Pointer to non initialized value converted to const pointer error

```
#include<stdio.h>

void Display_Parity()
 {
  int num,parity;
  const int* num_ptr = &num;
  /* Defect: Address &num does not store a value */

  printf("Enter a number\n:");
  scanf("%d",&num);

  parity=((*num_ptr)%2);
  if(parity==0)
    printf("The number is even.");
  else
    printf("The number is odd.");

 }
```

`num_ptr` is declared as a pointer to a constant. However the variable `num` does not contain a value when `num_ptr` is assigned the address `&num`.

#### Correction — Store Value in Address Before Assignment to Pointer

One possible correction is to obtain the value of `num` from the user before `&num` is assigned to `num_ptr`.

```
#include<stdio.h>

void Display_Parity()
 {
  int num,parity;
  const int* num_ptr;

  printf("Enter a number\n:");
  scanf("%d",&num);

 /* Fix: Assign &num to pointer after it receives a value */
  num_ptr=&num;
  parity=((*num_ptr)%2);
  if(parity==0)
    printf("The number is even.");
  else
    printf("The number is odd.");
 }
```

The `scanf` statement stores a value in `&num`. Once the value is stored, it is legitimate to assign `&num` to `num_ptr`.

### Non-initialized variable

#### Issue

**Non-initialized variable** occurs when a variable is not initialized before its value is read.

#### Risk

Unless a variable is explicitly initialized, the variable value is unpredictable. You cannot rely on the variable having a specific value.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned a value to the variable but the assignment is unreachable or you assigned a value to the variable in one of two branches of a conditional statement. Fix the unreachable code or missing assignment.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a variable at declaration.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Non-initialized variable error

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
```

```
      {
        val = getsensor();
      }

    return val;
    /* Defect: val does not have a value if command is not 2 */
}
```

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

#### Correction — Initialize During Declaration

One possible correction is to initialize `val` during declaration so that the initialization is not bypassed on some execution paths.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    /* Fix: Initialize val */
    int val=0;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
 }
```

`val` is assigned an initial value of 0. When `command` is not equal to 2, the function `get_sensor_value` returns this value.

Including tainted or out-of-domain input in a format string

## Description

### Rule Definition

*Including tainted or out-of-domain input in a format string.*

### Polyspace Implementation

This checker checks for these issues:

- **Format string specifiers and arguments mismatch**
- **Tainted string format**

.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted string format** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
  const char *message = "License not available";
  int err_number = ;-4
  printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", fst);
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

#### Correction — Use an Unsigned Long Format Specifier

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

#### Correction — Use an Integer Argument

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

### Tainted string format

#### Issue

**Tainted string format** occurs when `printf`-style functions use a format specifier constructed from unsecure sources.

#### Risk

If you use externally controlled elements to format a string, you can cause buffer overflow or data-representation problems. An attacker can use these string formatting elements to view the contents of a stack using `%x` or write to a stack using `%n`.

#### Fix

Pass a static string to format string functions. This fix ensures that an external actor cannot control the string.

Another possible fix is to allow only the expected number of arguments. If possible, use functions that do not support the vulnerable `%n` operator in format strings

#### Example — Get Elements from User Input

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf(userstr);//Noncompliant
}
```

This example prints the input argument `userstr`. The string is unknown. If it contains elements such as `%`, `printf` can interpret `userstr` as a string format instead of a string, causing your program to crash.

#### Correction — Print as String

One possible correction is to print `userstr` explicitly as a string so that there is no ambiguity.

```
#include "stdio.h"
#include <unistd.h>
#define MAX 40

void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf("%.20s", userstr);
}
```

Using a value for fsetpos other than a value returned from fgetpos

## Description

### Rule Definition

*Using a value for fsetpos other than a value returned from fgetpos.*

### Polyspace Implementation

This checker checks for **Invalid file position**.

## Examples

### Invalid file position

#### Issue

**Invalid file position** occurs when the file position argument of `fsetpos()` uses a value that is not obtained from `fgetpos()`.

#### Risk

The function `fgetpos(FILE *stream, fpos_t *pos)` gets the current file position of the stream. When you use any other value as the file position argument of `fsetpos(FILE *stream, const fpos_t *pos)`, you might access an unintended location in the stream.

#### Fix

Use the value returned from a successful call to `fgetpos()` as the file position argument of `fsetpos()`.

#### Example - `memset()` Sets File Position Argument

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset' */
    (void)memset(&offset, 0, sizeof(offset));

    /* Read data from file */

    /* Return to the initial position. offset was not
    returned from a call to fgetpos()    */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

In this example, `fsetpos()` uses `offset` as its file position argument. However, the value of `offset` is set by `memset()`. The preceding code might access the wrong location in the stream.

#### Correction — Use a File Position Returned From `fgetpos()`

Call `fgetpos()`, and if it returns successfully, use the position argument in your call to `fsetpos()`.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset'
    using fgetpos() */
    if (fgetpos(file, &offset) != 0)
    {
        /* Handle error */
    }

    /* Read data from file */

    /* Back to the initial position */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

# ISO/IEC TS 17961 [xfree]

Reallocating or freeing memory that was not dynamically allocated

## Description

### Rule Definition

*Reallocating or freeing memory that was not dynamically allocated.*

### Polyspace Implementation

This checker checks for **Invalid free of pointer**.

## Examples

### Invalid free of pointer

#### Issue

**Invalid free of pointer** occurs when a block of memory released using the `free` function was not previously allocated using `malloc`, `calloc`, or `realloc`.

#### Risk

The `free` function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `free` function or a previous `malloc` function on a different pointer.

#### Fix

In most cases, you can fix the issue by removing the `free` statement. If the pointer is not allocated memory from the heap with `malloc` or `calloc`, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of `free` or `malloc` on the wrong pointer, correct the error.

If the issue occurs because you use the `free` function to free memory allocated with the `new` operator, replace the `free` function with the `delete` operator.

#### Example - Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;

  free(p);
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer p is deallocated using the free function. However, p points to a memory location that was not dynamically allocated.

**Correction — Remove Pointer Deallocation**

If the number of elements of the array p is known at compile time, one possible correction is to remove the deallocation of the pointer p.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

**Correction — Introduce Pointer Allocation**

If the number of elements of the array p is not known at compile time, one possible correction is to dynamically allocate memory to the array p.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

# MISRA C++: 2008

# MISRA C++:2008 Rule 0-1-1

A project shall not contain unreachable code

## Description

### Rule Definition

*A project shall not contain unreachable code.*

### Rationale

This rule flags situations where a group of statements is unreachable because of syntactic reasons. For instance, code following a `return` statement are always unreachable.

Unreachable code involve unnecessary maintenance and can often indicate programming errors.

### Polyspace Implementation

Polyspace reports a defect if a statement in your code is not reachable.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Unreachable statements

```
int func(int arg) {
 int temp = 0;
 switch(arg) {
     temp = arg; // Noncompliant
     case 1:
     {
         break;
     }
     default:
     {
         break;
     }
 }
 return arg;
 arg++; // Noncompliant
}
```

These statements are unreachable:

- Statements inside a `switch` statement that do not belong to a `case` or `default` block.
- Statements after a `return` statement.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-2

A project shall not contain infeasible paths

## Description

### Rule Definition

*A project shall not contain infeasible paths.*

### Rationale

This rule flags situations where a group of statements is redundant because of nonsyntactic reasons. For instance, an `if` condition is always true or false. Code that is unreachable from syntactic reasons are flagged by rule 0-1-1.

Unreachable or redundant code involve unnecessary maintenance and can often indicate programming errors.

### Polyspace Implementation

Polyspace Bug Finder reports a violation of this if your code contains dead code and unnecessary `if` conditionals. See `Dead code` and `Useless if` checkers.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Boolean Operations with Invariant Results

```
void func (unsigned int arg) {
 if (arg >= 0U) //Noncompliant
     arg  = 1U;
 if (arg < 0U) //Noncompliant
     arg = 1U;
}
```

An `unsigned int` variable is nonnegative. Both `if` conditions involving the variable are always true or always false and are therefore redundant.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-3

A project shall not contain unused variables

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See “Checkers Deactivated in Polyspace as You Code Analysis”.*

### Rule Definition

*A project shall not contain unused variables.*

### Rationale

Presence of unused variables indicates that the wrong variable name might be used in the source code. Removing these variables reduces the possibility of the wrong variable being used in further development. Keep padding bits in bitfields unnamed to reduce unused variables in your project.

### Polyspace Implementation

The checker flags local or global variables that are declared or defined but not read or written in any source files of the project. This specification also applies to members of structures and classes.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Named Bit Field for Padding

```
#include <iostream>
struct S {
    unsigned char b1 : 3;
    unsigned char pad: 1;  //Noncompliant
    unsigned char b2 : 4;
};
void init(struct S S_obj)
{
    S_obj.b1 = 0;
    S_obj.b2 = 0;
}
```

In this example, the bit field `pad` is used for padding the structure. Therefore, the field is never read or written and causes a violation of this rule. To avoid the violation, use an unnamed field for padding.

```
#include <iostream>
struct S {
    unsigned char b1 : 3;
    unsigned char : 1;  //Compliant
    unsigned char b2 : 4;
};
void init(struct S S_obj)
{
    S_obj.b1 = 0;
    S_obj.b2 = 0;
}
```

# MISRA C++:2008 Rule 0-1-4

A project shall not contain non-volatile POD variables having only one use

## Description

### Rule Definition

*A project shall not contain non-volatile POD variables having only one use.*

### Rationale

If you use a non-volatile variable with a Plain Old Data type (`int`, `double`, etc.) *only once*, you can replace the variable with a constant literal. Your use of a variable indicates that you intended more than one use for that variable and might have a programming error in the code. You might have omitted the other uses of the non-volatile variable or incorrectly used other variables at intended points of use.

### Polyspace Implementation

The checker flags local and static variables that have a function scope (locally static) and file scope, which are used only once. The checker considers `const`-qualified global variables without the `extern` specifier as static variables with file scope.

The checker counts these use cases as one use of the non-volatile variable:

- An explicit initialization using a constant literal or the return value of a function
- An assignment
- A reference to the variable such as a read operation
- An assignment of the variable address to a pointer

If the variable address is assigned to a pointer, the checker assumes that the pointer might be dereferenced later and does not flag the variable.

Some objects are designed to be used only once by their semantics. Polyspace does not flag a single use of these objects:

- `lock_guard`
- `scoped_lock`
- `shared_lock`
- `unique_lock`
- `thread`
- `future`
- `shared_future`

If you use nonstandard objects that provide similar functionality as the objects in the preceding list, Polyspace might flag single uses of the nonstandard objects. Justify their single uses by using comments.

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Non-volatile Variable Used Only Once

```
#include <mutex>
int readStatus1();
int readStatus2();
void getReading(int*);
extern std::mutex m;
void foo()
{
    // Initiating lock 'lk'
    std::lock_guard<std::mutex> lk{m};
    int checkEngineStatus1 = readStatus1();
    int checkEngineStatus2 = readStatus2();//Noncompliant
    int sensorData;//Noncompliant
    getReading(&sensorData);
    if(checkEngineStatus1) {
        //Perform some actions if both statuses are valid
    }
    // Release lock when 'lk' is deleted at exit point of scope
}
```

In this example, the variable `checkEngineStatus2` is used only once. The single use of this variable might indicate a programming error. For instance, you might have intended to check both `checkEngineStatus1` and `checkEngineStatus2` in the `if` condition, but omitted the second check. The variable `sensorData` is also used only once when its address is passed to the function `getReading()`. Polyspace flags these single use variables.

The `lock_guard` object `lk` is used a single time. Because the semantics of a `lock_guard` object justifies its single use, Polyspace does not flag it.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-5

A project shall not contain unused type declarations

## Description

### Rule Definition

*A project shall not contain unused type declarations.*

### Rationale

If you declare a type but do not use it, determining if the type is redundant or left unused by mistake is difficult when you review your code.

For example, if you declare an enumerated data type to store some specialized data, but then use an integer type to store the data, the unused type can indicate a coding error.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains unused local types.

As an exception, Polyspace does not report a violation if you define the unused type with `public` access in a template class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused `enum` Declaration

In this example, you do not use the enumerated type `switchValue`.Because you declare the type but do not use it, Polyspace reports a violation.

```
enum switchValue {low, medium, high}; //Noncompliant

void operate(int userInput) {
    switch(userInput) {
        case 0: // Turn on low setting
                 break;
        case 1: // Turn on medium setting
                 break;
        case 2: // Turn on high setting
                 break;
        default: // Return error
    }
}
```

Perhaps the intention was to use the type as `switch` input like this.

```
enum switchValue {low, medium, high}; //Compliant

void operate(switchValue userInput) {
    switch(userInput) {
        case low: // Turn on low setting
                   break;
        case medium: // Turn on medium setting
                     break;
        case high: // Turn on high setting
                   break;
        default: // Return error
    }
}
```

#### Public Unused Types in Templates

When developing template classes, you might declare a public `typedef` that is used by the clients of the template, even if the template itself does not use the `typedef`. In such a case, Polyspace does not report a violation if a public `typedef` remains unused in a template. For instance, in this code, Polyspace does not report a violation for the unused type `T*`.

```
template<typename T>
  class myContainerIterator {
    public:
      using pointer = T*;              // Compliant
      typedef T* Pointer;              // Compliant

    //...
  };
```

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 0-1-6

A project shall not contain instances of non-volatile variables being given values that are never subsequently used.

## Description

### Rule Definition

*A project shall not contain instances of non-volatile variables being given values that are never subsequently used.*

### Rationale

If you assign a value to a variable but do not use the variable value subsequently, the assignment might indicate a programming error. Perhaps you forgot to use the variable later or incorrectly used other variables at the intended points of use.

### Polyspace Implementation

The checker flags value assignments to local and static variables with file scope if the assigned values are not subsequently used. The checker considers `const`-qualified global variables without the `extern` specifier as static variables with file scope.

The checker flags:

- Initializations if the initialized variable is not used.
- Non-initialization assignments if the assigned values are not used.

The checker does not flag the situation where an initialization value is immediately overwritten and therefore ends up unused.

The checker does not flag redundant assignments:

- To variables with class type.
- In the last iteration of a loop, if the assignments in the previous iterations are not redundant.

  For instance, the assignment `prevIter = i` in the last iteration of the loop is redundant but the assignments in the previous iterations are not.

  ```
  void doSomething(int);

  void func() {
    int prevIter=-1, uBound=100;
    for(int i=0; i < uBound; i++) {
          doSomething(prevIter);
          prevIter = i;
    }
  }
  ```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Initialization Value Not Used

```
class largeInteger {
       largeInteger(int d1, int d2, int d3):
            lastFiveDigits(d1), nextFiveDigits(d2), firstFiveDigits(d3){}
       largeInteger& operator=(const largeInteger& other) {
            if(&other !=this) {
              firstFiveDigits = other.firstFiveDigits;
              nextFiveDigits = other.nextFiveDigits;
              lastFiveDigits = other.lastFiveDigits;
            }
            return *this;
       }
       void printIntegerValue();
    private:
        int firstFiveDigits;
        int nextFiveDigits;
        int lastFiveDigits;
};

bool compareValues(largeInteger, largeInteger);

void func() {
    largeInteger largeUnit{10000,0,0}; //Compliant
    largeInteger smallUnit{1,0,0}; //Compliant
    largeInteger tinyUnit{0,1,0}; //Noncompliant
    if(compareValues (largeUnit, smallUnit)) {
        //Perform some action
    }
}
```

In this example, the variable `tinyUnit` is initialized but never used.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 0-1-7

The value returned by a function having a non- void return type that is not an overloaded operator shall always be used

## Description

### Rule Definition

*The value returned by a function having a non- void return type that is not an overloaded operator shall always be used.*

### Rationale

The unused return value might indicate a coding error or oversight.

Overloaded operators are excluded from this rule because their usage must emulate built-in operators which might not use their return value.

### Polyspace Implementation

The checker flags functions with non-`void` return if the return value is not used or not explicitly cast to a `void` type.

The checker does not flag the functions `memcpy`, `memset`, `memmove`, `strcpy`, `strncpy`, `strcat`, `strncat` because these functions simply return a pointer to their first arguments.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Return Value

```
#include <iostream>
#include <new>
#include <algorithm>
#include <cstdint>
#include <vector>

int assignMemory(int * ptr){
     int res = 1;
     ptr = new (std::nothrow) int;
     if(ptr==NULL) {
         res = 0;
     }
     return res;
}
void foo()
{
}

void main() {
    int val;
    int status;
    std::vector<std::int8_t> numVec{10,10,20,20,30,40,50,50,60};

    assignMemory(&val);   //Noncompliant
    status = assignMemory(&val); //Compliant
    (void)assignMemory(&val); //Compliant

    numVec.erase(std::unique(numVec.begin(), numVec.end()), numVec.end());// Noncompliant
}
```

In this example, Polyspace flags calls to functions with unused return value:

- Because `main` does not use the return value of the first call to the function `assignMemory`, Polyspace reports a violation.
- Because the return value of the second call to `assignMemory` is assigned to a local variable, it is compliant with this rule.
- Because the third call to `assignMemory` is cast to `void`, it is compliant with this rule
- Because `main` does not use the object returned by the function `std::vector::erase()`, Polyspace reports a violation.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 0-1-8

All functions with void return type shall have external side effect(s)

## Description

### Rule Definition

*All functions with void return type shall have external side effect(s).*

### Rationale

A function that has a `void` return type does not return anything. When such a function has no external side effects, it does not contribute to the output and consumes time. That these functions have no contribution to the output of the program might be contrary to developer expectation. Such a function might be unnecessary or indicate issues in the program design. Avoid such functions.

The MISRA C++:2008 standard considers these effects as external side effects:

- Reading or writing in resources such as a file or a stream.
- Changing the value of a nonlocal variable.
- Changing the value of a reference type argument.
- Using a `volatile` object.
- Raising an exception.

### Polyspace Implementation

Polyspace flags the definition of a `void` type function if the function has no side effects.

Polyspace considers a function to have side effects if the function performs any of these tasks:

- Calls an impure function other than itself.
- Changes the value or dereferences a reference or pointer type argument.
- Changes the value or deferences of a nonlocal variable.
- Uses a `volatile` object.
- Contains assembly instructions.
- Accesses the `this` pointer of its parent class.
- Raises an exception. Raising exceptions is considered as a side effect even if the function does not exit with an exception.
- Dereferences a local pointer that is assigned an absolute address.
- Accesses a `volatile` object, class member, or `struct` member.
- Sets the value of a class or `struct` member.

This checker does not flag placement `new` and `delete` functions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid void Functions That Have No Side-Effects

```
#include<cmath>

void init ( int refToInt )          // Noncompliant
{
    refToInt = 0;
}

void transform(double theta) //Noncompliant
{
    theta = sin(theta)/(1-cos(theta));
}
void foo(int val){ //Noncompliant
    if(val){
        foo(val--);
    }
}
```

In this example, Polyspace flags the `void` functions that have no side effects. For instance:

- The function `init()` initializes a local variable. This function returns no value and has no additional side effects. Perhaps the function is intended to initialize a reference and you missed an & in the declaration. Polyspace flags the function.
- The function `transform()` transforms a number to another number by calling the pure functions `sin()` and `cos()`. The function returns nothing and has no side effects. Perhaps the function is intended to return the transformed number and you missed a return statement. Polyspace flags the function.
- The function `foo()` sets up a recursion but has no effect on the output. Perhaps the recursion is set up improperly. Polyspace flags the function.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-9

There shall be no dead code

## Description

### Rule Definition

*There shall be no dead code.*

### Rationale

If an operation is reachable but removing the operation does not affect program behavior, the operation constitutes dead code. For instance, suppose that a variable is never read following a write operation. The write operation is redundant.

The presence of dead code can indicate an error in the program logic. Because a compiler can remove dead code, its presence can cause confusion for code reviewers.

### Polyspace Implementation

Polyspace reports violation of this rule on statements that have no effect on the code, such as writing a value to a variable that is not used subsequently.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Redundant Operations

```
#define ULIM 10000

int func(int arg) {
    int res;
    res = arg*arg + arg;
    if (res > ULIM)
        res = 0; //Noncompliant
    return arg;
}
```

In this example, the operations involving `res` are redundant because the function `func` returns its argument `arg`. All operations involving `res` can be removed without changing the effect of the function.

The checker flags the last write operation on `res` because the variable is never read after that point. The dead code can indicate an unintended coding error. For instance, you intended to return the value of `res` instead of `arg`.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-10

Every defined function shall be called at least once

## Description

### Rule Definition

*Every defined function shall be called at least once.*

### Rationale

If a function with a definition is not called, it might indicate a serious coding error. For instance, the function call is unreachable or a different function is called unintentionally.

### Polyspace Implementation

The checker detects situations where a static function is defined but not called at all in its translation unit.

### Additional Message in Report

Every defined function shall be called at least once. The static function *`funcName`* is not called.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Uncalled Static Function

```
static void func1() {
}

static void func2() { //Noncompliant
}

void func3();

int main() {
    func1();
    return 0;
}
```

The `static` function `func2` is defined but not called.

The function `func3` is not called either, however, it is only declared and not defined. The absence of a call to `func3` does not violate the rule.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-11

There shall be no unused parameters (named or unnamed) in nonvirtual functions

## Description

### Rule Definition

*There shall be no unused parameters (named or unnamed) in nonvirtual functions.*

### Rationale

Unused parameters often indicate later design changes. You perhaps removed all uses of a specific parameter but forgot to remove the parameter from the parameter list.

Unused parameters constitute an unnecessary overhead. You can also inadvertently call the function with a different number of arguments causing a parameter mismatch.

### Polyspace Implementation

The checker flags a function that has unused named parameters unless the function body is empty.

### Additional Message in Report

Function *funcName* has unused parameters.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Parameters

```
typedef int (*callbackFn) (int a, int b);

int callback_1 (int a, int b) { //Compliant
    return a+b;
}

int callback_2 (int a, int b) { //Noncompliant
    return a;
}

int callback_3 (int, int b) { //Compliant - flagged by Polyspace
    return b;
}

int getCallbackNumber();
int getInput();

void main() {
    callbackFn ptrFn;
    int n = getCallbackNumber();
    int x = getInput(), y = getInput();
    switch(n) {
        case 0: ptrFn = &callback_1; break;
        case 1: ptrFn = &callback_2; break;
        default: ptrFn = &callback_3; break;
    }

    (*ptrFn)(x,y);
}
```

In this example, the three functions `callback_1`, `callback_2` and `callback_3` are used as callback functions. One of the three functions is called via a function pointer depending on a value obtained at run time.

- Function `callback_1` uses all its parameters and does not violate the rule.
- Function `callback_2` does not use its parameter `a` and violates this rule.
- Function `callback_3` also does not use its first parameter but it does not violate the rule because the parameter is unnamed. However, Polyspace flags the unused parameter as a rule violation. If you see a violation of this kind, justify the violation with comments. See “Address Results in Polyspace User Interface Through Bug Fixes or Justifications”.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 0-1-12

There shall be no unused parameters (named or unnamed) in the set of parameters for a virtual function and all the functions that override it

## Description

### Rule Definition

*There shall be no unused parameters (named or unnamed) in the set of parameters for a virtual function and all the functions that override it.*

### Rationale

Unused parameters often indicate later design changes. You perhaps removed all uses of a specific parameter but forgot to remove the parameter from the parameter list.

Unused parameters constitute an unnecessary overhead. You can also inadvertently call the function with a different number of arguments causing a parameter mismatch.

### Polyspace Implementation

For each virtual function, the checker looks at all overrides of the function. If an override has a named parameter that is not used, the checker shows a violation on the original virtual function and lists the override as a supporting event.

Note that Polyspace checks for unused parameters in virtual functions within single translation units. For instance, if a base class contains a virtual method with an unused parameter but the derived class implementation of the method uses that parameter, the rule is not violated. However, if the base class and derived class are defined in different files, the checker, which operates file by file, flags a violation of this rule on the base class.

The checker does not flag unused parameters in functions with empty bodies.

### Additional Message in Report

There shall be no unused parameters (named or unnamed) in the set of parameters for a virtual function and all the functions that override it.

Function *funcName* has unused parameters.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Parameter in Virtual Function

```
class base {
    public:
       virtual void assignVal (int arg1, int arg2) = 0; //Noncompliant
       virtual void assignAnotherVal (int arg1, int arg2) = 0;
};

class derived1: public base {
    public:
       virtual void assignVal (int arg1, int arg2) {
           arg1 = 0;
       }
       virtual void assignAnotherVal (int arg1, int arg2) {
           arg1 = 1;
       }
};

class derived2: public base {
    public:
       virtual void assignVal (int arg1, int arg2) {
           arg1 = 0;
       }
       virtual void assignAnotherVal (int arg1, int arg2) {
           arg2 = 1;
       }
};
```

In this example, the second parameter of the virtual method `assignVal` is not used in any of the derived class implementations of the method.

On the other hand, the implementation of the virtual method `assignAnotherVal` in derived class `derived1` uses the first parameter of the method. The implementation in `derived2` uses the second parameter. Both parameters of `assignAnotherVal` are used and therefore the virtual method does not violate the rule.

# MISRA C++:2008 Rule 0-2-1

An object shall not be assigned to an overlapping object

## Description

### Rule Definition

*An object shall not be assigned to an overlapping object.*

### Rationale

When you assign an object to another object with overlapping memory, the behavior is undefined.

The exceptions are:

- You assign an object to another object with exactly overlapping memory and compatible type.
- You copy one object to another with `memmove`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Assignment of Union Members

```
void func (void) {
    union {
        short i;
        int j;
    } a = {0}, b = {1};

    a.j = a.i;   //Noncompliant
    a = b;       //Compliant
}
```

In this example, the rule is violated when `a.i` is assigned to `a.j` because the two variables have overlapping regions of memory.

# MISRA C++:2008 Rule 0-3-2

If a function generates error information, then that error information shall be tested

## Description

### Rule Definition

*If a function generates error information, then that error information shall be tested.*

### Rationale

If you do not check the return value of functions that indicate error information through their return values, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

For the `errno`-setting functions, to see if the function call completed without errors, check `errno` for error values. The return values of these `errno`-setting functions do not indicate errors. The return value can be one of the following:

- `void`
- Even if an error occurs, the return value can be the same as the value from a successful call. Such return values are called in-band error indicators. For instance, `strtol` converts a string to a long integer and returns the integer. If the result of conversion overflows, the function returns `LONG_MAX` and sets `errno` to `ERANGE`. However, the function can also return `LONG_MAX` from a successful conversion. Only by checking `errno` can you distinguish between an error and a successful conversion.

For the `errno`-setting functions, you can determine if an error occurred only by checking `errno`.

### Polyspace Implementation

The checker raises a violation when:

- You call sensitive functions that return information about possible errors and then you ignore the return value or use the output of the function without testing the return value.

  The checker covers function from the standard library and other well-known libraries such as the POSIX library or the WinAPI library. Polyspace considers a function as sensitive if the function call is prone to failure because of reasons such as:

  - Exhausted system resources (for example, when allocating resources).
  - Changed privileges or permissions.
  - Tainted sources when reading, writing, or converting data from external sources.
  - Unsupported features despite an existing API.

  Polyspace considers a function a critical sensitive when they perform critical tasks such as:

  - Set privileges (for example, `setuid`)
  - Create a jail (for example, `chroot`)

  - Create a process (for example, fork)
  - Create a thread (for example, pthread_create)
  - Lock or unlock mutex (for example, pthread_mutex_lock)
  - Lock or unlock memory segments (for example, mlock)

  For functions that are not critical, the checker is not flagged if you explicitly ignore the return value by casting it to void. Explicitly ignoring the return value of critical sensitive functions is flagged by Polyspace.

- You call a function that sets errno to indicate error conditions, but do not check errno after the call. For these functions, checking errno is the only reliable way to determine if an error occurred.

  Functions that set errno on errors include:

  - fgetwc, strtol, and wcstol.

    For a comprehensive list of functions, see documentation about errno.
  - POSIXerrno-setting functions such as encrypt and setkey.

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Sensitive Function Return Ignored

```
#include <pthread.h>
#include <string.h>
#include <stddef.h>
#include <stdio.h>
#include <cstdlib>
#define fatal_error() abort()

void initialize_1() {
    pthread_attr_t attr;
    pthread_attr_init(&attr); //Noncompliant
}

void initialize_2() {
    pthread_attr_t attr;
   (void)pthread_attr_init(&attr); //Compliant
}

void initialize_3() {
    pthread_attr_t attr;
    int result;
    result = pthread_attr_init(&attr); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

```
int read_file_1(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r");
  return 0; //Noncompliant

}
int read_file_2(int argc, char *argv[])
{
  FILE *in;
  if (argc != 2) {
    /* Handle error */
  }

  in = fmemopen (argv[1], strlen (argv[1]), "r"); //Compliant
  if (in==NULL){
      // Handle error
  }
  return 0;
}
```

This example shows a call to the sensitive functions `pthread_attr_init` and `fmemopen`. Polyspace raises a flag if:

- You implicitly ignore the return of the sensitive function. Explicitly ignoring the output of sensitive functions is not flagged.
- You obtain the return value of a sensitive function but do not test the value before exiting the relevant scope. The violation is raised on the exit statement.

To be compliant, you can explicitly cast their return value to `void` or test the return values to check for errors.

### Critical Function Return Ignored

```
#include <pthread.h>
#include <cstdlib>
#define fatal_error() abort()
extern void *start_routine(void *);

void returnnotchecked_1() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;

    (void)pthread_attr_init(&attr);
    (void)pthread_create(&thread_id, &attr, &start_routine, ((void *)0)); //Noncompliant
    pthread_join(thread_id,  &res); //Noncompliant
}

void returnnotchecked_2() {
    pthread_t thread_id;
    pthread_attr_t attr;
    void *res;
    int result;

    (void)pthread_attr_init(&attr);
    result = pthread_create(&thread_id, &attr, &start_routine, NULL); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }

    result = pthread_join(thread_id,  &res); //Compliant
    if (result != 0) {
        /* Handle error */
        fatal_error();
    }
}
```

In this example, two critical functions are called: `pthread_create` and `pthread_join`. The return value of the `pthread_create` is ignored by casting to void, but because `pthread_create` is a critical function (not just a sensitive function), the rule checker still raises a violation. The other critical function, `pthread_join`, returns a value that is ignored implicitly.

To be compliant, check the return value of these critical functions to verify the function performed as expected.

### `errno` Not Checked After Call to `strtol`

```
#include<cstdlib>
#include<cerrno>
#include<climits>
#include<iostream>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    long val = strtol(str, &endptr, base); //Noncompliant
    std::cout<<"Return value of strtol() = %ld\n" << val;

    errno = 0;
    long val2 = strtol(str, &endptr, base); //Compliant
    if((val2 == LONG_MIN || val2 == LONG_MAX) && errno == ERANGE) {
         std::cout<<"strtol error";
         exit(EXIT_FAILURE);
    }
    std::cout<<"Return value of strtol() = %ld\n" << val2;
}
```

In the noncompliant example, the return value of `strtol` is used without checking `errno`.

To be compliant, before calling `strtol`, set `errno` to zero . After a call to `strtol`, check the return value for `LONG_MIN` or `LONG_MAX` and `errno` for `ERANGE`.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 1-0-1

All code shall conform to ISO/IEC 14882:2003 "The C++ Standard Incorporating Technical Corrigendum 1"

## Description

**Note** To flag instances of code that does not comply with C++03 but complies with more recent versions of C++, specify the option `-cpp-version` as `cpp03`.

### Rule Definition

*All code shall conform to ISO/IEC 14882:2003 "The C++ Standard Incorporating Technical Corrigendum 1".*

### Polyspace Implementation

The checker reports compilation errors as detected by a compiler that strictly adheres to the C++03 Standard (ISO/IEC 14882:2003).

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C++:2008 Rule 2-3-1

Trigraphs shall not be used

## Description

### Rule Definition

*Trigraphs shall not be used.*

### Rationale

You denote trigraphs with two question marks followed by a specific third character (for instance,`'??-'` represents a `'~'` (tilde) character and `'??)'` represents a `']'`). These trigraphs can cause accidental confusion with other uses of two question marks.

For instance, the string

```
"(Date should be in the form ??-??-??)"
```

is transformed to

```
"(Date should be in the form ~~]"
```

but this transformation might not be intended.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C++:2008 Rule 2-5-1

Digraphs should not be used

## Description

### Rule Definition

*Digraphs should not be used.*

### Rationale

Digraphs are a sequence of two characters that are supposed to be treated as a single character. The checker flags use of these digraphs:

- `<%`, indicating {
- `%>`, indicating }
- `<:`, indicating [
- `:>`, indicating ]
- `%:`, indicating #
- `%:%:`, indicating ##

When developing or reviewing code with digraphs, the developer or reviewer can incorrectly consider the digraph as a sequence of separate characters.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 2-7-1

The character sequence /* shall not be used within a C-style comment

## Description

### Rule Definition

*The character sequence /* shall not be used within a C-style comment.*

### Rationale

If your code contains a `/*` in a `/* */` comment, it typically means that you have inadvertently commented out code. See the example that follows.

### Polyspace Implementation

You cannot justify a violation of this rule using source code annotations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `/*` in `/* */` Comment

```
void setup(void);
void foo() {
    /* Initializer functions
     setup();
    /* Step functions */  //Noncompliant
}
```

In this example, the call to `setup()` is commented out because the ending `*/` is omitted, perhaps inadvertently. The checker flags this issue by highlighting the `/*` in the `/* */` comment.

# MISRA C++:2008 Rule 2-7-2

Sections of code shall not be "commented out" using C-style comments

## Description

### Rule Definition

*Sections of code shall not be "commented out" using C-style comments.*

### Rationale

C-style comments enclosed in `/* */` do not support nesting. A comment beginning with `/*` ends at the first `*/` even when the `*/` is intended as the end of a later nested comment. If a section of code that is commented out already contains comments, you can encounter compilation errors (or at least comment out less code than you intend).

Commenting out code is not a good practice. The commented out code can remain out of sync with the surrounding code without causing compilation errors. Later, if you uncomment the code, you can encounter unexpected issues.

Use comments only to explain aspects of the code that are not apparent from the code itself.

### Polyspace Implementation

The checker uses internal heuristics to detect commented out code. For instance, characters such as `#`, `;`, `{` or `}` indicate comments that might potentially contain code. These comments are then evaluated against other metrics to determine the likelihood of code masquerading as comment. For instance, several successive words without a symbol in between reduces this likelihood.

The checker does not flag the following comments even if they contain code:

- Doxygen comments beginning with `/**` or `/*!`.
- Comments that repeat the same symbol several times, for instance, the symbol = here:

  ```
  /* =====================================
   * A comment
   * =====================================*/
  ```
- Comments on the first line of a file.
- Comments that mix the C style (`/* */`) and C++ style (`//`).

The checker considers that these comments are meant for documentation purposes or entered deliberately with some forethought.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code Commented Out With C-Style Comments

```
#include <iostream>
/* class randInt {//Noncompliant
    public:
      int getRandInt();
};
*/

int getRandInt();

/* Function to print random integers*/
void printInteger() {
    /* int val = getRandInt();//Noncompliant
     * val++;
     * std::cout << val;*/
    std::cout << getRandInt();
}
```

This example contains two blocks of commented out code, that constitutes two rule violations.

Sections of code should not be "commented out" using C++-style comments

## Description

### Rule Definition

*Sections of code should not be "commented out" using C++-style comments.*

### Rationale

Commenting out code is not a good practice. The commented out code can remain out of sync with the surrounding code without causing compilation errors. Later, if you uncomment the code, you can encounter unexpected issues.

Use comments only to explain aspects of the code that are not apparent from the code itself.

### Polyspace Implementation

The checker uses internal heuristics to detect commented out code. For instance, characters such as `#`, `;`, `{` or `}` indicate comments that might potentially contain code. These comments are then evaluated against other metrics to determine the likelihood of code masquerading as comment. For instance, several successive words without a symbol in between reduces this likelihood.

The checker does not flag the following comments even if they contain code:

- Doxygen comments beginning with `///` or `//!`.
- Comments that repeat the same symbol several times, for instance, the symbol = here:

```
// =====================================
// A comment
// =====================================*/
```

- Comments on the first line of a file.
- Comments that mix the C style (`/* */`) and C++ style (`//`).

The checker considers that these comments are meant for documentation purposes or entered deliberately with some forethought.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code Commented Out With C++-Style Comments

```
#include <iostream>
int getRandInt();

// Function to print random integers
```

```
void printInteger() {
    // int val = getRandInt();
    // val++;
    // std::cout << val;
    std::cout << getRandInt();
}
```

This example contains a block of commented out code that violates the rule.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 2-10-1

Different identifiers shall be typographically unambiguous

## Description

### Rule Definition

*Different identifiers shall be typographically unambiguous.*

### Rationale

When you use different identifiers that look typographically similar, you might inadvertently use the incorrect identifier later in your code. Such typographically ambiguous identifiers might lead to bugs that are difficult to diagnose.

Use identifiers that are unambiguously distinct. Avoid using identifiers that differ by a combination of these:

- The use of a lowercase letter instead of an uppercase one, and vice versa.
- The presence or absence of the underscore character.
- The interchange of the letter `O` and the digit `0`.
- The interchange of the letter `I` and the digit `1`.
- The interchange of the letter `I` and the letter `l`.
- The interchange of the letter `S` and the digit `5`.
- The interchange of the letter `Z` and the digit `2`.
- The interchange of the letter `n` and the letter `h`.
- The interchange of the letter `B` and the digit `8`.
- The interchange of the letters `rn` and the letter `m`.

### Polyspace Implementation

Polyspace reports a defect if two identifiers differ by a combination of ambiguous characters mentioned in the preceding list. The rule checker does not consider the fully qualified names of variables when checking this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Typographically Ambiguous Identifiers

```
void func(void) {
    int id1_numval;
    int id1_num_val;  //Non-compliant
    int id2_numval;
    int id2_numVal;   //Non-compliant

    int id3_lvalue;
    int id3_Ivalue;   //Non-compliant

    int id4_xyZ;
    int id4_xy2;      //Non-compliant

    int id5_zerO;
    int id5_zer0;     //Non-compliant

    int id6_rn;
    int id6_m;        //Non-compliant
}
```

In this example, the rule is violated when identifiers that can be confused for each other are used.

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 2-10-2

Identifiers declared in an inner scope shall not hide an identifier declared in an outer scope

## Description

### Rule Definition

*Identifiers declared in an inner scope shall not hide an identifier declared in an outer scope.*

### Rationale

The rule flags situations where the same identifier name is used in two variable declarations, one in an outer scope and the other in an inner scope.

```
int var;
...
{
...
  int var;
...
}
```

All uses of the name in the inner scope refers to the variable declared in the inner scope. However, a developer or code reviewer can incorrectly assume that the usage refers to the variable declared in the outer scope.

### Polyspace Implementation

The rule checker flags all cases of variable shadowing including when:

- The same identifier name is used in an outer and inner named namespace.
- The same name is used for a class data member and a variable outside the class.
- The same name is used for a method in a base and derived class.

To exclude these cases, switch to the more modern standard AUTOSAR C++14 and check for the rule `AUTOSAR C++14 Rule A2-10-1`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Local Variable Hiding Global Variable

```
int varInit = 1;

void doSomething(void);

void step(void) {
    int varInit = 0; //Noncompliant
    if(varInit)
       doSomething();
}
```

In this example, `varInit` defined in `func` hides the global variable `varInit`. The `if` condition refers to the local `varInit` and the block is unreachable, but you might expect otherwise.

### Loop Index Hiding Variable Outside Loop

```
void runSomeCheck(int);

void checkMatrix(int dim1, int dim2) {
  for(int index = 0; index < dim1; index++) {
      for(int index = 0; index < dim2; index++) { // Noncompliant
          runSomeCheck(index);
      }
  }
}
```

In this example, the variable `index` defined in the inner `for` loop hides the variable with the same name in the outer loop.

A typedef name (including qualification, if any) shall be a unique identifier

## Description

### Rule Definition

*A typedef name (including qualification, if any) shall be a unique identifier.*

### Rationale

When you use reuse `typedef` names, the code becomes confusing and difficult to maintain. You might use the wrong identifier and introduce bugs that are difficult to fix.

### Polyspace Implementation

The rule reports a violation on identifier declarations where the identifier name is the same as a previously declared typedef name. The checker does not flag situations where the conflicting names occur in different namespaces.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Typedef Name Conflicting with Other Identifiers

```
namespace NS1 {
    typedef int WIDTH;
}

namespace NS2 {
    float WIDTH; //Compliant
}

void f1() {
    typedef int TYPE;
}

void f2() {
    float TYPE; //Noncompliant
}
```

In this example, the declaration of `TYPE` in `f2()` conflicts with a typedef declaration in `f1()`.

The checker does not flag the redeclaration of `WIDTH` because the two declarations belong to different namespaces.

A class, union or enum name (including qualification, if any) shall be a unique identifier

## Description

### Rule Definition

*A class, union or enum name (including qualification, if any) shall be a unique identifier.*

### Rationale

Using nonunique identifiers makes the code confusing and difficult to maintain. You might use the wrong identifier in your code and introduce bugs that are difficult to fix.

### Polyspace Implementation

The rule flags identifier declarations where the identifier name is the same as a previously declared class, union or typedef name. The checker does not flag situations where the conflicting names occur in different namespaces.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Typedef Name Conflicting with Other Identifiers

```
void f1() {
    class floatVar {};
}

void f2() {
    float floatVar; //Noncompliant
}
```

In this example, the declaration of `floatVar` in `f2()` conflicts with a class declaration in `f1()`.

# MISRA C++:2008 Rule 2-10-5

The identifier name of a non-member object or function with static storage duration should not be reused

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*The identifier name of a non-member object or function with static storage duration should not be reused.*

### Rationale

Reusing the name of an identifier with static storage duration makes the code confusing and difficult to maintain. You might use the wrong identifier in your code and introduce bugs that are difficult to fix.

The rule applies even if the identifiers belong to different namespaces because the reuse leaves the chance that you mistake one identifier for the other.

### Polyspace Implementation

The rule flags situations where the name of an identifier with static storage duration is reused. The rule checker flags redefined functions only when there is a declaration.

The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions
- Uncalled and undefined local functions
- Unused types and variables

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Reuse of Identifiers in Different Namespaces

```
namespace NS1 {
    static int WIDTH;
}

namespace NS2 {
    float WIDTH; //Noncompliant
}
```

In this example, the identifier name `WIDTH` is reused in the two namespaces `NS1` and `NS2`.

If an identifier refers to a type, it shall not also refer to an object or a function in the same scope

## Description

### Rule Definition

*If an identifier refers to a type, it shall not also refer to an object or a function in the same scope.*

### Rationale

To maintain compatibility with C code, the C++ standard allows you to use the same name for a type and an object or function. However, the name reuse can cause confusion during development or code review.

### Polyspace Implementation

Polyspace reports a violation of this rule if you use an identifier both as a type name and as a function or object name. If the identifier is a function name and the function is both declared and defined, then the violation is reported once.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Reuse of Name for Type and Object

```
struct vector{
    int x;
    int y;
    int z;
}vector; //Noncompliant
```

In this example, the name `vector` is used both for the structured data type and for an object of that type.

# MISRA C++:2008 Rule 2-13-1

Only those escape sequences that are defined in ISO/IEC 14882:2003 shall be used

## Description

### Rule Definition

*Only those escape sequences that are defined in ISO/IEC 14882:2003 shall be used.*

### Rationale

Escape sequences are certain special characters represented in string and character literals. They are written with a backslash (\) followed by a character.

The C++ Standard (ISO/IEC 14882:2003, Sec. 2.13.2) defines a list of escape sequences. See Escape Sequences. Use of escape sequences (backslash followed by character) outside that list leads to undefined behavior.

### Additional Message in Report

Only those escape sequences that are defined in ISO/IEC 14882:2003 shall be used.

`\`*`char`* is not an ISO/IEC escape sequence.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Escape Sequences

```
void func () {
  const char a[2] = "\k"; //Noncompliant
  const char b[2] = "\b"; //Compliant
}
```

In this example, `\k` is not a recognized escape sequence.

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 2-13-2

Octal constants (other than zero) and octal escape sequences (other than "\0") shall not be used

## Description

### Rule Definition

*Octal constants (other than zero) and octal escape sequences (other than "\0") shall not be used.*

### Rationale

Octal constants are denoted by a leading zero. A developer or code reviewer can mistake an octal constant as a decimal constant with a redundant leading zero.

Octal escape sequences beginning with \ can also cause confusion. Inadvertently introducing an 8 or 9 in the digit sequence after \ breaks the escape sequence and introduces a new digit. A developer or code reviewer can ignore this issue and continue to treat the escape sequence as one digit.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Octal Constants and Octal Escape Sequences

```
void func(void) {
  int busData[6];

  busData[0] = 100;
  busData[1] = 108;
  busData[2] = 052;      //Noncompliant
  busData[3] = 071;      //Noncompliant
  busData[4] = '\109';   //Noncompliant
  busData[5] = '\100';   //Noncompliant

}
```

The checker flags all octal constants (other than zero) and all octal escape sequences (other than `\0`).

In this example:

- The octal escape sequence contains the digit 9, which is not an octal digit. This escape sequence has implementation-defined behavior.
- The octal escape sequence `\100` represents the number 64, but the rule checker forbids this use.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 2-13-3

A "U" suffix shall be applied to all octal or hexadecimal integer literals of unsigned type

## Description

### Rule Definition

*A "U" suffix shall be applied to all octal or hexadecimal integer literals of unsigned type.*

### Rationale

The signedness of a constant is determined from:

- Value of the constant.
- Base of the constant: octal, decimal or hexadecimal.
- Size of the various types.
- Any suffixes used.

Unless you use a suffix u or U, another developer looking at your code cannot determine easily whether a constant is signed or unsigned.

### Polyspace Implementation

Polyspace reports a violation of this rule if an unsigned octal or hexadecimal constant does not have the suffix U.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unsigned Integer Literal Missing Suffix

In this example, the unsigned integer literal 0x8000 does not have the U suffix. This literal is signed in a 32-bit environment but unsigned in a 16-bit environment. In a 16-bit environment, this code violates the rule. To see this rule violation, set -target to a 16-bit processor, such as c-167.

```
typedef unsigned int uint;
void foo ( )
{
uint a = 0U; // Compliant
uint b = 0x8000; //Noncompliant for a 16-bit processor
}
```

# MISRA C++:2008 Rule 2-13-4

Literal suffixes shall be upper case

## Description

### Rule Definition

*Literal suffixes shall be upper case.*

### Rationale

Literal constants can end with the letter `l` (el). Enforcing literal suffixes to be upper case removes potential confusion between the letter `l` and the digit `1`.

For consistency, use upper case constants for other suffixes such as `U` (unsigned) and `F` (float).

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Literal Constants with Lower Case Suffix

```
const int a = 0l; //Noncompliant
const int b = 0L; //Compliant
```

In this example, both `a` and `b` are assigned the same literal constant. However, from a quick glance, one can mistakenly assume that `a` is assigned the value `01` (octal one).

# MISRA C++:2008 Rule 2-13-5

Narrow and wide string literals shall not be concatenated

## Description

### Rule Definition

*Narrow and wide string literals shall not be concatenated.*

### Rationale

Narrow string literals are enclosed in double quotes without a prefix. Wide string literals are enclosed in double quotes with a prefix `L` outside the quotes. See string literals.

Concatenation of narrow and wide string literals can lead to undefined behavior.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Concatenation of Narrow and Wide String Literals

```
char array[] = "Hello" "World";
wchar_t w_array[] = L"Hello" L"World";
wchar_t mixed[] = "Hello" L"World"; //Noncompliant
```

In this example, in the initialization of the array `mixed`, the narrow string literal `"Hello"` is concatenated with the wide string literal `L"World"`.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 3-1-1

It shall be possible to include any header file in multiple translation units without violating the One Definition Rule

## Description

### Rule Definition

*It shall be possible to include any header file in multiple translation units without violating the One Definition Rule.*

### Rationale

If a header file with variable or function definitions appears in multiple inclusion paths, the header file violates the One Definition Rule possibly leading to unpredictable behavior. For instance, a source file includes the header file `include.h` and another header file, which also includes `include.h`.

### Polyspace Implementation

The rule checker flags variable and function definitions in header files.

Polyspace reports violation of this rule in header files. In a nonheader source file, violation of this rule is not reported.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Variable and Function Definitions in Header Files

In this example, Polyspace reports violations of this rule when variables and function definitions are placed in the header file `header.hpp`.

```
// header.hpp
#include <cstdint>
void F1();        // Compliant
extern void F2(); // Compliant
void F3()         // Noncompliant
{
}
static inline void F4()
{
} // Compliant
template <typename T>
void F5(T) // Compliant
{
}
std::int32_t a;                        // Noncompliant
extern std::int32_t b;                 // Compliant
constexpr static std::int32_t c = 10; // Compliant
namespace ns
{
    constexpr static std::int32_t d = 100; // Compliant
    const static std::int32_t e = 50;      // Compliant
    static std::int32_t f;                 // Noncompliant
    static void F6() noexcept;             // Noncompliant
}
```

```
//source.cpp
#include "header.hpp"
void foo()
{
    //...
}
```

# MISRA C++:2008 Rule 3-1-2

Functions shall not be declared at block scope

## Description

### Rule Definition

*Functions shall not be declared at block scope.*

### Rationale

It is a good practice to place all declarations at the namespace level.

Additionally, if you declare a function at block scope, it is often not clear if the statement is a function declaration or an object declaration with a call to the constructor.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function Declarations at Block Scope

```
class A {
};

void b1() {
    void func(); //Noncompliant
    A a();   //Noncompliant
}
```

In this example, the declarations of `func` and `a` are in the block scope of `b1`.

The second function declaration can cause confusion because it is not clear if `a` is a function that returns an object of type `A` or `a` is itself an object of type `A`.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-1-3

When an array is declared, its size shall either be stated explicitly or defined implicitly by initialization

## Description

### Rule Definition

*When an array is declared, its size shall either be stated explicitly or defined implicitly by initialization.*

### Rationale

Though you can declare an incomplete array type and later complete the type, specifying the array size during the first declaration makes the subsequent array access less error-prone.

### Additional Message in Report

When an array is declared, its size shall either be stated explicitly or defined implicitly by initialization.

Size of array `arrayName` should be explicitly stated.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Array Size Unspecified During Declaration

```
int array[10];
extern int array2[]; //Noncompliant
int array3[]= {0,1,2};
extern int array4[10];
```

In the declaration of `array2`, the array size is unspecified.

## Check Information

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-2-1

All declarations of an object or function shall have compatible types

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See “Checkers Deactivated in Polyspace as You Code Analysis”.*

### Rule Definition

*All declarations of an object or function shall have compatible types.*

### Rationale

If the declarations of an object or function in two different translation units have incompatible types, the behavior is undefined.

### Polyspace Implementation

Polyspace considers two types to be compatible if they have the same size and signedness in the environment that you use. The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions
- Uncalled and undefined local functions
- Unused types and variables

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Compatible and Incompatible Definitions in Two Files

**file1.cpp**

```
typedef          char         char_t;
typedef signed   short        int16_t;
typedef signed   long         int64_t;

namespace bar {
    int64_t a;
    int16_t c;

};
```

**file2.cpp**

```
typedef          char         char_t;
typedef signed   int          int32_t;

namespace bar {
    extern char_t c;// Noncompliant
    extern int32_t a;
    void foo(void){
        ++a;
        ++c;
    }
};
```

In this example, the variable `bar::c` is defined as a `char` in `file2.cpp` and as a `signed short` in `file1.cpp`. In the target processor i386, the size of these types are not equal. Polyspace flags the definition of `bar::c`.

The variable `bar::a` is defined as a `long` in `file1.cpp` and as an `int` in `file2.cpp`. In the target processor i386, both `int` and `long` has a size of 32 bits. Because the definitions of `bar::a` is compatible in both files, Polyspace does not raise a flag.

## Check Information

**Group:** Basic Concepts
**Category:** Required

# Version History

**Introduced in R2013b**

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-2-2

The One Definition Rule shall not be violated

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*The One Definition Rule shall not be violated.*

### Rationale

Violations of the One Definition Rule leads to undefined behavior.

### Polyspace Implementation

The checker flags situations where the same function or object has multiple definitions and the definitions differ by some token. The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions
- Uncalled and undefined local functions
- Unused types and variables

### Additional Message in Report

The One Definition Rule shall not be violated.

Declaration of class *`className`* violates the One Definition Rule:

it conflicts with other declaration (*`fileNamelineNumber`*).

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Different Tokens in Same Type Definition

This example uses two files:

- `file1.cpp`:

```
typedef struct S //Noncompliant
{
   int x;
   int y;
}S;
void foo(S& s){
//...
}
```

- `file2.cpp`:

```
typedef struct S
{
   int y;
   int x;
}S ;
void bar(S& s){
//...
}
```

In this example, both `file1.cpp` and `file2.cpp` define the structure `S`. However, the definitions switch the order of the structure fields.

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-2-3

A type, object or function that is used in multiple translation units shall be declared in one and only one file

## Description

### Rule Definition

*A type, object or function that is used in multiple translation units shall be declared in one and only one file.*

### Rationale

If you declare an identifier in a header file, you can include the header file in any translation unit where the identifier is defined or used. In this way, you ensure consistency between:

- The declaration and the definition.
- The declarations in different translation units.

The rule enforces the practice of declaring external objects or functions in header files.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** Basic Concepts
**Category:** Required

# Version History

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 3-2-4

An identifier with external linkage shall have exactly one definition

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See "Checkers Deactivated in Polyspace as You Code Analysis".*

### Rule Definition

*An identifier with external linkage shall have exactly one definition.*

### Rationale

If an identifier has multiple definitions or no definitions, it can lead to undefined behavior.

### Polyspace Implementation

The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions
- Uncalled and undefined local functions
- Unused types and variables

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Multiple Definitions of Identifier

This example uses two files:

- `file1.cpp`:

```
typedef signed   int          int32_t;

namespace NS {
    extern int32_t a;

    void foo(){
        a = 0;

    }
};
```

- `file2.cpp`:

```
typedef signed   int          int32_t;
typedef signed   long long         int64_t;

namespace NS {
    extern int64_t a; //Noncompliant
    void bar(){
        ++a;

    }
};
```

The same identifier `a` is defined in both files.

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-3-1

Objects or functions with external linkage shall be declared in a header file

## Description

### Rule Definition

*Objects or functions with external linkage shall be declared in a header file.*

### Rationale

If you declare a function or object in a header file, it is clear that the function or object is meant to be accessed in multiple translation units. If you intend to access the function or object from a single translation unit, declare it `static` or in an unnamed namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declaration in Header File Missing

This example uses two files:

- `decls.h`:

  ```
  extern int x;
  ```
- `file.cpp`:

  ```
  #include "decls.h"

  int x = 0;
  int y = 0; //Noncompliant
  static int z = 0;
  ```

In this example, the variable `x` is declared in a header file but the variable `y` is not. The variable `z` is also not declared in a header file but it is declared with the `static` specifier and does not have external linkage.

## Check Information

**Group:** Basic Concepts
**Category:** Required

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-3-2

If a function has internal linkage then all re-declarations shall include the static storage class specifier

## Description

### Rule Definition

*If a function has internal linkage then all re-declarations shall include the static storage class specifier.*

### Rationale

If a function declaration has the `static` storage class specifier, it has internal linkage. Subsequent redeclarations of the function have internal linkage even without the `static` specifier.

However, if you do not specify the `static` keyword explicitly, it is not immediately clear from a declaration whether the function has internal linkage.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing `static` Specifier from Redeclaration

```
static void func1 ();
static void func2 ();

void func1() {}  //Noncompliant
static void func2() {}
```

In this example, the function `func1` is declared `static` but defined without the `static` specifier.

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 3-4-1

An identifier declared to be an object or type shall be defined in a block that minimizes its visibility

## Description

### Rule Definition

*An identifier declared to be an object or type shall be defined in a block that minimizes its visibility.*

### Rationale

Defining variables with the minimum possible block scope reduces the possibility that they might later be accessed unintentionally.

For instance, if an object is meant to be accessed in one function only, declare the object local to the function.

### Polyspace Implementation

The rule checker determines if an object is used in one block only. If the object is used in one block but defined outside the block, the checker raises a violation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Global Variable in Single Function

```
static int countReset; //Noncompliant

volatile int check;

void increaseCount() {
    int count = countReset;
    while(check%2) {
     count++;
    }
}
```

In this example, the variable `countReset` is declared global used in one function only. A compliant solution declares the variable local to the function to reduce its visibility.

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 3-9-1

The types used for an object, a function return type, or a function parameter shall be token-for-token identical in all declarations and re-declarations

## Description

### Rule Definition

*The types used for an object, a function return type, or a function parameter shall be token-for-token identical in all declarations and re-declarations.*

### Rationale

If a redeclaration is not token-for-token identical to the previous declaration, it is not clear from visual inspection which object or function is being redeclared.

### Polyspace Implementation

The rule checker compares the current declaration with the last seen declaration.

### Additional Message in Report

The types used for an object, a function return type, or a function parameter shall be token-for-token identical in all declarations and re-declarations.

Variable *varName* is not compatible with previous declaration.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Identical Declarations That Do Not Match Token for Token

```
typedef int* intptr;

int* map;
extern intptr map; //Noncompliant

intptr table;
extern intptr table; //Compliant
```

In this example, the variable `map` is declared twice. The second declaration uses a `typedef` which resolves to the type of the first declaration. Because of the `typedef`, the second declaration is not token-for-token identical to the first.

typedefs that indicate size and signedness should be used in place of the basic numerical types

## Description

### Rule Definition

*typedefs that indicate size and signedness should be used in place of the basic numerical types.*

### Rationale

When the amount of memory being allocated is important, using specific-length types makes it clear how much storage is being reserved for each object.

### Polyspace Implementation

The rule checker does not raise violations in templates that are not instantiated.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Direct Use of Basic Numerical Types

```
typedef unsigned int uint32_t;

unsigned int x = 0;       //Noncompliant
uint32_t y = 0;  //Compliant
```

In this example, the declaration of `x` is noncompliant because it uses the basic type `int` directly.

`Check MISRA C++:2008 (-misra-cpp)`

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 3-9-3

The underlying bit representations of floating-point values shall not be used

## Description

### Rule Definition

*The underlying bit representations of floating-point values shall not be used.*

### Rationale

The underlying bit representations of floating point values vary across compilers. If you directly use the underlying representation of floating point values, your program is not portable across implementations.

### Polyspace Implementation

The rule checker flags conversions from pointers to floating point types into pointers to integer types, and vice versa.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using Underlying Representation of Floating-Point Values

```
float fabs2(float f) {
    unsigned int* ptr = reinterpret_cast <unsigned int*> (&f); //Noncompliant
    *(ptr + 3) &= 0x7f;
    return f;
}
```

In this example, the `reinterpret_cast` attempts to cast a floating-point value to an integer and access the underlying bit representation of the floating point value.

# MISRA C++:2008 Rule 4-5-1

Expressions with type bool shall not be used as operands to built-in operators other than the assignment operator =, the logical operators &&, ||, !, the equality operators == and !=, the unary & operator, and the conditional operator

## Description

### Rule Definition

*Expressions with type bool shall not be used as operands to built-in operators other than the assignment operator =, the logical operators &&, ||, !, the equality operators == and !=, the unary & operator, and the conditional operator.*

### Rationale

Operators other than the ones mentioned in the rule do not produce meaningful results with `bool` operands. Use of `bool` operands with these operators can indicate programming errors. For instance, you intended to use the logical operator `||` but used the bitwise operator `|` instead.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Compliant and Noncompliant Uses of `bool` Operands

```
void boolOperations() {
    bool lhs = true;
    bool rhs = false;

    int res;

    if(lhs & rhs) {} //Noncompliant
    if(lhs < rhs) {} //Noncompliant
    if(~rhs) {}      //Noncompliant
    if(lhs ^ rhs) {} //Noncompliant
    if(lhs == rhs) {} //Compliant
    if(!rhs) {}       //Compliant
    res = lhs? -1:1;  //Compliant
}
```

In this example, `bool` operands do not violate the rule when used with the `==`, `!` and the `?` operators.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 4-5-3

Expressions with type (plain) char and wchar_t shall not be used as operands to built-in operators other than the assignment operator =, the equality operators == and !=, and the unary & operator N

## Description

### Rule Definition

*Expressions with type (plain) char and wchar_t shall not be used as operands to built-in operators other than the assignment operator =, the equality operators == and !=, and the unary & operator. N*

### Rationale

The C++03 Standard only requires that the characters `'0'` to `'9'` have consecutive values. Other characters do not have well-defined values. If you use these characters in operations other than the ones mentioned in the rule, you implicitly use their underlying values and might see unexpected results.

### Additional Message in Report

Expressions with type (plain) char and wchar_t shall not be used as operands to built-in operators other than the assignment operator =, the equality operators == and !=, and the unary & operator. N

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Compliant and Noncompliant Uses of Character Operands

```
void charManipulations (char ch) {

    char initChar = 'a'; //Compliant
    char finalChar = 'z'; //Compliant

    if(ch == initChar) {} //Compliant
    if( (ch >= initChar) && (ch <= finalChar)) {} //Noncompliant
    else if( (ch >= '0') && (ch <= '9') ) {} //Compliant by exception
}
```

In this example, character operands do not violate the rule when used with the = and == operators. Character operands can also be used with relational operators as long as the comparison is performed with the digits `'0'` to `'9'`.

# MISRA C++:2008 Rule 4-10-1

NULL shall not be used as an integer value

## Description

### Rule Definition

*NULL shall not be used as an integer value.*

### Rationale

In C++, you can use the literals 0 and NULL as both an integer and a null pointer constant. However, use of 0 as a null pointer constant or NULL as an integer can cause developer confusion.

This rule restricts the use of NULL to null pointer constants. `MISRA C++:2008 Rule 4-10-2` restricts the use of the literal 0 to integers.

### Polyspace Implementation

The checker flags assignment of NULL to an integer variable or binary operations involving NULL and an integer. Assignments can be direct or indirect such as passing NULL as integer argument to a function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Compliant and Noncompliant Uses of `NULL`

```
#include <cstddef>

void checkInteger(int);
void checkPointer(int *);

void main() {
    checkInteger(NULL); //Noncompliant
    checkPointer(NULL); //Compliant
}
```

In this example, the use of `NULL` as argument to the `checkInteger` function is noncompliant because the function expects an `int` argument.

Literal zero (0) shall not be used as the null-pointer-constant

## Description

### Rule Definition

*Literal zero (0) shall not be used as the null-pointer-constant.*

### Rationale

In C++, you can use the literals 0 and NULL as both an integer and a null pointer constant. However, use of 0 as a null pointer constant or NULL as an integer can cause developer confusion.

This rule restricts the use of the literal 0 to integers. `MISRA C++:2008 Rule 4-10-1` restricts the use of NULL to null pointer constants.

### Polyspace Implementation

The checker flags assignment of 0 to a pointer variable or binary operations involving 0 and a pointer. Assignments can be direct or indirect such as passing 0 as pointer argument to a function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Compliant and Noncompliant Uses of Literal 0

```
#include <cstddef>

void checkInteger(int);
void checkPointer(int *);

void main() {
    checkInteger(0); //Compliant
    checkPointer(0); //Noncompliant
}
```

In this example, the use of 0 as argument to the `checkPointer` function is noncompliant because the function expects an `int *` argument.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-1

The value of an expression shall be the same under any order of evaluation that the standard permits

## Description

### Rule Definition

*The value of an expression shall be the same under any order of evaluation that the standard permits.*

### Rationale

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

### Polyspace Implementation

Polyspace raises a violation if an expression satisfies any of these conditions:

- The same variable is modified more than once in the expression or it is both read and written.
- The expression allows more than one order of evaluation.
- The expression contains a single `volatile` object that occurs multiple times.
- The expression contains more than one `volatile` object.

Because `volatile` objects can change their value at anytime, an expression containing multiple `volatile` variables or multiple instances of the same `volatile` variable might have different results depending on the order of evaluation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Modified More Than Once in Expression

```
int a[10], b[10];
#define COPY_ELEMENT(index) (a[(index)]=b[(index)])
void main () {
    int i=0, k=0;

    COPY_ELEMENT (k);         // Compliant
    COPY_ELEMENT (i++);    // // Non-compliant
}
```

In this example, the rule is violated by the statement `COPY_ELEMENT(i++)` because `i++` occurs twice and the order of evaluation of the two expressions is unspecified.

### Variable Modified and Used in Multiple Function Arguments

```
void f (unsigned int param1, unsigned int param2) {}

void main () {
    unsigned int i=0;
    f ( i++, i );                 // Noncompliant
}
```

In this example, the rule is violated because it is unspecified whether the operation `i++` occurs before or after the second argument is passed to `f`. The call `f(i++,i)` can translate to either `f(0,0)` or `f(0,1)`.

### Multiple `volatile` Objects in an Expression

```
volatile int a, b;
int mathOp(int x, int y);

int foo(void){
    int temp = mathOp(5,a) + mathOp(6,b);//Noncompliant
    return temp * mathOp(a,a);//Noncompliant
}
```

In this example, this rule is violated twice.

- The declaration of `temp` uses two `volatile` objects in the expression. Because the value of `volatile` objects might change at any time, the expression might evaluate to different values depending on the order of evaluation. Polyspace flags the second `volatile` object in the expression.
- The `return` statement uses the same `volatile` object twice. Because the expression might have different results depending on the order of evaluation, Polyspace raises this defect.

# MISRA C++:2008 Rule 5-0-2

Limited dependence should be placed on C++ operator precedence rules in expressions

## Description

### Rule Definition

*Limited dependence should be placed on C++ operator precedence rules in expressions.*

### Rationale

Use parentheses to clearly indicate the order of evaluation.

Depending on operator precedence can cause the following issues:

- If you or another code reviewer reviews the code, the intended order of evaluation is not immediately clear.
- It is possible that the result of the evaluation does not meet your expectations. For instance:
  - In the operation `*p++`, it is possible that you expect the dereferenced value to be incremented. However, the pointer `p` is incremented before the dereference.
  - In the operation `(x == y | z)`, it is possible that you expect `x` to be compared with `y | z`. However, the `==` operation happens before the `|` operation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Evaluation Order Dependent on Operator Precedence Rules

```
#include <cstdio>

void showbits(unsigned int x) {
    for(int i = (sizeof(int) * 8) - 1; i >= 0; i--) {
       (x & 1u << i) ? putchar('1') : putchar('0'); // Noncompliant
    }
    printf("\n");
}
```

In this example, the checker flags the operation `x & 1u << i` because the statement relies on operator precedence rules for the `<<` operation to happen before the `&` operation. If this is the intended order, the operation can be rewritten as `x & (1u << i)`.

# MISRA C++:2008 Rule 5-0-3

A cvalue expression shall not be implicitly converted to a different underlying type

## Description

### Rule Definition

*A cvalue expression shall not be implicitly converted to a different underlying type.*

### Rationale

This rule ensures that the result of the expression does not overflow when converted to a different type.

### Polyspace Implementation

Expressions flagged by this checker follow the detailed specifications for cvalue expressions from the MISRA C++ documentation.

The underlying data type of a cvalue expression is the widest of operand data types in the expression. For instance, if you add two variables, one of type `int8_t` (`typedef` for `char`) and another of type `int32_t` (`typedef` for `int`), the addition has underlying type `int32_t`. If you assign the sum to a variable of type `int8_t`, the rule is violated.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Implicit Conversion of Cvalue Expression

```
#include<cstdint>

void func ( )
  {
    int32_t s32;
    int8_t s8;
    s32 = s8 + s8; //Noncompliant
    s32 = s32 + s8; //Compliant
  }
```

In this example, the rule is violated when two variables of type `int8_t` are added and the result is assigned to a variable of type `int32_t`. The underlying type of the addition does not take into account the integer promotion involved and is simply the widest of operand data types, in this case, `int8_t`.

The rule is not violated if one of the operands has type `int32_t` and the result is assigned to a variable of type `int32_t`. In this case, the underlying data type of the addition is the same as the type of the variable to which the result is assigned.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 5-0-4

An implicit integral conversion shall not change the signedness of the underlying type

## Description

### Rule Definition

*An implicit integral conversion shall not change the signedness of the underlying type.*

### Rationale

Some conversions from signed to unsigned data types can lead to implementation-defined behavior. You can see unexpected results from the conversion.

### Polyspace Implementation

The checker flags implicit conversions from a signed to an unsigned integer data type or vice versa.

The checker assumes that `ptrdiff_t` is a signed integer.

### Additional Message in Report

An implicit integral conversion shall not change the signedness of the underlying type.

Implicit conversion of one of the binary + operands whose underlying types are *`typename_1`* and *`typename_2`*.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Implicit Conversions that Change Signedness

```
typedef char int8_t;
typedef unsigned char uint8_t;

void func()
  {
    int8_t s8;
    uint8_t u8;

    s8 = u8; //Noncompliant
    u8 = s8 + u8; //Noncompliant
    u8 = static_cast< uint8_t > ( s8 ) + u8; //Compliant
}
```

In this example, the rule is violated when a variable with a variable with signed data type is implicitly converted to a variable with unsigned data type or vice versa. If the conversion is explicit, as in the preceding example, the rule violation does not occur.

## Check Information

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-5

There shall be no implicit floating-integral conversions

## Description

### Rule Definition

*There shall be no implicit floating-integral conversions.*

### Rationale

If you convert from a floating point to an integer type, you lose information. Unless you explicitly cast from floating point to an integer type, it is not clear whether the loss of information is intended. Additionally, if the floating-point value cannot be represented in the integer type, the behavior is undefined.

Conversion from an integer to floating-point type can result in an inexact representation of the value. The error from conversion can accumulate over later operations and lead to unexpected results.

### Polyspace Implementation

The checker flags implicit conversions between floating-point types (`float` and `double`) and integer types (`short`, `int`, etc.).

This rule takes precedence over 5-0-4 and 5-0-6 if they apply at the same time.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Conversion Between Floating Point and Integer Types

```
typedef signed int int32_t;
typedef float float32_t;

void func ( )
  {
    float32_t f32;
    int32_t   s32;
    s32 = f32;   //Noncompliant
    f32 = s32;   //Noncompliant
    f32 = static_cast< float32_t > ( s32 ); //Compliant
  }
```

In this example, the rule is violated when a floating-point type is *implicitly* converted to an integer type. The violation does not occur if the conversion is explicit.

## Check Information

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-6

An implicit integral or floating-point conversion shall not reduce the size of the underlying type

## Description

### Rule Definition

*An implicit integral or floating-point conversion shall not reduce the size of the underlying type.*

### Rationale

A conversion that reduces the size of the underlying type can result in loss of information. Unless you explicitly cast to the narrower type, it is not clear whether the loss of information is intended.

### Polyspace Implementation

The checker flags implicit conversions that reduce the size of a type.

If the conversion is to a narrower integer with a different sign, then rule 5-0-4 takes precedence over rule 5-0-6. Only rule 5-0-4 is shown.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Conversion That Reduces Size of Type

```
typedef signed short int16_t;
typedef signed int int32_t;

void func ( )
  {
    int16_t   s16;;
    int32_t   s32;
    s16 = s32;   //Noncompliant
    s16 = static_cast< int16_t > ( s32 ); //Compliant
  }
```

In this example, the rule is violated when a type is *implicitly* converted to a narrower type. The violation does not occur if the conversion is explicit.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-7

There shall be no explicit floating-integral conversions of a cvalue expression

## Description

### Rule Definition

*There shall be no explicit floating-integral conversions of a cvalue expression.*

### Rationale

Expressions flagged by this checker follow the detailed specifications for cvalue expressions from the MISRA C++ documentation.

If you evaluate an expression and later cast the result to a different type, the cast has no effect on the underlying type of the evaluation (the widest of operand data types in the expression). For instance, in this example, the result of an integer division is then cast to a floating-point type.

```
short num;
short den;
float res;
res= static_cast<float> (num/den);
```

However, a developer or code reviewer can expect that the evaluation uses the data type to which the result is cast later. For instance, one can expect a floating-point division because of the later cast.

### Additional Message in Report

There shall be no explicit floating-integral conversions of a cvalue expression.

Complex expression of underlying type *typeBeforeConversion* may only be cast to narrower integer type of same signedness, however the destination type is *typeAfterconversion*.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Conversion of Division Result from Integer to Floating Point

```
void func() {
     short num;
     short den;
     short res_short;
     float res_float;

     res_float = static_cast<float> (num/den); //Noncompliant

     res_short = num/den;
     res_float = static_cast<float> (res_short); //Compliant
}
```

In this example, the first cast on the division result violates the rule but the second cast does not.

- The first cast can lead to the incorrect expectation that the expression is evaluated with an underlying type `float`.
- The second cast makes it clear that the expression is evaluated with the underlying type `short`. The result is then cast to the type `float`.

## Check Information

# MISRA C++:2008 Rule 5-0-8

An explicit integral or floating-point conversion shall not increase the size of the underlying type of a cvalue expression

## Description

### Rule Definition

*An explicit integral or floating-point conversion shall not increase the size of the underlying type of a cvalue expression.*

### Rationale

Expressions flagged by this checker follow the detailed specifications for cvalue expressions from the MISRA C++ documentation.

If you evaluate an expression and later cast the result to a different type, the cast has no effect on the underlying type of the evaluation (the widest of operand data types in the expression). For instance, in this example, the sum of two `short` operands is cast to the wider type `int`.

```
short op1;
short op2;
int res;
res= static_cast<int> (op1 + op2);
```

However, a developer or code reviewer can expect that the evaluation uses the data type to which the result is cast later. For instance, one can expect a sum with the underlying type `int` because of the later cast.

### Additional Message in Report

An explicit integral or floating-point conversion shall not increase the size of the underlying type of a cvalue expression.

Complex expression of underlying type *`typeBeforeConversion`* may only be cast to narrower integer type of same signedness, however the destination type is *`typeAfterconversion`*.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Conversion of Sum to Wider Integer Type

```
void func() {
     short op1;
     short op2;
     int res;

     res = static_cast<int> (op1 + op2); //Noncompliant
```

```
    res = static_cast<int> (op1) + op2; //Compliant

}
```

In this example, the first cast on the sum violates the rule but the second cast does not.

- The first cast can lead to the incorrect expectation that the sum is evaluated with an underlying type `int`.
- The second cast first converts one of the operands to `int` so that the sum is actually evaluated with the underlying type `int`.

# MISRA C++:2008 Rule 5-0-9

An explicit integral conversion shall not change the signedness of the underlying type of a cvalue expression

## Description

### Rule Definition

*An explicit integral conversion shall not change the signedness of the underlying type of a cvalue expression.*

### Rationale

Expressions flagged by this checker follow the detailed specifications for cvalue expressions from the MISRA C++ documentation.

If you evaluate an expression and later cast the result to a different type, the cast has no effect on the underlying type of the evaluation (the widest of operand data types in the expression).. For instance, in this example, the sum of two `unsigned int` operands is cast to the type `int`.

```
unsigned int op1;
unsigned int op2;
int res;
res= static_cast<int> (op1 + op2);
```

However, a developer or code reviewer can expect that the evaluation uses the data type to which the result is cast later. For instance, one can expect a sum with the underlying type `int` because of the later cast.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Conversion of Sum to Wider Integer Type

```
typedef int int32_t;
typedef unsigned int uint32_t;

void func() {
     uint32_t op1;
     uint32_t op2;
     int32_t res;

     res = static_cast<int32_t> (op1 + op2); //Noncompliant
     res = static_cast<int32_t> (op1) +
           static_cast<int32_t> (op2); //Compliant

}
```

In this example, the first cast on the sum violates the rule but the second cast does not.

- The first cast can lead to the incorrect expectation that the sum is evaluated with an underlying type `int32_t`.
- The second cast first converts each of the operands to `int32_t` so that the sum is actually evaluated with the underlying type `int32_t`.

# MISRA C++:2008 Rule 5-0-10

If the bitwise operators ~ and << are applied to an operand with an underlying type of unsigned char or unsigned short, the result shall be immediately cast to the underlying type of the operand

## Description

### Rule Definition

*If the bitwise operators ~ and << are applied to an operand with an underlying type of unsigned char or unsigned short, the result shall be immediately cast to the underlying type of the operand.*

### Rationale

When the bitwise operators ~ and << are applied to small integer types, such as unsigned short and unsigned char, the operations are preceded by integral promotion. That is, the small integer types are first promoted to a larger integer type, and then the operation takes place. The result of these bitwise operation might contain unexpected higher order bits. For instance:

```
uint8_t var = 0x5aU;
uint8_t result = (~var)>>4;
```

The binary representation of `var` is `0101 1010` and that of `~var` is `1010 0101`. You might expect that `result` is `0000 1010`. Because `var` is promoted to a larger integer before `~var` is calculated, result becomes `1111 1010`. The higher order bits might be unexpected. The results of such operations might depend on the size of `int` in your implementation.

To avoid confusion and unexpected errors, cast the result of the bitwise ~ and >> operators back to the underlying type of the operands before using the results. For instance:

```
uint8_t var = 0x5aU;
uint8_t result = (static_cat<unit8_t>(~var))>>4;
```

The binary representation of `result` in this case is `0000 1010`, which is the expected value.

As an exception, casting is not required if you apply these bitwise operators on short integer types, and then immediately assign the result to an object of the same underlying type. For instance, the value of result in this case is `0000 1010` without requiring a cast.

```
uint8_t var = 0x5aU;
unit8_t result = ~var; // No higher order bits
                       // due to implicit conversion
uint8_t result = results>>4;
```

### Polyspace Implementation

Polyspace flags the use of the bitwise ~ and >> operators if all of these conditions are true:

- The operators are used on an `unsigned short` or `unsigned char` operand.
- The result of the operation is not immediately assigned to an object that has the same underlying type as the operand.
- The result is used without being cast to the underlying type of the operand.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Cast Results of ~ and << Operators to the Operand Type When the Operand Is Small Integer Type

```
#include<cstdint>
void foo(){
    uint8_t var = 0x5aU;
    uint8_t result;
    result = ( ~var ) >> 4; // Non-compliant
    result = static_cast<uint8_t>(( ~var )) >> 4; // Compliant
    uint8_t cbe = ~var;//Compliant by Exception
}
```

In this example, Polyspace flags the use of ~ on the small integer `var`. The ~ operator is flagged because:

- It operates on an unsigned short integer `var`.
- The result of the operator is used in an expression without casting ~`var` to `uint8_t`.

When the result of ~ operator is cast to `unit8_t`, the use is compliant with this rule. When the result of ~ is immediately assigned to a `unit8_t` variable, the use is compliant to this rule by exception.

# MISRA C++:2008 Rule 5-0-11

The plain char type shall only be used for the storage and use of character values

## Description

### Rule Definition

*The plain char type shall only be used for the storage and use of character values.*

### Rationale

The signedness of plain `char` is implementation-defined. Because its sign is not well defined, the plain `char` type is not suitable to be used with numeric values. Use plain `char` for the storage and use of character values.

### Polyspace Implementation

The checker raises a violation when a value of signed or unsigned integer type is implicitly converted to the plain char type.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using Plain `char` For Numeric Data

```
#include<stdint.h>
typedef  char char_t;
void foo(){
char a = 'a'; // Compliant
char_t b = '\r'; // Compliant
char_t c = 10; // Noncompliant
char d = 'd'; // Compliant
}
```

In this example, Polyspace flags the use of plain `char` for numeric data.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 5-0-12

Signed char and unsigned char type shall only be used for the storage and use of numeric values

## Description

### Rule Definition

*Signed char and unsigned char type shall only be used for the storage and use of numeric values.*

### Rationale

In C/C++, there are three types of `char`:

- Plain `char`
- `signed char`
- `unsigned char`

The signedness of plain `char` is implementation-defined. Plain `char` cannot be interchangeably used with the other types. For instance, you might assume `char` is unsigned and use `unsigned char` to store character. Your implementation might interpret characters as signed. In such a situation, your code might behave in unexpected manner, leading to bugs that are difficult to diagnose.

MISRA C++:2008 limits the use of these three types of `char` for different applications. The `signed` and `unsigned char` type is appropriate for numeric values and storage. The plain `char` is appropriate for character data. Avoid using `signed` or `unsigned char` when you intend to use the plain `char`.

This rule also applies to the different `typedef` of these `char` types, such as `uint8_t` and `int8_t`. See `MISRA C++:2008 Rule 3-9-2`.

### Polyspace Implementation

Polyspace raises a violation of this rule when a plain `char` is implicitly converted to either `signed char` or `unsigned char`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use Plain `char` to Store Characters

```
typedef signed   char         int8_t;
typedef unsigned char         uint8_t;

namespace foo
{
    int8_t        ch_1   =   'a';     // Noncompliant
    uint8_t       ch_2  =   '\r';     // Noncompliant
    char          ch_3  =   'A';      // Compliant
    int8_t        num_1   =   10;     // Compliant
    uint8_t       num_2   =   12U;    // Compliant
    signed char   num_3   =   11;     // Compliant

};
```

In this example, Polyspace flags the use of `signed char` and `unsigned char` to store character data. The character literals are of plain `char` types, and Polyspace flags the implicit conversion of these plain `char` types to explicitly `signed` or `unsigned char` types.

# MISRA C++:2008 Rule 5-0-13

The condition of an if-statement and the condition of an iteration- statement shall have type bool

## Description

### Rule Definition

*The condition of an if-statement and the condition of an iteration- statement shall have type bool.*

### Rationale

When you use a non-Boolean expression as a condition for `if`, `while`, and `for` statements, the expression is implicitly converted to `bool`. Such an implicit conversion might make developer intent unclear and hide errors that lead to bugs that are difficult to diagnose. For instance:

```
int flag;
//...
if(flag = 0){
//..
}
```

In the preceding code, it is not clear whether the condition `flag = 0` is intended to be an assignment. The compiler casts the return value of the assignment operation into a `bool`, which is used as the condition for the if statement. If the developer intent is to test whether `flag` equals `0`, then the missing = in the code results in bugs that are difficult to diagnose.

As an exception, conditions of the format `type-specifier-seq declarator` does not need to be Boolean. For instance:

```
while(int* p_int = foo())
```

In this case, the developer intent is clear because of the presence of the type specifier. Avoiding such assignments might make the code difficult to read.

### Polyspace Implementation

Polyspace flags the use of non-Boolean expressions as conditions in `if`, `for`, and `while` statements. As an exception, Polyspace does not flag a non-Boolean condition if the expression is a declaration.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Non-Boolean Expressions as Conditions

```
typedef unsigned char         uint8_t;
typedef signed   int          int32_t;
typedef          bool         bool_t;
```

```
#include <cstddef>

namespace NS
{
extern int32_t* fn();
extern bool      fn2();
void foo(uint8_t u8)
{
    while (int32_t* p = fn()) {                   // Compliant by exception
        // Code
    }
    // Avoiding assignment altogather in condition statements
    // sometimes lead to clunky code
    do {
        int32_t* p = fn();
        if (NULL == p) {
            break;
        }
        // Code/*...*/
    } while (true);

    while (bool flag = fn2()) {                      // Compliant
        // Code
    }

    if (u8) {}                                       // Non-compliant

}
};
```

In this example, Polyspace flags the use of non-Boolean expressions as conditions.

As the `do-while` loop shows, avoiding declarations in condition statement might lead to code that is difficult to read. Non-Boolean conditions that are declarations are compliant with this rule as exceptions.

## Check Information

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-14

The first operand of a conditional-operator shall have type bool

## Description

### Rule Definition

*The first operand of a conditional-operator shall have type bool.*

### Rationale

When you use a non-Boolean expression as the first operand of the ? operator, the expression is implicitly converted to bool. Such an implicit conversion might make developer intent unclear and hide errors that lead to bugs that are difficult to diagnose. For instance:

```
int flag, val;
//...
flag= 1;
val = (flag=0)?2:3;
```

In the preceding code, it is not clear whether the condition flag = 0 is intended to be an assignment. The compiler casts the return value of the assignment operation into a bool, which is used as the condition for the ? operator. In this case, the developer intent might be to test the value of flag. You might expect val to be 3, but it becomes 2 because of the implicit conversion to bool in the first operand.

### Polyspace Implementation

Polyspace raises a violation of this rule if a non-Boolean expression is used as the first argument of the ? operator.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Non-Boolean Expression as the First Argument in ? Operator

```
void foo()
{
    int val, flag;
    flag = 0;
    val = (flag = 0) ? 2 : 3;//Noncompliant
    val = (flag==0)? 2:3; //Compliant
}
```

In this example, Polyspace flags the non-Boolean expression flag = 0 that is used as the first argument of the ? operator.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-15

Array indexing shall be the only form of pointer arithmetic

## Description

### Rule Definition

*Array indexing shall be the only form of pointer arithmetic.*

### Rationale

You can traverse an array in two ways:

- Increment or decrement an array index, and then use the array index to access an element.
- Increment or decrement a pointer to the array, and then dereference the pointer.

The first method is clearer and less error-prone. All other forms of explicit pointer arithmetic introduce the risk of accessing unintended memory locations.

As an exception, incrementing or decrementing pointer based iterators is compliant with this rule.

### Polyspace Implementation

The checker flags:

- Arithmetic operations on all pointers, for instance `p+I`, `I+p` and `p-I`, where `p` is a pointer and `I` an integer..
- Array indexing on nonarray pointers.

Polyspace does not flag incrementing or decrementing pointer based iterators, including these standard iterator types:

- `iterator`
- `cont_iterator`
- `reverse_iterator`
- `const_reverse_iterator`

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Explicitly Calculated Pointer Value When Indexing

```
#include<vector>
template < typename IterType >
int sumValues(IterType iter, IterType end)
{
    int result = 0;
    while (iter != end) {
        result += *iter;
        ++iter;  //Noncompliant
    }
    return result;
}
int sumVec(std::vector<int>& v)
{
    int res = 0;
    for (auto it = v.begin(); it != v.end(); ++it) //Compliant by exception
    res += *it;
    return res;
}
int sumVecModern(std::vector<int>& v)
{
    int res = 0;
    for(auto i:v){
        res+=i;
    }
    return res;
}
void foo(int* p_int, int arr_int[])
{
    p_int = p_int + 1; //Noncompliant
    arr_int[0] = arr_int[1];

    p_int[5] = 0; //Noncompliant
    *(p_int + 5) = 0; //Noncompliant
    arr_int[5] = 0.0;

    int a[100];
    std::vector<int> v(100);
    sumValues(&a[0],&a[99]);

}
```

In this example, indexing is done by using array indexing and by calculating the pointer values explicitly. In the function `foo()`:

- Polyspace flags the instances where a pointer value is explicitly calculated, such as `p_int+1` or `*(p_int+5)`.
- Polyspace flags the use of array indexing on the nonarray pointer `p_int`.

Polyspace does not flag uses of array indexing on an array that is compliant with this rule.

Incrementing and decrementing iterators to containers is compliant with this rule by exception. Because `sumVec()` increments an `iterator` object, Polyspace does not flag the increment operation. This exception does not apply to raw pointers. For instance, `sumValues` is instantiated in `foo()` with `int*`. Polyspace flags incrementing the raw pointer. In modern C++, the best practice is to use range-based for loops, as shown in the function `sumVecModern()`.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-0-16

A pointer operand and any pointer resulting from pointer arithmetic using that operand shall both address elements of the same array.

## Description

### Rule Definition

*A pointer operand and any pointer resulting from pointer arithmetic using that operand shall both address elements of the same array.*

### Rationale

It is undefined behavior when the result of a pointer arithmetic operation that uses a pointer to an array element does not point to either:

- An element of the array.
- One past the last element of the array. For instance:

  ```
  int arr[3];
  int* res;
  res = arr+3; // res points to one beyond arr
  ```

The rule applies to these operations. `ptr` is a pointer to an array element and `int_exp` is an integer expression.

- `ptr` + `int_exp`
- `int_exp` + `ptr`
- `ptr` - `int_exp`
- `ptr` + +
- ++`ptr`
- --`ptr`
- `ptr`--
- `ptr` [ `int_exp` ]

### Polyspace Implementation

- Single objects that are not part of an array are considered arrays of one element. For instance, in this code example, `arr_one` is equivalent to an array of one element. Polyspace does not flag the increment of pointer `ptr_to_one` because it points to one past the last element of `arr_one`.

  ```
  void f_incr(int* x){
      int* ptr_to_one = x;
      ++ptr_to_one;  // Compliant
  }

  void func(){
      int arr_one=1; // Equivalent to array of one element
      f_incr(&arr_one);
  }
  ```

- Polyspace does not flag the use of pointer parameters in pointer arithmetic operations when those pointers point to arrays. For instance, in this code snippet, the use of `&a1[2]` in `f1` is compliant when you pass an array to `f1`.

  ```
  void f1( int* const a1){
         int* b= &a1[2]; // Compliant
  }
  void f2(){
      int arr[3] {};
      f1(arr);
  }
  ```
- In structures with multiple elements, Polyspace does not flag the result of a pointer arithmetic operation on an element that results in a pointer that points to a different element if the pointer points within the allocated memory of the structure or to one past the last element of the structure.

  For instance, in this code snippet, the assignment to `ptr_to_struct` is compliant because it remains inside `myStruct`, even if it points outside `myStruct.elem1`. Using an index larger than the element dimension to access the content of that element is not compliant, even if the resulting address is within the allocated memory of the structure.

  ```
  void func(){
      struct {
          char elem1[10];
          char elem2[10];
      } myStruct;

      char* ptr_to_struct = &myStruct.elem1[11]; //Compliant
        // Address of myStruct.elem1[11] is inside myStruct
        char val_to_struct = myStruct.elem1[11]; // Non-compliant
  }
  ```
- In multidimensional arrays, Polyspace flags any use of indices that are larger than a subarray dimension to access an element of that subarray. Polyspace does not flag the assignment of the address of that same subarray element if the address is inside the allocated memory of the top-level array.

  For example, in this code snippet, the assignment to pointer `ptr_to_arr` is compliant because the pointer points to an address that is within the allocated memory of `multi_arr`. The assignment to variable `arr_val` is not compliant because the index used to access the subarray element (3) is larger than the dimension of the subarray (2).

  ```
  void func(){
      int multi_arr[5][2];

        // Assigned memory is inside top level array
      int* ptr_to_arr = &multi_arr[2][3]; //Compliant

      // Use of index 3 with subarray of size 2
      int arr_val = multi_arr[2][3]; // Non-compliant
  }
  ```
- Polyspace flags the dereference of a pointer when that pointer points to one past the last element of an array. For instance, in this code snippet, the assignment of `ptr` is compliant, but the dereference of `ptr` is not. `tab+3` is one past the last element of tab.

  ```
  void derefPtr(){
      int tab[3] {};
  ```

```
    int* ptr = tab+3; //Compliant
    int res = *(tab+3); // Non-compliant
}
```

- Polyspace does not raise this checker when the result of a pointer arithmetic operation results in `nullptr`. For instance, consider this code:

  ```
  void g(int *p);

  void add(int* p, int n) {
      g(p + n);   //Compliant}

  void foo() {
      add(nullptr, 0);

  }
  ```

  The pointer arithmetic in `add()` results in a `nullptr`. Polyspace does not flag this operation.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pointer Arithmetic by Using Pointers to Array Elements

```
void f_incr(int* x)
{
    int* ptr_to_one = x;
    ++ptr_to_one;  // Compliant
}

void f1(int* const a1)
{
    int* b = &a1[2]; // Compliant
}

int main()
{

    int arr_one = 1; // Equivalent to array of one element
    f_incr(&arr_one);

    int arr[3] {};
    f1(arr);

    struct {
        char elem1[10];
```

```
        char elem2[10];
    } myStruct;

    char* ptr_to_struct = &myStruct.elem1[11]; // Compliant
    ptr_to_struct = &myStruct.elem2[11]; //Non-compliant

    int tab[3] {1, 2, 3};
    int* ptr =  &tab[2];
    int res = tab[2];
    ++ptr; // Compliant
    res = *ptr; //Non-compliant

    return 0;
}
```

In this example:

- The increment of `ptr_to_one` inside `f_incr()` is compliant because the operation results in a pointer that points to one past the last element of array `x`. The integer that is passed to `f_incr()` is equivalent to an array of one element.
- The operation on pointer parameter `a1` inside `f1()` is compliant because the pointer points to array `arr`.
- The first assignment of `ptr_to_struct` is compliant because `elem1[11]` is still inside `myStruct`. The second assignment of `ptr_to_struct` is not compliant because the result of the operation does not point to either inside `myStruct` or to one past the last element of `myStruct`.
- The increment of `ptr` is compliant because the result of the operation points to one past the last element of `tab`. The dereference of `ptr` on the next line is not compliant.

# MISRA C++:2008 Rule 5-0-17

Subtraction between pointers shall only be applied to pointers that address elements of the same array

## Description

### Rule Definition

*Subtraction between pointers shall only be applied to pointers that address elements of the same array.*

### Rationale

When you subtract between two pointers to elements in the same array, the result is the distance between the two array elements. If the pointers are null or point to different arrays, a subtraction operation is undefined. If you use the subtraction result as a buffer index, it can cause a buffer overflow.

Before you subtract between pointers to array elements, make sure that they are non-null and that they point to the same array.

### Polyspace Implementation

Polyspace flags subtraction between pointers to elements of different arrays.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Subtracting Pointers to Elements of Different Arrays

```
void foo(){
    int a[10];
    int b[10];
    int distance = a-b;//Noncompliant

}
```

In this example, Polyspace flags the subtraction between `a` and `b`, which are elements of different arrays.

>, >=, <, <= shall not be applied to objects of pointer type, except where they point to the same array

## Description

### Rule Definition

*>, >=, <, <= shall not be applied to objects of pointer type, except where they point to the same array.*

### Rationale

When you compare two pointers to array elements, the result is the positions of the pointers relative to each other. If the pointers are null or point to different arrays, a comparison operation is undefined.

Before you use >, >=, <, or <= between pointers to array elements, check that they are non-null and that they point to the same array.

### Polyspace Implementation

Polyspace flags the use of >, >=, <, or <= operators between pointers to elements of different arrays.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Comparing Pointers to Elements of Different Arrays

```
bool foo(){
    int a[10];
    int b[10];
    return (a<b); //Noncompliant

}
```

In this example, Polyspace flags the comparison between a and b, which are elements of different arrays.

# MISRA C++:2008 Rule 5-0-19

The declaration of objects shall contain no more than two levels of pointer indirection

## Description

### Rule Definition

*The declaration of objects shall contain no more than two levels of pointer indirection.*

### Rationale

If you use pointers with more than two levels of indirection, a developer reading the code might find it difficult to understand the behavior of the code.

### Polyspace Implementation

Polyspace flags all declarations of objects that contain more than two levels of pointer indirection.

- If you use type aliases, the checker includes pointer indirections from the alias in the evaluation of the level of indirection. For instance, in this code snippet, the declaration of `var` is non-compliant. The type of `var` is `const` pointer to a `const` pointer to a pointer to `char`, which is three levels of pointer indirection. The declaration of `var2` has two levels of pointer indirection and is compliant.

  ```
  using ptrToChar = char*;

  void func()
  {
      ptrToChar* const* const var = nullptr; //Non-compliant, 3 levels of indirection
      char* const* const var2 = nullptr; //Compliant, 2 levels of indirection
      //...
  }
  ```
- If you pass an array to a function, the conversion of the array to a pointer to the first element of the array is included in the evaluation of the level of indirection. For instance, in this code snippet, parameter `arrParam` is non-compliant. The type of `arrParam` is a pointer to a pointer to a pointer to `char` (three levels of pointer indirection). The declaration of `arrVar` is compliant because `arrVar` has type array of pointer to pointer to char (two levels of pointer indirection).

  ```
  void func(char** arrParam[])  //Non-compliant
  {
      //...
      char** arrVar[5]; //Compliant
  }
  ```

This checker does not flag the use of objects with more than two levels of indirection. For instance, in this code snippet, the declaration of `var` is non-compliant, but the evaluation of the size of `var` is compliant.

```
#include<iostream>

using charToPtr = char*;

void func()
{
    charToPtr* const* const var = nullptr; //Non-compliant
```

```
    std::cout << sizeof(var) << std::endl; //Compliant

}
```

### Troubleshooting

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 5-0-20

Non-constant operands to a binary bitwise operator shall have the same underlying type

## Description

### Rule Definition

*Non-constant operands to a binary bitwise operator shall have the same underlying type.*

### Rationale

In a binary bitwise operation, if you use operands that have different underlying types, then it is not clear which type you considered when designing the operation. For instance, in this code:

```
uint8_t mask = ~(0x10);
uint16_t value;
value ^= mask; // Non-compliant
```

It is not clear whether you are designing an 8-bit `mask` or a 16-bit `mask`. To avoid such confusion, use the same underlying type for nonconstant operands of binary bitwise operators.

### Polyspace Implementation

If the nonconstant operands of a binary bitwise operator have different underlying types, Polyspace raises a violation of this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Operands of Mismatched Types in Binary Bitwise Operators

```
#include<cstdint>

void foo()
{
    uint8_t a, b;
    uint16_t c;
    //...
    uint8_t d = a ^ b; //Compliant
    uint16_t e = a ^ c; //Noncompliant

}
```

In this example, Polyspace flags the bitwise operation `a^c` because `a` and `c` are of mismatched underlying data types.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 5-0-21

Bitwise operators shall only be applied to operands of unsigned underlying type

## Description

### Rule Definition

*Bitwise operators shall only be applied to operands of unsigned underlying type.*

### Rationale

Bitwise operations are not meaningful when they are applied to signed operands. Applying bitwise operations to signed operands might result in an unexpected and implementation dependent result. For instance, if you right shift a negative number, the result varies depending on your environment. Avoid using bitwise operations on signed operands.

### Polyspace Implementation

Polyspace raises a violation of this rule when you apply a bitwise operation on a signed operand or expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use Bitwise Operations on Unsigned Operands

```
typedef signed   short        int16_t;
typedef unsigned short        uint16_t;

void foo(uint16_t ua, uint16_t ub, int16_t a)
{
    if   (   ( ua & a ) == 0x1234U ) {}        // Noncompliant
    if   (   ( ua | ub ) == 0x1234U ) {}       // Compliant
    if   (   ~a == 0x1234U ) {}                // Noncompliant
    if   (   ~ua == 0x1234U ) {}               // Compliant
}
```

In this example, Polyspace flags the use of bitwise operations on signed operand `a`. Bitwise operations that involve unsigned operands such as `ua`, `ub`, and the hexadecimal number `0x1234U`, are compliant with this rule.

# MISRA C++:2008 Rule 5-2-1

Each operand of a logical && or || shall be a postfix-expression

## Description

### Rule Definition

*Each operand of a logical && or || shall be a postfix-expression.*

### Rationale

This rule effectively requires that operands of a logical && or `||` operation be appropriately parenthesized. For instance, instead of `a + b || c`, the rule requires `(a + b) || c` or `a + (b || c)`. In both compliant cases, the left operand of `||`, that is `(a + b)` or `b`, is a primary expression and therefore also a postfix expression. For more information on postfix expressions, see the C++03 Standard (Section 5.2).

Enclosing operands in parentheses improves readability of code and makes sure that the operations occur in the order that the developer intends.

### Polyspace Implementation

The checker raises a violation if a logical && or `||` operand is not a postfix expression.

A postfix expression can be a primary expression such as a simple identifier or a combination of identifiers enclosed in parentheses, but also one of the following:

- Function call such as `func()`.
- Array element access such as `arr[]`.
- Structure member access such as `aStructVar.aMember`.

For the complete list of postfix expressions, see the C++03 Standard (Section 5.2).

The checker allows exceptions on associative chains such as `(a && b && c)` or `(a || b || c)`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant and Compliant Expressions Involving Logical Operations

```
bool Operations(bool a, bool b, bool c, bool priority) {
    bool res;
    if(priority) {
        res = a && b || c;  //Noncompliant
    }
    else {
        res = a && (b || c); //Compliant
    }
    return res;
}
```

In this example, the expression `a && b || c` violates the rule because the right operand of && and the left operand of `||` are not postfix expressions.

# MISRA C++:2008 Rule 5-2-2

A pointer to a virtual base class shall only be cast to a pointer to a derived class by means of `dynamic_cast`

## Description

### Rule Definition

*A pointer to a virtual base class shall only be cast to a pointer to a derived class by means of `dynamic_cast`.*

### Rationale

A `virtual` base implies that multiple classes might be derived from it.

```
class Base{};
class childA: virtual public Base{};
class childB: virtual public Base{};
class childFinal: public childA, public childB{};;
```

In the preceding code, the derived classes `childA` and `childB` share the same instance of the class `Base`. The necessary pointer arithmetic is unknown at compile time when you cast from `Base*` to `childA*` or `childB*`. The offset of the child classes compared to `Base` is known only at run time.

Use `dynamic_cast` when downcasting a pointer to a virtual base class into a pointer to a child class. Using any other casting operation for this purpose results in an undefined behavior.

### Polyspace Implementation

Polyspace raises a violation if these conditions are met:

- A virtual base class is downcast.
- The casting operation is not done by using `dynamic_cast`

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use `dynamic_cast` to Downcast Pointers to `virtual` Base

```
class Base{};
class childA: virtual public Base{};
class childB: virtual public Base{};
class childFinal: public childA, public childB{};

void bar(){
    Base* pB;
    //...
    static_cast<childA*>(pB);//Noncompliant
}
```

In this example, the pointer to a `virtual` base `pB` is downcast to a pointer to a derived class. The information needed to cast `pB` to a `childA*` type is known at run time only. Using `static_cast` to perform these casts results in an undefined behavior. Polyspace raises a violation. This issue might also be reported as a compilation error.

# MISRA C++:2008 Rule 5-2-3

Casts from a base class to a derived class should not be performed on polymorphic types

## Description

### Rule Definition

*Casts from a base class to a derived class should not be performed on polymorphic types.*

### Rationale

Explicitly casting a polymorphic base class into a derived class bypasses the layers of abstraction in the implementation hierarchy, resulting in increased coupling and dependency between the classes.

When using a polymorphic class, avoid performing explicit downcasts. A pointer to the polymorphic base class does not require explicit casting into a pointer to a derived class.

### Polyspace Implementation

Polyspace raises a violation if a base class is cast to a derived class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Downcasting In a Polymorphic Class Hierarchy

```
class Base{ //Abstract base class
    //...
public:
    virtual bool getStatus() const = 0;
};
class Derived: public Base{
    //...
public:
    virtual bool getStatus() const{ //Implementation of getStatus()
        //...
    }
};
void printStatus(const Base& B){
    const Derived* D = dynamic_cast<const Derived*>(&B);//Noncompliant
    D->getStatus();
}
void printStatus_compliant(const Base& B){
    B.getStatus();//Compliant
}
```

In this example, the `Base` class pointer `B` is cast to a `Derived` class pointer in `printStatus`. This cast is noncompliant and Polyspace raises a violation. The function `getStatus_compliant()` shows a compliant implementation of this functionality, where `virtual` functions invoke the `Derived` class member function through a pointer to the `Base` class.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-2-4

C-style casts (other than void casts) and functional notation casts (other than explicit constructor calls) shall not be used

## Description

### Rule Definition

*C-style casts (other than void casts) and functional notation casts (other than explicit constructor calls) shall not be used.*

### Rationale

C-style casts are difficult to distinguish in the source code. The developer intent in casting from one type to another is not communicated. Code that contains C-style casts are difficult to understand and debug. Avoid C-style casts.

C++ introduces explicit casting operations that are easily identified and that clearly communicate the developer intent behind each cast. Use these casting operations instead.

### Polyspace Implementation

Polyspace flags c-style casts in your code. Compliant C++ style casting operations include:

- std::static_cast
- std::reinterpret_cast
- std::const_cast
- std::dynamic_cast
- Cast by using {} notation

In addition, the reference_cast operation from the boost library and the safe_cast operation from the Miscrosoft library are also allowed.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid C Style Casts

```
#include <cstdint>
class Base
{
public:
    explicit Base(std::int32_t) {}
    virtual void Fn() noexcept {}
};
class Derived : public Base
```

```
{
public:
    void Fn() noexcept override {}
};
class myClass
{
};
std::int32_t G() noexcept
{
    return 7;
}

void Foo() noexcept(false)
{
    Base obj = Base{10};        // Compliant
    const Base obj3(5);
    Base* obj4 = const_cast<Base*>(&obj3);        //Compliant
    Base* obj2;
    myClass* d1 = reinterpret_cast<myClass*>(obj4); // Compliant
    Derived* d2 = dynamic_cast<Derived*>(obj2);       // Compliant
    std::int16_t var1 = 20;
    std::int32_t var2 = static_cast<std::int32_t>(var1);      // Compliant
    std::int32_t var4 = 10;
    float f1 = static_cast<float>(var4);                    // Compliant

    std::int32_t var5 = static_cast<std::int32_t>(f1);      //Compliant

    std::uint32_t var7 = std::uint32_t{0};//Compliant
    static_cast<void>(G());                               //Compliant
}
void Bar(){
    Base obj = Base{1};
    Base* obj2 = (Base*)(&obj); //Noncompliant
    std::int16_t var1 = 20;
    std::int32_t var3 = (std::int32_t)var1;                   // Noncompliant
    float f = (float)var3;                                 // Noncompliant
    std::int32_t var6 = (std::int32_t)f;                   // Noncompliant
}
```

In this example, the function `Foo()` shows several C++ style casting operations. These operations are easily identified, and their purpose is clear. For instance, in `Base* obj4 = const_cast<Base*>(&obj3)`, it is clear that the cast operation removes the const qualifier from `obj3`. These cast operations are compliant and Polyspace does not flag them.

The function `Bar()` shows several C style casts. These operations are difficult to find understand. Polyspaceflags these C-style casts.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-2-5

A cast shall not remove any const or volatile qualification from the type of a pointer or reference

## Description

### Rule Definition

*A cast shall not remove any const or volatile qualification from the type of a pointer or reference.*

### Rationale

Removing the `const` or `volatile` qualification from a pointer or reference might be unexpected. Consider this code:

```
void foo(const char* p){
  *const_cast< char_t * >( p ) = '\0'
}
```

The function `foo()` accepts a `const` pointer to a `char`. The caller of this functions expects that the parameter `p` remains unchanged. Modifying `p` in `foo()` by converting it to a non-`const` pointer is unexpected. If `*p` dereferences to a `const` character, this modification might lead to unexpected behavior. Avoid casting the `const` or `volatile` away from a pointer or reference.

### Polyspace Implementation

Polyspace raises a violation of this rule if you remove the `const` or `volatile` qualification from the type of a pointer or a reference by using a casting operation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Casting Away `Const` from Pointers

```
void foo(const char* p){
  *const_cast< char * >( p ) = '\0';//Noncompliant
}

void foo1(volatile char* p){
  (char*) p ;//Noncompliant
}
```

In this example, Polyspace flags the casting operations that cast away the `const` and `volatile` qualifiers from pointers.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-2-6

A cast shall not convert a pointer to a function to any other pointer type, including a pointer to function type

## Description

### Rule Definition

*A cast shall not convert a pointer to a function to any other pointer type, including a pointer to function type.*

### Rationale

Because calling a function through a pointer with incompatible type results in undefined behavior, the rule forbids these cast operations:

- Casting from a function pointer to any other type.
- Casting from a function pointer to another function pointer, if the function pointers have different arguments and return types.

### Polyspace Implementation

Polyspace raises a violation of this rule if the source type of a cast operation is a pointer to a function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Casting Function Pointers

```
void* (*func1) (int);
void* (*func2)(float);
void bar(void* (*)(int));
void foo(){

    bar(reinterpret_cast<void* (*) (int)> (func2)); //Noncompliant
    bar(func1);
}
```

In this example, the function `bar` accepts a pointer to a function that takes an `int` as an input and returns a `void*` pointer. In `foo()`, the function pointer `func2` is converted so that it can be passed to `bar`. Polyspace flags the noncompliant conversion of function pointers.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-2-7

An object with pointer type shall not be converted to an unrelated pointer type, either directly or indirectly

## Description

### Rule Definition

*An object with pointer type shall not be converted to an unrelated pointer type, either directly or indirectly.*

### Rationale

If you convert a pointer to a pointer of unrelated type, the result of the operation is unspecified. To avoid unexpected results, do not convert a pointers to an unrelated pointer type.

### Polyspace Implementation

The checker flags all pointer conversions including between a pointer to a `struct` object and a pointer to the first member of the same `struct` type.

Indirect conversions from a pointer to non-pointer type are not detected.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C++:2008 Rule 5-2-8

An object with integer type or pointer to void type shall not be converted to an object with pointer type

## Description

### Rule Definition

*An object with integer type or pointer to void type shall not be converted to an object with pointer type.*

### Polyspace Implementation

The checker allows an exception on zero constants, such as `0x0`, `0`, or `0U`.

Objects with pointer type include objects with pointer-to-function type.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Converting to Pointers

In this example, Polyspace flags the conversion of integers to pointers. Polyspace does not flag converting zero constants such as `0`, `0x0`, or `0U` to pointers. Such conversions are equivalent to zero initialization of a pointer, which has a specified behavior.

```
void foo ()
{
  void *p1;
  void *p2;
  void *p3;

  p1 = static_cast < void *>(0x0);    //Compliant
  p2 = static_cast < void *>(0U);    //Compliant
  p3 = static_cast < void *>(0);    //Compliant

  p1 = (void *) 0xDEADBEEF;    //Noncompliant
  p2 = (void *) 03;        //Noncompliant
  p3 = (void *) 12345678U;    //Noncompliant
}
```

# MISRA C++:2008 Rule 5-2-9

A cast should not convert a pointer type to an integral type

## Description

### Rule Definition

*A cast should not convert a pointer type to an integral type.*

### Rationale

The C++ standard specifies only the minimum size required for integral types. The implemented size of integral types and pointers depends on your hardware and development environment. In an environment where pointers have a larger size than integral types, casting a pointer type to an integral type results in an overflow. Avoid casting pointers to integral types.

### Polyspace Implementation

Polyspace flags a casting operation if it converts a pointer type variable to an integral type variable.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Casting Pointers to Integers

```
void foo(){
    int* pInt;
    //...
    int address = reinterpret_cast<int>(pInt);//Noncompliant
}
```

In this example, the pointer `pInt` is cast to an int. Depending on your environment, this operation might result in an overflow. For instance, in a 64-bit system, the size of `pInt` might be 64-bit and the size of `address` might be 32-bit. Polyspace flags this casting operation.

The increment ( ++ ) and decrement ( -- ) operators should not be mixed with other operators in an expression

## Description

### Rule Definition

*The increment ( ++ ) and decrement ( -- ) operators should not be mixed with other operators in an expression.*

### Rationale

Using the increment and decrement operators with other operators in an expressions results in code that is difficult to read. Such code might lead to undefined behavior.

### Polyspace Implementation

Polyspace flags an expression if it contains the increment or decrement operators mixed with other operators. If an expression contains multiple increment or decrement operators mixed with other operators, Polyspace flags the first increment or decrement operator.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Mixing Increment or Decrement Operators with Other Operators

```
void foo(int a, int b){
    int c = ++a + b--; //Noncompliant
    if(--c + --a - ++b){ //Noncompliant
        //...
    }
}
```

Polyspace flags the mixing of the ++ and `--` operators with other mathematical operators in an expression.

## Check Information

**Group:** Expressions

# MISRA C++:2008 Rule 5-2-11

The comma operator, && operator and the || operator shall not be overloaded

## Description

### Rule Definition

*The comma operator, && operator and the || operator shall not be overloaded.*

### Rationale

When you overload an operator, the overloaded operator behaves as a function call. The comma operator, the && operator, and the `||` operator have certain behaviors that cannot be replicated by their overloaded counterpart. For instance, a compiler might short circuit the builtin && or `||` operators. But such short circuiting is not possible when you use an overloaded version of these operators.

Overloading these operators creates confusion about how these operators behave. Avoid overloading the comma operator, the && operator, and the `||` operator.

### Polyspace Implementation

Polyspace flags the overloading of these operators:

- Comma operator
- && operator
- `||` operator

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Overload the && Operator

```
class flag{/**/};
class Util
{
public:
flag getValue ( );
flag setValue ( int const & );
};

bool operator && ( flag const &, flag const & ); // Noncompliant
void f2 ( Util & in3, Util & in4 )
{
in3.getValue ( ) && in4.setValue ( 0 ); // Both operands evaluated
}
```

In this example, the && operator is overloaded for the class `flag`. In `f2()`, the overloaded operator is used. The overloading prevent the short circuiting. The behavior of the overloaded operator might be unexpected. Polyspace flags the overloading of the && operator.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 5-2-12

An identifier with array type passed as a function argument shall not decay to a pointer

## Description

### Rule Definition

*An identifier with array type passed as a function argument shall not decay to a pointer.*

### Rationale

When you pass an array to a function as a pointer, the size information of the array becomes lost. Losing information about the array size might lead to confusion and unexpected behavior.

Avoid passing arrays as pointers to function. To pass arrays into a function, encapsulate the array into a class object and pass the object to functions. Starting in C++11, the standard template library implements several container classes that can be used to pass an array to a function. C++20 has the class `std::span`, which preserves the size information.

### Polyspace Implementation

Polyspace raises a violation when you use an array in a function interface.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Arrays in Function Interfaces

```
void f1( int p[ 10 ] ); // Noncompliant

void f2( int ( &p )[ 10 ] );// Compliant
void foo ()
{
int a[ 10 ];
f1( a );

f2( a );
}
```

In this example,the interface of `f1()` uses an array. When you pass the array `a[10]` to `f1()` as a pointer, the size of the array `a` is lost. Polyspace flags the declaration of `f1()`. If you pass arrays to function while preserving the dimensionality information, as shown by `f2()`, Polyspace does not raise a violation.

# MISRA C++:2008 Rule 5-3-1

Each operand of the ! operator, the logical && or the logical || operators shall have type bool

## Description

### Rule Definition

*Each operand of the ! operator, the logical && or the logical || operators shall have type bool.*

### Rationale

Use of non-`bool` operands with the logical operators `!`, && or `||`, is likely to indicate a programming error.

### Polyspace Implementation

The checker reports a violation if the operands of the logical operators `!`, && or `||`, are not effectively boolean. Allowed operands are:

- Variables of type `bool` or specified as effectively boolean using the option `Effective boolean types (-boolean-types)`.
- Expressions that compare two variables using operators such as == or < and return a boolean.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Logical && With Boolean and Non-Boolean Operands

In this example, both operands of the logical && in the `if` condition are effectively boolean and comply with the rule. The right operand of the logical && in the `else if` condition has a non-boolean type (`int32_t`) and violates the rule.

```
#include <cstdint>

class Pair
{
    int32_t leftVal;
    int32_t rightVal;
public:
    bool operator==(const Pair& anotherPair) {
        return(((*this).leftVal == anotherPair.leftVal)
             &&((*this).rightVal == anotherPair.rightVal));
    }
};

Pair getAPair();
int32_t checkPair(const Pair*);
```

```
void main() {
    Pair aPair = getAPair();
    Pair anotherPair = getAPair();
    Pair athirdPair = getAPair();

    if((aPair == anotherPair) &&
       (aPair == athirdPair)) //Compliant
       {}
    else if((aPair == anotherPair) && //Noncompliant
            (checkPair(&athirdPair)))
       {}
}
```

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 5-14-1

The right hand operand of a logical && or || operator shall not contain side effects

## Description

### Rule Definition

*The right hand operand of a logical && or || operator shall not contain side effects.*

### Rationale

When evaluated, an expression with side effect modifies at least one of the variables in the expression. For instance, `n++` is an expression with side effect.

The right-hand operand of a:

- Logical && operator is evaluated only if the left-hand operand evaluates to true.
- Logical `||` operator is evaluated only if the left-hand operand evaluates to false.

In other cases, the right-hand operands are not evaluated, so side effects of the expression do not take place. If your program relies on the side effects, you might see unexpected results in those cases.

### Polyspace Implementation

The checker flags logical && or `||` operators whose right operands are expressions that have side effects. Polyspace assumes:

- Expressions that modifies at least one of its variables have side effects.
- Explicit constructors or conversion functions that are declared but not defined have no side effects. Defined conversion functions have side effects.
- Volatile accesses and function calls have no side effects.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Side Effects in Right Operand of Logical Operation

```
class real32_T {
public:
    real32_T() = default;

    /* Casting operations */
    explicit real32_T(float a) {
        // ...
    }
    /* Relational operators */
    bool operator==(real32_T a) const;
    bool operator>(real32_T a) const;
};

void bar() {
    real32_T d;

    if ((d == static_cast<real32_T>(0.0F))
    || (static_cast<real32_T>(0.0F) > d)) {//Noncompliant
        /**/
    }
}

void foo(int i, int j){
    if(i==0 && ++j==i){ //Noncompliant
        --i;
    }
}
```

In the function `foo`, the right operand of the && operator contains an increment operation, which has a side effect. Polyspace flags the operator. In the function `bar`, the right operand of the `||` operator contains a conversion function that is implemented in the class. Polyspace considers such constructor to have side effects. Because the right operator has side effects, the operator is flagged.

# MISRA C++:2008 Rule 5-18-1

The comma operator shall not be used

## Description

### Rule Definition

*The comma operator shall not be used.*

### Rationale

The comma operator takes two operands. It evaluates the operators from left to right, discards the value of the left operand,and returns the value of the right operand. This operator has the lowest operator precedence. These properties make the use of the comma operator nonintuitive. For instance, consider this code:

```
array[i++,j] = 1
```

At a glance, it might appear that the preceding code accesses a multidimensional array. In fact, this code is equivalent to:

```
i++;
array[j] = 1;
```

The use of the comma operator makes the code difficult to read and maintain. To avoid confusion, do not use the comma operator. Refactor the expression into multiple statements instead.

### Polyspace Implementation

Polyspace flags the use of comma operator. Violations are not raised when you use comma operator for function calls and initializations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Comma Usage in C++ Code

```
typedef signed int abc, xyz, jkl;
static void func1 ( abc, xyz, jkl );       /* Compliant - case 1 */
int foo(void)
{
    volatile int rd = 1;                   /* Compliant - case 2*/
    int var=0, foo=0, k=0, n=2, p, t[10];  /* Compliant - case 3*/
    int abc = 0, xyz = abc + 1;            /* Compliant - case 4*/
    int jkl = ( abc + xyz, abc + xyz );    /* Noncompliant - case 1*/
    var = 1, foo += var, n = 3;          /* Noncompliant - case 2*/
    var = (n = 1, foo = 2);              /* Noncompliant - case 3*/
    for ( int *ptr = &t[ 0 ],var = 0 ;
          var < n; ++var, ++ptr){}    /* Noncompliant - case 4*/
    if ((abc,xyz)<0) { return 1; }         /* Noncompliant - case 5*/
}
```

In this example, the code shows various uses of commas in C code.

**Noncompliant Cases**

| Case | Reason for noncompliance |
|---|---|
| 1 | When reading the code, it is not immediately obvious what `jkl` is initialized to. For example, you could infer that `jkl` has a value `abc+xyz`, `(abc+xyz)*(abc+xyz)`, `f((abc+xyz),(abc+xyz))`, and so on. |
| 2 | When reading the code, it is not immediately obvious whether `foo` has a value 0 or 1 after the statement. |
| 3 | When reading the code, it is not immediately obvious what value is assigned to `var`. |
| 4 | When reading the code, it is not immediately obvious which values control the `for` loop. |
| 5 | When reading the code, it is not immediately obvious whether the `if` statement depends on `abc`, `xyz`, or both. |

**Compliant Cases**

| Case | Reason for compliance |
|---|---|
| 1 | Using commas to call functions with variables is allowed. |
| 2 | Comma operator is not used. |
| 3 & 4 | When using the comma for initialization, the variables and their values are immediately obvious. |

# MISRA C++:2008 Rule 5-19-1

Evaluation of constant unsigned integer expressions should not lead to wrap-around

## Description

### Rule Definition

*Evaluation of constant unsigned integer expressions should not lead to wrap-around.*

### Rationale

Unsigned integer expressions do not strictly overflow, but instead wraparound. Although there may be good reasons to use modulo arithmetic at run time, intentional use at compile time is less likely and might imply logic errors.

### Polyspace Implementation

Polyspace flags the constant expressions that might wraparound.

Different compilers might define compile-time constants differently. In the following code, `c+1u` is considered a constant expression by GCC compilers, but not by the standard C++ compiler.

```
const uint16_t c = 0xffffu;
uint16_t y = c + 1u;
```

Whether you see a violation of this rule in the preceding code might depend on your compiler.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unsigned Integer Wraparounds in Constant Expression

```
#define BEGIN        0x8000
#define FIN          0xFFFF
#define POS          0x8000
#if ( ( BEGIN + POS ) > FIN )
//....
#endif
#if ( ( ( FIN - BEGIN ) - POS ) < 0 )   //Noncompliant
//...
#endif

  void fn ( )
  {
    if ( ( BEGIN + POS ) > FIN ) {   // Noncompliant
      //...
    }
  }
```

In this example, the constant expressions `(( FIN - BEGIN ) - POS)` and `(( BEGIN + POS ) > FIN)` might lead to wraparounds. Polyspace flag these expressions.

# MISRA C++:2008 Rule 6-2-1

Assignment operators shall not be used in sub-expressions

## Description

### Rule Definition

*Assignment operators shall not be used in sub-expressions.*

### Rationale

When used in a subexpression, assignment operators have side effects that are difficult to predict. These side effects might produce results contrary to developer expectations. This rule helps in avoiding confusion between the assignment operator (=) and the equal to operator (==). Do not use assignment operators in subexpressions.

### Polyspace Implementation

Polyspace raises this defect whenever a subexpression contains an assignment operator.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Assignment Operators in Sub-Expressions Are Noncompliant

```
#include <cstdint>

bool example(int x, int y)
{
    if (x == 10)         //Compliant
    {
        return true;
    }

       if ((x = y) == 0)            //Noncompliant
    {
        return false;
    }

    return false;
}
```

Because the assignment operator = is used in the subexpression `(x = y)`, Polyspace flags it as noncompliant.

# MISRA C++:2008 Rule 6-2-2

Floating-point expressions shall not be directly or indirectly tested for equality or inequality

## Description

### Rule Definition

*Floating-point expressions shall not be directly or indirectly tested for equality or inequality.*

### Rationale

Due to the inherent rounding errors of floating-point numbers, there is no way to reliably compare floating-point numbers for equality. This includes both direct and indirect tests of equivalency. Comparisons of floating-point numbers can result in a false outcome when you expect equivalence. This behavior is unpredictable and can vary between implementations.

Avoid using floating-point numbers for equivalence comparisons. Alternatively, write a library that implements your comparison operations. Take into account the magnitude of numbers to compare as well as floating-point granularity during creation of this library.

### Polyspace Implementation

The rule checker detects the use of == or != with floating-point variables or expressions. Additionally, the rule checker detects indirect tests of equality or inequality of floating-point variables. For example:

```
float x, y = 0.0;
if ((x < y) || (x > y))           //Noncompliant
{
    //...
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Floating-Point Number Comparisons of Equivalence

This code contains different examples of floating-point number comparisons. Polyspace reports a violation for each of these floating-point tests of equality or inequality.

- `x == y`, due to the use of ==
- `x == 0.0f`, due to the use of `!=`
- `((x <= y) && (x >= y))`, due to an indirect comparison of equality
- `((x < y) || (x > y))`, due to an indirect comparison of inequality

```
#include <cmath>
#include <limits>
```

```
void main()
{
    float x, y = 0.0;
    if (x == y)          //Noncompliant
    {
        //...
    }
    if (x != 0.0f)       //Noncompliant
    {
        //...
    }
    if ((x <= y) && (x >= y))         //Noncompliant
    {
        //...
    }
    if ((x < y) || (x > y))           //Noncompliant
    {
        //...
    }
}
```

# MISRA C++:2008 Rule 6-2-3

Before preprocessing, a null statement shall only occur on a line by itself; it may be followed by a comment, provided that the first character following the null statement is a white-space character

## Description

### Rule Definition

*Before preprocessing, a null statement shall only occur on a line by itself; it may be followed by a comment, provided that the first character following the null statement is a white-space character.*

### Rationale

A null statement:

```
;
```

used on a line with other code can indicate a programming error. If you want to enter a null statement, place the statement on a line by itself.

A comment can follow a null statement, but use a white space character between the null statement and the comment to provide a visual cue for reviewers.

### Polyspace Implementation

The rule checker considers a null statement as a line where the first character excluding comments is a semicolon. The rule checker reports violations for situations where:

- Comments appear before the null statement.

  For instance:

  ```
  /* wait for pin */ ;
  ```
- Comments appear immediately after the semicolon without a white space in between.

  For instance:

  ```
  ;// wait for pin
  ```

The rule checker also reports a violation when a second statement appears on the same line following the null statement.

For instance:

```
; count++;
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Proper Formatting for Null Statement

In this example, there are three different versions of comments after a null statement.

- The first option is compliant. The comment comes after the null statement, the null statement is the only statement on the line, and there is a white space separating the semicolon and the comment.
- The second option is noncompliant. The comment comes before the null statement.
- The third option is noncompliant. A white space does not separate the semicolon and comment.

```
#include <iostream>

void main()
{
    std::cout << "Hello World" << std::endl;
     ; // comment here - Compliant
     /* comment here */ ; // Noncompliant
     ;//comment here - Noncompliant

}
```

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-3-1

The statement forming the body of a switch, while, do while or for statement shall be a compound statement

## Description

### Rule Definition

*The statement forming the body of a switch, while, do ... while or for statement shall be a compound statement.*

### Rationale

A compound statement is included in braces.

If a block of code associated with an iteration or selection statement is not contained in braces, you can make mistakes about the association. For example:

- You can wrongly associate a line of code with an iteration or selection statement because of its indentation.
- You can accidentally place a semicolon following the iteration or selection statement. Because of the semicolon, the line following the statement is no longer associated with the statement even though you intended otherwise.

This checker enforces the practice of adding braces following a selection or iteration statement even for a single line in the body. Later, when more lines are added, the developer adding them does not need to note the absence of braces and include them.

### Polyspace Implementation

The checker flags `for` loops where the first token following a `for` statement is not a left brace, for instance:

```
for (i=init_val; i > 0; i--)
   if (arr[i] < 0)
      arr[i] = 0;
```

Similar checks are performed for `switch`, `for` and `do..while` statements.

The second line of the message on the **Result Details** pane indicates which statement is violating the rule. For instance, in the preceding example, the second line of the message states that the `for` loop is violating the rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-4-1

An if ( condition ) construct shall be followed by a compound statement. The else keyword shall be followed by either a compound statement, or another if statement

## Description

### Rule Definition

*An if ( condition ) construct shall be followed by a compound statement. The else keyword shall be followed by either a compound statement, or another if statement.*

### Rationale

If you use single statements as bodies of if or if...else constructs, then attempting to change the body into a compound statement might result in logic errors and unexpected results. This rule ensures that braces are not missed or forgotten when attempting to turn a single statement body into a compound statement body. Failure to use compound statements might provide unexpected results and cause developer confusion. Use `{ }` braces to create compound statements. Use braces even when the if statement is simple and contains only a single statement.

### Polyspace Implementation

Polyspace raises this defect whenever a compound statement does not immediately follow an if statement, else-if statement, or else statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using Compound Statements in If...Else Conditionals

```
#include <cstdint>

int example(int test, int result)
{
    if (test > 5)
    {
        test--;
        result = test + result;   //Compliant
    }
    else if (test <= 5)
    {
        result = test - result;   //Compliant
    }
    else                          //Noncompliant
        result = test;

    return result;
}
```

Because the else statement does not use `{ }` braces to form a compound statement, Polyspace flags it as noncompliant.

## Check Information

**Group:** Statements

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 6-4-2

All if … else if constructs shall be terminated with an else clause

## Description

### Rule Definition

*All if … else if constructs shall be terminated with an else clause.*

### Rationale

Ending an if... else if construct with an `else` statement is defensive programming. This final `else` statement acts as a fail-safe in case a unique situation occurs where the code progresses past the `if` and `else if` statements.

When an `if` statement is followed by one or more `else if` statements, follow the final `else if` statement with an `else` statement. Within the `else` statement provide an action. If no action is needed, provide a comment as to why no action is taken.

### Polyspace Implementation

Polyspace raises this defect whenever an `if … else if` construct does not end with an `else` statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### If Construct With No Else If Statements

```
#include <cstdint>

int example(int test, int result)
{
    if (test > 5)
    {
        test--;
        result = test + result;
    }

    return result;
}
```

Because no `else if` statement exists in this `if` construct, no final `else` statement is required within the construct.

### If Construct Containing Else-If Statements

```
#include <cstdint>
```

```
int example(int test, int result)
{
    if (test > 5)
    {
        test--;
        result = test + result;
    }
    else if (test <= 5)             //Noncompliant
    {
        result = test - result;
    }

    return result;
}
```

Because the final `else if` statement is not followed by a closing else statement, Polyspace marks it as noncompliant. Even though there should be no situation where a value of test progresses past both the `if` and `else if` statements, the additional else statement is required.

# MISRA C++:2008 Rule 6-4-3

A switch statement shall be a well-formed switch statement

## Description

### Rule Definition

*A switch statement shall be a well-formed switch statement.*

### Rationale

In addition to the C++ standard syntax rules, MISRA defines their own syntax rules for creating well-formed switch statements. These additional syntax rules create a consistent structure for switch statements.

The additional MISRA syntax rules include:

| Rule | Syntax |
|---|---|
| switch-statement | `switch` (condition) {case-label-clause-list default-label-clause$_{opt}$} |
| case-label-clause-list | case-label case-clause$_{opt}$<br>case-label-clause-list case-label case-clause$_{opt}$ |
| case-label | `case` const-expression |
| case-clause | case-block-seq$_{opt}$ `break` ;<br>case-block-seq$_{opt}$ `throw` assignment-expression$_{opt}$ ;<br>{ statement-seq$_{opt}$ `break` ; }<br>{ statement-seq$_{opt}$ `throw` assignment-expression$_{opt}$ ; } |
| default-label-clause | default-label default-clause |
| default-label default-clause | `default` : case-clause |
| case-block | expression_statement<br>compound_statement<br>selection_statement<br>iteration_statement<br>try_block |
| case-block-seq | case-block<br>case-block-seq case-block |

These terms from the table are defined as such:

- switch-label — Either a case-label or default-label.
- case-clause — The code between any two switch-labels.
- default-clause — The code between the default-label and the end of the switch statement.
- switch-clause — Either a case-clause or a default-clause.

The MISRA C++ switch syntax rules do not include the following statements, but do permit them within the compound statements that form the body of a switch-clause statement.

- labelled_statement
- jump_statement
- declaration_statement

### Polyspace Implementation

The rule checker reports a violation in these situations:

- A statement occurs between the switch statement and the first case statement.

  For instance:

  ```
  switch(ch) {
    int temp;
    case 1:
      break;
    default:
      break;
  }
  ```
- A label or a jump statement such as goto or return occurs in the switch block.
- A variable is declared in a case statement that is outside any block.

  For instance:

  ```
  switch(ch) {
    case 1:
      int temp;
      break;
    default:
      break;
  }
  ```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Adhere to MISRA Rules for Well-Formed Switch Statements

The example fails to follow two of the well-formed switch statement rules from MISRA.

- The statement int temp; occurs between the switch statement and the first case statement.

- `case 2` contains a return statement.

Polyspace reports a single violation for the entire `switch` statement despite multiple violations within the `switch` statement.

```
int example(int x)
{
    switch (x) {            //Noncompliant
        int temp;
        case 0:
            break;
        case 1:
        case 2:
            return x;
        default:
            break;
    }

    return x;
}
```

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-4-4

A switch-label shall only be used when the most closely-enclosing compound statement is the body of a switch statement

## Description

### Rule Definition

*A switch-label shall only be used when the most closely-enclosing compound statement is the body of a switch statement.*

### Rationale

Placing a case-label or default-label of a switch statement in different scopes might result in unstructured code. Unstructured code might lead to unexpected behavior resulting in developer confusion. To prevent this issue, all case-labels and the default-label must be at the same scope of the compound statement forming the body of the switch statement.

### Polyspace Implementation

Polyspace raises this defect whenever a case-label belongs to any scope other than the switch statement body.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Case-Label Nested Within Another Case-Label Is Noncompliant

```
#include <cstdint>

int y, sum;

int heresASum(int a, int b)
{
    sum = a + b;
    return sum;
}

int example(int x)
{
    switch (x) {
    case 1:                         //compliant
        if (y > 0) {
        case 2:                     //noncompliant
            y = heresASum(x, y);
            break;
        }
        break;
    case 3:
        break;

    default:
        break;
    }

    return x;
}
```

Because the case-label `case 2` in nested under the `case 1` case-label, it is considered in a different scope from the other case-label statements and the default-label statement. All of these other case-label statements are in the same scope of the body of the switch-label statement.

# MISRA C++:2008 Rule 6-4-5

An unconditional throw or break statement shall terminate every non - empty switch-clause

## Description

### Rule Definition

*An unconditional throw or break statement shall terminate every non - empty switch-clause.*

### Rationale

If a throw or break statement is not used at the end of a switch-clause, control flow falls into the next switch-clause. If unintentional, this behavior might cause unexpected results. Using a throw or break statement helps to prevent unintentional fall-through behavior. Use a throw or break statement as the last statement of each case-clause and the default-clause.

Using an empty case-label is acceptable when utilizing fall-through to group together multiple clauses that otherwise require identical statements.

### Polyspace Implementation

Polyspace raises this defect whenever a case-label contains any statements and a throw or break statement is not the final statement of the case-label.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Noncompliant Unintentional Fall Through Case-Label

```
#include <cstdint>

int x, y = 2;

int example(int x)
{
    switch (x) { //Noncompliant error shows here
    case 0:              //Compliant empty fall through
    case 1:
        break;           //Compliant break
    case 2:
        x = y ^ 2;       //Unintentional fall through
    case 3:              //Compliant throw
        throw;

    default:             //Compliant break
        break;
    }
    return x;
}
```

Because `case 2` does not contain a throw or break statement, it falls over into `case 3`. This type of fall through is noncompliant.

Because it is an empty case-label, `Case 0` will fall through to `case 1`. This is a compliant empty case-label fall through.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-4-6

The final clause of a `switch` statement shall be the default-clause

## Description

### Rule Definition

*The final clause of a `switch` statement shall be the default-clause.*

### Rationale

It is a good defensive programming technique to always use a `default` clause as the final clause of a `switch` statement. The `default` clause must either take appropriate action or contain a comment as to why the `default` clause takes no action.

### Polyspace Implementation

The rule checker detects `switch` statements that do not have a final `default` clause.

The rule checker does not report a violation if the `switch` variable is an enumeration with finite number of values and you have a `case` clause for each value. For instance:

```
enum Colors { RED, BLUE, YELLOW } color;

switch (color) {
      case RED:
        break;
      case BLUE:
        break;
      case YELLOW:
        break;
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Example

### Use Default Clause as Final `Switch` Clause

Polyspace flags both `switch` statements in this example as noncompliant.

- `switch (i)` contains multiple `case` statements. However, there is no `default` clause to handle cases where `i` is any value other than 0, 1, or 2. Even if `i` can only be 0, 1, or 2, using a `default` clause is defensive programming to catch any circumstance where `i` is unexpectedly a different value.
- `switch (colors)` uses an enumeration for the `switch` variable. However, each value does not have an associated `case` clause. Adding the `case` clause for `case BLUE` makes this `switch` statement compliant.

```
#include <cstdint>

int main(){
    int i;
    //...
    switch (i)        //Noncompliant
    {
    case 0:
        break;
    case 1:
    case 2:
        break;
    }

    enum Colors { RED, BLUE, YELLOW } colors;

    switch (colors) {    //Noncompliant
    case RED:
        break;
    case YELLOW:
        break;
    }

    return 0;
}
```

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-4-7

The condition of a switch statement shall not have bool type

## Description

### Rule Definition

*The condition of a switch statement shall not have bool type.*

### Rationale

Switch statements that have a bool condition might cause confusion or mistakes not caught by the compiler. If statements are better suited to handling bool evaluations. Use If...else statements in place of switch statements that have a bool condition.

### Polyspace Implementation

Polyspace raises this defect whenever a switch-case conditional results in a bool.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using Bools in Switch Conditions Is Noncompliant

```
#include <cstdint>

int x = 10;

int example(int x)
{
    switch (x > 0) { //Noncompliant
    case true:
        x += 10;
        break;

    case false:
        x -= 10;
        break;

    default:
        x = 0;
        break;
    }

    return x;
}
```

Because the switch statement condition `x > 0` results in a bool, Polyspace marks it as noncompliant.

Use the following if statement in place of the above switch-case:

```
#include <cstdint>

int x = 10;

int example(int x)
{
    if (x > 0) {
        x += 10;
    } else if (x <= 0) {
        x -= 10;
    } else {
        x = 0;
    }

    return x;
}
```

## Check Information

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-4-8

Every switch statement shall have at least one case-clause

## Description

### Rule Definition

*Every switch statement shall have at least one case-clause.*

### Rationale

A switch statement that does not have any case-clauses always results in the default-clause. This behavior is redundant if intentional. If unintentional, a missing case-clause might cause unexpected results. Always provide at least one case-clause to avoid redundancy. If no case-clause is needed, replace or remove the switch statement.

### Polyspace Implementation

Polyspace raises this defect whenever a switch statement contains no case-clause.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Switch Statements Without Case-Clauses Are Noncompliant

```
#include <cstdint>

int x = 10;

int example(int x)
{
    switch (x) { //Noncompliant

    default:
        x = 0;
        break;
    }

    return x;
}
```

Because the switch statement contains only a default clause and no case-clause, Polyspace marks it as noncompliant.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 6-5-1

A for loop shall contain a single loop-counter which shall not have floating type

## Description

### Rule Definition

*A for loop shall contain a single loop-counter which shall not have floating type.*

### Rationale

A `for` loop without a loop-counter can be replaced with a `while` loop. Use a `while` loop instead in these situations.

Floating-point types are rounded to fit into a finite representation. This causes rounding errors to be introduced with floating-point calculations which can cause unexpected results when performing comparisons.

### Polyspace Implementation

This rule checker flags these situations:

- The `for` loop index has a floating point type.
- More than one loop counter is incremented in the `for` loop increment statement.

  For instance:

  ```
  for(i=0, j=0; i<10 && j < 10;i++, j++) {}
  ```
- A loop counter is not incremented in the `for` loop increment statement.

  For instance:

  ```
  for(i=0; i<10;) {}
  ```

  Even if you increment the loop counter in the loop body, Polyspace still raises a violation. According to the MISRA C++ specifications, a loop counter is one that is initialized in or prior to the loop expression, acts as an operand to a relational operator in the loop expression and *is modified in the loop expression*. If the increment statement in the loop expression is missing, the checker cannot find the loop counter modification and considers as if a loop counter is not present.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Example

### Only Use a Single Loop Counter

Because both loop counters `x` and `i` are incremented, the following example is noncompliant.

```
#include <iostream>

int main()
{
    int x = 0;
    for (int i = 0; i >= x; i = x++)   // Non-compliant
    {
        //...
    }
}
```

### Avoid Using Floating Point Numbers as Loop Counters

In this example, because floating-point calculations can contain rounding errors, the for loop will only execute nine times. This is due to the value of `x` being slightly larger than `1.0f` on the tenth loop.

```
#include <iostream>

int main()
{
    for (float x = 0.1f; x <= 1.0f; x += 0.1f) {   //Noncompliant
        std::cout << x << std::endl;
    }
}
```

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-5-2

If loop-counter is not modified by -- or ++, then, within condition, the loop-counter shall only be used as an operand to <=, <, > or >=

## Description

### Rule Definition

*If loop-counter is not modified by -- or ++, then, within condition, the loop-counter shall only be used as an operand to <=, <, > or >=.*

### Rationale

If the loop counter increments or decrements by more than one per iteration, avoid using == or `!=` in the loop termination condition. It is unclear from visual inspection if such loop termination conditions are ever satisfied.

For instance, if a loop counter `ctr` increments by more than one per iteration, such as `ctr+=2`, and the termination condition is `ctr == someVal`, the counter might skip the value `someVal`, resulting in a nonterminating loop.

Nonterminating loops can result in developer confusion or unexpected values.

### Polyspace Implementation

Polyspace raises this defect whenever all the following are true:

- The loop-counter is not modified by `--` or `++`
- The loop-condition does not contain <=, <, > or >=

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Nonterminating Loops Created by Using Noncompliant Operand Pairings

```
#include <cstdint>

uint32_t row, col;

void example()
{
    for (row = 0; row <= 10; row++) {                 //Compliant
        for (col = 100; col != 10; col -= 4) {        //Noncompliant
            //...
        }
    }
    for (row = 0; row != 10; row++) {            //Compliant
        //...
    }
}
```

Because the second for loop-counter is not modified by `--` or ++, `!=` becomes a noncompliant operand. Use one of the following operands instead: <=, <, > or >=.

# MISRA C++:2008 Rule 6-5-3

The loop-counter shall not be modified within condition or statement

## Description

### Rule Definition

*The loop-counter shall not be modified within condition or statement.*

### Rationale

The `for` loop has a specific syntax for modifying the loop counter. A code reviewer expects modification using that syntax. Modifying the loop counter elsewhere can make the code harder to review.

### Polyspace Implementation

The checker flags modification of a `for` loop counter in the loop body or the loop condition (the condition that is checked to see if the loop must be terminated).

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 6-5-4

The loop-counter shall be modified by one of: --, ++, -=n, or +=n ; where n remains constant for the duration of the loop

## Description

### Rule Definition

*The loop-counter shall be modified by one of: --, ++, -=n, or +=n ; where n remains constant for the duration of the loop.*

### Rationale

If the loop-counter modifier of the loop is not constant, the loop might end unpredictably, causing results contrary to your expectations. Constant increments create predictable loop termination.

### Polyspace Implementation

Polyspace reports this defect whenever the modifier of a loop-counter is not constant. Polyspace also reports this defect when you modify a loop by -=*n* or +=*n* and modify *n* within the loop.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant Nonconstant Loop-Counter Modifiers

```
#include <cstdint>

int i, x = 0;
int y, z = 1;

int ex2()
{
    return z;
}

void example()
{
    for (i = 0; i <= 10; i += x) {          //Noncompliant
        x += 1;
    }

    for (i = 0; i <= 10; i += y) {          //Compliant
        z += i;
    }

    for (i = 0; i >= 10; i -= ex2()) {      //Noncompliant
        z += i;
    }
}
```

Because the first `for` loop uses the loop-counter modifier of `+=x` and modifies the variable `x` within the `for` loop, Polyspace flags the `for` loop as noncompliant.

The second `for` loop shows a compliant case of using a loop-counter modifier of `+=y`, where `y` is not modified within the loop.

The third `for` loop modifies the loop counter by using the return value of a function, `ex2()`. Because the function returns a different value in each iteration, the loop-counter modifier is not constant. Polyspace flags the `for` loop as noncompliant.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-5-5

A loop-control-variable other than the loop-counter shall not be modified within condition or expression

## Description

### Rule Definition

*A loop-control-variable other than the loop-counter shall not be modified within condition or expression.*

### Rationale

Loops are easier to understand and predict if loop-control-variables, other than loop counters, are not modified within the condition or increment/decrement expression. A volatile typed loop-control-variable is an exception and you can modify it outside of the statement without triggering this violation.

Loop-control-variables are any variables that occur in the loop init-statement, condition, or expression. Loop-control-variables include loop-counters and flags used for early loop termination. A loop-counter is a loop-control-variable that is:

- Initialized prior to the `for` loop or in the init-statement of the `for` loop.
- An operand to a relational operator in the condition of the `for` loop.
- Modified in the expression of the `for` loop.

### Polyspace Implementation

Polyspace raises this defect whenever a loop-counter or flag used for early termination is modified within the condition or expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Modifying Loop-Control-Variables Within the Loop Condition

```
#include <cstdint>

bool tf_test, tf_test2 = false;
int32_t x = 0;

bool a_test(bool a)
{
    if (x % 2 == 0)
    {
        a = true;
    }
    else
    {
        a = false;
    }
    return a;
}

void example()
{

    for (x = 0; (x < 10) && (tf_test = a_test(tf_test)); x++)        //noncompliant
    {
        //...
    }

    for (x = 0; (x < 10) && tf_test2; x++)         //compliant
    {
             //...
        tf_test2 = a_test(tf_test2);
    }
}
```

In the first `for` loop, because `tf_test` is a flag used for early loop termination that is modified within the condition, Polyspace flags it as noncompliant.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-5-6

A loop-control-variable other than the loop-counter which is modified in statement shall have type bool

## Description

### Rule Definition

*A loop-control-variable other than the loop-counter which is modified in statement shall have type bool.*

### Rationale

Loops terminate when the loop-counter value meets a termination condition. You can use additional loop-control-variables if you want to end a loop early.

For instance:

`for(ctr = 0 ; ctr <= 10; ctr++) {…}` terminates when the value of `ctr` is greater than `10`.

`for(ctr = 0 ; ctr <= 10 && level > 0; ctr++) {…}` terminates when the value of `ctr` is greater than `10` or when the value of `level` is greater than `0`.

In the second instance, it is not clear why the condition `level >= 0` terminates the loop early. By using a Boolean variable as a loop-control-variable for early termination, you can use a more descriptive name that reflects the early termination state.

For example:

```
for(ctr = 0 ; ctr <= 10 && fuelTankNotEmpty; ctr++)
{
    /...
    fuelTankNotEmpty = (level >= 0);
}
```

This Boolean variable is called a flag. Boolean flags make loop control logic easier to understand.

### Polyspace Implementation

Polyspace raises this defect whenever a non-Boolean loop-control-variable is modified within the loop statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Modifying Non-Boolean Loop-Control-Variables Within the Loop Statement

```
#include <cstdint>
```

```
int32_t ctr, level = 1;
bool fuelTankNotEmpty = true;

void example()
{
    for(ctr = 0 ; ctr <= 10 && level >= 0; ctr++)        //Noncompliant
    {
        level--;
    }

    for (ctr = 0; ctr <= 10 && fuelTankNotEmpty; ctr++)    //Compliant
    {
        level--;
        fuelTankNotEmpty = (level >= 0);
    }

}
```

In the first `for` loop, because `level` is not a Boolean and is modified within the statement, Polyspace flags it as noncompliant.

The second loop shows how to use a Boolean flag to be compliant with this rule.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-6-1

Any label referenced by a goto statement shall be declared in the same block, or in a block enclosing the goto statement

## Description

### Rule Definition

*Any label referenced by a goto statement shall be declared in the same block, or in a block enclosing the goto statement.*

### Rationale

Using a `goto` statement to jump into nested blocks creates complex control flow, which might cause developer confusion or unexpected results. To avoid unexpected results, place the label the `goto` statement is referring to in the same block or in a block that encloses the `goto` statement.

### Polyspace Implementation

Polyspace raises this defect when the `goto` destination is in a different block than the `goto` statement. This defect is not raised if the `goto` destination is in a block enclosing the `goto` statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using goto Statements to Exit Out of a Block

```
#include <iostream>

int x, y = 0;

void foo1()
{
    int i = 0;
    if (x <= 10) {
        goto err;                    //Noncompliant
    }

    if(x > 10) {
    err:
        std::cout << "Error encountered in loop" << std::endl;
    }

}

void foo2()
{
    for (x = 0; x < 100; ++x) {
        for (y = 0; y < 100; ++y) {
            if (x > y) {
                goto stop;            //Compliant
            }
            //...
        }
    }
stop:
    std::cout << "Error encountered in loop" << std::endl;
}
```

Because the label `err` is located within a separate code block than `goto err`, and that code block does not enclose the code block where `goto err` resides, Polyspace flags the `goto` statement as noncompliant.

The label `stop` is not in the same block as `goto stop`, but is in a block enclosing the `goto stop` statement. This behavior is compliant behavior.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-6-2

The goto statement shall jump to a label declared later in the same function body

## Description

### Rule Definition

*The goto statement shall jump to a label declared later in the same function body.*

### Rationale

Using a `goto` statement to jump to a label earlier in the same function body creates an iteration. Avoid creating iterations by using `goto` statements. Use iteration statements defined by the core language because they are easier to understand and maintain than goto statements.

### Polyspace Implementation

Polyspace raises this defect when an iteration is formed by using `goto` statements.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Creating Iterations by Using goto Statements

```
#include<iostream>
void foo(int x, int y)
{
test:
    x++;
    if (x <= y) {
        std::cout << x << std::endl;
        goto test;   //Noncompliant
    }
}
```

Because `goto test` sends the code back to the beginning of the function, the goto statement creates a loop. Use looping statements such as `while` or `for` instead.

```
#include<iostream>
void foo(int x, int y)
{
    while (x < y)
    {
        x++;
        std::cout << x << std::endl;
    }
}
```

The continue statement shall only be used within a well-formed for loop

## Description

### Rule Definition

*The continue statement shall only be used within a well-formed for loop.*

### Rationale

Using a continue statement can add unnecessary complexity to code, which can cause issues during testing due to the additional logic required.

### Polyspace Implementation

The rule checker reports a violation for the use of continue statements in:

- for loops that are not well-formed, that is, for loops that violate rules 6-5-x
- while loops

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Example

### Only Use continue Statement in Well-Formed for Loops

The for loop in this code is not well-formed as it breaks MISRA C++:2008 Rule 6-5-2. Because the for loop in the example is not well-formed and contains a continue statement, Polyspace raises this violation.

```
#include <cstdint>

uint32_t row, col;

void example()
{
    for (row = 0; row <= 10; row++) {
        for (col = 100; col != 10; col -= 4) {
            //...
            continue;        //Noncompliant
        }
    }
}
```

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 6-6-4

For any iteration statement there shall be no more than one break or goto statement used for loop termination

## Description

### Rule Definition

*For any iteration statement there shall be no more than one break or goto statement used for loop termination.*

### Rationale

Using multiple `break` or `goto` statements within an iteration statement increases the complexity of the code. For good structured programming, use a single `break` or `goto` statement.

### Polyspace Implementation

Polyspace raises this defect when multiple `break` statements, `goto` statements, or a combination of these statements are present in a single loop.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Multiple break or goto Statements to Terminate a Loop

```
#include<iostream>
void foo(int x, int y)
{
    for (x = 0; x <= y; x++)
    {
        if (x == y)
        {
            // do this
            break;        //Compliant
        }
        else if (x > y)
        {
            goto error;      //Noncompliant
        }
        else
        {
            //do this
        }
    }

error:
    std::cout << "Error message" << std::endl;
}
```

Because the `if` statement contains a `break` and a `goto` statement, Polyspace flags the statement as noncompliant. In this scenario, Polyspace labels the first `break` or `goto` statement as compliant. Polyspace flags all subsequent `break` or `goto` statements as noncompliant.

# MISRA C++:2008 Rule 6-6-5

A function shall have a single point of exit at the end of the function

## Description

### Rule Definition

*A function shall have a single point of exit at the end of the function.*

### Rationale

This rule requires that a `return` statement must occur as the last statement in the function body. Otherwise, the following issues can occur:

- Code following a `return` statement can be unintentionally omitted.
- If a function that modifies some of its arguments has early `return` statements, when reading the code, it is not immediately clear which modifications actually occur.

### Polyspace Implementation

The checker flags these situations:

- A function has more than one `return` statement.
- A non-`void` function has one `return` statement only but the `return` statement is not the last statement in the function.

A `void` function need not have a `return` statement. If a `return` statement exists, it need not be the last statement in the function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 7-1-1

A variable which is not modified shall be const qualified

## Description

### Rule Definition

*A variable which is not modified shall be const qualified.*

### Rationale

Declaring a variable `const` reduces the chances that you modify the variable inadvertently.

### Polyspace Implementation

The checker flags:

- Function parameters or local variables that are not const-qualified but never modified in the function body.
- Pointers that are not const-qualified but point to the same location during its lifetime.

Function parameters of integer, float, enum, and Boolean types are not flagged.

If a variable is passed to another function by reference or pointers, the checker assumes that the variable can be modified. These variables are not flagged.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unmodified Local Variable

```
#include <cstddef>

char getNthChar(const char* str, int N){//Noncompliant
    int index=0;
    while(*(str+index)!='\0'){
        if(index==N)
            return *(str+N);
        ++index;
    }
    return '\0';
}
char getNthChar_const_safe(const char* const str, int N){
    int index=0;

    while(*(str+index)!='\0'){
        if(index==N)
            return *(str+N);
        ++index;
    }
    return '\0';
}
```

In the function `getNthChar()`, the C-string `str` is passed as a `const char*` parameter, meaning that the string `*str` is `const`. Because the pointer `str` does not change value, the pointer itself must be `const` qualified, as shown in the function `getNthChar_const_safe`. Polyspace flags the parameter `str`.

# MISRA C++:2008 Rule 7-1-2

A pointer or reference parameter in a function shall be declared as pointer to const or reference to const if the corresponding object is not modified

## Description

### Rule Definition

*A pointer or reference parameter in a function shall be declared as pointer to const or reference to const if the corresponding object is not modified.*

### Polyspace Implementation

The checker flags pointers where the underlying object is not const-qualified but never modified in the function body.

If a variable is passed to another function by reference or pointers, the checker assumes that the variable can be modified. Pointers that point to these variables are not flagged.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 7-2-1

An expression with enum underlying type shall only have values corresponding to the enumerators of the enumeration.

## Description

### Rule Definition

*An expression with enum underlying type shall only have values corresponding to the enumerators of the enumeration.*

### Rationale

If your program evaluates an expression with `enum` underlying type and returns a value that is not part of the enumerator list of the enumeration, the behavior is unspecified.

Compliance with this rule validates the assumption made by other rules in this standard that objects of type `enum` contain only values corresponding to the enumerators.

To avoid unspecified behavior when evaluating expressions of type `enum`, use a `switch` statement. For example:

```
#include <cstdio>
enum class E : size_t { Pass, Warning, Error };

E Evaluate(size_t input) noexcept {
    E output = E::Pass;
    switch (input) {
      case 0: {
          output = E::Pass;
          break;
      }
      case 1: {
          output = E::Warning;
          break;
      }
      case 2: {
          output = E::Error;
          break;
      }
      default: {
          output = static_cast<E>(0);
      }
    }
    return output;
}
```

### Polyspace Implementation

Polyspace flags the use of a value that is not part of the enumerators of an enumeration.

Polyspace does not flag the use of unknown values, even if you do not check the range of the value before you use it in the `enum` expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Value Does Not Correspond to Enumerators of Enumeration

```
#include <cstdint>

enum class Suit : uint8_t { None = 1, Diamonds, Clubs, Hearts, Spades };

Suit resetRedSuit(uint8_t card) noexcept {
    Suit hand = Suit::None;
    if(card < 6){ //check range of card is inside Suit enum
        hand = static_cast<Suit>(card);
    }

    if (hand == Suit::Diamonds ||
        hand == Suit::Hearts) {
            hand = static_cast<Suit>(0); // Noncompliant
    }
    return hand;
}
```

In this example, Polyspace flags the second `static_cast` in function `resetRedSuit` because the expression uses a value (0) that is not part of the enumerator list of enumerator `Suit`.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 7-3-1

The global namespace shall only contain main, namespace declarations and extern "C" declarations

## Description

### Rule Definition

*The global namespace shall only contain main, namespace declarations and extern "C" declarations.*

### Rationale

The rule makes sure that all names found at global scope are part of a namespace. Adhering to this rule avoids name clashes and ensures that developers do not reuse a variable name, resulting in compilation/linking errors, or shadow a variable name, resulting in possibly unexpected issues later.

### Polyspace Implementation

Other than the `main` function, the checker flags all names used at global scope that are not part of a namespace.

The checker does not flag names at global scope if they are declared in `extern "C"` blocks (C code included within C++ code). However, if you use the option `Ignore link errors (-no-extern-c)`, these names are also flagged.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# MISRA C++:2008 Rule 7-3-2

The identifier main shall not be used for a function other than the global function main

## Description

### Rule Definition

*The identifier main shall not be used for a function other than the global function main.*

### Rationale

Typically, the `main` function lives in the global namespace and acts as the entry point to a program. The use of `main` in other contexts might defy developer expectations.

### Polyspace Implementation

The rule checker reports a violation if you use the identifier `main` in a namespace other than the global namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Nonstandard Uses of `main`

```
#include <cstdint>

int32_t main() { //Compliant
    //...
    return 0;
}

namespace Backups {
    int32_t main() { //Noncompliant
        //...
        return 0;
    }
}
```

The use of `main` in a namespace other than the global namespace violates the rule.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 7-3-3

There shall be no unnamed namespaces in header files

## Description

### Rule Definition

*There shall be no unnamed namespaces in header files.*

### Rationale

According to the C++ standard, names in an unnamed namespace, for instance, `aVar`:

```
namespace {
   int aVar;
}
```

have internal linkage by default. If a header file contains an unnamed namespace, each translation unit with a source file that `#include`-s the header file defines its own instance of objects in the namespace. The multiple definitions are probably not what you intended and can lead to unexpected results, unwanted excess memory usage, or inadvertently violating the one-definition rule.

### Polyspace Implementation

The checker flags unnamed namespaces in header files.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unexpected Results from Unnamed Namespaces in Header Files

Header File: `aHeader.h`

```
namespace { //Noncompliant
   int aVar;
}
```

First source file: `aSource.cpp`

```
#include "aHeader.h"
#include <iostream>

void setVar(int arg) {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = arg;
    std::cout << "Value set at: " << aVar << std::endl;
}
```

Second source file: `anotherSource.cpp`

```
#include "aHeader.h"
#include <iostream>

extern void setVar(int);

void resetVar() {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = 0;
    std::cout << "Value set at: 0" << std::endl;
}

void main() {
    setVar(1);
    resetVar();
}
```

In this example, the noncompliant unnamed namespace leads to two definitions of `aVar` in the translation unit from `aSource.cpp` and the translation unit from `anotherSource.cpp`. The two definitions can lead to possible unexpected output:

```
Current value: 0
Value set at: 1
Current value: 0
Value set at: 0
```

# MISRA C++:2008 Rule 7-3-4

using-directives shall not be used

## Description

### Rule Definition

*using-directives shall not be used.*

### Rationale

`using` directives can inadvertently expose more variables to name lookup than you intend. The wider scope for name lookup increases the likelihood of a variable being unintentionally used. For instance:

```
namespace NS {
    int i;
    int j;
}
using namespace NS;
```

exposes both `NS::i` and `NS::j` to name lookup, but you might have intended to use only one of the variables.

It is preferable to only expose variables that you intend to use or refer to variables by their fully qualified name when you use them. For instance, in the previous example, if you use the variable `NS::i`, expose only this variable to name lookup:

```
using NS::i;
```

or refer to `NS::i` instead of `i` in all instances.

### Polyspace Implementation

The rule checker reports a violation on `using` directives. These directives contain the keyword `using` followed by the keyword `namespace` and the name of a namespace. The `using` directives make all members of a namespace available to the current scope.

The checker does not flag `using` declarations. These declarations also contain the keyword `using` but not the keyword `namespace`. The `using` declarations only expose specific members of a namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Namespace Exposed Through `using` Directive

```
namespace currentDataModel {
    int nodes;
    int count;
}
using namespace currentDataModel; //Noncompliant

namespace lastDataModel {
    int nodes;
    int count;
}
using lastDataModel::count; //Compliant
```

In this example, the `using` directive that exposes all members of the namespace `currentDataModel` violates the rule.

#### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 7-3-5

Multiple declarations for an identifier in the same namespace shall not straddle a using-declaration for that identifier

## Description

### Rule Definition

*Multiple declarations for an identifier in the same namespace shall not straddle a using-declaration for that identifier.*

### Rationale

This rule requires that an identifier must not be declared in a namespace *after* an `using` declaration has already introduced an identifier with the same name. The declaration after the `using` statement can lead to developer confusion.

For instance, a `using` declaration such as:

```
using NS::func;
```

introduces the name `func` from the namespace `NS` in the current scope. If there are two overloads of `func` in `NS`, one declared before and another after the `using` statement, only the overload declared before is exposed to name lookup and invoked when `func` is called. However, in a specific call to `func`, a developer might expect the overload declared later to be invoked (perhaps because that overload is a better match based on function arguments).

### Polyspace Implementation

The rule checker reports a violation if an identifier is declared in a namespace after these two events:

1. Another identifier with the same name has been previously declared in the same namespace.
2. A `using` declaration has already exposed that name to name lookup.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Multiple Declarations of Same Name on Either Side of `using` Declaration

```
#include <cstdint>

namespace initialTests {
    void validateInput(uint16_t input);
}

using initialTests::validateInput;

namespace initialTests {
    void validateInput(uint32_t input); //Noncompliant
}

namespace periodicTests {
    void validateResults(uint16_t results);
    void validateResults(uint32_t results); //Compliant
}

using periodicTests::validateResults;

void main() {
    validateInput(0U);
    validateResults(0U);
}
```

In this example:

- The declaration of `validateInput(uint32_t)` in the namespace `initialTests` violates the rule because the name `validateInput` from this namespace has already been exposed with an `using` declaration. This second declaration of `validateInput()` can cause developer confusion. For instance, the call to `validateInput()` in `main` invokes `validateInput(uint16_t)` but a developer might expect `validateInput(uint32_t)` to be invoked because it is a better match for the call.
- The declarations of `validateResults()` in the namespace `periodicTests` do not violate the rule because both declarations appear before the `using` statement. When the function `validateResults()` is called, all overloads of `validateResults()` are exposed to name lookup. A developer can use only the parameters of `validateResults()` in the overload declarations to decide which overload is invoked, thereby reducing chances of confusion.

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 7-3-6

using-directives and using-declarations (excluding class scope or function scope using-declarations) shall not be used in header files

## Description

### Rule Definition

*using-directives and using-declarations (excluding class scope or function scope using-declarations) shall not be used in header files.*

### Rationale

If `using` directives or declarations are present in a header file, the order in which the header is included might affect the final program results. It is a good practice to ensure that the program behavior does not depend on the order of inclusion of headers.

### Polyspace Implementation

The checker flags `using` directives or declarations in header files.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `using` Directives in Headers Introduce Dependence on Order of Inclusion

Header File: `headerUnits.h`:

```
void checkValueForOverflows(int32_t);

namespace Units {
    void checkValueForOverflows(int8_t);
}

inline void convertToAcceptedUnit(int8_t originalValue) {
    checkValueForOverflows(originalValue);
}
```

Header File: `headerAcceptedUnits.h`:

```
namespace Units {

}

using namespace Units; //Noncompliant
```

Source file that includes previous two headers:

```
#include <cstdint>
#include "headerUnits.h"
```

```
#include "headerAcceptedUnits.h"

int8_t convert(int8_t meterReading) {
    convertToAcceptedUnit(meterReading);
}
```

In this example, the `using` directive in the header file `headerAcceptedUnits.h` exposes the namespace `Units`. This directive plus the inlined function in the header makes the order of inclusion of `headerUnits.h` and `headerAcceptedUnits.h` important for the final program execution.

- If `headerAcceptedUnits.h` is included before `headerUnits.h`, the function `convertToAcceptedUnit()` invokes the function `checkValueForOverflows(int32_t)`.
- If `headerAcceptedUnits.h` is included after `headerUnits.h`, as shown above, the function `convertToAcceptedUnit()` invokes the function `checkValueForOverflows(int8_t)`.

# MISRA C++:2008 Rule 7-4-2

Assembler instructions shall only be introduced using the asm declaration

## Description

### Rule Definition

*Assembler instructions shall only be introduced using the asm declaration.*

### Rationale

The `asm` declaration is available in all C++ implementations[6] but other ways of introducing assembler instructions might not be available. Using the `asm` declaration makes your code portable across implementations.

### Polyspace Implementation

The rule checker reports uses of methods other than `asm` declarations as rule violations.

For instance, the rule checker allows the `asm` declaration:

```
asm("ADD a0,1")
```

But if the same assembler instructions are introduced through a `#pragma asm`, the checker reports a violation:

```
#pragma asm
   "ADD a0,1"
#pragma endasm
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Introduction of Assembler Instructions Using Nonportable Methods

```
void Delay1 ( void ) {
#pragma asm    //Noncompliant
   "ADD a0,1"
#pragma endasm
     ;
}

void Delay2 ( void ) {
   asm("ADD a0,1"); //Compliant
}
```

The use of `#pragma asm` violates this rule.

[6] How the `asm` declaration is implemented might vary across compilers. See also `AUTOSAR C++14 Rule A7-4-1`.

# MISRA C++:2008 Rule 7-4-3

Assembly language shall be encapsulated and isolated

## Description

### Rule Definition

*Assembly language shall be encapsulated and isolated.*

### Rationale

Assembler instructions can be difficult to port across implementations. Encapsulating and isolating them in a function helps to make your code portable. You can easily track down assembler instructions or provide alternative implementations without changing the rest of the code.

### Polyspace Implementation

The checker flags `asm` statements unless they are encapsulated in a function call.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Assembler Instructions Not Encapsulated in Function Call

```
void DoSomething(void);

void Delay ( void ) {
    asm( "NOP"); //Compliant
    asm( "NOP"); //Compliant
}
void DoSomethingAndDelay (void) {
    DoSomething();
    Delay();// Assembler is encapsulated
    DoSomething();
    asm("NOP"); //Noncompliant
    DoSomething();
}
```

The `asm` statement in the function `DoSomethingAndDelay()` is mixed with regular C code and violates the rule. The `asm` statements in the function `Delay()` are compliant because they form the only instructions in this function. The `Delay()` function thus effectively encapsulates the assembler instructions.

# MISRA C++:2008 Rule 7-5-1

A function shall not return a reference or a pointer to an automatic variable (including parameters), defined within the function

## Description

### Rule Definition

*A function shall not return a reference or a pointer to an automatic variable (including parameters), defined within the function.*

### Rationale

Local objects of a function are destroyed at the end of a function call. If you return the address of such an object via a pointer, you might access a destroyed object. For instance:

```
int* foo(int a){
    int b = a^2;
    return &b;
}
```

The function `foo()` returns a pointer to `b`. The variable `b` goes out of scope at the end of the function call and the pointer returned by `foo()` points to a destroyed object. Accessing the pointer leads to undefined behavior.

### Polyspace Implementation

Polyspace raises a violation if a function returns a reference or pointer to a variable that goes out of scope at the end of the function call.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Returning Pointers to Local Variables

```
int gVal;
//...

int* foo(void){
    int val;
    //...
    return &val;//Noncompliant
}
```

In this example, the function `foo()` returns the address of `val`. This local variables goes out of scope at the end of the function call. Accessing the pointer returned by `foo()` results in undefined behavior. Polyspace raises a violation.

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 7-5-2

The address of an object with automatic storage shall not be assigned to another object that may persist after the first object has ceased to exist

## Description

### Rule Definition

*The address of an object with automatic storage shall not be assigned to another object that may persist after the first object has ceased to exist.*

### Rationale

If an object continues to point to another object *after* the latter object ceases to exist, dereferencing the first object leads to undefined behavior.

### Polyspace Implementation

The checker flags situations where the address of a local variable is assigned to a pointer defined at global scope.

The checker does not raise violations of this rule if:

- A function returns the address of a local variable. `MISRA C++:2008 Rule 7-5-1` covers this situation.
- The address of a variable defined at block scope is assigned to a pointer that is defined with greater scope, but not global scope.

  For instance:

  ```
   void foobar ( void )
    {
      char * ptr;
      {
        char var;
        ptr = &var;
      }
    }
  ```

  Only if the pointer is defined at global scope is a rule violation raised. For instance, the rule checker flags the assignment here:

  ```
  char * ptr;
  void foobar ( void )
    {
        char var;
        ptr = &var;
    }
  ```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Address of Local Variable Assigned to Global Pointer

```
char * ptr;

void foo (void) {
    char varInFoo;
    ptr = &varInFoo; //Noncompliant
}

void bar (void) {
    char varInBar = *ptr;
}

void main() {
    foo();
    bar();
}
```

The assignment `ptr = &varInFoo` is noncompliant because the global pointer `ptr` might be dereferenced outside the function `foo`, where the variable `varInFoo` is no longer in scope. For instance, in this example, `ptr` is dereferenced in the function `bar`, which is called after `foo` completes execution.

Functions should not call themselves, either directly or indirectly

## Description

### Rule Definition

*Functions should not call themselves, either directly or indirectly.*

### Rationale

Variables local to a function are stored in the call stack. If a function calls itself directly or indirectly several times, the available stack space can be exceeded, causing serious failure. Unless the recursion is tightly controlled, it is difficult to determine the maximum stack space required.

### Polyspace Implementation

The checker reports each function that calls itself, directly or indirectly. Even if several functions are involved in one recursion cycle, each function is individually reported.

You can calculate the total number of recursion cycles using the code complexity metric `Number of Recursions`. Note that unlike the checker, the metric also considers implicit calls, for instance, to compiler-generated constructors during object creation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Direct and Indirect Recursion

```
void foo1(int);
void foo2(int);

void foo1( int n ) {    // Non-compliant - Indirect recursion foo1->foo2->foo1...
    if(n > 0) {
        foo2(n);
        foo1(n);    // Non-compliant - Direct recursion
        n--;
    }
}

void foo2( int n ) { // Non-compliant - Indirect recursion foo2->foo1->foo2...
    foo1(n);
}
```

In this example, the rule is violated because of:

- Direct recursion `foo1` → `foo1`.

- Indirect recursion `foo1` → `foo2` → `foo1`.
- Indirect recursion `foo2` → `foo1` → `foo2`.

Note that the location of the rule violation is different for direct and indirect recursions:

- When a function calls itself directly, the rule violation is shown on the function call.
- When several functions are involved in an indirect recursion chain, for every function in the chain, a rule violation is shown on the function signature in the function body.

# MISRA C++:2008 Rule 8-0-1

An init-declarator-list or a member-declarator-list shall consist of a single init-declarator or member-declarator respectively

## Description

### Rule Definition

*An init-declarator-list or a member-declarator-list shall consist of a single init-declarator or member-declarator respectively.*

### Rationale

Init-declarator-lists that have multiple declarators might result in ambiguous type assignments and might cause a developer to assign unintended types to certain identifiers. Having a single init-declarator for each declaration clarifies the declaration type and reduces the risk of unwanted type assignments. Avoid multiple declarators in an init-declarator-list or a member-declarator-list.

### Polyspace Implementation

Polyspace flags declarators after the first declarator in an init-declarator-list or a member-declarator-list.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Multiple Declarators Within an Init-Declarator-List

```
#include <cstdint>
#include <string>

class exampleClass{};

void foo() {

    double a, b, c; //Noncompliant

    exampleClass objectOne, objectTwo; //Noncompliant

    int32_t d; int32_t e; //Compliant

    std::string f;  //Compliant

}
```

In this example, Polyspace flags init-declarator-lists that have multiple declarators. For instance:

- `double a, b, c` is noncompliant because the init-declarator-list consists of more than one init-declarator and the `b` and `c` declarators are flagged.
- `exampleClass objectOne, objectTwo` is noncompliant because the init-declarator-list consists of more than one init-declarator and the `objectTwo`declarator is flagged.
- `int32_t d, int32_t e` and `std::string f` are compliant because each init-declarator-list consists of a single init-declarator.

The identifiers used for the parameters in a re-declaration of a function shall be identical to those in the declaration

## Description

### Rule Definition

*The identifiers used for the parameters in a re-declaration of a function shall be identical to those in the declaration.*

### Polyspace Implementation

The checker detects mismatch in parameter names between:

- A function declaration and the corresponding definition.
- Two declarations of a function, provided they occur in the same file.

  If the declarations occur in different files, the checker does not raise a violation for mismatch in parameter names. Redeclarations in different files are forbidden by `MISRA C++:2008 Rule 3-2-3`.

# MISRA C++:2008 Rule 8-5-1

All variables shall have a defined value before they are used

## Description

### Rule Definition

*All variables shall have a defined value before they are used.*

### Rationale

The C++ standard does not specify what the value of an uninitialized memory is. This value is unpredictable and can be different every time the program runs. Reading and using the value of an uninitialized memory results in unexpected behavior.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains these issues:

- `Non-initialized variable`
- `Member not initialized in constructor`
- `Non-initialized pointer`

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Read Before Initialization

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val; //Noncompliant

}
```

### Member Not Initialized in Constructor

In this example, if `flag` is not 0, the member `_c` is not initialized.

The defect appears on the closing brace of the constructor. Following are some tips for navigating in the source code:

- On the **Result Details** pane, see which members are not initialized.
- To navigate to the class definition, right-click a member that is initialized in the constructor. Select **Go To Definition**. In the class definition, you can see all the members, including those members that are not initialized in the constructor.

```
class MyClass {
public:
    explicit MyClass(int);
private:
    int _i;
    char _c;
};

MyClass::MyClass(int flag) {
    if(flag == 0) {
        _i = 0;
        _c = 'a';
    }
    else {
        _i = 1;
    }
}//Noncompliant
```

### Pointer Dereferenced Before Initialization

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j; //Noncompliant

    return pi;
}
```

# MISRA C++:2008 Rule 8-5-2

Braces shall be used to indicate and match the structure in the non- zero initialization of arrays and structures

## Description

### Rule Definition

*Braces shall be used to indicate and match the structure in the non- zero initialization of arrays and structures.*

### Rationale

The use of nested braces in initializer lists to match the structures of nested objects in arrays, unions, and structs encourages you to consider the order of initialization of complex data types and makes your code more readable. For example, the use of nested braces in the initialization of ex1 makes it easier to see how the nested arrays arr1 and arr2 in struct ex1 are initialized.

```
struct Example
{
    int num;
    int arr1[2];
    int arr2[3];
};

//....
struct Example ex1 {1, {2, 3}, {4, 5, 6}}; //Compliant
```

The rule does not require the use of nested braces if you zero initialize an array, a union, or a struct with nested structures are the top-level, for instance:

```
struct Example ex1 {}; //Compliant
```

### Polyspace Implementation

If you non-zero initialize an array, union, or struct that contains nested structures and you do not use nested braces to reflect the nested structure, Polyspace flags the first element of the first nested structure in the initializer list. For instance, in this code snippet, Polyspace flags the number 2 because it corresponds to the first element of nested structure arr1 inside struct ex1.

```
struct Example
{
    int num;
    int arr1[2];
    int arr2[3];
};

//....
struct Example ex1 {1, 2, 3, 4, 5, 6}; // Non-compliant
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing Nested Braces in Initializer of Two-Dimensional Arrays

```
char arr1[2][3] {'a', 'b', 'c', 'd', 'e', 'f'}; //Non-compliant
char arr2[2][3] {{'a', 'b', 'c'}, {'d', 'e', 'f'}}; //Compliant
char arr_top_level[2][3] { }; //Compliant
char arr_sub_level[2][3] { {}, {'d', 'e', 'f'}}; //Non-compliant
```

In this example, two-dimensional array `arr1` is non-compliant because the initializer list does not reflect the nested structure of this array (two arrays of three elements each). The initialization of `arr2` uses nested braces to reflect the nested structure of the array and is compliant. Similarly, the initialization of `arr_top_level` is compliant because it zero initializes the array at the top level. Note that the initialization of `arr_sub_level` is non-compliant because zero-initializes only the first sub-array while explicitly initializing all the elements of the other sub-array.

# MISRA C++:2008 Rule 9-3-1

const member functions shall not return non-const pointers or references to class-data

## Description

### Rule Definition

*const member functions shall not return non-const pointers or references to class-data.*

### Rationale

A `const` object cannot be changed post initialization and can only invoke class member functions that are also declared as `const`. These member functions are not expected to change the state of the object.

If a `const` member function returns a non-`const` pointer or reference to a data member of the class, the function can modify the state of an object and violate developer expectations. To avoid this situation, when you define a `const` member function that returns a reference or a pointer to a class data member, specify the return type as `const`.

### Polyspace Implementation

Polyspace flags a violation of this rule only if a `const` member function returns a non-`const` pointer or reference to a non-`static` data member. The rule does not apply to `static` data members.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Specify Return Type of `const` Member Function as `const`

```
class A{

    private:

    int& rInt;
    public:

    int* getR() const{ //Noncompliant
        return &rInt;
    }

    const int* getConstR() const{ //Compliant
        return &rInt;
    }
};
```

In this example:

- The `const` member function `getR()` returns a non-`const` pointer and violates the rule.
- The `const` member function `getConstR()` returns a `const` pointer and is compliant with the rule.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 9-3-3

If a member function can be made static then it shall be made static, otherwise if it can be made const then it shall be made const

## Description

### Rule Definition

*If a member function can be made static then it shall be made static, otherwise if it can be made const then it shall be made const.*

### Rationale

`const` member functions cannot modify the data members of the class. `static` member function cannot modify the nonstatic data members of the class. If a member function does not need to modify the nonstatic data members of the class, limit their access to data by declaring the member functions as `const` or `static`. Such declaration clearly expresses and enforces the design intent. That is, if you inadvertently attempt to modify a data member through a `const` member function, the compiler catches the error. Without the `const` declaration, this kind of inadvertent error might lead to bugs that are difficult to find or debug.

### Polyspace Implementation

The checker performs these checks in this order:

1. The checker first checks if a class member function accesses a data member of the class. Functions that do not access data members can be declared static.
2. The checker then checks functions that access data members to determine if the function modifies any of the data members. Functions that do not modify data members can be declared const.

A violation on a const member function means that the function does not even access a data member of the class and can be declared static.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Explicitly Restrict Access for Member Functions that Do Not Modify Data Members

```
#include<cstdint>
void Connector(void);
class A
{
public:
    int16_t foo ( ) // Noncompliant
    {
        return m_i;
    }
    int16_t foo2 ( ) // Noncompliant
    {
        Connector();// Might have side-effect
        return m_i;
    }
    int16_t foo3 ( ) // Noncompliant
    {
        return m_s;
    }
    int16_t inc_m ( ) // Compliant
    {
        return ++m_i;
    }
    int16_t& getref()//Noncompliant
    {
        return m_i_ref;
    }
private:
    int16_t m_i;
    static int16_t m_s;
    int16_t& m_i_ref;
};
```

In this example, Polyspace flags the functions `foo`, `foo2`, `foo3`, and `getref` as noncompliant.

- The functions `foo` and `foo3` do not modify any nonstatic data members. Because their data access is not explicitly restricted by declaring them as `const`, Polyspace flags these functions. To fix these defects, declare `foo` and `foo3` as `const`.
- The function `foo2` does not explicitly modify any of the data members. Because it is not declared as `const`, Polyspace flags the function. `foo2` calls the global function `Connector`, which might have side effects. Do not declare `foo2` as a `const` function. In C++11 or later, `const` member functions are expected to be thread-safe, but `foo2` might not be thread-safe because of the side effects of `Connector`. To avoid data races, keep `foo2` as a nonconst function. Justify the defect by using review information or code comments.
- The function `getref` does not modify any data members. Because it is not declared as `const`, Polyspace flags it. Declaring `getref` as `const` resolves this defect, but that is not enough to restrict write access of `getref` because it returns a nonconst reference to `m_i_ref`. To restrict `getref` from modifying `m_i_ref`, the return type of `getref` must also be `const`.

# MISRA C++:2008 Rule 9-5-1

Unions shall not be used

## Description

### Rule Definition

*Unions shall not be used.*

### Rationale

Using unions to store a value might result in misinterpretation of the value and lead to undefined behavior. For instance:

```
union Data{
    int i;
    double d;
};
void bar_int(int);
void bar_double(double);
void foo(void){
    Data var;
    var.d = 3.1416;
    bar_int(var.d);//Undefined Behavior
}
```

In the call to `bar_int`, the `double` data in the union is misinterpreted as an `int`, which is undefined behavior. Compilers might react to this misinterpretation differently depending on their implementation. To avoid undefined behaviors, do not use a `union`.

In some cases, use of unions might be necessary to increase efficiency. In such cases, use unions after documenting the relevant implementation-defined compiler behaviors. In the preceding case, before using a `union`, consult the manual of the compiler that you use and document how the compiler reacts to interpreting a `double` as an `int`.

### Polyspace Implementation

Polyspace flags the declaration of a `union`. You might consider the use of `union` necessary or acceptable in your code. In such cases, justify the violation by annotating the result or by using code comments. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using union

```
#include <iostream>

union Pi{ //Noncompliant
    int i;
    double d;
};

void foo(void){

    std::cout << std::endl;

    Pi pi;
    pi.d = 3.1416;// pi holds a double
    std::cout << "pi.d: " << pi.d << std::endl;
    std::cout << "pi.i: " << pi.i << std::endl;      // Undefined Behavior

    std::cout << std::endl;

    pi.i = 4;     // pi holds an int
    std::cout << "pi.i: " << pi.i << std::endl;
    std::cout << "pi.d: " << pi.d << std::endl;      // Undefined Behavior

    std::cout << std::endl;

}
```

In this example, the `union Pi` contains a `double` and an `int`. In the code, a `double` is misinterpreted as an `int` and vice versa by using the `union`. These misinterpretations are undefined behaviors and might lead to bugs and implementation dependent code behavior. Polyspace flags the `union` declaration.

# MISRA C++:2008 Rule 9-6-2

Bit-fields shall be either bool type or an explicitly unsigned or signed integral type

## Description

### Rule Definition

*Bit-fields shall be either bool type or an explicitly unsigned or signed integral type.*

### Rationale

Using bit-fields require that their underlying bit representations are not implementation-defined. For types other than `bool` and `signed` or `unsigned` integral types, the underlying bit representation is not explicitly known. For instance, the underlying representation of an `int` bit-field can be either signed or unsigned based on implementation. Similarly, ISO/IEC 14882:2003 does not explicitly define the signedness of the underlying bit representation of `wchar_t` types.

Using types other than `bool` and `signed` or `unsigned` integral types as bit fields might result in code that behaves in an implementation-dependent manner and result in bugs that are difficult to diagnose. When using bit fields, use `bool`, `signed` integral types, or `unsigned` integral types.

### Polyspace Implementation

Polyspace reports a violation of this rule if the type of a bit field is:

- An integral type that does not have an explicit sign specification
- A `wchar_t`

Polyspace does not report a violation if the type of a bit field is:

- A `bool`
- An explicitly signed or explicitly unsigned integral type
- An explicitly signed or unsigned `char`

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Specify Signedness of Types When Using Bit Fields

```
#include <cstdint>
struct S
{
    signed int sInt_f : 2; // Compliant
    unsigned int uInt_f : 2; // Compliant
    char Ch_f : 2; // Noncompliant
    signed char sCh_f : 2; // Compliant
    unsigned char uCh_f : 2; // Compliant
    short Sh_f : 2; // Noncompliant
    signed short sSh_f : 2; // Compliant
    unsigned short uSh_f : 2; // Compliant
    int Int_f : 2; // Noncompliant
    bool Bool_f : 2; // Compliant
    wchar_t wch_f : 2; // Noncompliant
    int32_t sInt32_f : 2; // Noncompliant
    int8_t sInt8_f : 2; // Compliant
    long Long_f:2; //Noncompliant
    unsigned long uLong_f:2; //Compliant
};
```

In this example, Polyspace flags the integral type bit fields that are not explicitly signed or unsigned and the `wchar_t` type bit fields.

# MISRA C++:2008 Rule 9-6-3

Bit-fields shall not have enum type

## Description

### Rule Definition

*Bit-fields shall not have enum type.*

### Rationale

Using bit fields requires that their underlying bit representations are not implementation-defined. The ISO/IEC 14882:2003 does not explicitly define the signedness of the underlying bit representation of `enum` types. Because the sign of an `enum` type depends on the implementation, the exact number of bits that is required to represent the values in the `enum` is implementation-defined.

To avoid code that behaves differently in different implementations and bugs that are difficult to diagnose, do not use `enum` types as bit fields.

### Polyspace Implementation

Polyspace reports a violation of this rule when you use `enum` types as bit fields.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using `enum` Types in Bit Fields

```
enum Spin {CW, CCW};
void foo(){
    struct DataStruct{
        Spin electron:2; //Noncompliant
    };
}
```

In this example, Polyspace flags the declaration of the object `electron` as a bit field because `electron` is a `enum` type.

Named bit-fields with signed integer type shall have a length of more than one bit

## Description

### Rule Definition

*Named bit-fields with signed integer type shall have a length of more than one bit.*

### Rationale

Variables with signed integer bit-field types of length one might have values that do not meet developer expectations. For instance, signed integer types of fixed width such as `std::int16_t` (from `cstdint`) have a two's complement representation. In this representation, a single bit is just the sign bit and the value might be 0 or -1.

### Polyspace Implementation

The checker flags declarations of named variables having signed integer bit field types of length equal to one.

Bit field types of length zero are not flagged.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Compliant and Noncompliant Bit-Field Types

```
#include <cstdint>

typedef struct
{
   std::uint16_t IOFlag :1;    //Compliant - unsigned type
   std::int16_t InterruptFlag :1; //Noncompliant
   std::int16_t Register1Flag :2; //Compliant - Length more than one bit
   std::int16_t : 1; //Compliant - Unnamed
   std::int16_t : 0; //Compliant - Unnamed
   std::uint16_t SetupFlag :1; //Compliant - unsigned type
} InterruptConfigbits_t;
```

In this example, only the second bit-field declaration is noncompliant. A named variable is declared with a signed type of length one bit.

Classes should not be derived from virtual bases

## Description

### Rule Definition

*Classes should not be derived from virtual bases.*

### Rationale

The use of virtual bases can lead to many confusing behaviors.

For instance, in an inheritance hierarchy involving a virtual base, the most derived class calls the constructor of the virtual base. Intermediate calls to the virtual base constructor are ignored.

### Polyspace Implementation

Polyspace raises a violation if a class is derived from a `virtual` base class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of Virtual Bases

```
class Base {};
class Intermediate: public virtual Base {}; //Noncompliant
class Final: public Intermediate {};
```

In this example, the rule checker raises a violation when the `Intermediate` class is derived from the class `Base` with the `virtual` keyword.

The following behavior can be a potential source of confusion. When you create an object of type `Final`, the constructor of `Final` directly calls the constructor of `Base`. Any call to the `Base` constructor from the `Intermediate` constructor are ignored. You might see unexpected results if you do not take into account this behavior.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 10-1-2

A base class shall only be declared virtual if it is used in a diamond hierarchy

## Description

### Rule Definition

*A base class shall only be declared virtual if it is used in a diamond hierarchy.*

### Rationale

This rule is less restrictive than `MISRA C++:2008 Rule 10-1-1`. Rule 10-1-1 forbids the use of a virtual base anywhere in your code because a virtual base can lead to potentially confusing behavior.

Rule 10-1-2 allows the use of virtual bases in the one situation where they are useful, that is, as a common base class in diamond hierarchies.

For instance, the following diamond hierarchy violates rule 10-1-1 but not rule 10-1-2.

```
class Base {};
class Intermediate1: public virtual Base {};
class Intermediate2: public virtual Base {};
class Final: public Intermediate1, public Intermediate2 {};
```

### Polyspace Implementation

Polyspace flags a class if the class is used as a virtual base in a single and linear hierarchy. In such a hierarchy, `virtual` bases are unnecessary.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using `virtual` Base Classes in Linear Hierarchy

In this example, the classes `B` and `C` in the linear hierarchy `A->B->C` uses virtual base classes. In this hierarchy, using virtual base classes is unnecessary and might cause confusion. Polyspace raises a violation. The class hierarchy `alpha->...->omega` is a diamond hierarchy and in this case, the use of virtual base classes is necessary. Polyspace does not flag this class hierarchy.

```
class A{};
class B: public virtual A{};
class C: public virtual B{}; //Noncompliant

class alpha{};

class beta: public virtual alpha{};
class gamma: public virtual alpha{};
class omega: public beta, public gamma{}; //Compliant
```

# MISRA C++:2008 Rule 10-1-3

An accessible base class shall not be both virtual and non-virtual in the same hierarchy

## Description

### Rule Definition

*An accessible base class shall not be both virtual and non-virtual in the same hierarchy.*

### Rationale

The checker flags situations where the same class is inherited as a virtual base class and a non-virtual base class in the same derived class. These situations defeat the purpose of virtual inheritance and causes multiple copies of the base class sub-object in the derived class object.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Base Class Both Virtual and Non-Virtual in Same Hierarchy

```
class Base {};
class Intermediate1: virtual public Base {};
class Intermediate2: virtual public Base {};
class Intermediate3: public Base {};
class Final: public Intermediate1, Intermediate2, Intermediate3 {}; //Noncompliant
```

In this example, the class `Base` is inherited in `Final` both as a virtual and non-virtual base class. The `Final` object contains at least two copies of a `Base` sub-object.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 10-2-1

All accessible entity names within a multiple inheritance hierarchy should be unique

## Description

### Rule Definition

*All accessible entity names within a multiple inheritance hierarchy should be unique.*

### Rationale

Data members and nonvirtual functions within the same inheritance hierarchy that have the same name might cause developer confusion. The entity the developer intended for use might not be the entity the compiler chooses. Avoid using nonunique names for accessible entities within a multiple inheritance hierarchy.

### Polyspace Implementation

This checker flags entities from separate classes that belong to the same derived class if they have an ambiguous name. The name of an entity is ambiguous if:

- Two variables share the same name, even if they are of different types.
- Two functions share the same name, same parameters, and the same return type.

If the data member accessed in the derived class is ambiguous, Polyspace reports this issue as a compilation issue, not a coding rule violation. The checker does not check for conflicts between entities of different kinds such as member functions against data members.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant Data Members in a Multiple Inheritance Hierarchy

```
#include<iostream>
#include<cstdlib>
#include<cstdint>

using namespace std;

class A
{
public:
    int32_t num;
    int32_t total;
    int32_t sum(int32_t toSum)
    {
        total = toSum + num;
    };
};

class B
{
public:
    int32_t num;
    int32_t total();
    int32_t sum(int32_t toSum)
    {
        num = toSum + num;
    };
};

class C : public A, public B        //Noncompliant
{
public:
    void foo()
    {
        num = total;
        sum(num);
    }
};
```

- Because `class A` and `class B` define their own local variable `int32_t num`, and because `class C` is a multiple inheritance hierarchy containing `class A` and `class B`, Polyspace flags both `int32_t num` variables as noncompliant.
- Because `int32_t sum()` in `class A` and `int32_t sum()` in `class B` share the same name, return type, arguments, and are members of the same multiple inheritance hierarchy, both functions are flagged by Polyspace as noncompliant.
- Because `int32_t total` and `int_32t total()` are different types of class members, Polyspace does not flag them even though they are part of the same multiple inheritance hierarchy.

The ambiguous data members might be reported as compilation issues.

### Nonunique Entity Names When Classes Derive From Templates

Because templates generate code, a class hierarchy deriving from a template might have nonunique names. In this example, the classes `Deriv1` and `Deriv2` derives from two separate instances of the template `myObj`. Then, the class `FinalDerived` derives from both `Deriv1` and `Deriv2`. The template `myObj` generates two version of the function `get()` in the `FinalDerived` class: one from the `myObj<int>` instance and one from the `myObj<short>` instance. The nonunique name might result in unexpected behavior. Polyspace reports a violation

```
template <typename T>
class myObj {
    //...
public:
    void get(void);
};

class Deriv1: public myObj<int> {
public:
    //...
};
```

```
class Deriv2: public myObj<short> {
public:
    //...
};

class FinalDerived: public Deriv1, public Deriv2 { //Noncompliant

public:
    //...
};
```

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 10-3-1

There shall be no more than one definition of each virtual function on each path through the inheritance hierarchy

## Description

### Rule Definition

*There shall be no more than one definition of each virtual function on each path through the inheritance hierarchy.*

### Rationale

The checker flags virtual member functions that have multiple definitions on the same path in an inheritance hierarchy. If a function is defined multiple times, it can be ambiguous which implementation is used in a given function call.

### Polyspace Implementation

The checker also raises a violation if a base class member function is redefined in the derived class without the `virtual` keyword.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Virtual Function Redefined in Derived Class

```
class Base {
    public:
      virtual void foo() {
     }
};

class Intermediate1: public virtual Base {
    public:
      virtual void foo() { //Noncompliant
      }
};

class Intermediate2: public virtual Base {
    public:
       void bar() {
          foo();  // Calls Base::foo()
      }
};

class Final: public Intermediate1, public Intermediate2 {
};
```

```
void main() {
    Intermediate2 intermediate2Obj;
    intermediate2Obj.bar(); // Calls Base::foo()
    Final finalObj;
    finalObj.bar(); //Calls Intermediate1::foo()
                    //but you might expect Base::foo()
}
```

In this example, the `virtual` function `foo` is defined in the base class `Base` and also in the derived class `Intermediate1`.

A potential source of confusion can be the following. The class `Final` derives from `Intermediate1` and also derives from `Base` through another path using `Intermediate2`.

- When an `Intermediate2` object calls the function `bar` that calls the function `foo`, the implementation of `foo` in `Base` is called. An `Intermediate2` object does not know of the implementation in `Intermediate1`.
- However, when a `Final` object calls the same function `bar` that calls the function `foo`, the implementation of `foo` in `Intermediate1` is called because of dominance of the more derived class.

You might see unexpected results if you do not take this behavior into account.

To prevent this issue, declare a function as pure virtual in the base class. For instance, you can declare the class `Base` as follows:

```
class Base {
    public:
      virtual void foo()=0;
};

void Base::foo() {
      //You can still define Base::foo()
}
```

# MISRA C++:2008 Rule 10-3-3

A virtual function shall only be overridden by a pure virtual function if it is itself declared as pure virtual

## Description

### Rule Definition

*A virtual function shall only be overridden by a pure virtual function if it is itself declared as pure virtual.*

### Rationale

In C++, an abstract class is the base of a polymorphic class hierarchy and the derived classes implement variation of the abstract class. When a virtual function is overridden in a derived class by a pure virtual function, the derived class becomes an abstract class. That a derived class is defined as an abstract class or an implemented function is overridden by a pure virtual function is unexpected behavior, which might confuse a developer.

### Polyspace Implementation

Polyspace flags a pure virtual function if it overrides a function that is not pure virtual.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Redeclare Functions as Pure Virtual

```
class Conic{
    //...
    public:
    double centerAbscissa;
    double centerOrdinate;
    //..
    virtual double  getArea()=0;
};
class Circle: public Conic{
    //...
    public:
    //...
    double getArea() override{
        //calculate area of circle
    }
};
class Ellipse: public Circle{
    //...
    public:
    //...
    virtual double getArea()=0; //Noncompliant
};
```

In this example, the base class `Conic` is an abstract class because the function `getArea()` is a pure virtual function. The derived class `Circle` implements the function `getArea`. The expectation from such a polymorphic hierarchy is that the virtual function `getArea` calculates the area correctly based on the derived class. When the derived class `Ellipse` redeclares `getArea` as a pure virtual function, the derived class `Ellipse` becomes abstract and the function `Ellipse.getArea()` cannot be invoked. Developers might expect `Ellipse.getArea()` to return the area of the ellipse. Because this redeclaration as a pure virtual function does not meet developer expectation, Polyspace flags the declaration.

# MISRA C++:2008 Rule 11-0-1

Member data in non- POD class types shall be private

## Description

### Rule Definition

*Member data in non- POD class types shall be private.*

### Rationale

If classes have data members that are publicly accessible, other classes and functions might interact with the class data members directly. Any change in the class might require updating the clients that use the class. If a class is not a plain-old-data (POD) type, restricting access to its data members enables encapsulation of the class. In such an encapsulated class, the implementation details of the class are opaque to the clients that use it. The class retains control over its implementation and can be maintained independently without impacting the clients that use the class.

### Polyspace Implementation

Polyspace flags nonprivate data members in classes that are not POD types. Polyspace space uses the same definition of POD classes as the standard.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declare Data Members in Non-POD Classes as `private`

```
class nonPOD{
    nonPOD(){
        //...
    }
    ~nonPOD(){
        //...
    }
    public:
    int getX();
    int setX(int&);
    int getY();
    int setY(int&);
    int getZ();
    int setZ(int&);
    int x; //Noncompliant
    protected:
    int y; //Noncompliant
    private:
    int z;
};
```

In this example, the data members `y` and `z` are not `private`. Polyspace flags them.

# MISRA C++:2008 Rule 12-1-1

An object's dynamic type shall not be used from the body of its constructor or destructor

## Description

### Rule Definition

*An object's dynamic type shall not be used from the body of its constructor or destructor.*

### Rationale

The dynamic type of an object is the type of its most derived class. For instance:

```
struct B {
    virtual ~B() {}
};
struct D: B {};
D d;
B* ptr = &d;
```

The dynamic type of the object pointed to by `*ptr` is `D` because that is the most derived class in the polymorphic hierarchy.

When you invoke the dynamic type of a polymorphic object in its constructor or destructor, you might get the type of the constructed or destroyed object instead of the type of the most derived object. This is because when you invoke the dynamic type during construction or destructor, the derived classes might not be constructed yet. Using dynamic types in constructors and destructors might result in unexpected behavior. Calling pure virtual functions from constructors and destructors results in undefined behavior. Avoid using the dynamic type of an object in its constructors or destructors.

### Polyspace Implementation

Polyspace flags these items when they are used in a constructor or a destructor of a polymorphic class:

- The operator `typeid`
- Virtual or pure virtual functions
- The function `dynamic_cast` or implicit C-style casts

Polyspace assumes that a class is polymorphic if it has any virtual member.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Dynamic Type in Constructors and Destructors

```
#include <cassert>
#include <typeinfo>
```

```
class PS
{
public:
    PS ( )
    {
        typeid ( PS );                // Compliant
    }
};

class PS_1
{
public:
    virtual ~PS_1 ( );
    virtual void bar ( );
    PS_1 ( )
    {
        typeid ( PS_1 );                // Noncompliant
        PS_1::bar ( );                  // Compliant
        bar ( );                      // Noncompliant
        dynamic_cast< PS_1* > ( this ); // Noncompliant
    }
};
```

In this example, class PS has no virtual member. Polyspace does not consider PS a polymorphic class. Because PS is not polymorphic, its dynamic type does not change at run time. Polyspace does not flag using the `typeid` operator in the constructor `PS::PS()`.

`PS_1` is considered polymorphic because it has a `virtual` member function. Because it is polymorphic, its dynamic type changes during run time. Polyspace flags the invocation of its dynamic type in the constructor `PS_1::PS_1()`.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 12-1-2

All constructors of a class should explicitly call a constructor for all of its immediate base classes and all virtual base classes

## Description

### Rule Definition

*All constructors of a class should explicitly call a constructor for all of its immediate base classes and all virtual base classes.*

### Rationale

Derived classes that do not explicitly call all base class constructors create ambiguity over which base constructor is used during object construction.

Consider this diamond class hierarchy.

```
            SuperClass
              /    \
       ClassA      ClassB
              \    /
              ClassC
```

When constructing a `ClassC` object, it is unclear whether `ClassA` or `ClassB` is responsible for initializing the `SuperClass`. If the `SuperClass` is constructed with unintended initial values, then the risk of unexpected code behavior increases. Having `ClassC` explicitly specify the constructor used to initialize the `SuperClass` resolves the diamond ambiguity.

To avoid invalid state and unintended initial values, directly call the necessary base class constructors in the derived class constructor initialization list.

### Polyspace Implementation

Polyspace flags the constructor of a derived class if its initialization list:

- Does not explicitly call the constructors of the virtual base classes.
- Does not explicitly call the constructors of the direct nonvirtual base classes.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Class Construction When Using Multiple Inheritance

```
#include <cstdint>

class A {
public:
    A() : a{1} {}
    virtual void abstractA() const = 0;
private:
    int a;
};

class B : public  A {
public:
    B() : b{1} {} //Noncompliant
    void abstractA() const override {}
private:
    int b;
};

class C {
public:
    C() : c{3} {}
private:
    int c;
};

class D : public B, public C {
public:
    D() : B(), C(), e{5} {} //Compliant
private:
    int e;
};

int main() {
    D dName;
    return 0;
}
```

In this example, Polyspace flags the class constructors that do not explicitly initialize the base classes and nonstatic data members. For instance:

- The B class constructor is noncompliant because it is missing an explicit initialization of its base class A. To resolve this issue, call the A class constructor in the B constructor initialization list.
- The D class constructor is compliant because it explicitly initializes both of its direct nonvirtual base classes through initialization list constructor calls.

### Class Construction When Using Multiple and Virtual Inheritance

```
#include <cstdint>

class A {
public:
    A() : a{1} {}
    virtual void abstractA() const = 0;
private:
    int a;
};

class B : public virtual A {
public:
    B() : A(), b{1} {} //Compliant
    void abstractA() const override {}
private:
    int b;
};

class C : public virtual A {
public:
    C() : c{3} {} //Noncompliant
    void abstractA() const override {}
private:
    int c;
};

class D : public B, public C {
public:
    D() : B(), C(), e{5} {} //Noncompliant
private:
    int e;
};

int main() {
    D dName;
    return 0;
}
```

In this example, Polyspace flags the class constructors that do not explicitly initialize the base classes and nonstatic data members. For instance:

- The B class constructor is compliant because it explicitly initializes its direct base class within its initialization list.
- The C class constructor is noncompliant because it does not explicitly call its direct base class A. To resolve this issue, call the A class constructor in the C constructor initialization list.
- The D class constructor is noncompliant because it does not explicitly call its virtual base class A. As a result of multiple and virtual inheritance, the most derived class must initialize the virtual base class. To resolve this issue, call the A class constructor in the D constructor initialization list.

# MISRA C++:2008 Rule 14-5-1

A non-member generic function shall only be declared in a namespace that is not an associated namespace

## Description

### Rule Definition

*A non-member generic function shall only be declared in a namespace that is not an associated namespace.*

### Rationale

This rule forbids placing generic functions in the same namespace as class (struct) type, enum type, or union type declarations. If the class, enum or union types are used as template parameters, the presence of generic functions in the same namespace can cause unexpected call resolutions. Place generic functions only in namespaces that cannot be associated with a class, enum or union type.

Consider the namespace `NS` that combines a class `B` and a generic form of `operator==`:

```
namespace NS {
   class B {};
   template <typename T> bool operator==(T, std::int32_t);
}
```

If you use class `B` as a template parameter for another generic class, such as this template class `A`:

```
template <typename T> class A {
    public:
      bool operator==(std::int64_t);
}

template class A<NS::B>;
```

the entire namespace `NS` is used for overload resolution when operators of class `A` are called. For instance, if you call `operator==` with an `int32_t` argument, the generic `operator==` in the namespace `NS` with an `int32_t` parameter is used instead of the `operator==` in the original template class `A` with an `int64_t` parameter. You or another developer or code reviewer might expect the operator call to resolve to the `operator==` in the original template class `A`.

### Polyspace Implementation

For each generic function, the rule checker determines if the containing namespace also contains declarations of class types, enum types, or union types. If such a declaration is found, the checker flags a rule violation on the operator itself.

The checker also flags generic functions defined in the global namespace if the global namespace also has class, enum or union declarations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Generic Operator in Same Namespace as Class Type

```
#include <cstdint>

template <typename T> class Pair {
    std::int32_t item1;
    std::int32_t item2;
    public:
      bool operator==(std::int64_t ItemToCompare);
      bool areItemsEqual(std::int32_t itemValue) {
          return (*this == itemValue);
      }
};

namespace Operations {
    class Data {};
    template <typename T> bool operator==(T, std::int32_t); //Noncompliant
}

namespace Checks {
    bool checkConsistency();
    template <typename T> bool operator==(T, std::int32_t); //Compliant
}

template class Pair<Operations::Data>;
```

In this example, the namespace Operations violates the rule because it contains the class type Data alongside the generic operator==. The namespace Checks does not violate the rule because the only other declaration in the namespace, besides the generic operator==, is a function declaration.

In the method areItemsEqual in template class Pair<Operations::Data>, the == operation invokes the generic operator== method in the Operations namespace. The invocation resolves to this operator== method based on the argument data type (std_int32_t). This method is a better match compared to the operator== method in the original template class Pair.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 14-5-3

A copy assignment operator shall be declared when there is a template assignment operator with a parameter that is a generic parameter

## Description

### Rule Definition

*A copy assignment operator shall be declared when there is a template assignment operator with a parameter that is a generic parameter.*

### Rationale

When declaring a user-defined assignment operator, the corresponding implicit operator is suppressed. When declaring a template assignment operator that has a generic parameter, this behavior is not preserved. In that case, to suppress the implicit shallow-copying operator, explicitly instantiate a version of the copy assignment operator for the class.

If you do not declare the copy assignment operator for the class, the compiler-generated copy assignment operator might be used instead on implementation. Not declaring a copy assignment operator explicitly might result in an unexpected outcome, such as creating a shallow copy when a deep copy was intended.

### Polyspace Implementation

Polyspace flags this checker if a structure, class, or union contains a template assignment operator that has a generic parameter but no copy assignment operator is present within the structure, class, or union.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant Template Assignment Operator That Has Generic Parameter

```
#include<cstdint>
namespace example
{
  class A  //Noncompliant
  {
    public:

      template <typename T>
      T & operator= ( T const & rhs )
      {
        if ( this != &rhs ) {
          delete i;
          i = new int32_t;
          *i = *rhs.i;
        }
        return *this;
      }
    private:
      int32_t * i;      // Member requires deep copy
  };

  void f ( A const & a1, A & a2 )
  {
    a2 = a1;
  }
};
```

Because no copy assignment operator is declared within the class, Polyspace flags `class A`. The implicitly defined copy assignment operator is not suppressed by the template assignment operator and results in a shallow copy of a1 to a2 when you might want a deep copy.

### Template Assignment Operator That Has a Generic Parameter and Copy Assignment Operator Declared

```
#include<cstdint>
namespace example
{
  class A//Compliant
  {
    public:
      A & operator= (A const & rhs) {};

      template <typename T>
      T & operator= ( T const & rhs )
      {
        if ( this != &rhs ) {
          delete i;
          i = new int32_t;
          *i = *rhs.i;
        }
        return *this;
      }
    private:
      int32_t * i;
  };

  void f ( A const & a1, A & a2 )
  {
    a2 = a1;
  }
};
```

Because this class contains a copy assignment operation declaration, Polyspace does not flag `class A`.

# MISRA C++:2008 Rule 14-6-1

In a class template with a dependent base, any name that may be found in that dependent base shall be referred to using a qualified-id or this->

## Description

### Rule Definition

*In a class template with a dependent base, any name that may be found in that dependent base shall be referred to using a qualified-id or this->*

### Rationale

When a class template derives from another class template, there might be confusion arising from the use of names that exist in both the base template and the current scope or namespace. When the same name exists in the base class template and a namespace that contains the classes, the scope resolution of these names is dependent on the compiler, which might be contrary to developer's expectation. To avoid confusion, use fully qualified id or `this->` to explicitly disambiguate the intended object when such a name conflict exists.

### Polyspace Implementation

Polyspace flags names for which all of these conditions are true:

- The name exists in the base class.
- The name exists in a namespace that contains the base class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use Fully Qualified Names in Class Templates That Have Dependent Base Classes

```
typedef signed   int          int32_t;
namespace NS0{
    typedef int32_t TYPE;

    void bar( );
    namespace NS1{
        namespace NS{

            template <typename T>
            class Base;
            template <typename T>
            class Derived : public Base<T>
            {
                void foo ( )
                {
                    TYPE t = 0;                           // Noncompliant
                    bar ( );                                // Noncompliant
                }
                void foo2 ( )
                {
                    NS0::TYPE t1 = 0;                      // Compliant
                    NS0::bar ( );                            // Compliant
                    typename Base<T>::TYPE t2 = 0; // Compliant
                    this->bar ( );                // Compliant
                }
            };
            template <typename T>
            class Base
            {
            public:
                typedef T TYPE;
                void bar ( );
            };
            template class Derived<int32_t>;
        }
    }
}
```

In this example, the names `Type` and `bar` are defined both in the namespace `NS0` and within the class template `Base`. The class template `Derived` derives from `Base`. In `Derived::foo1()`, these names are used without using the fully qualified names or `this->`. It is not clear whether the `TYPE` in `Base::foo1` resolves to `NS0::TYPE` or `Base::TYPE`. You might get different results depending on the implementation of the compiler. Polyspace flags these ambiguous statements.

In `Derived::foo2()`, `TYPE` and `bar` are invoked by using their fully qualified name or `this->`. By using qualified names or `this->`, the ambiguity in scope resolution is bypassed. Polyspace does not flag these uses.

# MISRA C++:2008 Rule 14-6-2

The function chosen by overload resolution shall resolve to a function declared previously in the translation unit

## Description

### Rule Definition

*The function chosen by overload resolution shall resolve to a function declared previously in the translation unit.*

### Rationale

In general, you cannot call a function before it is declared, so you expect a function call to resolve to a previously declared function. However, in case of overload resolution of a function call inside a template, this expectation might not be satisfied. The resolution of this overload occurs at the point of template instantiation, not at the point of template definition. So, the call might resolve to a function that is declared *after* the template definition and lead to unexpected results. See examples below.

To satisfy the expectation that a function call *always* resolves to a previously declared function, declare the overloads of a function prior to calling it. Alternatively, use the scope resolution operator `::` or parenthesis to explicitly call a specific previously declared function and bypass the overload resolution mechanism.

### Polyspace Implementation

The checker flags a call to a function or operator in a function template definition if the function or operator is declared *after* the template definition.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function Call Resolves to Function Declared Later

```
void show (int);

namespace helpers {
    struct params {
        operator int () const;
    };
}

template <typename T> void displayParams(T const & arg) {
    show(arg);    //Non-compliant
    ::show(arg);  //Compliant
    (show)(arg);  //Compliant
}
```

```
namespace helpers {
    void show (params const &);
}

void main() {
    helpers::params aParam;
    displayParams(aParam);
}
```

In this example, the call `show(arg)` in the template `displayParams` resolves to `helpers::show()`, but a developer or code reviewer might not expect this call resolution, since `helpers::show()` is declared later. Polyspace flags this call.

The calls `::show(arg)` and `(show)(arg)` explicitly indicate the previously declared function `show()` declared in the global namespace. Polyspace does not flag these calls.

Overloaded function templates shall not be explicitly specialized

## Description

### Rule Definition

*Overloaded function templates shall not be explicitly specialized.*

### Polyspace Implementation

The checker first checks within file scope to find overloads. The checker later looks for call to a specialized template function later. As a result, the checker flags all specializations of overloaded templates even if overloading occurs after the call.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 15-0-3

Control shall not be transferred into a try or catch block using a goto or a switch statement

## Description

### Rule Definition

*Control shall not be transferred into a try or catch block using a goto or a switch statement.*

### Rationale

Transferring control into a `try` or `catch` block by using a `goto` or a `switch` statement results in ill-formed code that is difficult to understand. The intended behavior of such code is difficult to identify and the code might result in unexpected behavior. Abruptly entering into an exception handling block might cause compilation failure in some compilers while other compilers might not diagnose the issue. To improve code understanding and reduce unexpected behavior, avoid transferring control into a try or a catch block.

### Polyspace Implementation

Polyspace flags the `goto` and `switch` statements that jump into a `try` or a `catch` block.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Jumping into `try` or `catch` Blocks

```
#include<cstdint>
void foo ( int32_t input )
{
    if ( input==1 )
    {
        goto Label_1; // Noncompliant
    }
    if ( input==2 )
    {
        goto Label_2; // Noncompliant
    }
    switch ( input ) //Noncompliant
    {
    case 1:
        try
        {
            Label_1:
        case 2:
            break;
        }
        catch ( ... )
        {
            Label_2:
        case 3:
            break;
        }
        break;
    default:
        {
            //...
            break;
        }
    }
}
```

In this example, `goto` and `switch` statements are used to jump into a `try-catch` block. Jumping into a try-catch block makes the code difficult to understand. Abrupt transfer of control into a `try` block or a `catch` block might result in compilation failure. Polyspace flags the `goto` and `switch` statements.

# MISRA C++:2008 Rule 15-1-1

The assignment-expression of a throw statement shall not itself cause an exception to be thrown

## Description

### Rule Definition

*The assignment-expression of a throw statement shall not itself cause an exception to be thrown.*

### Rationale

In C++, you can use a `throw` statement to raise exceptions explicitly. The compiler executes such a `throw` statement in two steps:

- First, it creates the argument for the `throw` statement. The compiler might call a constructor or evaluate an assignment expression to create the argument object.
- Then, it raises the created object as an exception. The compiler tries to match the exception object to a compatible handler.

If an unexpected exception is raised when the compiler is creating the expected exception in a `throw` statement, the unexpected exception is raised instead of the expected one. Consider this code where a `throw` statement raises an explicit exception of class `myException`.

```
class myException{
    myException(){
        msg = new char[10];
        //...
    }
    //...
};

foo(){
    try{
        //..
        throw myException();
    }
    catch(myException& e){
        //...
    }
}
```

During construction of the temporary `myException` object, the `new` operator can raise a `bad_alloc` exception. In such a case, the `throw` statement raises a `bad_alloc` exception instead of `myException`. Because `myException` was the expected exception, the catch block is incompatible with `bad_alloc`. The `bad_alloc` exception becomes an unhandled exception. It might cause the program to abort abnormally without unwinding the stack, leading to resource leak and security vulnerabilities.

Unexpected exceptions arising from the argument of a `throw` statement can cause resource leaks and security vulnerabilities. To prevent such unwanted outcome, avoid using expressions that might raise exceptions as argument in a `throw` statement.

### Polyspace Implementation

Polyspace flags the expressions in `throw` statements that can raise an exception. Expressions that can raise exceptions can include:

- Functions that are specified as `noexcept(false)`
- Functions that contain one or more explicit `throw` statements
- Constructors that perform memory allocation operations
- Expressions that involve dynamic casting

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Expressions That Can Raise Exceptions in `throw` Statements

This example shows how Polyspace flags the expressions in `throw` statements that can raise unexpected exceptions.

```
int f_throw() noexcept(false);

class WithDynamicAlloc {
public:
    WithDynamicAlloc(int n) {
        m_data = new int[n];
    }
    ~WithDynamicAlloc() {
        delete[] m_data;
    }
private:
    int* m_data;
};

class MightThrow {
public:
    MightThrow(bool b) {
        if (b) {
            throw 42;
        }
    }
};

class Base {
    virtual void bar() =0;
};
class Derived: public Base {
    void bar();
};
class UsingDerived {
public:
    UsingDerived(const Base& b) {
        m_d =
        dynamic_cast<const Derived&>(b);
    }
private:
    Derived m_d;
};
class CopyThrows {
public:
    CopyThrows() noexcept(true);
    CopyThrows(const CopyThrows& other) noexcept(false);
};
int foo(){
    try{
        //...
        throw WithDynamicAlloc(10); //Noncompliant
        //...
        throw MightThrow(false);//Noncompliant
        throw MightThrow(true);//Noncompliant
        //...
        Derived d;
        throw  UsingDerived(d);// Noncompliant
        //...
        throw f_throw(); //Noncompliant
        CopyThrows except;
        throw except;//Noncompliant
    }
    catch(WithDynamicAlloc& e){
        //...
    }
    catch(MightThrow& e){
        //...
    }
    catch(UsingDerived& e){
        //...
    }
}
```

- When constructing a `WithDyamicAlloc` object by calling the constructor `WithDynamicAlloc(10)`, exceptions can be raised during dynamic memory allocation. Because the expression `WithDynamicAlloc(10)` can raise an exception, Polyspace flags the `throw` statement `throw WithDynamicAlloc(10);`
- When constructing a `UsingDerived` object by calling the constructor `UsingDervide()`, exceptions can be raised during the dynamic casting operation. Because the expression `UsingDerived(d)` can raise exceptions, Polyspace flags the statement `throw UsingDerived(d)`.
- In the function `MightThrow()`, exceptions can be raised depending on the input to the function. Because Polyspace analyzes functions statically, it assumes that the function `MightThrow()` can raise exceptions. Polyspace flags the statements `throw MightThrow(false)` and `throw MightThrow(true)`.
- In the statement `throw except`, the object `except` is copied by implicitly calling the copy constructor of the class `CopyThrows`. Because the copy constructor is specified as `noexcept(false)`, Polyspace assumes that the copy operation might raise exceptions. Polyspace flags the statement `throw except`
- Because the function `f_throw()` is specified as `noexcept(false)`, Polyspace assumes that it can raise exceptions. Polyspace flags the statement `throw f_throw()`.

# MISRA C++:2008 Rule 15-1-2

NULL shall not be thrown explicitly

## Description

### Rule Definition

*NULL shall not be thrown explicitly.*

### Rationale

The macro NULL is commonly used to refer to null pointers. Compliers interpret NULL as an integer with value zero, instead of a pointer. When you use NULL explicitly in a throw statement, you might expect the statement to raise a pointer type exception. The throw(NULL) is equivalent to throw(0) and raises an integer exception. This behavior might be contrary to developer expectation and might result in bugs that are difficult to find. Avoid using NULL explicitly in a throw statement.

### Polyspace Implementation

Polyspace flags a throw statement that raises a NULL explicitly. Polyspace does not flag the statement when NULL is raised after casting to a specific type or assigning it to a pointer type.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Do Not Throw NULL Explicitly

```
typedef          char        char_t;
typedef signed   int         int32_t;

#include <cstddef>

void foo()
{
    try {
        char_t * p1 = NULL;
        throw ( NULL );            // Noncompliant
        throw(p1); //Compliant
        throw ( static_cast < const char_t * > ( NULL ) ); // Compliant
    } catch ( int32_t i ) {        // NULL exception handled here
        // /*...*/
    } catch ( const char_t * ) { // Other two exceptions are handled here
        // /*...*/
    }
}
```

In this example, three exceptions are raised directly by using throw statements.

- Polyspace flags the statement throw(NULL) because it explicitly raises NULL as exception. You might expect that this statement raises a pointer type exception that is handled in the second catch block. This statement actually raises an int exception that is handled in the first catch block.
- The other throw statements show the compliant method of using NULL in a throw statement. For instance, the second throw statement raises a char* that is assigned the value NULL. The third throw statement raises a char* by casting NULL to a char*. Because these statements do not raise NULL explicitly, Polyspace does not flag them.

# MISRA C++:2008 Rule 15-1-3

An empty throw (throw;) shall only be used in the compound- statement of a catch handler

## Description

### Rule Definition

*An empty throw (throw;) shall only be used in the compound- statement of a catch handler.*

### Rationale

When you use an empty throw statement `(throw;)`, the compiler checks if an exception object is present in the current scope. If the current scope contains an exception object, the compiler raises a temporary object containing the current exception. If the current scope does not contain an exception objects, the compiler invokes `std::terminate()` implicitly. The function `std::terminate()` terminates the program execution in an implementation-defined manner. That is, the exact process of program termination depends on the software and hardware that you are using. For instance, `std:terminate()` might invoke `std::abort()` to abnormally abort the execution without unwinding the stack, leading to resource leak and security vulnerabilities.

The best practice is to use an empty throw statement only in the `catch` block of a `try-catch` construct, which enables you to spread the handling of an exception across multiple catch blocks. Avoid using empty throw statements in scopes that might not contain an exception.

### Polyspace Implementation

Polyspace flags an empty throw statement if it is not within a catch block.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Empty `throw` Statements Outside `catch` Blocks

```
#include <iostream>
#include <typeinfo>
#include <exception>

void handleException()//function to handle all exception
{
    try {
        throw; // Noncompliant
    }
    catch (std::bad_cast& e) {
        //...Handle bad_cast...
    }
    catch (std::bad_alloc& e) {
        //...Handle bad_alloc...
    }
    catch(...){
        //...Handle other exceptions
    }
}

void f()
{
    try {
        //...something that might throw...
    }
    catch (...) {
        handleException();
    }
}
```

In this example, the function `handleException()` raises the current exception by using an empty throw statement, and then directs it to the appropriate `catch` block. This method of delegating the exception handling works as intended only when the function `handleException()` is called from within a `catch` block. The empty throw statement might cause abrupt termination of the program if the function is called in any other scope that does not contain an exception. Polyspace flags the empty throw statement.

#### Use Empty `throw` Statement to Handle Exceptions in Multiple Blocks

```
#include <iostream>
#include <typeinfo>
#include <exception>
void foo()//function to handle all exception
{
    try {
        //...
    }
    catch (std::bad_cast& e) {
        //...Handle bad_cast...
    }
    catch (std::bad_alloc& e) {
        //...Handle bad_alloc...
    }
    catch(std::exception& e){
        //...Handle std::exceptions
        // if exception cannot be handled
        // throw it again
        throw;//Compliant
    }
}

int main(){
    try{
        foo();
    }
    catch(...){

    }
}
```

This example shows a compliant use of an empty throw statement. The function `foo` contains a `try-catch` construct that handles specific exceptions. If the raised exception cannot be handled, `foo` raises the exception again as an unhandled exception by using an empty throw statement. In `main`, the function `foo` is invoked and any unhandled exception arising from `foo` is handled in a generic `catch(...)` block. By using the empty throw statement, the handling of the exception is spread across the catch blocks of `foo` and `main`. In this case, the empty throw statement is executed only when there is an exception in the same scope because it is within a `catch` block. Polyspace does not flag it.

# MISRA C++:2008 Rule 15-3-1

Exceptions shall be raised only after start-up and before termination of the program

## Description

### Rule Definition

*Exceptions shall be raised only after start-up and before termination of the program.*

### Rationale

In c++, the process of exception handling runs during execution of `main()`, where exceptions arising in different scopes are handled by exception handlers in the same or adjacent scopes. Before starting the execution of `main()`, the compiler is in startup phase, and after finishing the execution of `main()`, the compiler is in termination phase. During these two phases, the compiler performs a set of predefined operations but does not execute any code.

If an exception is raised during either the startup phase or the termination phase, you cannot write an exception handler that the compiler can execute in those phases. For instance, you might implement `main()` as a `function-try-catch` block to handle exceptions. The `catch` blocks in `main()` can handle only the exceptions raised in `main()`. None of the `catch` blocks can handle exceptions raised during startup or termination phase. When such exceptions are raised, the compiler might abnormally terminate the code execution without unwinding the stack. Consider this code where the construction and destruction of the static object `obj` might cause an exception.

```
class A{
    A(){throw(0);}
    ~A(){throw(0)}
};

static A obj;

main(){
    //...
}
```

The static object `obj` is constructed by calling `A()` before `main()` starts, and it is destroyed by calling `~A()` after `main()` ends. When `A()` or `~A()` raises an exception, no exception handler can be matched with them. Based on the implementation, such an exception can result in program termination without stack unwinding, leading to memory leak and security vulnerabilities.

Avoid operations that might raise an exception in the parts of your code that might be executed before startup or after termination of the program. For instance, avoid operations that might raise exceptions in the constructor and destructor of static or global objects.

### Polyspace Implementation

Polyspace flags global or static variable declaration that uses a callable entity that might raise an exception. For instance:

- Functions: When you call an initializer function or constructor directly to initialize a global or static variable, Polyspace checks whether the function raises an exception and flags the variable declaration if the function might raise an exception. Polyspace deduces whether a function might raise an exception regardless of its exception specification. For instance, If a `noexcept` constructor raises an exception, Polyspace flags it. If the initializer or constructor calls another function, Polyspace assumes the called function might raise an exception only if it is specified as `noexcept(<false>)`. Some standard library functions, such as the constructor of `std::string`, uses pointers to functions to perform memory allocation, which might raise exceptions. Polyspace does not flag the variable declaration when these functions are used.

- External function: When you call external functions to initialize a global or static variable, Polyspace flags the declaration if the external function is specified as `noexcept(<false>)`.
- Virtual function: When you call a virtual function to initialize a global or static variable, Polyspace flags it if the virtual function is specified as `noexcept(<false>)` in any derived class. For instance, if you use a virtual initializer function that is declared as `noexcept(<true>)` in the base class, and `noexcept(<false>)` in a subsequent derived class, Polyspace flags it.
- Pointers to function: When you use a pointer to a function to initialize a global or static variable, Polyspace assumes that pointer to function do not raise exceptions.

Polyspace ignores:

- Exceptions raised in destructors
- Exceptions raised in `atext()` operations

Polyspace also ignores the dynamic context when checking for exceptions. For instance, you might initialize a global or static variable by using function that raises exceptions only in certain dynamic context. Polyspace flags such a declaration even if the exception might never be raised. You can justify such a violation using comments in Polyspace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Exceptions Before `main()` Starts

This example shows how Polyspace flags construction or initialization of a global or static variable that might raise an exception. Consider this code where static and global objects are initialized by using various callable entities.

```
#include <stdexcept>
#include <string>
class C
{
public:
    C ( ){throw ( 0 );}
    ~C ( ){throw ( 0 );}
};
int LibraryFunc();
int LibraryFunc_noexcept_false() noexcept(false);
int LibraryFunc_noexcept_true() noexcept(true);
int  g() noexcept {
    throw std::runtime_error("dead code");
    return 0;
}
int f() noexcept {
    return g();
}
int init(int a) {
    if (a>10) {
        throw std::runtime_error("invalid case");
    }
    return a;
}
void* alloc(size_t s) noexcept {
    return new int[s];
}
int a = LibraryFunc() +
LibraryFunc_noexcept_true();            // Compliant
int c =
LibraryFunc_noexcept_false() +          // Noncompliant
LibraryFunc_noexcept_true();
static C static_c;                      //Noncompliant
static C static_d;                      //Compliant
C &get_static_c(){
    return static_c;
}
C global_c;                             //Noncompliant
int a3 = f();                           //Compliant
int b3 = g();                           //Noncompliant
int a4 = init(5);                       //Noncompliant
int b5 = init(20);                      //Noncompliant
int* arr = (int*)alloc(5);              //Noncompliant

int main(){
    //...
}
```

- The global pointer arr is initialized by using the function alloc(). Because alloc() uses new to allocate memory, it can raise an exception when initializing arr during the startup of the program. Polyspace flags the declaration of arr and highlights the use of new in the function alloc().
- The integer variable b3 is initialized by calling the function g(), which is specified as noexcept. Polyspace deduces that the correct exception specification of g() is noexcept(false) because it contains a throw() statement. Initializing the global variable b3 by using g() might raise an exception when initializing arr during the startup of the program. Polyspace flags the declaration of b3 and highlights the throw statement in g(). The declaration of a3 by calling f() is not flagged. Because f() is a noexcept function that does not throw, and calls another noexcept function, Polyspace deduces that f() does not raise an exception.
- The global variables a4 and b5 are initialized by calling the function init(). The function init() might raise an exception in certain cases, depending on the context. Because Polyspace deduces the exception specification of a function statically, it assumes that init() might raise an exception regardless of context. Consequently, Polyspace flags the declarations of both a4 and b5, even though init() raises an exception only when initializing b5.
- The global variable global_int is initialized by calling two external functions. The external function LibraryFunc_noexcept_false() is specified as noexcept(false) and Polyspace assumes that this external function might raise an exception. Polyspace flags the declaration of global_int. Polyspace does not flag the declaration of a because it is initialized by calling external functions that are not specified as noexcept(false).

- The static variable `static_c` and the nonstatic global variable `global_c`is declared and initialized by using the constructor of the class `C`, which might raise an exception. Polyspace flags the declarations of these variables and highlights the `throw()` statement in the constructor of class `C`. Polyspace does not flag the declaration of the unused static variable `static_d`, even though its constructor might raise an exception. Because it is unused, `static_d` is not initialized and its constructor is not called. Its declaration does not raise any exception.

# MISRA C++:2008 Rule 15-3-2

There should be at least one exception handler to catch all otherwise unhandled exceptions

## Description

### Rule Definition

*There should be at least one exception handler to catch all otherwise unhandled exceptions.*

### Polyspace Implementation

The checker reports a violation if any of these conditions are true:

- There is no `try`/`catch` in the `main` function.
- The `catch` block does not include a catch-all (`catch(...)`) handler block.

The rule is not checked if a `main` function does not exist.

The checker does not determine if an exception of an unhandled type eventually propagates to `main`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 15-3-3

Handlers of a function-try-block implementation of a class constructor or destructor shall not reference non-static members from this class or its bases

## Description

### Rule Definition

*Handlers of a function-try-block implementation of a class constructor or destructor shall not reference non-static members from this class or its bases.*

### Rationale

The handler `catch` blocks of a function `try` block handle exception that are raised from the body of the function and the initializer list. When used in class constructors and destructors, these `catch` blocks might handle exceptions that arise during the creation or destruction of the class nonstatic members. That is, the `catch` blocks might be executed before or after the lifetime of the nonstatic members of a class. If the nonstatic members of a class are accessed in such `catch` blocks, the compiler might attempt to access objects that are not created yet or already deleted, which is undefined behavior. For instance:

```
class C{

    private:
    int* inptr_x;
    public:
    C() try: inptr_x(new int){}
    catch(...){
        intptr_x = nullptr;
        //...
    }
};
```

Here, the constructor of `C` is implemented by using a function `try` block to handle any exception arising from the memory allocation operation in the initializer list. In the `catch` block of this function-`try` block, the class member `C.intptr_x` is accessed. The catch block executes when the memory allocation for `intptr_x` failed. That is, the catch block attempts to access the member before its lifetime, which is undefined behavior.

To avoid undefined behavior, avoid using the nonstatic data members or base classes of an object in the catch block of the function-try-block implementation of its constructors and destructor.

### Polyspace Implementation

If a statement in the catch block of a constructor or destructor function-`try` block accesses any of these, Polyspace flags the statement:

- The nonstatic members of the object
- The base classes of the object
- The nonstatic members of the base classes

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Accessing Nonstatic Members of Classes in `function-trycatch` Blocks

```
#include<cstdint>
class B
{
public:
    B ( ) try: x(0){/*...*/}
    catch ( ... )
    {
        if ( 0 == x ){/*...*/}  //Noncompliant
        //...
    }
    ~B ( ) try{/*...*/}
    catch ( ... )
    {
        if ( 0 == x ){/*...*/} //Noncompliant
        //...
        else if (sb == 1){/*...*/} //Compliant
        //....
    }
public:
    static int32_t sb;
protected:
    int32_t x;
};

class D : public B
{
public:
    D ( ) try: B(),y{0}{/*...*/}
    catch ( ... )
    {
        if ( 0 == x ){/*...*/}  //Noncompliant
        //...
        else if (y == 1){/*...*/}   //Noncompliant
        //...
    }
    ~D ( )try {/*...*/}
    catch ( ... )
    {
        if ( 0 == x ) {/*...*/} //Noncompliant
        //...
    }
protected:
    int32_t y;
};
```

In this example, the constructors and destructors of `B` and `D` are implemented by using function-try blocks. The `catch` blocks of these function-`try` blocks access the nonstatic members of the class and its base class. Polyspace flags accessing these nonstatic members in the `catch` blocks. Because the lifetime of `static` members is greater than the lifetime of the object itself, Polyspace does not flag accessing `static` objects in these `catch` blocks.

# MISRA C++:2008 Rule 15-3-4

Each exception explicitly thrown in the code shall have a handler of a compatible type in all call paths that could lead to that point

## Description

### Rule Definition

*Each exception explicitly thrown in the code shall have a handler of a compatible type in all call paths that could lead to that point.*

### Rationale

In C++, when an operation raises an exception, the compiler tries to match the exception with a compatible exception handler in the current and adjacent scopes. If no compatible exception handler for a raised exception exists, the compiler invokes the function `std::terminate()` implicitly. The function `std::terminate()` terminates the program execution in an implementation-defined manner. That is, the exact process of program termination depends on the particular set of software and hardware that you use. For instance, `std::terminate()` might invoke `std::abort()` to abnormally abort the execution without unwinding the stack. If the stack is not unwound before program termination, then the destructors of the variables in the stack are not invoked, leading to resource leak and security vulnerabilities.

Consider this code where multiple exceptions are raised in the try block of code.

```
class General{/*...  */};
class Specific : public General{/*...*/};
class Different{}
void foo() noexcept
{
    try{
        //...
        throw(General e);
        //..
        throw( Specific e);
        // ...
        throw(Different e);
    }
    catch (General& b){

    }
}
```

The catch block of code accepts references to the base class `General`. This catch block is compatible with exceptions of the base class `General` and the derived class `Specific`. The exception of class `Different` does not have a compatible handler. This unhandled exception violates this rule and might result in resource leaks and security vulnerabilities.

Because unhandled exceptions can lead to resource leak and security vulnerabilities, match the explicitly raised exceptions in your code with a compatible handler.

### Polyspace Implementation

- Polyspace flags a `throw` statement in a function if a compatible catch statement is absent in the call path of the function. If the function is not specified as `noexcept`, Polyspace ignores it if its call path lacks an entry point like `main()`.
- Polyspace flags a `throw` statement that uses a `catch(â€¦)` statement to handle the raised exceptions.
- Polyspace does not flag rethrow statements, that is, `throw` statements within catch blocks.
- You might have compatible catch blocks for the `throw` statements in your function in a nested try-catch block Polyspace ignores nested try-catch blocks. Justify `throw` statements that have compatible catch blocks in a nested structure by using comments. Alternatively, use a single level of try-catch in your functions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Match `throw` Statements with Compatible Catch Blocks

This example shows how Polyspace flags operations that raise exceptions without any compatible handler. Consider this code.

```
#include <stdexcept>

class MyException : public std::runtime_error {
public:
    MyException() : std::runtime_error("MyException") {}
};

void ThrowingFunc() {
    throw MyException(); //Noncompliant
}

void CompliantCaller() {
    try {
        ThrowingFunc();
    } catch (std::exception& e) {
        /* ... */
    }
}

void NoncompliantCaller() {
    ThrowingFunc();
}

int main(void) {
    CompliantCaller();
    NoncompliantCaller();
}

void GenericHandler() {
    try {
        throw MyException(); //Noncompliant
    } catch (...) {
        /* ... */
    }
}

void TrueNoexcept() noexcept {
    try {
        throw MyException();//Compliant
    } catch (std::exception& e) {
        /* ... */
    }
}

void NotNoexcept() noexcept {
    try {
        throw MyException(); //Noncompliant
    } catch (std::logic_error& e) {
        /* ... */
    }
}
```

- The function `ThrowingFunc()` raises an exception. This function has multiple call paths:

  - `main()->CompliantCaller()->ThrowingFunc()`: In this call path, the function `CompliantCaller()` has a catch block that is compatible with the exception raised by `ThrowingFunc()`. This call path is compliant with the rule.
  - `main()->NoncompliantCaller()->ThrowingFunc()`: In this call path, there are no compatible handlers for the exception raised by `ThrowingFunc()`. Polyspace flags the `throw` statement in `ThrowingFunc()` and highlights the call path in the code.

  The function `main()` is the entry point for both of these call paths. If `main()` is commented out, Polyspace ignores both of these call paths. If you want to analyze a call path that lacks an entry point, specify the top most calling function as `noexcept`.
- The function `GenericHandler()` raises an exception by using a `throw` statement and handles the raised exception by using a generic catch-all block. Because Polyspace considers such catch-all handler to be incompatible with exceptions that are raised by explicit `throw` statements, Polyspace flags the `throw` statement in `GenericHandler()`.
- The `noexcept` function `TrueNoexcept()` contains an explicit `throw`statement and a catch block of compatible type. Because this `throw` statement is matched with a compatible `catch` block, it is compliant with the rule.
- The `noexcept` function `NotNoexcept()` contains an explicit `throw` statement, but the catch block is not compatible with the raised exception. Because this `throw` statement is not matched with a compatible catch block, Polyspace flags the `throw` statement in `NotNoexcept()`.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 15-3-5

A class type exception shall always be caught by reference

## Description

### Rule Definition

*A class type exception shall always be caught by reference.*

### Rationale

If a class type exception is caught by value, the exception object might be sliced. For instance:

```
class baseException();
class derivedException : public baseException {};

void foo() {
    try {
        //...
        throw derivedException();
    }
    catch (baseException e) { //slices the thrown exception
        //...
    }
}
```

When the catch block in `foo()` catches the `derivedException` object, you might expect the object to remain a `derivedException` object. Because the object is caught by value, it is sliced to a `baseException` object. Unintended object slicing risks unexpected code behavior at runtime. To avoid object slicing, catch class type exceptions by reference or `const` reference.

### Polyspace Implementation

Polyspace flags catch statements where class type exceptions are caught by value.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Catch Exceptions by Reference

```
#include <exception>
#include <iostream>

class baseException : public std::exception {
public:
    baseException() : exception() {}
    const char* what() const noexcept(true) override {
        return "Base Exception Object";
    }
};

class derivedException : public baseException {
public:
    derivedException() : baseException() {}
    const char* what() const noexcept(true) override {
        return "Derived Exception Object";
    }
};

class exampleException{};

void foo() {
    try {
        throw derivedException();
    }
    catch (baseException e) { //Noncompliant
        std::cout << e.what();
    }
    catch (derivedException e) { //Noncompliant
        std::cout << e.what();
    }
    catch (exampleException e) { //Noncompliant
    }
    catch (baseException &e) { //Compliant
        std::cout << e.what();
    }
    catch (const baseException &e) { //Compliant
        std::cout << e.what();
    }
    catch (derivedException &e) { //Compliant
        std::cout << e.what();
    }
    catch (const derivedException &e) { //Compliant
        std::cout << e.what();
    }
}
```

In this example, Polyspace flags the `catch` blocks that catches exception objects by value. For instance:

- Catch blocks for exceptions of type `baseException`, `derivedException`, and `exampleException` are noncompliant because the thrown class type exception is caught by value. These blocks might slice the exception objects.
- Catch blocks for exceptions of type `baseException &`, `const baseException &`, `derivedException &`, and `const derivedException &` are compliant because the class type exception is caught by reference or `const` reference.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 15-3-6

Where multiple handlers are provided in a single try-catch statement or function-try-block for a derived class and some or all of its bases, the handlers shall be ordered most-derived to base class

## Description

### Rule Definition

*Where multiple handlers are provided in a single try-catch statement or function-try-block for a derived class and some or all of its bases, the handlers shall be ordered most-derived to base class.*

### Rationale

In a `try-catch` or `function-try` block, exception objects of a derived class match to handler `catch` blocks that accept the base class. If you place handlers of the base exception class before handlers of the derived exception class, the base class handler handles both base and derived class exceptions. The derived class handler becomes unreachable code, which is unexpected behavior. When using a class hierarchy to raise exceptions, make sure that the handler of a derived class precedes the handler of a base class.

### Polyspace Implementation

Polyspace flags a handler block if it follows a handler of a base class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Order Handler Blocks from most Derived to Base Class

```
#include<exception>
// classes used for exception handling
class MathError { };
class NotANumber: public MathError { };
class DivideByZero: public NotANumber{};

void bar(void){
    try
    {
        // ...
    }
    catch ( MathError &e )
    {
        // ...
    }
    catch ( NotANumber &nan ) // Noncompliant
    {
        // Unreachable Code
    }
    catch (DivideByZero &dbz)//Noncompliant
    {
        //Unreachable Code
    }
}
```

In this example, three classes in a hierarchy might arise in the `try` block. The handler `catch` blocks handle the exceptions.

- The block `catch ( NotANumber &nan )` follows the handler of its base class `catch ( MathError &e )`. Because the exception of class `NotANumber` also matches to the handler `catch ( MathError &e )`, the handler block `catch ( NotANumber &nan )` becomes unreachable code. The order of this block is noncompliant with this rule. Polyspace flags the handler block.
- The block `catch ( DivideByZero &dbz )` becomes unreachable code because exceptions of the class `DivideByZero` match to the preceding handlers of its base classes. Polyspace flags the handler block `catch ( DivideByZero &dbz )`.

Where multiple handlers are provided in a single try-catch statement or function-try-block, any ellipsis (catch-all) handler shall occur last

## Description

### Rule Definition

*Where multiple handlers are provided in a single try-catch statement or function-try-block, any ellipsis (catch-all) handler shall occur last.*

### Rationale

In a try-catch statement or function-try block, the compiler matches the raised exception with a `catch()` handler. The `catch(â€¦)` handler matches any exception. Handlers after the catch-all handler within the same try-catch statement or function try-block are ignored by the compiler during the exception handling process and are unreachable code.

Having a handler after the catch-all handler might result in developer confusion as to why certain intended handlers are not being executed. Likewise, the catch-all handler might not handle the exception in the way the developer intends, resulting in confusion.

### Polyspace Implementation

Polyspace raises this defect whenever a handler appears after the catch-all handler within the try-catch statement or function try-block.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Handlers After the Catch-All Handler Are Noncompliant

```
#include <iostream>
#include <exception>

using namespace std;

int main()
{

    try
    {
        //some code
    } catch(exception& e1) {     //Compliant

        //...

    } catch(...) {               //Compliant
```

```
        //...

    } catch(exception& e2) {     //Noncompliant

        //...

    }
    }

    return 0;
}
```

Because the `catch (exception& e2)` handler comes after the `catch(â€¦)` handler, Polyspace flags the handler before the catch-all handler as noncompliant. This issue might result in a compilation error.

# MISRA C++:2008 Rule 15-4-1

If a function is declared with an exception-specification, then all declarations of the same function (in other translation units) shall be declared with the same set of type-ids

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis . See “Checkers Deactivated in Polyspace as You Code Analysis”.*

### Rule Definition

*If a function is declared with an exception-specification, then all declarations of the same function (in other translation units) shall be declared with the same set of type-ids.*

### Rationale

Declaring a function with different exception specification in different source files leads to undefined behavior.

### Polyspace Implementation

Polyspace reports a violation is there is a mismatch in the exception specification of a function in different source files.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Mismatched Exception Specification

In this example, the function `foo()` is specified to raise `std::bad_alloc` exceptions in `src1.cpp`. In another file `src2.cpp`, `foo()` is specified to raise `std::exception`, perhaps inadvertently. The mismatch leads to undefined behavior in the function `bar()`. Polyspace reports a violation of this rule.

```
//src1.cpp
#include<new>
void foo() throw(std::bad_alloc){
    try{
    int *p1 = new int[50];
    }catch(...){
        //....
        std::bad_alloc e;
        throw e;
    }
}
```

```
//src2.cpp
#include<new>
#include<stdexcept>
extern bool condition();
extern void foo() throw(std::exception);//Noncomplian
void bar() {
    foo();

}
```

# MISRA C++:2008 Rule 15-5-1

A class destructor shall not exit with an exception

## Description

### Rule Definition

*A class destructor shall not exit with an exception.*

### Polyspace Implementation

The checker flags exceptions thrown in the body of the destructor. If the destructor calls another function, the checker does not detect if that function throws an exception.

The checker does not detect these situations:

- A `catch` statement does not catch exceptions of all types that are thrown.

  The checker considers the presence of a `catch` statement corresponding to a `try` block as indication that an exception is caught.
- `throw` statements inside `catch` blocks

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 15-5-2

Where a function's declaration includes an exception-specification, the function shall only be capable of throwing exceptions of the indicated type(s)

## Description

### Rule Definition

*Where a function's declaration includes an exception-specification, the function shall only be capable of throwing exceptions of the indicated type(s).*

### Polyspace Implementation

The checker flags situations where the data type of the exception thrown does not match the exception type listed in the function specification.

For instance:

```
void goo ( ) throw ( Exception )
  {
    throw 21; // Non-compliant - int is not listed
  }
```

The checker limits detection to `throw` statements that are in the body of the function. If the function calls another function, the checker does not detect if the called function throws an exception.

The checker does not detect `throw` statements inside `catch` blocks.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 15-5-3

The terminate() function shall not be called implicitly

## Description

### Rule Definition

*The terminate() function shall not be called implicitly.*

### Polyspace Implementation

The checker flags situations that might result in calling the function `std::terminate()` implicitly. These situations might include:

- An exception escapes uncaught. This also violates `MISRA C++:2008 Rule 15-3-2`. For instance:
  - Before an exception is caught, it escapes through another function that throws an uncaught exception. For instance, a catch statement or exception handler invokes a copy constructor that throws an uncaught exception.
  - An empty `throw` expression raises an uncaught exception again.
- A class destructor raises an exception. Exceptions in destructors also violates `MISRA C++:2008 Rule 15-5-1`.
- A termination handler that is passed to `std::atexit` raises an unhandled exception.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unhandled Exceptions

```
#include <stdexcept>
#include <new>
class obj
{
public:
    obj() noexcept(false){}
    obj(const obj& a){
        //...
        throw -1;
    }
    ~obj()
    {
        try{
            // ...
            throw std::runtime_error("Error2"); // Noncompliant
        }catch(std::bad_alloc& e){
        }
    }
};
obj globalObject;
void atexit_handler(){//Noncompliant
    throw std::runtime_error("Error in atexit function");
}
void main(){//Noncompliant
    try{
        //...
        obj localObject = globalObject;
        std::atexit(atexit_handler);
    }catch(std::exception& e){

    }
}
```

In this example, Polyspace flags unhandled exceptions because they result in implicit calls to `std::terminate()`.

- The destructor `~obj()` does not catch the exception raised by the `throw` statement. The unhandled exception in the destructor results in abrupt termination of the program through an implicit call to `std::terminate`. Polyspace flags the `throw` statement in the destructor of `obj`.
- The `main()` function does not handle all exceptions raised in the code. Because an unhandled exception might result in an implicit call to `std::terminate()`, Polyspace flags the `main()` function.
- The termination handler `atexit_handler` raises an uncaught exception. The function `atexit_handler` executes after the main finishes execution. Unhandled exceptions in this function cannot be handled elsewhere, leading to an implicit call to `std::terminate()`. Polyspace flags the function.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 16-0-1

#include directives in a file shall only be preceded by other preprocessor directives or comments

## Description

### Rule Definition

*#include directives in a file shall only be preceded by other preprocessor directives or comments.*

### Rationale

Grouping all #include preprocessor directives at the beginning of the source file makes the code more readable. #include directives might include header files where macros are defined. If you use such a macro before including its definition, you might encounter unexpected code behavior.

### Polyspace Implementation

Polyspace raises this defect when an `#include` directive comes after any code that is not a comment or preprocessor directive. Polyspace ignores code that is hidden by using conditional compilation directives such as `#if` or `#ifdef`. Polyspace does not report a violation of this rule when an `#include` directive is located within an `extern "C"` block.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### #include Directive Preceded by Noncompliant Code

```
//this comment is compliant     //Compliant
/*
    This comment is compliant
*/

#ifndef TESTING_H               //Compliant
#define TESTING_H               //Compliant

#include <iostream>             //Compliant
using namespace std;            //Compliant
#include <exception>            //Noncompliant

#endif
```

Because an include directive follows a code statement that is neither a preprocessor directive nor a comment, `Polyspace` flags the include directive.

# MISRA C++:2008 Rule 16-0-2

Macros shall only be #define 'd or #undef 'd in the global namespace

## Description

### Rule Definition

*Macros shall only be #define 'd or #undef 'd in the global namespace.*

### Rationale

If you define or undefine macros in a local namespace, you might expect the macro to be valid only in the local namespace. But macros do not follow the scoping mechanism. Instead, the compiler replaces all occurrences of a macro by its defined value beginning at the `#define` statement until the end of file or until the macro is redefined. This behavior of macros might be contrary to developer expectation and might cause logic errors that result in bugs.

### Polyspace Implementation

Polyspace flags a `#define` or `#undef` statement that is placed within a block instead of in the global namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Macros in Local Namespaces

```
#include<cstdlib>
#define HCUT 1
namespace unnormalized{
    #define HCUT 6582 //Noncompliant
    void foo(){
        //...
    }
};
void bar(){
    int intEnergy = HCUT*10;
    //HCUT is 6582, you might expect HCUT=1;
}

namespace uniteV{
    const double hcut = 6582; //eV
    void foo(){

    }
};
```

In this example, different values of `HCUT` are defined, perhaps to accommodate code written by using different systems of unit. You might expect the definition of `HCUT` in the namespace `unnormalized` to remain limited to the namespace. But the value of HCUT remains 6582 until the end of file. For instance, in the function bar, you might expect that HCUT is one, but the value of HCUT remains 6582, which might cause logic error, unexpected results, and bugs. Polyspace flags the #define statement within the local namespace.

To implement constants that might have different values in different scopes, use const variables, as shown in the namespace uniteV. Avoid using macros to represent constants that might require different values in different scopes.

Arguments to a function-like macro shall not contain tokens that look like preprocessing directives

## Description

### Rule Definition

*Arguments to a function-like macro shall not contain tokens that look like preprocessing directives.*

### Rationale

When a compiler encounters function-like macros, it replaces the argument of the macro into the replacement code. If the argument contains a token that looks like preprocessing directives, the replacement process during macro expansion is undefined. Depending on the environment, such a function-like macro might behave in unexpected ways, leading to errors and bugs.

### Polyspace Implementation

Polyspace flags calls to function-like macros if their argument starts with the character #.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

### Avoid Arguments That Start with # in Function-Like Macros

```
#include<cstdlib>
#include<iostream>
#define PRINT(ARG) std::cout<<#ARG
//....
#define Error1
//...

void foo(void){
    PRINT(
    #ifdef Error1  //Noncompliant
    "Error 1"
    #else
    "Error 2"
    #endif  //Noncompliant
    );

}
```

In this example, the function-like macro `PRINT` is invoked with an argument that chooses between two strings by using an `#ifdef` block. Depending on the environment, the output of this code might be `#ifdef Error1 //Noncompliant "Error 1" #else "Error 2" #endif // Noncompliant` or `Error 1`. Polyspace flags the arguments that start with the character #.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 16-0-6

In the definition of a function-like macro, each instance of a parameter shall be enclosed in parentheses, unless it is used as the operand of # or ##

## Description

### Rule Definition

*In the definition of a function-like macro, each instance of a parameter shall be enclosed in parentheses, unless it is used as the operand of # or ##.*

### Rationale

When you invoke function-like macros, the compiler expands the macro by replacing its parameters with the tokens. Then the compiler substitutes the expanded macro into the code. This expansion and substitution process does not take precedence of operation into account. The function-like macros might produce unexpected results if their parameters are not enclosed in parenthesis. For instance, consider this function-like macro:

```
#define dustance_from_ten(x) x>10? x-10:10-x
```

The macro is intended to measure the distance of a number from ten. When you invoke the macro with the argument (a-b), the macro expands to:

```
a-b>10: a-b-10:10-a-b
```

The expression `10-a-b` is equivalent to `10-(a+b)` instead of the intended distance `10-(a-b)`. This unexpected behavior might result in errors and bugs. To avoid such unexpected behaviors, enclose parameters of a function-like macro in parentheses.

The exception to this rule is when a parameter is used as an operand of # or ##.

### Polyspace Implementation

Polyspace flags function-like macro definitions if the parameters are not enclosed in parenthesis. Polyspace does not flag unparenthesized parameters if they are preceded by the operators `.`, `->`, or the characters #, ##.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Enclose Parameters of Function-Like Macros in Parentheses

```
#include<iostream>
#include<cmath>
#define abs(x) (x>0) ? x:-x //Noncompliant

double foo(double num1, double num2){
    return log(abs(num1-num2));
}

int main(){
    std::cout<<foo(10,10.5);
}
```

In this example, when you invoke `foo(10,10.5)`, you might expect the output to be `log(0.5)` or `-0.69`. Because the parameters of `abs` are not enclosed in parentheses, the output becomes `log(-20.5)` or `NaN`, which is unexpected and might lead to bugs. Polyspace flags the function-like macro definition.

# MISRA C++:2008 Rule 16-0-7

Undefined macro identifiers shall not be used in #if or #elif preprocessor directives, except as operands to the defined operator

## Description

### Rule Definition

*Undefined macro identifiers shall not be used in #if or #elif preprocessor directives, except as operands to the defined operator.*

### Rationale

If you attempt to use a macro identifier in a preprocessing directive, and you have not defined that identifier, then the preprocessor assumes that it has a value of zero. This value might not meet developer expectations.

### Polyspace Implementation

Polyspace flags an `#if` or `#elif` statement if it uses an undefined macro identifier.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Macro Identifiers

```
#if M == 0           //Noncompliant
#endif

#if defined (M)      //Complaint
#if M == 0           //Executes only when M is defined
#endif
#endif

#if defined (M) && (M == 0)  //Compliant
//...
#endif
```

This example shows various uses of `M` in preprocessing directives:

- The first `#if` clause uses the undefined identifier `M`. Because `M` is undefined when this preprocessor directive is evaluated, the compiler assumes that `M` is zero, which results in unexpected results. Such a use of undefined identifiers is not compliant with this rule. Polyspace flags the `#if` statement.
- The second and third `#if` statements use the undefined identifier `M` as the operand to the `defined` operator. These use of undefined identifiers are compliant with this rule.

### Topics

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 16-0-8

If the # token appears as the first token on a line, then it shall be immediately followed by a preprocessing token

## Description

### Rule Definition

*If the # token appears as the first token on a line, then it shall be immediately followed by a preprocessing token.*

### Rationale

The # character precedes a preprocessor directive when it is the first character on a line. If the # character is not immediately followed by a preprocessor directive, the preprocessor directive might be malformed.

Preprocessor directives might be used to exclude portions of code from compilation. The compiler excludes code until it encounters an #else, #elif, or #endif preprocessor directive. If one of those preprocessor directives is malformed, the compiler continues excluding code beyond the intended end point, resulting in bugs and unexpected behavior which can be difficult to diagnose.

Avoid malformed preprocessor directives by placing the preprocessor token directly after a # token. Specifically, do not place any characters other than white space between the # token and preprocessor token in #else and #endif directives.

### Polyspace Implementation

Polyspace raises this defect when the # character is followed by any character that is not part of a properly formed preprocessor token. A preprocessor token that is preceded or followed by any character other than white space causes Polyspace to raise this defect. Polyspace raises this defect when a preprocessor token is badly formed due to misspelling or improper capitalization.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Poorly Formed Preprocessor Tokens Following # Character

```
#define TESTING_H       //Compliant

namespace Example
{
#ifndef TESTING_H       //Compliant
    // code here
#elseX;                 //Noncompliant
    // code here
#else;                  //Compliant
```

```
    // code here
#endnif                 //Noncompliant
    // code here
  }

};
```

Because elseX is not a preprocessor directive and follows directly after the # character, Polyspace flags it as noncompliant.

#endnif is not a properly formed preprocessor directive. Polyspace flags it as noncompliant.

#define TESTING_H, #ifndef TESTING_H, and #else are properly formed preprocessor conditionals and are compliant with this rule.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 16-1-1

The defined preprocessor operator shall only be used in one of the two standard forms

## Description

### Rule Definition

*The defined preprocessor operator shall only be used in one of the two standard forms.*

### Rationale

The `defined` preprocessor operator checks whether an identifier is defined as a macro. In C, the only two permissible forms for this operator are:

- `defined (identifier)`
- `defined identifier`

Using any other form results in invalid code that compiler might not report. For instance, if you use expressions as arguments for the `defined` operator, the code is invalid. If the compiler does not report the invalid usage of `defined`, diagnosing the invalid code is difficult.

If your `#if` or similar preprocessor directives expand to create a `defined` statement, the code behavior is undefined. For instance:

```
#define DEFINED defined
#if DEFINED(X)
```

The `#if` preprocessor directive expands to form a `defined` operation. Depending on your environment, the code might behave in unexpected ways, leading to bugs that are difficult to diagnose.

To avoid invalid code, bugs, and undefined behavior, use only the permitted forms when using the `defined` operator.

### Polyspace Implementation

Polyspace flags incorrect usages of the `defined` operator, such as:

- The operator `defined` is used without an identifier.
- The operator `defined` appears after macro expansion.
- The operator `defined` is used with a complex expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use `defined` Operators With Identifiers

```
#if defined (X<Y)//Noncompliant
//...
#endif
#if defined (X) && defined (Y) &&(X<Y)//Compliant
//...
#endif
```

In this example, a block of code is conditionally executed only if the identifiers X and Y are defined and if X is smaller than Y. Constructing this condition by using an expression as the argument for the `defined` operator is not permissible and results in invalid code. Polyspace flags the impermissible `defined` statement. The permissible way to define such a condition is to use individual identifiers with `defined`.

### Topics

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 16-1-2

All #else, #elif and #endif preprocessor directives shall reside in the same file as the #if or #ifdef directive to which they are related

## Description

### Rule Definition

*All #else, #elif and #endif preprocessor directives shall reside in the same file as the #if or #ifdef directive to which they are related.*

### Rationale

You use preprocessor directives, such as `#if...#elif...#else...#endif`, to conditionally include or exclude blocks of code. If the different branches of such a directive reside in different source files, the code can be confusing. If all the branches are not included in a project, the code might behave in unexpected ways. To avoid confusion and unexpected behavior, keep the branches of a conditional preprocessor directive within the same source file.

### Polyspace Implementation

Polyspace raises a violation of this rule if either of these conditions are true:

- A corresponding `#if` directive cannot be found within a source file for every `#else`, `#elif`, or `#endif` directive.
- A corresponding `#endif` directive cannot be found within a source file for every `#if` directive.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Incomplete Conditional Preprocessor Directives

```
//file1.h
#if !defined (FILE)
//.....
#elif //Noncompliant
//...///
```

```
//file2.h
#else //Noncompliant
//...
#endif //Noncompliant
///
```

In this example, a conditional directive is split across two source files.

- In `file1.h`, the `#if` directive has no corresponding `#endif` directive. Polyspace flags the block.

- In `file2.h`, the `#else` and `#endif` directives have no corresponding `#if` directive. Polyspace flags both directives.

# MISRA C++:2008 Rule 16-2-1

The preprocessor shall only be used for file inclusion and include guards

## Description

### Rule Definition

*The preprocessor shall only be used for file inclusion and include guards.*

### Rationale

Aside from inclusion and include guarding, you might use preprocessor directives for other purposes such as defining constants or function-like macros. These preprocessor directives do not obey typical linkage and lack scoping mechanism or type safety. Preprocessor directives are less safe as compared to equivalent C++ features. For instance, a constant defined by using a `#define` statement retains its value across all scopes even if it is defined in a local scope. Using the `#define` preprocessor instead of a `constexpr` might lead to confusion if you define a constant differently in different scopes. Because a `constexpr` variable maintains a well defined scope, it is a safer alternative. The `constexpr` is efficient because it is a compile time constant.

Avoid preprocessor directives if they are not used for inclusion or include guards. Instead, use features such as inline functions, `const` or `constexpr` objects, and templates.

### Polyspace Implementation

Polyspace raises a violation of this rule in an included header file when either of these conditions is true:

- `#define` is used outside of an include guard. These `#define` statements typically define constants and function-like macros.
- `#ifndef` is used outside of an include guard.

Polyspace considers this idiom as the correct include guard idiom:

```
#ifndef <identifier>
#define <identifier>
#endif
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid #define Directives Outside Include Guards

| file1.h | main.cpp |
|---|---|
| `#ifndef MY_FILE`<br>`#define MY_FILE //Compliant`<br>`#endif`<br>`#define PI 3.1416 //Noncompliant`<br>`constexpr double pi = 3.1416;` | `#include"file1.h"`<br>`//...` |

In this example, include file `file1.h` contains two `#define` statements. The first `#define` directive is used within an include guard. This directive is compliant with this rule. The second `#define` directive defines the constant macro `PI`. This directive is noncompliant with this rule and Polyspace flags it. A better alternative is to use a `constexpr` variable.

# MISRA C++:2008 Rule 16-2-2

C++ macros shall only be used for: include guards, type qualifiers, or storage class specifiers

## Description

### Rule Definition

*C++ macros shall only be used for: include guards, type qualifiers, or storage class specifiers.*

### Rationale

Aside from defining include guards, type qualifiers, and storage class specifiers, you might use C++ macros for other purposes such as defining constants or function-like macros. These macros do not obey typical linkage and lack scoping mechanism or type safety. Compared to available alternatives in C++, macros are less safe. For instance, a constant defined by using a `#define` statement retains its value across all scopes even if it is defined in a local scope. Using a macro instead of a `constexpr` might lead to confusion if you define a constant differently in different scopes. Because a `constexpr` variable maintains a well-defined scope, it is a safer alternative. The `constexpr` is efficient because it is a compile time constant.

Avoid macros if they are not used for defining include guards, type qualifiers, and storage class specifiers. Instead, use features such as inline function, `const` or `constexpr` objects, and function templates.

### Polyspace Implementation

The checker flags `#define` statements where the macros expand to something other than include guards, type qualifiers or storage class specifiers such as `static`, `inline`, `volatile`, `auto`, `register`, and `const`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Noncompliant Use of Macros

```
#ifndef IDENTIFIER //Compliant
#define IDENTIFIER //Compliant
#endif             //Compliant - Include guard

#define STOR extern      // Compliant - Storage class specifier
#define VOL volatile     //Compliant - Type qualifier

#define CLOCK (xtal/16)              // Noncompliant
#define PLUS2(X) ((X) + 2)           // Noncompliant
#define PI 3.14159F                  // Noncompliant
#define int32_t long                 // Noncompliant
#define STARTIF if(                  // Noncompliant
#define INIT(value) {(value), 0, 0}  // Noncompliant
```

```
#define HEADER "filename.h"          // Noncompliant
```

In this example, Polyspace flags all macros except those that define include guards, storage class specifiers, and type qualifiers.

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 16-2-3

Include guards shall be provided

## Description

### Rule Definition

*Include guards shall be provided.*

### Rationale

When a translation unit contains a complex hierarchy of nested header files, it is possible for a particular header file to be included more than once, leading to confusion. If this multiple inclusion produces multiple or conflicting definitions, then your program can have undefined or erroneous behavior.

For instance, suppose that a header file contains:

```
#ifdef _WIN64
   int env_var;
#elseif
   long int env_var;
#endif
```

If the header file is contained in two inclusion paths, one that defines the macro `_WIN64` and another that undefines it, you can have conflicting definitions of `env_var`.

To avoid multiple inclusion of the same file, add include guards to the beginning of header files. Use either of these formats:

-
  ```
  <start-of-file>
  // Comments allowed here
  #if !defined ( identifier )
  #define identifier
  // Contents of file
  #endif
  <end-of-file>
  ```

-
  ```
  <start-of-file>
  // Comments allowed here
  #ifndef identifier
  #define identifier
  // Contents of file
  #endif
  <end-of-file>
  ```

### Polyspace Implementation

The checker raises a violation if a header file does not contain an include guard.

For instance, this code uses an include guard for the `#define` and `#include` statements. This code does not violate the rule:

```
// Contents of a header file
#ifndef FILE_H
```

```
#define FILE_H
#include "libFile.h"
#endif
```

If you use include guards that do not adhere to the suggested format, Polyspace flags them. For instance:

- You might mistakenly use different identifiers in the `#ifndef` and `#define` statements:

  ```
  #ifndef MACRO
  #define MICRO
  //...
  #endif
  ```
- You might inadvertently use `#ifdef` instead of `#ifndef` or omit the `#define` statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing or Incorrectly Formatted Include Guard

| file1.h | file2.h | mainfile.cpp |
|---|---|---|
| `#ifndef MACRO`<br>`#define MICRO`<br>`//...`<br>`#endif` | `#ifdef DO_INCLUDE`<br>`#define DO_INCLUDE`<br>`void foo();`<br>`#endif` | `#include"file1.h"`<br>`#include"file2.h"`<br>`int main(){`<br>`    return 0;`<br>`}` |

In this example, two header files are included in the file `mainfile.cpp`.

- The include guard in `file1.h` queries the definition of `MACRO` but conditionally defines a different identifier `MICRO`, perhaps inadvertently. This include guard is incorrectly formatted. Polyspace flags the file.
- The include guard in `file2.h` uses `#ifdef` instead of `#ifndef`. This include guard is incorrect and Polyspace flags the file.

# MISRA C++:2008 Rule 16-2-4

The ', ", /* or // characters shall not occur in a header file name

## Description

### Rule Definition

*The ', ", /* or // characters shall not occur in a header file name.*

### Rationale

You include header files in a source file by enclosing its name between the delimiters <> or `""`. Using the characters `'`, ", `/*`, or `//` between the delimiters < and > is undefined behavior. Using the characters `'`, `/*`, or `//` between the " delimiters also results in undefined behavior. Depending on your environment and compiler, using these characters in a header filer name might result in unexpected behavior.

Avoid the characters `'`, ", `/*`, or `//` in a header file name.

### Polyspace Implementation

Polyspace raises a violation of this rule if the name of a header file includes one of these characters:

- `'`
- `"`
- `/*`
- `//`

If you use the character " between the delimiter ", Polyspace interprets the portion of the header name between two successive " delimiters as the header file name. For instance, in this code,

```
#include "foo\".h"
```

Polyspace interprets `foo\` as the header name. In such cases, Polyspace does not raise a violation of this rule, but because the compiler looks for a header file that does not exist, you might get a compilation warning.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Undefined Behavior

```
#include<dummy'file> //Noncompliant
#include<dummy"file> //Noncompliant

#include<dummy/*file> //Noncompliant
#include<dummy//file> //Noncompliant
```

```
#include "dummy'file" //Noncompliant
#include "dummy file"   //Compliant

#include "dummy/*file" //Noncompliant
#include "dummy//file" //Noncompliant
```

In this example, Polyspace flags the use of the characters `'`, `"`, `/*`, or `//` in header file names.

# MISRA C++:2008 Rule 16-2-5

The \ character should not occur in a header file name

## Description

### Rule Definition

*The \ character should not occur in a header file name.*

### Rationale

You include header files in a source file by enclosing its name between the delimiters <> or `""`. Using the character `\`between the delimiters < and > or between the delimiters `"` is undefined behavior. Using `/` in a header file name might result in unexpected behavior.

Some environments use the character `\` as a file name delimiter, for instance, when describing paths. Compilers for these environments might support the use of `\` in an `#include` directive.

### Polyspace Implementation

Polyspace raises a violation of this rule if the character `\` occurs in a header file name.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using \ in Header File Name

```
#include"incguard\5\.h" //Noncompliant
#include"inc\\guard.h" //Noncompliant
```

In this example, Polyspace flags the `#include` statements that have header file names where the `\` character occurs.

# MISRA C++:2008 Rule 16-2-6

The #include directive shall be followed by either a <filename> or "filename" sequence

## Description

### Rule Definition

*The #include directive shall be followed by either a <filename> or "filename" sequence.*

### Rationale

This rule applies only after macro replacement.

The code behavior is undefined if an `#include` directive does not use one of these forms:

- `#include <filename>`
- `#include "filename"`

Using other forms of `#include` directives is not permitted by ISO/IEC 14882:2003. To avoid unexpected behavior, avoid using malformed `#include` statements.

### Polyspace Implementation

Polyspace raises a violation of this rule if an `#include` directive is not followed by either `<filename>` or `"Filename"`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Malformed #include Directives

```
#include"incguard.h" //Compliant
#include<incguard.h> //Compliant

#define MH "myheader.h"
#define STR <string>
#include MH //Compliant
#include STR //Compliant

#include myfile.h //Noncompliant
```

In this example, Polyspace flags the directive that attempts to include `myfile.h` because it does not follow either of the permissible forms. The other directives follow the permissible forms after applicable macro replacements.

"Check for and Review Coding Standard Violations"

# MISRA C++:2008 Rule 16-3-1

There shall be at most one occurrence of the # or ## operators in a single macro definition

## Description

### Rule Definition

*There shall be at most one occurrence of the # or ## operators in a single macro definition.*

### Rationale

The evaluation of the # and ## preprocessor operators does not have a specified execution order. When more than one occurrence of the # or ## operators exists in a single macro definition, it is unclear which preprocessor operator is executed first by the compiler. The uncertainty of execution order might result in developer confusion or unexpected macro calculations. Use only one of the # or ## preprocessor operators for each macro definition.

### Polyspace Implementation

Polyspace raises this defect whenever more than one instance of the # or ## operators is used in a single macro definition.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Multiple # and ## Operators Used in a Single Macro Definition

```
#define STRING(X) { #X }                          //compliant
#define CONCAT(X, Y) {X ## Y}                     //compliant
#define STRING_CONCAT(x, y) {#x ## y}             //noncompliant
#define MULTI_CONCAT(x, y, xy, z) {x ## y ## z}   //noncompliant
```

Because the macro `STRING_CONCAT` uses both the # and ## operators, Polyspace flags the macro as noncompliant.

Polyspace flags the macro `MULTI_CONCAT` as noncompliant because it uses multiple ## operators.

## Check Information

**Group:** Preprocessing Directives
**Category:** Required

# MISRA C++:2008 Rule 16-3-2

The # and ## operators should not be used

## Description

### Rule Definition

*The # and ## operators should not be used.*

### Rationale

The evaluation of the # and ## preprocessor operators does not have a specified execution order. Different compilers might evaluate these operators in different order of execution. The uncertainty of execution order might result in developer confusion or unexpected macro calculations. When possible, avoid using the # and ## preprocessor operators.

### Polyspace Implementation

Polyspace raises this advisory when the # or ## operators are used in a macro definition.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using # and ## Operators in Macro Definition

```
#define STRING(X) { #X }                            //noncompliant
#define CONCAT(X, Y) {X ## Y}                       //noncompliant
```

Because the macro `STRING(X)` uses the # operator, Polyspace flags the macro as noncompliant.

Polyspace flags the macro `CONCAT(X, Y)` as noncompliant because it uses the ## operator.

# MISRA C++:2008 Rule 16-6-1

All uses of the #pragma directive shall be documented

## Description

### Rule Definition

*All uses of the #pragma directive shall be documented.*

### Rationale

Because the behaviors of `#pragma` directives depend on the set of software, hardware, and compilers that you use, the developer's intent for a `#pragma` directive might be unclear. To clearly communicate the developer intent and the expected behavior of a `#pragma` directive, for each of these directives, document:

- The meaning
- The detailed expected behavior
- The implication of the directive for the code

Document the preceding factors in sufficient detail to show that you fully understand what the `#pragma` directives mean and how they might impact the code. Avoid using `#pragma` directives as much as possible. Encapsulate their use in dedicated functions whenever possible.

### Polyspace Implementation

To check this rule, list the pragmas that are allowed in source files by using the option `Allowed pragmas (-allowed-pragmas)`. If Polyspace finds a pragma not in the allowed pragma list, a violation is raised.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** Preprocessing Directives
**Category:** Document

# Version History

“Check for and Review Coding Standard Violations”

# MISRA C++:2008 Rule 17-0-1

Reserved identifiers, macros and functions in the Standard Library shall not be defined, redefined or undefined

## Description

### Rule Definition

*Reserved identifiers, macros and functions in the Standard Library shall not be defined, redefined or undefined.*

### Rationale

Redefining or undefining reserved identifiers, macros and functions from the Standard Library is not good practice. In some cases, these actions can lead to undefined behavior.

### Polyspace Implementation

The checker raises a violation if identifiers and macros from the Standard Library are defined, redefined or undefined.

In general, the checker considers identifiers and macros that begin with an underscore followed by an uppercase letter as reserved for the Standard Library.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Defining, Redefining, and Undefining Reserved C++ Identifiers, Macros, and Functions

```
#define __TIME__ 3  //Noncompliant
#undef __TIME__   //Noncompliant

#define __cplusplus 3 //Noncompliant
#undef __cplusplus //Noncompliant

#define break 3 //Noncompliant
#undef break //Noncompliant

#define pow 3 //Noncompliant
#undef pow //Noncompliant

#define example 3 //Compliant
#undef example //Compliant

#define example 7 //Compliant
```

In this example, Polyspace flags preprocessor directives that define or undefine reserved C++ identifiers and macros. For instance:

- Defining and undefining `__TIME__` is noncompliant because `__TIME__` is a reserved C++ macro.
- Defining and undefining `__cplusplus` is noncompliant because `__cplusplus` is a reserved C++ macro.
- Defining and undefining `break` is noncompliant because `break` is a reserved C++ identifier.
- Defining and undefining `pow` is noncompliant because `pow` is a reserved C++ function.
- Defining, undefining, and redefining `example` is compliant because `example` is not a reserved C++ macro, identifier, or function.

# MISRA C++:2008 Rule 18-0-2

The library functions atof, atoi and atol from library <cstdlib> shall not be used

## Description

### Rule Definition

*The library functions atof, atoi and atol from library <cstdlib> shall not be used.*

### Rationale

Converting strings to a numeric value by using the functions `atof`, `atoi` and `atol` from the library <cstdlib> might result in error conditions. For instance, using the preceding functions might cause an error when the input string:

- Does not contain a number
- Contains a number, but is out of range
- Contains additional data after a number

When using the preceding functions, failure to convert a string to a numeric value might result in undefined behavior. To avoid undefined behavior and undetected errors, check the error state of output when converting strings to a numeric value.

### Polyspace Implementation

Polyspace flags the C standard library string-to-number functions of `atoi()`, `atol()`, and `atof()`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use C++ Library Functions for Converting Strings to Numeric Value

```
#include <cstdlib>
#include <iostream>
#include <string>

void foo() {
    std::string str1 = "7";
    std::string str2 = "3.1415";
    std::string str3 = "three";

    int myint1 = std::stoi(str1); //Compliant
    float myint2 = std::stof(str2); //Compliant
    long myint3 = std::stol(str3); //Compliant

    const char* str4 = "12";
    const char* str5 = "2.7182";
    const char* str6 = "undefinedError";
    int num4 = atoi(str4); //Noncompliant
    float num5 = atof(str5); //Noncompliant
    long num6 = atol(str6); //Noncompliant
    //...
}
```

In this example, Polyspace flags the use of C standard library functions for converting strings to numeric value. For instance:

- The string-to-number functions from the C standard library, such as `atoi()`, `atof()`, and `atol()` are noncompliant flagged because an invalid conversion results in undefined behavior.
- The string-to-number functions from the C++ standard library `std::stoi()`, `std::stof()`, and `std::stol()` are not flagged because an invalid conversion produces a `std::invalid_argument` exception, which is defined behavior.

# MISRA C++:2008 Rule 19-3-1

The error indicator errno shall not be used

## Description

### Rule Definition

*The error indicator errno shall not be used.*

### Rationale

Observing this rule encourages the good practice of not relying on `errno` to check error conditions.

Checking `errno` is not sufficient to guarantee absence of errors. Functions such as `fopen` might not set `errno` on error conditions. Often, you have to check the return value of such functions for error conditions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `errno`

```
#include <cstdlib>
#include <cerrno>

void func (const char* str) {
    errno = 0;  // Noncompliant
    int i = atoi(str);
    if(errno != 0) { // Noncompliant
        //Handle Error
    }
}
```

The use of `errno` violates this rule. The function `atoi` is not required to set `errno` if the input string cannot be converted to an integer. Checking `errno` later does not safeguard against possible failures in conversion.

# MISRA C++:2008 Rule 27-0-1

The stream input/output library <cstdio> shall not be used

## Description

### Rule Definition

*The stream input/output library <cstdio> shall not be used.*

### Rationale

Functions in `cstdio` such as `gets`, `fgetpos`, `fopen`, `ftell`, etc. have unspecified, undefined and implementation-defined behavior.

For instance:

- The `gets` function:

  ```
  char * gets ( char * buf );
  ```

  does not check if the number of characters provided at the standard input exceeds the buffer `buf`. The function can have unexpected behavior when the input exceeds the buffer.
- The `fopen` function has implementation-specific behavior related to whether it sets `errno` on errors or whether it accepts additional characters following the standard mode specifiers.

### Polyspace Implementation

Polyspace reports a violation of this rule if you use the functions from the `cstdio` library. Polyspace detects the use of these `cstdio` functions:

- File operation functions such as `remove` and `rename`.
- File access functions such as `fclose`,`fflush`, and `fopen`.
- Formatted input/output functions such as `fprintf`, `fscanf`, `printf`, and `scanf`.
- Character input output functions such as `fgetc`, `fgets`, `fputc`, and `getc`.
- Direct input/output functions such as `fread` and `fwrite`.
- File positioning functions such as `fgetpos` and `fsetpos`.
- Error handling functions such as `clearerr`, `ferror`, and `perror`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `gets`

```
#include <cstdio>
```

```
void func()
{
    char array[10];
    fgets(array, sizeof array, stdin); //Noncompliant
}
```

The use of `fgets` violates this rule.

Declare objects with appropriate storage durations

## Description

### Rule Definition

*Declare objects with appropriate storage durations.*

### Polyspace Implementation

The rule checker checks for **Pointer or reference to stack variable leaving scope**.

## Examples

### Pointer or reference to stack variable leaving scope

#### Issue

**Pointer or reference to stack variable leaving scope** occurs when a pointer or reference to a local variable leaves the scope of the variable. For instance:

- A function returns a pointer to a local variable.
- A function performs the assignment `globPtr = &locVar`. `globPtr` is a global pointer variable and `locVar` is a local variable.
- A function performs the assignment `*paramPtr = &locVar`. `paramPtr` is a function parameter that is, for instance, an `int**` pointer and `locVar` is a local `int` variable.
- A C++ method performs the assignment `memPtr = &locVar`. `memPtr` is a pointer data member of the class the method belongs to. `locVar` is a variable local to the method.

The defect also applies to memory allocated using the `alloca` function. The defect does not apply to static, local variables. Polyspace assumes that the local objects within a function definition are in the same scope.

#### Risk

Local variables are allocated an address on the stack. Once the scope of a local variable ends, this address is available for reuse. Using this address to access the local variable value outside the variable scope can cause unexpected behavior.

If a pointer to a local variable leaves the scope of the variable, Polyspace Bug Finder highlights the defect. The defect appears even if you do not use the address stored in the pointer. For maintainable code, it is a good practice to not allow the pointer to leave the variable scope. Even if you do not use the address in the pointer now, someone else using your function can use the address, causing undefined behavior.

#### Fix

Do not allow a pointer or reference to a local variable to leave the variable scope.

#### Example - Pointer to Local Variable Returned from Function

```
void func2(int *ptr) {
    *ptr = 0;
}

int* func1(void) {
    int ret = 0; //Noncompliant
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

In this example, `func1` returns a pointer to local variable `ret`.

In `main`, `ptr` points to the address of the local variable. When `ptr` is accessed in `func2`, the access is illegal because the scope of `ret` is limited to `func1`,

#### Example - Pointer to Local Variable Escapes Through Lambda Expression

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;  //Noncompliant
  auto adder = [&] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

In this example, the `createAdder` function defines a lambda expression `adder` that captures the local variable `addThis` by reference. The scope of `addThis` is limited to the `createAdder` function. When the object returned by `createAdder` is called, a reference to the variable `addThis` is accessed outside its scope. When accessed in this way, the value of `addThis` is undefined.

#### Correction – Capture Local Variables by Copy in Lambda Expression Instead of Reference

If a function returns a lambda expression object, avoid capturing local variables by reference in the lambda object. Capture the variables by copy instead.

Variables captured by copy have the same lifetime as the lambda object, but variables captured by reference often have a smaller lifetime than the lambda object itself. When the lambda object is used, these variables accessed outside scope have undefined values.

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;
  auto adder = [=] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

Avoid information leakage in structure padding

## Description

### Rule Definition

*Avoid information leakage in structure padding.*

### Polyspace Implementation

The rule checker checks for **Information leak via structure padding**.

## Examples

### Information leak via structure padding

#### Issue

**Information leak via structure padding** occurs when you do not initialize the padding data of a structure or union before passing it across a trust boundary. A compiler adds padding bytes to the structure or union to ensure a proper memory alignment of its members. The bit-fields of the storage units can also have padding bits.

**Information leak via structure padding** raises a defect when:

- You call an untrusted function with structure or union pointer type argument containing uninitialized padding data.

  All external functions are considered untrusted.
- You copy or assign a structure or union containing uninitialized padding data to an untrusted object.

  All external structure or union objects, the output parameters of all externally linked functions, and the return pointer of all external functions are considered untrusted objects.

#### Risk

The padding bytes of the passed structure or union might contain sensitive information that an untrusted source can access.

#### Fix

- Prevent the addition of padding bytes for memory alignment by using the `pack` pragma or attribute supported by your compiler.
- Explicitly declare and initialize padding bytes as fields within the structure or union.
- Explicitly declare and initialize bit-fields corresponding to padding bits, even if you use the `pack` pragma or attribute supported by your compiler.

#### Example - Structure with Padding Bytes Passed to External Function

```
#include <stddef.h>
#include <stdlib.h>
```

```
#include <string.h>

typedef struct s_padding
{
 /* Padding bytes may be introduced between
 * 'char c' and 'int i'
 */
        char c;
    int i;

/*Padding bits may be introduced around the bit-fields
* even if you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/

    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
/*Padding bytes not initialized*/

    S_Padding s = {'A', 10, 1, 3, {}};
/*Structure passed to external function*/

    copy_object((void *)out_buffer, (void *)&s, sizeof(s)); //Noncompliant
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

In this example, structure `s1` can have padding bytes between the `char c` and `int i` members. The bit-fields of the storage units of the structure can also contain padding bits. The content of the padding bytes and bits is accessible to an untrusted source when `s1` is passed to `func`.

**Correction — Use pack Pragma to Prevent Padding Bytes**

One possible correction in Microsoft Visual Studio is to use `#pragma pack()` to prevent padding bytes between the structure members. To prevent padding bits in the bit-fields of `s1`, explicitly declare and initialize the bit-fields even if you use `#pragma pack()`.

```
 #include <stddef.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>

#define CHAR_BIT 8

#pragma pack(push, 1)
```

```
typedef struct s_padding
{
/*No Padding bytes when you use "#pragma pack" (Windows) or
* __attribute__((__packed__)) (GNU)*/
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
/* Padding bits explicitely declared */
    unsigned int bf_filler : sizeof(unsigned) * CHAR_BIT - 3;
    unsigned char buffer[20];
}

    S_Padding;

#pragma pack(pop)

/* External function */
extern void copy_object(void *out, void *in, size_t s);

void func(void *out_buffer)
{
    S_Padding s = {'A', 10, 1, 3, 0 /* padding bits */, {}};
    copy_object((void *)out_buffer, (void *)&s, sizeof(s));
}

void main(void)
{
    S_Padding s1;
    func(&s1);
}
```

Do not create incompatible declarations of the same function or object

## Description

*This checker is deactivated in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

### Rule Definition

*Do not create incompatible declarations of the same function or object.*

### Polyspace Implementation

The rule checker checks for **Declaration mismatch**.

## Examples

### Declaration mismatch

#### Issue

**Declaration mismatch** occurs when a function or variable declaration does not match other instances of the function or variable.

#### Risk

When a mismatch occurs between two variable declarations in different compilation units, a typical linker follows an algorithm to pick one declaration for the variable. If you expect a variable declaration that is different from the one chosen by the linker, you can see unexpected results when the variable is used.

A similar issue can occur with mismatch in function declarations.

#### Fix

The fix depends on the type of declaration mismatch. If both declarations indeed refer to the same object, use the same declaration. If the declarations refer to different objects, change the names of the one of the variables. If you change a variable name, remember to make the change in all places that use the variable.

Sometimes, declaration mismatches can occur because the declarations are affected by previous preprocessing directives. For instance, a declaration occurs in a macro, and the macro is defined on one inclusion path but undefined in another. These declaration mismatches can be tricky to debug. Identify the divergence between the two inclusion paths and fix the conflicting macro definitions.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Inconsistent Declarations in Two Files

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
double foo(void); //Noncompliant

int bar(void) {
    return (int)foo();
}
```

In this example, *file1.cpp* declares `foo()` as returning an integer. In *file2.cpp*, `foo()` is declared as returning a double. This difference raises a defect on the second instance of `foo` in *file2*.

#### Correction — Align the Function Return Values

One possible correction is to change the function declarations so that they match. In this example, by changing the declaration of `foo` in *file2.cpp* to match *file1.cpp*, the defect is fixed.

*file1.c*

```
int foo(void) {
    return 1;
}
```

*file2.c*

```
int foo(void);

int bar(void) {
    return foo();
}
```

#### Example - Inconsistent Structure Alignment

*test1.c*

```
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*test2.c*

```
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square; //Noncompliant
```

In this example, a declaration mismatch defect is raised on `square` in *square.h* because Polyspace infers that `square` in *square.h* does not have the same alignment as `square` in *test2.cpp*. This error occurs because the `#pragma pack(1)` statement in *circle.h* declares specific alignment. In *test2.cpp*, *circle.h* is included before *square.h*. Therefore, the `#pragma pack(1)` statement from *circle.h* is not reset to the default alignment after the `aCircle` structure. Because of this omission, *test2.cpp* infers that the `aSquare square` structure also has an alignment of `1` byte.

#### Correction — Close Packing Statements

One possible correction is to reset the structure alignment after the `aCircle` struct declaration. For the GNU or Microsoft Visual compilers, fix the defect by adding a `#pragma pack()` statement at the end of *circle.h*.

*test1.c*

```
#include "square.h"
#include "circle.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*test2.c*

```
#include "circle.h"
#include "square.h"
struct aCircle circle;
struct aSquare square;

int main(){
    square.side=1;
    circle.radius=1;
    return 0;
}
```

*circle.h*

```
#pragma pack(1)

extern struct aCircle{
    int radius;
} circle;

#pragma pack()
```

*square.h*

```
extern struct aSquare {
    unsigned int side:1;
} square;
```

Other compilers require different `#pragma pack` syntax. For your syntax, see the documentation for your compiler.

#### Correction — Use the `Ignore pragma pack directives` Option

One possible correction is to add the `Ignore pragma pack directives` option to your Bug Finder analysis. If you want the structure alignment to change for each structure, and you do not want to see this **Declaration mismatch** defect, use this correction.

1. On the Configuration pane, select the **Advanced Settings** pane.
2. In the **Other** box, enter `-ignore-pragma-pack`.
3. Rerun your analysis.

The **Declaration mismatch** defect is resolved.

Do not declare or define a reserved identifier

## Description

### Rule Definition

*Do not declare or define a reserved identifier.*

### Polyspace Implementation

This checker checks for:

- **Defining or undefining reserved identifier or macro**
- **User-defined literal operator not starting with underscore**

## Examples

### Defining or undefining reserved identifier or macro

#### Issue

The issue occurs when you define, redefine, or undefine a reserved identifier, macro, or function in the Standard Library.

In general, the checker considers identifiers and macros that begin with an underscore followed by an uppercase letter as reserved for the Standard Library.

### User-defined literal operator not starting with underscore

#### Issue

This issue occurs when you define operators of the form

`operator "" *suffix*`

where *`suffix`* does not begin with an underscore or following the underscore, contains characters other than letters (numbers, special characters, and so on).

#### Risk

Since C++11, you can add suffixes to literals that convert numeric values under the hood. For instance, in code where you perform all calculations in a common unit, you can leave unit conversions to dedicated operators and simply use literal suffixes for the units when defining constant values.

In this example, the literal suffixes `_m` and `_km` resolve to calls to `operator"" _m()` and `operator"" _km()` respectively. The operators ensure that all values are converted to the same unit.

```
constexpr long double operator"" _m(long double metres) {
    return metres;
}
```

```
constexpr long double operator"" _km(long double kilometres) {
    return 1000*kilometres;
}
...
long double minSteps = 100.0_m;
long double interCityDist = 100.0_km;
```

User defined literal suffixes must begin with an underscore (_). Literal suffixes not beginning with underscore are reserved for Standard Library.

#### Fix

Make sure that user-defined literal operators begin with an underscore followed by letters only.

Never qualify a reference type with const or volatile

## Description

### Rule Definition

*Never qualify a reference type with const or volatile.*

### Polyspace Implementation

The rule checker checks for these issues:

- **C++ reference type qualified with const or volatile**.
- **C++ reference to const-qualified type with subsequent modification**.

## Examples

### C++ reference type qualified with const or volatile

#### Issue

**const-Qualified Reference Type** occurs when a variable with reference type is declared with the `const` or `volatile` qualifier, for instance:

```
char &const c;
```

#### Risk

The C++14 Standard states that `const` or `volatile` qualified references are ill formed (unless they are introduced through a `typedef`, in which case they are ignored). For instance, a reference to one variable cannot be made to refer to another variable. Therefore, using the `const` qualifier is not required for a variable with a reference type.

Often the use of these qualifiers indicate a coding error. For instance, you meant to declare a reference to a `const`-qualified type:

```
char const &c;
```

but instead declared a `const`-qualified reference:

```
char &const c;
```

If your compiler does not detect the error, you can see unexpected results. For instance, you might expect `c` to be immutable but see a different value of `c` compared to its value at declaration.

#### Fix

See if the `const` or `volatile` qualifier is incorrectly placed. For instance, see if you wanted to refer to a `const`-qualified type and entered:

```
char &const c;
```

instead of:

```
char const &c;
```

If the qualifier is incorrectly placed, fix the error. Place the `const` or `volatile`qualifier before the & operator. Otherwise, remove the redundant qualifier.

#### Example – `const`-Qualified Reference Type

```
int func (int &const iRef) { //Noncompliant
    iRef++;
    return iRef%2;
}
```

In this example, `iRef` is a `const`-qualified reference type. Since `iRef` cannot refer to another variable, the `const` qualifier is redundant.

#### Correction — Remove `const` Qualifier

Remove the redundant `const` qualifier. Since `iRef` is modified in `func`, it is not meant to refer to a `const`-qualified variable. Moving the `const` qualifier before & will cause a compilation error.

```
int func (int &iRef) {
    iRef++;
    return iRef%2;
}
```

#### Correction — Fix Placement of `const` Qualifier

If you do not identify to modify `iRef` in `func`, declare `iRef` as a reference to a `const`-qualified variable. Place the `const` qualifier before the & operator. Make sure you do not modify `iRef` in `func`.

```
int func (int const &iRef) {
    return (iRef+1)%2;
}
```

### C++ reference to const-qualified type with subsequent modification

#### Issue

This defect occurs when a variable that refers to a `const`-qualified type is modified after declaration.

For instance, in this example, `refVal` has a type `const int &`, but its value is modified in a subsequent statement.

```
using constIntRefType = const int &;
void func(constIntRefType refVal, int val){
   ...
   refVal = val; //refVal is modified
   ...
}
```

#### Risk

The `const` qualifier on a reference type implies that a variable of the type is initialized at declaration and will not be subsequently modified.

Compilers can detect modification of references to `const`-qualified types as a compilation error. If the compiler does not detect the error, the behavior is undefined. Polyspace flags this defect regardless of a compilation error.

#### Fix

Avoid modification of `const`-qualified reference types. If the modification is required, remove the `const` qualifier from the reference type declaration.

#### Example – Modification of const-qualified Reference Types

```
typedef const int cint;
typedef cint& ref_to_cint;

void func(ref_to_cint refVal, int initVal){ //Noncompliant
   refVal = initVal;
}
```

In this example, `ref_to_cint` is a reference to a `const`-qualified type. The variable `refVal` of type `ref_to_cint` is supposed to be initialized when `func` is called and not modified subsequently. The modification violates the contract implied by the `const` qualifier. Because `refVal` is a `const` reference, the compilation might fail. Polyspace flags the violation.

#### Correction — Avoid Modification of const-qualified Reference Types

One possible correction is to avoid the `const` in the declaration of the reference type.

```
typedef int& ref_to_int;

void func(ref_to_int refVal, int initVal){
   refVal = initVal;
}
```

Do not write syntactically ambiguous declarations

## Description

### Rule Definition

*Do not write syntactically ambiguous declarations.*

### Polyspace Implementation

The rule checker checks for **Ambiguous Declaration Syntax**.

## Examples

### Ambiguous declaration syntax

#### Issue

This defect occurs when it is not clear from a declaration whether an object declaration or function/parameter declaration is intended. The ambiguity is often referred to as most vexing parse.

For instance, these declarations are ambiguous:

- `ResourceType aResource();`

  It is not immediately clear if `aResource` is a function returning a variable of type `ResourceType` or an object of type `ResourceType`.
- `TimeKeeper aTimeKeeper(Timer());`

  It is not immediately clear if `aTimeKeeper` is an object constructed with an unnamed object of type `Timer` or a function with an unnamed function pointer type as parameter. The function pointer refers to a function with no argument and return type `Timer`.

The checker does not flag ambiguous declarations with global scope. For instance, the analysis does not flag declarations with global scope using the format *`Type`* `a()` where *`Type`* is a class type with a default constructor. The analysis interprets `a` as a function returning the type *`Type`*.

#### Risk

In case of an ambiguous declaration, the C++ Standard chooses a specific interpretation of the syntax. For instance:

- `ResourceType aResource();`

  is interpreted as a declaration of a function `aResource`.
- `TimeKeeper aTimeKeeper(Timer());`

  is interpreted as a declaration of a function `aTimeKeeper` with an unnamed parameter of function pointer type.

If you or another developer or code reviewer expects a different interpretation, the results can be unexpected.

For instance, later you might face a compilation error that is difficult to understand. Since the default interpretation indicates a function declaration, if you use the function as an object, compilers might report a compilation error. The compilation error indicates that a conversion from a function to an object is being attempted without a suitable constructor.

**Fix**

Make the declaration unambiguous. For instance, fix these ambiguous declarations as follows:

- `ResourceType aResource();`

  *Object declaration*:

  If the declaration refers to an object initialized with the default constructor, rewrite it as:

  ```
  ResourceType aResource;
  ```

  prior to C++11, or as:

  ```
  ResourceType aResource{};
  ```

  after C++11.

  *Function declaration*:

  If the declaration refers to a function, use a typedef for the function.

  ```
  typedef ResourceType(*resourceFunctionType)();
  resourceFunctionType aResource;
  ```
- `TimeKeeper aTimeKeeper(Timer());`

  *Object declaration*:

  If the declaration refers to an object `aTimeKeeper` initialized with an unnamed object of class `Timer`, add an extra pair of parenthesis:

  ```
  TimeKeeper aTimeKeeper( (Timer()) );
  ```

  prior to C++11, or use braces:

  ```
  TimeKeeper aTimeKeeper{Timer{}};
  ```

  after C++11.

  *Function declaration*:

  If the declaration refers to a function `aTimeKeeper` with a unnamed parameter of function pointer type, use a named parameter instead.

  ```
  typedef Timer(*timerType)();
  TimeKeeper aTimeKeeper(timerType aTimer);
  ```

**Example – Function or Object Declaration**

```
class ResourceType {
      int aMember;
    public:
      int getMember();
};
```

```
void getResource() {
    ResourceType aResource(); //Noncompliant
}
```

In this example, `aResource` might be used as an object but the declaration syntax indicates a function declaration.

#### Correction — Use {} for Object Declaration

One possible correction (after C++11) is to use braces for object declaration.

```
class ResourceType {
      int aMember;
    public:
      int getMember();
};

void getResource() {
    ResourceType aResource{};
}
```

#### Example – Unnamed Object or Unnamed Function Parameter Declaration

```
class MemberType {};

class ResourceType {
      MemberType aMember;
    public:
      ResourceType(MemberType m) {aMember = m;}
      int getMember();
};

void getResource() {
    ResourceType aResource(MemberType());  //Noncompliant
}
```

In this example, `aResource` might be used as an object initialized with an unnamed object of type `MemberType` but the declaration syntax indicates a function with an unnamed parameter of function pointer type. The function pointer points to a function with no arguments and type `MemberType`.

#### Correction — Use {} for Object Declaration

One possible correction (after C++11) is to use braces for object declaration.

```
class MemberType {};

class ResourceType {
      MemberType aMember;
    public:
      ResourceType(MemberType m) {aMember = m;}
      int getMember();
};

void getResource() {
    ResourceType aResource{MemberType()};
}
```

#### Example – Unnamed Object or Named Function Parameter Declaration

```
class Integer {
    int aMember;
public:
    Integer(int d) {aMember = d;}
    int getMember();
};

int aInt = 0;
void foo(){
    Integer aInteger(Integer(aInt)); //Noncompliant
}
```

In this example, `aInteger` might be an object constructed with an unnamed object `Integer(aInt)` (an object of class `Integer` which itself is constructed using the variable `aInt`). However, the declaration syntax indicates that `aInteger` is a function with a named parameter `aInt` of type `Integer` (the superfluous parenthesis is ignored).

#### Correction — Use of {} for Object Declaration

One possible correction (after C++11) is to use {} for object declaration.

```
class Integer {
    int aMember;
public:
    Integer(int d) {aMember = d;}
    int getMember();
};

int aInt = 0;
void foo(){
    Integer aInteger(Integer{aInt});
}
```

#### Correction — Remove Superfluous Parenthesis for Named Parameter Declaration

If `aInteger` is a function with a named parameter `aInt`, remove the superfluous () around `aInt`.

```
class Integer {
       int aMember;
    public:
       Integer(int d) {aMember = d;}
       int getMember();
};

Integer aInteger(Integer aInt);
```

Overload allocation and deallocation functions as a pair in the same scope

## Description

### Rule Definition

*Overload allocation and deallocation functions as a pair in the same scope.*

### Polyspace Implementation

The rule checker checks for **Missing overload of allocation or deallocation function**.

## Examples

### Missing overload of allocation or deallocation function

#### Issue

**Missing overload of allocation or deallocation function** occurs when you overload `operator new` but do not overload the corresponding `operator delete`, or vice versa.

#### Risk

You typically overload `operator new` to perform some bookkeeping in addition to allocating memory on the free store. Unless you overload the corresponding `operator delete`, it is likely that you omitted some corresponding bookkeeping when deallocating the memory.

The defect can also indicate a coding error. For instance, you overloaded the placement form of `operator new[]`:

```
void *operator new[](std::size_t count, void *ptr);
```

but the non-placement form of `operator delete[]`:

```
void operator delete[](void *ptr);
```

instead of the placement form:

```
void operator delete[](void *ptr, void *p );
```

#### Fix

When overloading `operator new`, make sure that you overload the corresponding `operator delete` in the same scope, and vice versa.

For instance, in a class, if you overload the placement form of `operator new`:

```
class MyClass {
   void* operator new  ( std::size_t count, void* ptr ){
   //...
   }
};
```

Make sure that you also overload the placement form of `operator delete`:

```
class MyClass {
   void operator delete  ( void* ptr, void* place ){
   ...
   }
};
```

To find the `operator delete` corresponding to an `operator new`, see the reference pages for `operator new` and `operator delete`.

**Example – Mismatch Between Overloaded `operator new` and `operator delete`**

```
#include <new>
#include <cstdlib>

int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
      global_store++;
   else
      global_store--;
}

void *operator new(std::size_t size, const std::nothrow_t& tag);
void *operator new(std::size_t size, const std::nothrow_t& tag) { //Noncompliant
    void *ptr = (void*)malloc(size);
    if (ptr != nullptr)
        update_bookkeeping(ptr, true);
    return ptr;
}

void operator delete[](void *ptr, const std::nothrow_t& tag);
void operator delete[](void* ptr, const std::nothrow_t& tag) { //Noncompliant
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

In this example, the operators `operator new` and `operator delete[]` are overloaded but there are no overloads of the corresponding `operator delete` and `operator new[]` operators.

The overload of `operator new` calls a function `update_bookkeeping` to change the value of a global variable `global_store`. If the default `operator delete` is called, this global variable is unaffected, which might defy developer's expectations.

**Correction – Overload the Correct Form of `operator delete`**

If you want to overload `operator new`, overload the corresponding form of `operator delete` in the same scope.

```
#include <new>
#include <cstdlib>

int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
      global_store++;
   else
      global_store--;
}

void *operator new(std::size_t size, const std::nothrow_t& tag);
void *operator new(std::size_t size, const std::nothrow_t& tag) {
    void *ptr = (void*)malloc(size);
    if (ptr != nullptr)
        update_bookkeeping(ptr, true);
    return ptr;
}

void operator delete(void *ptr, const std::nothrow_t& tag);
void operator delete(void* ptr, const std::nothrow_t& tag) {
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

Avoid information leakage when passing a class object across a trust boundary

## Description

### Rule Definition

*Avoid information leakage when passing a class object across a trust boundary.*[7]

### Polyspace Implementation

The rule checker checks for **Information leakage due to structure padding**.

## Examples

### Information Leakage Due to Structure Padding

#### Issue

**Information leakage due to structure padding** occurs when sending a pointer to a data structure across a trust boundary without first initializing any padding bits in the data structure.

#### Risk

Class objects can contain padding bits. Because padding bits are defined by implementation, the layout of a class object can be unique between different compilers and architectures. Padding bits can be present at any location within a class object instance.

Sensitive information such as personal data, passwords, or pointers to kernel data structures can remain within the padding bits if the data is not properly initialized. If a class object is sent across a trust barrier, the sensitive data stored within padding bits can be exposed.

#### Fix

Verify that no sensitive data is contained within the padding bits before sending a class object instance across a trust boundary. Explicitly declare padding bits as fields within the class object or serialize the data before external use.

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

### Example – Possible Leak of Sensitive Data Via Structure Padding

In this example, the structure `test` contains padding bits in order to properly align class data members. These padding bits may contain sensitive data which could be leaked when the data is copied to user space.

```
#include <cstddef>

struct example {
    int car;
    char model;
    int vin;
};

extern int send_to_external(void* dest, void* src, std::size_t size);

void processData(void* user_buffer) {
    example test{};
    test.car = 1;
    test.model = 2;
    test.vin = 3;

    send_to_external(user_buffer, &test, sizeof(test));//Noncompliant
}
```

### Correction – Serialize Data Structure Before Copy

Serialize the data structure before you copy it to an untrusted context so no padding bits contain sensitive data.

```
#include <cstddef>
#include <cstring>

struct example {
    int car;
    char model;
    int vin;
};

extern int send_to_external(void* dest, void* src, std::size_t size);

void processData(void* user_buffer) {
    example test{ 1, 2, 3 };

    unsigned char buff[sizeof(test)];
    std::size_t offset = 0;

    std::memcpy(buff + offset, &test.car, sizeof(test.car));
    offset += sizeof(test.car);
    std::memcpy(buff + offset, &test.model, sizeof(test.model));
    offset += sizeof(test.model);
    std::memcpy(buff + offset, &test.vin, sizeof(test.vin));
    offset += sizeof(test.vin);

    send_to_external(user_buffer, buff, offset /* size of info copied */);
}
```

Avoid cycles during initialization of static objects

## Description

### Rule Definition

*Avoid cycles during initialization of static objects.*[8]

### Polyspace Implementation

The rule checker checks for these issues:

- **Recursive initialization of static variables**
- **Undetermined initialization order of global variables**

## Examples

### Recursive Initialization of Static Variables

#### Issue

This issue occurs when you declare a static variable in a function and initialize the static variable by calling the same function.

```
int foo(int) {
    static int var = foo(0);
    //...
}
```

#### Risk

Recursively initializing a static variable might result in undefined behavior. The code does not need to be infinitely recursive for undefined behavior to occur.

#### Fix

Avoid recursive calls when initializing variables. For example, use zero-initialization at the declaration of a static variable, then compute the values.

[8] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

### Example

In the following example, the behavior is undefined because the initialization of the static variable `buffer` is within the `fibonacci` function, and the initialization of `buffer` requires reentering the same function `fibonacci`.

```
#include <stdexcept>

int fibonacci(int i) noexcept(false)
{
    if (i < 0) {
        //no negative fibonacci number
        throw std::domain_error("Input must be nonegative");
    }
    static const int buffer[] = { fibonacci(0), fibonacci(1),  //Noncompliant
        fibonacci(2), fibonacci(3), fibonacci(4), fibonacci(5),
        fibonacci(6), fibonacci(7) };

    if (i < (sizeof(buffer) / sizeof(int))) {
        return buffer[i];
    }

    return i > 0 ? fibonacci(i - 1) + fibonacci(i - 2) : 1;
}
```

The `fibonacci` function cannot calculate the next value until computation of the previous value is complete.

### Correction

Use zero-initialization to determine if every member of the array an assigned value. If not, recursively compute the value.

```
#include <stdexcept>

int fibonacci(int i) noexcept(false)
{
    if (i < 0) {
        //no negative fibonacci number
        throw std::domain_error("Input must be nonegative");
    }

    static int buffer[7]; // default zero-initailization

    if (i < sizeof(buffer) / sizeof(int))
    {
        if (0 == buffer[i])
        {
            buffer[i] = i > 0 ? fibonacci(i - 1) + fibonacci(i - 2) : 1;
        }
        return buffer[i];
    }

}
```

### Undetermined Initialization Order of Global Variables

#### Issue

This issue occurs when a global variable initialization in a file depends on global variables that are initialized in another file.

#### Risk

If a static variable is used before it is initialized, it may cause unspecified behavior.

#### Fix

Verify that global objects are initialized before their first use.

#### Example

In this example, the file `aSource.cpp` contains the variable `int tacos`. The value of `int tacos` relies on the initialization of `TacoOrder t`. However, `TacoOrder t` might not be initialized by `get_default_taco()` in the source file `otherSource.cpp` before `t.get_num_tacos()` is called inside the source file `aSource.cpp`.

`aHeader.h`:

```
class TacoOrder {
    int numTacos;

public:
    TacoOrder() : numTacos(2) {}
    explicit TacoOrder(int numTacos) : numTacos(numTacos) {}

    int get_num_tacos() const { return numTacos; }
};
```

`aSource.cpp`:

```
#include "aHeader.h"
#include <iostream>

extern TacoOrder t;
int tacos = t.get_num_tacos();

void main()
{
    std::cout << tacos << std::endl;
}
```

`otherSource.cpp`:

```
#include "aHeader.h"

TacoOrder get_default_taco() { return TacoOrder(6); }
TacoOrder t = get_default_taco();
```

#### Correction

In this example, the only file that needs to be changed is `aSource.cpp`.

aHeader.h:

```
class TacoOrder {
    int numTacos;

public:
    TacoOrder() : numTacos(2) {}
    explicit TacoOrder(int numTacos) : numTacos(numTacos) {}

    int get_num_tacos() const { return numTacos; }
};
```

aSource.cpp:

```
#include "aHeader.h"
#include <iostream>

int &get_num_tacos() {
    extern TacoOrder t;
    static int tacos = t.get_num_tacos();
    return tacos;
}

void main()
{
    std::cout << get_num_tacos << std::endl;
}
```

otherSource.cpp:

```
#include "aHeader.h"

TacoOrder get_default_taco() { return TacoOrder(6); }
TacoOrder t = get_default_taco();
```

The initialization of `tacos` happens after the declaration when you move the `static int tacos` object inside the body of a function. `TacoOrder t` is initialized by `get_default_taco()` in source file `otherSource.cpp` by the time `get_num_tacos()` is called inside of `main()`.

Do not let exceptions escape from destructors or deallocation functions

## Description

### Rule Definition

*Do not let exceptions escape from destructors or deallocation functions.*

### Polyspace Implementation

The rule checker checks for **Class destructor exiting with an exception**.

## Examples

### Class destructor exiting with an exception

#### Issue

The checker flags:

- Explicit `throw` statements in the body of a destructor outside of a `try-catch` block. If the destructor calls another function, the checker does not detect if the called function raises an exception.
- The exception specification `noexcept(false)` in the declaration of the destructor.

The checker does not detect:

- A `catch` statement that does not catch exceptions of all types that are thrown.

  The checker considers the presence of a `catch` statement corresponding to a `try` block as an indication that an exception is caught.
- `throw` statements inside `catch` blocks.

#### Risk

Destructors are invoked at the end of code execution. When exceptions arise at this stage, they become unhandled. When such unhandled exceptions arise, depending on the hardware and software that you use, the compiler might abruptly terminate the program execution without deleting the objects in stack. Such abrupt termination might result in a resource leak and security vulnerabilities.

#### Fix

To avoid this issue:

- Declare destructors as `noexcept(true)`.
- Handle exceptions that might arise in destructors by using a `try-catch` block that includes a `catch(...)` block.

#### Example

```
#include<stdexcept>
class C {
    //...
    ~C() noexcept(false) { //Noncompliant
        //...
        throw std::logic_error("Error"); //Noncompliant
    }

};
```

In this example, the destructor of class `C` is specified as `noexcept(false)`. Polyspace flags the declaration. The destructor contains an explicit `throw` statement without encasing it in a `try-catch` block. Polyspace flags the `throw` statement.

#### Correction

One possible correction is to declare destructors as `noexcept(true)`, and then encase any `throw` statement in a `try-catch` block.

```
#include<stdexcept>
class C {
    //...
    ~C() noexcept(true) { //Compliant
        //...
        try{
            throw std::logic_error("Error"); //Compliant
        }catch(...){

        }
    }

};
```

Do not modify the standard namespaces

## Description

### Rule Definition

*Do not modify the standard namespaces.*

### Polyspace Implementation

The rule checker checks for **Modification of standard namespaces**.

## Examples

### Modification of standard namespaces

#### Issue

**Modification of standard namespaces** occurs when you make additions to the namespaces `std`, `posix`, or their subspaces, or you specialize class or function templates from these namespaces.

#### Risk

Adding declarations or definitions to namespace `std` or its subspaces, or to `posix` or its subspaces, leads to undefined behavior. Likewise, explicitly specializing a member function or member class of a standard library leads to undefined behavior.

The standard allows exceptions to the specialization aspect of the rule for standard library templates that require a user-defined type. If you have a process that all rule violations must be justified and an issue flagged by the checker belongs to this category of exceptions, justify the issue using comments in your result or code. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

Do not define an unnamed namespace in a header file

## Description

### Rule Definition

*Do not define an unnamed namespace in a header file.*

### Polyspace Implementation

The rule checker checks for **Unnamed namespace in header file**.

## Examples

### Unnamed namespace in header file

#### Issue

**Unnamed namespace in header file** detects an unnamed namespace in a header file, which can lead to multiple definitions of objects in the namespace.

#### Risk

According to the C++ standard, names in an unnamed namespace, for instance, `aVar` here:

```
namespace {
   int aVar;
}
```

have internal linkage by default. If a header file contains an unnamed namespace, each translation unit `#include`-ing the header file defines its own instance of objects in the namespace. The multiple definitions are probably not what you intended and can lead to unexpected results, undesired memory usage or inadvertently violating the one-definition rule.

#### Fix

Specify names for namespaces in header files or avoid using namespaces in header files.

#### Example – Unexpected Results from Unnamed Namespaces in Header Files

Header File: `aHeader.h`

```
namespace { //Noncompliant
   int aVar;
}
```

First source file: `aSource.cpp`

```
#include "aHeader.h"
#include <iostream>

void setVar(int arg) {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = arg;
    std::cout << "Value set at: " << aVar << std::endl;
}
```

Second source file: `anotherSource.cpp`

```
#include "aHeader.h"
#include <iostream>

extern void setVar(int);

void resetVar() {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = 0;
    std::cout << "Value set at: 0" << std::endl;
}

void main() {
    setVar(1);
    resetVar();
}
```

In this example, the unnamed namespace leads to two definitions of `aVar` in the translation unit from `aSource.cpp` and the translation unit from `anotherSource.cpp`. The two definitions lead to the possibly unexpected output:

```
Current value: 0
Value set at: 1
Current value: 0
Value set at: 0
```

#### Correction – Avoid the Unnamed Namespace

One possible correction is to simply avoid a namespace in the header file.

Header File: `aHeader.h`

```
extern int aVar;
```

First source file: `aSource.cpp`

```
#include "aHeader.h"
#include <iostream>

void setVar(int arg) {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = arg;
    std::cout << "Value set at: " << aVar << std::endl;
}
```

Second source file: `anotherSource.cpp`

```
#include "aHeader.h"
#include <iostream>

extern void setVar(int);
int aVar;

void resetVar() {
    std::cout << "Current value: " << aVar << std::endl;
    aVar = 0;
    std::cout << "Value set at: 0" << std::endl;
}

void main() {
    setVar(1);
    resetVar();
}
```

You now see the expected sequence in the output:

```
Current value: 0
Value set at: 1
Current value: 1
Value set at: 0
```

Obey the one-definition rule

## Description

### Rule Definition

*Obey the one-definition rule.*

### Polyspace Implementation

This checker checks for:

- **Inline constraint not respected**
- **Nonidentical definitions of function or object across modules**

## Examples

### Inline Constraint Not Respected

#### Issue

**Inline constraint not respected** occurs when you refer to a file scope modifiable static variable or define a local modifiable static variable in a nonstatic inlined function. The checker considers a variable as modifiable if it is not `const`-qualified.

For instance, `var` is a modifiable `static` variable defined in an `inline` function `func`. `g_step` is a file scope modifiable static variable referred to in the same inlined function.

```
static int g_step;
inline void func (void) {
   static int var = 0;
   var += g_step;
}
```

#### Risk

When you modify a static variable in multiple function calls, you expect to modify the same variable in each call. For instance, each time you call `func`, the same instance of `var1` is incremented but a separate instance of `var2` is incremented.

```
void func(void) {
   static var1 = 0;
   var2 = 0;
   var1++;
   var2++;
}
```

If a function has an inlined and a noninlined definition in separate files, when you call the function, the C standard allows compilers to use either the inlined or the noninlined form (see ISO/IEC 9899:2011, sec. 6.7.4). If your compiler uses an inlined definition in one call and the noninlined definition in another, you are no longer modifying the same variable in both calls. This behavior defies the expectations from a static variable.

### Fix

Use one of these fixes:

- If you do not intend to modify the variable, declare it as `const`.

  If you do not modify the variable, there is no question of unexpected modification.
- Make the variable non-`static`. Remove the `static` qualifier from the declaration.

  If the variable is defined in the function, it becomes a regular local variable. If defined at file scope, it becomes an extern variable. Make sure that this change in behavior is what you intend.
- Make the function `static`. Add a `static` qualifier to the function definition.

  If you make the function `static`, the file with the inlined definition uses the inlined definition when the function is called. Other files use another definition of the function. The compiler does not decide which function definition is used.

### Example - Static Variable Use in Inlined and External Definition

```
/* file1. c  : contains inline definition of get_random()*/

inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef; //Noncompliant
    static unsigned int m_w = 0xbaddecaf; //Noncompliant

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}
```

```
/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

In this example, get_random() has an inline definition in file1.c and an external definition in file2.c. When get_random is called in file1.c, compilers can to choose whether to use the inline or the external definition.

Depending on the definition used, you might or might not modify the version of m_z and m_w in the inlined version of get_random(). This behavior contradicts the usual expectations from a static variable. When you call get_random(), you expect to modify the same m_z and m_w.

**Correction — Make Inlined Function Static**

One possible correction is to make the inlined get_random() static. Irrespective of your compiler, calls to get_random() in file1.c then use the inlined definition. Calls to get_random() in other files use the external definition. This fix removes the ambiguity about which definition is used and whether the static variables in that definition are modified.

```
/* file1. c  : contains inline definition of get_random()*/

static inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef; //Compliant
    static unsigned int m_w = 0xbaddecaf; //Compliant

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}

/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

### Nonidentical Definitions of Function or Object Across Modules

#### Issue

**Nonidentical definitions of function or object across modules** occurs when a function or object is defined in multiple modules, but with differences in tokens like identifiers, keywords, literals, operators, punctuators, and other separators. The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions
- Uncalled and undefined local functions
- Unused types and variables

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See "Checkers Deactivated in Polyspace as You Code Analysis".*

#### Risk

Having different definitions of the same object or noninlined function in different modules results in unexpected behavior. The program might crash and leak memory depending on the software and hardware that you use.

#### Fix

Define objects and noninlined functions without any differences in tokens. Use the same sequence and types of tokens in the definitions of objects and noninline functions across modules.

#### Example: Definition of Object Has Token Difference

This example uses two files:

- `file1.cpp`:

```
typedef struct S
{
   int x;
   int y;
}S;
void foo(S& s){
//...
}
```

- `file2.cpp`:

```
typedef struct S //Noncompliant
{
   int y;
   int x;
}S ;
void bar(S& s){
//...
}
```

In this example, both `file1.cpp` and `file2.cpp` define the structure `S`. The definitions switch the order of the structure fields.

#### Correction: Use Identical Definition Across Modules

One possible correction is to define the structure `S` in a header file and include the header in the two modules.

- `S.h`:

  ```
  struct S //Compliant
  {
     int x;
     int y;
  };
  ```
- `file1.cpp`:

  ```
  #include"S.h"
  void foo(S& s){
  //...
  }
  ```
- `file2.cpp`:

  ```
  #include"S.h"
  void bar(S& s){
  //...
  }
  ```

Do not dereference null pointers

## Description

### Rule Definition

*Do not dereference null pointers.*

### Polyspace Implementation

The rule checker checks for **Null pointer**.

### Extend Checker

A default Bug Finder analysis might not flag a **Null pointer** issue when the input values are unknown and only a subset of inputs cause the issue. To check for a **Null pointer** issue caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Null pointer

**Issue**

**Null pointer** occurs when you use a pointer with a value of NULL as if it points to a valid memory location.

**Risk**

Dereferencing a null pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

**Fix**

Check a pointer for NULL before dereference.

If the issue occurs despite an earlier check for NULL, look for intermediate events between the check and the subsequent dereference. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

**Example - Null pointer error**

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 int* p=NULL;
 *p=arr[0];  //Noncompliant
 /* Defect: Null pointer dereference */

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

The pointer `p` is initialized with value of `NULL`. However, when the value `arr[0]` is written to `*p`, `p` is assumed to point to a valid memory location.

#### Correction — Assign Address to Null Pointer Before Dereference

One possible correction is to initialize `p` with a valid memory address before dereference.

```
#include <stdlib.h>

int FindMax(int *arr, int Size)
{
 /* Fix: Assign address to null pointer */
 int* p=&arr[0];

 for(int i=0;i<Size;i++)
  {
   if(arr[i] > (*p))
     *p=arr[i];
  }

 return *p;
}
```

Do not modify objects with temporary lifetime

## Description

### Rule Definition

*Do not modify objects with temporary lifetime.*

### Polyspace Implementation

The rule checker checks for **Accessing object with temporary lifetime**.

## Examples

### Accessing object with temporary lifetime

#### Issue

**Accessing object with temporary lifetime** occurs when you attempt to read from or write to an object with temporary lifetime that is returned by a function call. In a structure or union returned by a function, and containing an array, the array members are temporary objects. The lifetime of temporary objects ends:

- When the full expression or full declarator containing the call ends, as defined in the C11 Standard.
- After the next sequence point, as defined in the C90 and C99 Standards. A sequence point is a point in the execution of a program where all previous evaluations are complete and no subsequent evaluation has started yet.

For C++ code, **Accessing object with temporary lifetime** raises a defect only when you write to an object with a temporary lifetime.

If the temporary lifetime object is returned by address, no defect is raised.

#### Risk

Modifying objects with temporary lifetime is undefined behavior and can cause abnormal program termination and portability issues.

#### Fix

Assign the object returned from the function call to a local variable. The content of the temporary lifetime object is copied to the variable. You can now modify it safely.

#### Example - Modifying Temporary Lifetime Object Returned by Function Call

```
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6
```

```
struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

/* func_temp() returns a struct value containing
* an array with a temporary lifetime.
*/
int func(void) {

/*Writing to temporary lifetime object is
 undefined behavior
 */
    return ++(func_temp().a[0]); //Noncompliant
}

void main(void) {
    (void)func();
}
```

In this example, `func_temp()` returns by value a structure with an array member `a`. This member has temporary lifetime. Incrementing it is undefined behavior.

**Correction — Assign Returned Value to Local Variable Before Writing**

One possible correction is to assign the return of the call to `func_temp()` to a local variable. The content of the temporary object `a` is copied to the variable, which you can safely increment.

```
 #include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

int func(void) {

/* Assign object returned by function call to
 *local variable
 */
    struct S_Array s = func_temp();

/* Local variable can safely be
 *incremented
 */
    ++(s.a[0]);
    return s.a[0];
}

void main(void) {
    (void)func();
}
```

Do not cast pointers into more strictly aligned pointer types

## Description

### Rule Definition

*Do not cast pointers into more strictly aligned pointer types.*

### Polyspace Implementation

The rule checker checks for **Source buffer misaligned with destination buffer**.

## Examples

### Source buffer misaligned with destination buffer

#### Issue

The issue **Source buffer misaligned with destination buffer** occurs when the source pointer and the target pointer in a pointer-to-pointer conversion do not align. The misalignment occurs for reasons such as:

- The source pointer points to a buffer that is smaller than what the target pointer points to.
- The source pointer points to a buffer that is larger than what the target pointer points to, but the buffer size is not an exact multiple of the destination buffer size.

Polyspace does not report violations of this rule if:

- You use an environment that allows conversion between misaligned pointers. For instance, in 32bit and 64bit `x86` environment, converting `char*` into `uint16_t*` does not terminate a program abnormally.
- You use a source pointer that aligns correctly to the target type. For instance:
  - You use the `alignas` specifier to match the alignment of the source pointer with that of the target pointer.
  - You use pointers returned by functions such as `aligned_alloc()`, `malloc()`, and `realloc()`. These pointers matches the alignment of the target pointer.

#### Risk

If the alignment of a pointer changes in a pointer-to-pointer conversion, dereferencing the converted pointer causes abnormal program termination.

#### Fix

Avoid changing the alignment of a pointer in a pointer-to-pointer conversion.

#### Example — Change in Pointer Alignment During Conversion

```
#include <string.h>
struct record {
  int len;
  /* ... */
};

int copyBuffer (char *data, int offset)
{
  struct record *tmp;
  struct record dest;
  tmp = (struct record *) (data + offset);   //Noncompliant
  memcpy (&dest, tmp, sizeof (dest));
  /* ... */

  return dest.len;
}
```

In this example, the function `copyBuffer` converts a `char*` pointer into a `struct record*` pointer, followed by a `memcpy` operation. The `memcpy` operation assumes a `struct record*` alignment of `tmp`, which leads to undefined behavior. The rule checker reports a violation of this rule.

To avoid the issue, use `data + offset` as the source argument of the `memcpy` operation instead of using an intermediate `struct record*` pointer.

#### Example — Use alignas Specifier to Avoid Alignment Mismatch

This example aligns the `char` pointer `char_p` as an `int` by using the `alignas` specifier. Because `char_p` is aligned as an `int`, converting it to an `int*` does not violate this rule.

```
#include <stdalign.h>
#include <assert.h>

void foo(void) {
  /* Align char_p to the alignment of an int */
  alignas(int) char char_p = 'a';
  int *int_p = (int *)&char_p; //Compliant
  char *char_new = (char *)int_p;
  /* Both char_new and &char_p point to equally aligned objects */

}
```

Call functions with the correct number and type of arguments

## Description

### Rule Definition

*Call functions with the correct number and type of arguments.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Bad file access mode or status**.
- **Unreliable cast of function pointer**.
- **Standard function call with incorrect arguments**.
- **Function declaration mismatch**
- **Incompatible Argument**

## Examples

### Bad file access mode or status

#### Issue

**Bad file access mode or status** occurs when you use functions in the `fopen` or `open` group with invalid or incompatible file access modes, file creation flags, or file status flags as arguments. For instance, for the `open` function, examples of valid:

- Access modes include `O_RDONLY`, `O_WRONLY`, and `O_RDWR`
- File creation flags include `O_CREAT`, `O_EXCL`, `O_NOCTTY`, and `O_TRUNC`.
- File status flags include `O_APPEND`, `O_ASYNC`, `O_CLOEXEC`, `O_DIRECT`, `O_DIRECTORY`, `O_LARGEFILE`, `O_NOATIME`, `O_NOFOLLOW`, `O_NONBLOCK`, `O_NDELAY`, `O_SHLOCK`, `O_EXLOCK`, `O_FSYNC`, `O_SYNC` and so on.

The defect can occur in the following situations.

| Situation | Risk | Fix |
|---|---|---|
| You pass an empty or invalid access mode to the `fopen` function.<br>According to the ANSI C standard, the valid access modes for `fopen` are:<br>• `r`,`r+`<br>• `w`,`w+`<br>• `a`,`a+`<br>• `rb`, `wb`, `ab`<br>• `r+b`, `w+b`, `a+b`<br>• `rb+`, `wb+`, `ab+` | `fopen` has undefined behavior for invalid access modes.<br>Some implementations allow extension of the access mode such as:<br>• GNU: `rb+cmxe,ccs=utf`<br>• Visual C++: `a+t`, where `t` specifies a text mode.<br>However, your access mode string must begin with one of the valid sequences. | Pass a valid access mode to `fopen`. |
| You pass the status flag `O_APPEND` to the `open` function without combining it with either `O_WRONLY` or `O_RDWR`. | `O_APPEND` indicates that you intend to add new content at the end of a file. However, without `O_WRONLY` or `O_RDWR`, you cannot write to the file.<br>The `open` function does not return -1 for this logical error. | Pass either `O_APPEND\|O_WRONLY` or `O_APPEND\|O_RDWR` as access mode. |
| You pass the status flags `O_APPEND` and `O_TRUNC` together to the `open` function. | `O_APPEND` indicates that you intend to add new content at the end of a file. However, `O_TRUNC` indicates that you intend to truncate the file to zero. Therefore, the two modes cannot operate together.<br>The `open` function does not return -1 for this logical error. | Depending on what you intend to do, pass one of the two modes. |
| You pass the status flag `O_ASYNC` to the `open` function. | On certain implementations, the mode `O_ASYNC` does not enable signal-driven I/O operations. | Use the `fcntl(pathname, F_SETFL, O_ASYNC);` instead. |

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.

- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Access Mode with fopen

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "rw"); //Noncompliant
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

In this example, the access mode `rw` is invalid. Because `r` indicates that you open the file for reading and `w` indicates that you create a new file for writing, the two access modes are incompatible.

#### Correction — Use Either r or w as Access Mode

One possible correction is to use the access mode corresponding to what you intend to do.

```
#include <stdio.h>

void func(void) {
    FILE *file = fopen("data.txt", "w");
    if(file!=NULL) {
        fputs("new data",file);
        fclose(file);
    }
}
```

### Unreliable cast of function pointer

#### Issue

**Unreliable cast of function pointer** occurs when a function pointer is cast to another function pointer that has a different argument or return type.

#### Risk

If you cast a function pointer to another function pointer that has a different argument or return type, and then use the latter function pointer to call a function, the behavior is undefined.

#### Fix

Avoid a cast between two function pointers that have a mismatch in argument or return types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Unreliable Cast of Function Pointer Error

```
int f(char c) {
    return c;
}

int g(int i) {
    return i;
}

typedef int (*fptr_t)(char);
typedef int (*gptr_t)(int);

void call() {
    gptr_t ptr = (gptr_t) f;//Noncompliant
    int i = ptr(511); // Undefined behavior
}
```

In this example, the pointer to function `f` is cast to `gptr_t`, which is the type of the function `g`. When the function pointer is used to call `f` by using integers, the code behavior is undefined. Polyspace flags the unreliable cast of the function pointer.

#### Correction — Avoid Function Pointer Cast

To avoid undefined behavior, refactor your code so that the function `f` is not cast into a different argument type. For instance:

```
 int f(int c) { //Fix: declare f with int argument
    return c;
}

int g(int i) {
    return i;
}

typedef int (*fptr_t)(char);
typedef int (*gptr_t)(int);

void call() {
    gptr_t ptr = (gptr_t) f;//Compliant
    int i = ptr(511);
}
```

### Standard function call with incorrect arguments

#### Issue

**Standard function call with incorrect arguments** occurs when the arguments to certain standard functions do not meet the requirements for their use in the functions.

For instance, the arguments to these functions can be invalid in the following ways.

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| String manipulation functions such as `strlen` and `strcpy` | The pointer arguments do not point to a `NULL`-terminated string. | The behavior of the function is undefined. | Pass a `NULL`-terminated string to string manipulation functions. |
| File handling functions in `stdio.h` such as `fputc` and `fread` | The `FILE*` pointer argument can have the value `NULL`. | The behavior of the function is undefined. | Test the `FILE*` pointer for `NULL` before using it as function argument. |
| File handling functions in `unistd.h` such as `lseek` and `read` | The file descriptor argument can be -1. | The behavior of the function is undefined.<br>Most implementations of the `open` function return a file descriptor value of -1. In addition, they set `errno` to indicate that an error has occurred when opening a file. | Test the return value of the `open` function for -1 before using it as argument for `read` or `lseek`.<br>If the return value is -1, check the value of `errno` to see which error has occurred. |
| | The file descriptor argument represents a closed file descriptor. | The behavior of the function is undefined. | Close the file descriptor only after you have completely finished using it. Alternatively, reopen the file descriptor before using it as function argument. |
| Directory name generation functions such as `mkdtemp` and `mkstemps` | The last six characters of the string template are not `XXXXXX`. | The function replaces the last six characters with a string that makes the file name unique. If the last six characters are not `XXXXXX`, the function cannot generate a unique enough directory name. | Test if the last six characters of a string are `XXXXXX` before using the string as function argument. |
| Functions related to environment variables such as `getenv` and `setenv` | The string argument is `""`. | The behavior is implementation-defined. | Test the string argument for `""` before using it as `getenv` or `setenv` argument. |
| | The string argument terminates with an equal sign, `=`. For instance, `"C="` instead of `"C"`. | The behavior is implementation-defined. | Do not terminate the string argument with `=`. |

| Function Type | Situation | Risk | Fix |
|---|---|---|---|
| String handling functions such as `strtok` and `strstr` | • `strtok`: The delimiter argument is `""`.<br>• `strstr`: The search string argument is `""`. | Some implementations do not handle these edge cases. | Test the string for `""` before using it as function argument. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - `NULL` Pointer Passed as `strnlen` Argument

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};

int func() {
    char* s = NULL;
    return strnlen(s, SIZE20); //Noncompliant
}
```

In this example, a `NULL` pointer is passed as `strnlen` argument instead of a `NULL`-terminated string.

Before running analysis on the code, specify a GNU compiler. See `Compiler (-compiler)`.

#### Correction — Pass `NULL`-terminated String

Pass a `NULL`-terminated string as the first argument of `strnlen`.

```
#include <string.h>
#include <stdlib.h>

enum {
    SIZE10 = 10,
    SIZE20 = 20
};
```

```
int func() {
    char* s = "";
    return strnlen(s, SIZE20);
}
```

### Function declaration mismatch

#### Issue

**Note** In C++ code, this checker applies to functions that are specified as `extern "C"`.

**Function declaration mismatch** occurs when the prototype of a `extern "C"` function does not match its definition. Type mismatch between the arguments of the function definition and the function prototype might depend on your environment. Polyspace considers two types as compatible if they have the same size and signedness in the environment that you use. For instance, if your specify `-target` as i386, Polyspace considers `long` and `int` as compatible types.

In C++, if a function is not specified as `extern "C"` and its prototype does not match any function definition, the compiler treats the prototype as that of an undefined overload of the function. Polyspace does not flag calls to such undefined functions.

*The checker does not flag this issue in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”.*

#### Risk

Function declaration mismatch might result in undefined behavior. When function declarations are specified with `extern "C"`, mismatches between definition and declaration of a function might produce only warnings during compilation, resulting in code that compiles but behaves in an unexpected way.

#### Fix

- Before you call a function, provide its complete prototype, even if you define the function later in the same file.
- Avoid any mismatch between the number arguments in the function prototype declaration and the function definition.
- Avoid any mismatch between the argument types of the function prototype declaration and the function definition.

#### Example — Noncompliant Function Calls

```
// file1.c
extern "C" void foo(int iVar){
    //...
}
extern "C" void bar(int iVar){
    //...
}
extern "C" void fubar(int A, ...){
    //...
}
```

```
//prototype.h
extern "C" void foo(void);
extern "C" void fubar(int A, ...);
extern "C" void bar(long iVar);
```

```
//file2.c
//file2.c
#include"prototype.h"
void call_funcs(){
    int iTemp;
    float fTemp;
    long lTemp;
    foo(); //Noncompliant
    bar(lTemp);//Noncompliant in x86_64
    fubar(iTemp,fTemp);//Compliant

}
```

In this example, the functions `foo`, `bar`, and `fubar` are defined in the file `file1.c`. Their prototypes are declared in `prototype.h`. These functions are then called in the file `file2.c`.

- The function `foo` is defined with an `int` argument but its prototype is declared without any argument. Because of this mismatch, Polyspace flags the function call.
- The function `bar` is defined with an `int` argument but its prototype is declared with a `long` argument. These two types are not compatible in `x86_64` environment. When you specify `-target` as `x86_64`, Polyspace flags the function call.
- The call to the variadic function `fubar` is compliant because its call signature, prototype, and definition matches.

#### Correction — Compliant Function Calls

The fix for this defect is to declare complete and accurate prototypes for the called functions. In this case, fix the raised issues by resolving the mismatches between the function definition and prototype declaration. Update the function calls to match the updated prototypes.

```
// file1.c
extern "C" void foo(int iVar){
    //...
}
extern "C" void bar(int iVar){
    //...
}
extern "C" void fubar(int A, ...){
    //...
}
```

```
//prototype.h
extern "C" void foo(int);
extern "C" void fubar(int A, ...);
extern "C" void bar(int iVar);
```

```
//file2.c
//file2.c
#include"prototype.h"
void call_funcs(){
    int iTemp;
    float fTemp;
    long lTemp;
    foo(iTemp); //Compliant
    bar(iTemp);//Compliant in x86_64
    fubar(iTemp,fTemp);//Compliant

}
```

### Incompatible Argument

#### Issue

**Incompatible Argument** occurs when an external function is called by using an argument that is not compatible with the prototype. The compatibility of types might depend on the set of hardware and software that you use. For instance, consider this code:

```
extern long foo(int);
```

```
long bar(long i) {
    return foo(i); //Noncompliant: calls foo(int) with a long
}
```

The external function `foo` is called with a `long` when an `int` is expected. In environments where the size of an `int` is smaller than the size of a `long`, this function call is incompatible with the prototype, resulting in a defect.

In C++, this defect might cause a compilation error.

#### Risk

Calling external functions with arguments that are incompatible with the parameter is undefined behavior. Depending on your environment, the code might compile but behave in an unexpected way.

#### Fix

When calling external functions, use argument types that are smaller or equal in size compared to the parameter type defined in the prototype. Check the sizes of various integer types in your environment to determine compatibility of argument and parameter types.

#### Example — Call External Functions with Incompatible argument

```
extern long foo1(int);
extern long foo2(long);
void bar(){
    int varI;
    long varL;
    foo1(varL);//Noncompliant
    foo2(varI);//Compliant
}
```

In this example, the external function `foo1` is called with a `long` argument, while the prototype specifies the parameter as an `int`. In `x86` architecture, the size of `long` is larger than the size of `int`. The call `foo1(varL)` might result in undefined behavior. Polyspace flags the call. The call `foo2(varI)` uses an `int` argument while the parameter is specified as a `long`. This type of mismatch is compliant with this rule because the size of `int` is not larger than the size of `long`.

To run this example in Polyspace, use these options:

- `-target x86_64`

See `Target processor type (-target)`.

#### Correction — Cast Variables Explicitly to Match Argument to Parameter

To fix this issue, cast the argument of `foo1` explicitly so that argument type and parameter type matches.

```
extern long foo1(int);
extern long foo2(long);
void bar(){
    int varI;
    long varL;
    foo1((int)varL);//Compliant
    foo2(varI);//Compliant
}
```

Do not access a variable through a pointer of an incompatible type

## Description

### Rule Definition

*Do not access a variable through a pointer of an incompatible type.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Pointer conversion to unrelated pointer type**
- **Reading memory reallocated from object of another type without reinitializing first**

.

## Examples

### Pointer conversion to unrelated pointer type

#### Issue

This issue occurs when you convert a pointer to an unrelated pointer type. The checker flags all pointer conversions including between a pointer to a `struct` object and a pointer to the first member of the same `struct` type. Indirect conversions from a pointer to non-pointer type are not detected.

#### Risk

The outcome of the conversion between pointers of unrelated types is unspecified in the C standard. Such conversion might result in unexpected behavior.

#### Fix

Avoid converting pointers to unrelated types. Refactor your code and logic to reduce the necessity of pointer conversions.

### Reading memory reallocated from object of another type without reinitializing first

#### Issue

This issue occurs when you do the following in sequence:

1. Reallocate memory to an object with a type that is different from the original allocation.

   For instance, in this code snippet, a memory originally allocated to a pointer with type `struct A*` is reallocated to a pointer with type `struct B*`:

   ```
   struct A;
   struct B;

   struct A *Aptr = (struct A*) malloc(sizeof(struct A));
   struct B *Bptr = (struct B*) realloc(Aptr, sizeof(struct B));
   ```

2 Read from this reallocated memory without reinitializing the memory first.

Read accesses on the pointer to the reallocated memory can happen through pointer dereference or array indexing. Passing the pointer to a function that takes a pointer to a `const`-qualified object as the corresponding parameter also counts as a read access.

**Risk**

Reading from reallocated memory that has not been reinitialized is undefined behavior.

**Fix**

Reinitialize memory after reallocation and before the first read access.

The checker considers any write access on the pointer to the reallocated memory as satisfying the reinitialization requirement (even if the object might only be partially reinitialized). Write accesses on the pointer to the reallocated memory can happen through pointer dereference or array indexing. Passing the pointer to a function that takes a pointer to a non-`const`-qualified object as the corresponding parameter also counts as a write access.

**Example – Noncompliant: Reading from Reallocated Memory Without Reinitializing First**

```
#include<cstdlib>

struct group {
    char *groupFirst;
    int groupSize;
};

struct groupWithID {
    int groupID;
    char *groupFirst;
    int groupSize;
};

char* readName();
int readSize();

void createGroup(int nextAvailableID) {
    struct group *aGroup;
    struct groupWithID *aGroupWithID;

    aGroup = (struct group*) malloc(sizeof(struct group));
    aGroup->groupFirst = readName();
    aGroup->groupSize  = readSize();

    if(!aGroup) {
        /*Handle error*/
    }

    /* Reassign to group with ID */
    aGroupWithID = (struct groupWithID*) realloc(aGroup, sizeof(struct groupWithID));
    if(!aGroupWithID) {
        free(aGroup);
        /*Handle error*/
    }

    if(aGroupWithID -> groupSize > 0) { /* Noncompliant */
```

```
        /* ... */
    }

    /* ...*/
    free(aGroupWithID);
}
```

In this example, the memory allocated to a `group*` pointer using the `malloc` function is reallocated to a `groupWithID*` pointer using the `realloc` function. There is a read access on the reallocated memory before the memory is reinitialized.

**Correction – Reinitialize Memory After Reallocation and Before First Read**

Reinitialize the memory assigned to the `groupWithID*` pointer before the first read access. All bits of the memory can be reinitialized using the `memset` function.

```
#include<cstdlib>
#include<cstring>

struct group {
    char *groupFirst;
    int groupSize;
};

struct groupWithID {
    int groupID;
    char *groupFirst;
    int groupSize;
};

char* readName();
int readSize();

void createGroup(int nextAvailableID) {
    struct group *aGroup;
    struct groupWithID *aGroupWithID;

    aGroup = (struct group*) malloc(sizeof(struct group));
    aGroup->groupFirst = readName();
    aGroup->groupSize  = readSize();

    if(!aGroup) {
        /*Handle error*/
    }

    /* Reassign to group with ID */
    aGroupWithID = (struct groupWithID*) realloc(aGroup, sizeof(struct groupWithID));
    if(!aGroupWithID) {
        free(aGroup);
        /*Handle error*/
    }

    memset(aGroupWithID, 0 , sizeof(struct groupWithID));
    /* Reinitialize group */
    if(aGroupWithID -> groupSize > 0) {
        /* ... */
    }
    /* ...*/
    free(aGroupWithID);
}
```

Do not compare padding data

## Description

### Rule Definition

*Do not compare padding data.*

### Polyspace Implementation

The rule checker checks for **Memory comparison of padding data**.

## Examples

### Memory comparison of padding data

#### Issue

**Memory comparison of padding data** occurs when you use the `memcmp` function to compare two structures as a whole. In the process, you compare meaningless data stored in the structure padding.

For instance:

```
struct structType {
    char member1;
    int member2;
    //...
    //...
};

structType var1;
structType var2;
//...
//...
if(memcmp(&var1,&var2,sizeof(var1)))
{...}
```

#### Risk

If members of a structure have different data types, your compiler introduces additional padding for data alignment in memory. For an example of padding, see `Higher Estimate of Size of Local Variables`.

The content of these extra padding bytes is meaningless. The C Standard allows the content of these bytes to be indeterminate, giving different compilers latitude to implement their own padding. If you perform a byte-by-byte comparison of structures with `memcmp`, you compare even the meaningless data stored in the padding. You might reach the false conclusion that two data structures are not equal, even if their corresponding members have the same value.

#### Fix

Instead of comparing two structures in one attempt, compare the structures member by member.

For efficient code, write a function that does the comparison member by member. Use this function for comparing two structures.

You can use `memcmp` for byte-by-byte comparison of structures only if you know that the structures do not contain padding. Typically, to prevent padding, you use specific attributes or pragmas such as `#pragma pack`. However, these attributes or pragmas are not supported by all compilers and make your code implementation-dependent. If your structures contain bit-fields, using these attributes or pragmas cannot prevent padding.

#### Example - Structures Compared with `memcmp`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{

    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    if (0 == memcmp(left, right, sizeof(S_Padding))) //Noncompliant
    {
        return 1;
    }
    else
        return 0;
}
```

In this example, `memcmp` compares byte-by-byte the two structures that `left` and `right` point to. Even if the values stored in the structure members are the same, the comparison can show an inequality if the meaningless values in the padding bytes are not the same.

#### Correction — Compare Structures Member by Member

One possible correction is to compare individual structure members.

**Note** You can compare entire arrays by using `memcmp`. All members of an array have the same data type. Padding bytes are not required to store arrays.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define fatal_error() abort()

typedef struct s_padding
{
    char c;
    int i;
    unsigned int bf1:1;
    unsigned int bf2:2;
    unsigned char buffer[20];
} S_Padding ;

/* Function that guarantees safe access to the input memory */
extern int trusted_memory_zone(void *ptr, size_t sz);

int func(const S_Padding *left, const S_Padding *right)
{
    if (!trusted_memory_zone((void *)left, sizeof(S_Padding)) ||
        !trusted_memory_zone((void *)right, sizeof(S_Padding))) {
        fatal_error();
    }

    return ((left->c == right->c) &&
            (left->i == right->i) &&
            (left->bf1 == right->bf1) &&
            (left->bf2 == right->bf2) &&
            (memcmp(left->buffer, right->buffer, 20) == 0));
}
```

Do not perform assignments in selection statements

## Description

### Rule Definition

*Do not perform assignments in selection statements.*

### Polyspace Implementation

The rule checker checks for **Invalid use of = (assignment) operator**.

## Examples

### Invalid use of = (assignment) operator

#### Issue

**Invalid use of = operator** occurs when an assignment is made inside the predicate of a conditional, such as `if` or `while`.

In C and C++, a single equal sign is an assignment not a comparison. Using a single equal sign in a conditional statement can indicate a typo or a mistake.

#### Risk

- Conditional statement tests the wrong values— The single equal sign operation assigns the value of the right operand to the left operand. Then, because this assignment is inside the predicate of a conditional, the program checks whether the new value of the left operand is nonzero or not NULL.
- Maintenance and readability issues — Even if the assignment is intended, someone reading or updating the code can misinterpret the assignment as an equality comparison instead of an assignment.

#### Fix

- If the assignment is a bug, to check for equality, add a second equal sign (==).
- If the assignment inside the conditional statement was intentional, to improve readability, separate the assignment and the test. Move the assignment outside the control statement. In the control statement, simply test the result of the assignment.

  If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

  - “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
  - “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
  - “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Single Equal Sign Inside an `if` Condition

```
#include <stdio.h>

void bad_equals_ex(int alpha, int beta)
{
    if(alpha = beta) //Noncompliant
    {
        printf("Equal\n");
    }
}
```

The equal sign is flagged as a defect because the assignment operator is used within the predicate of the if-statement. The predicate assigns the value `beta` to `alpha`, then implicitly tests whether `alpha` is true or false.

#### Correction — Change Expression to Comparison

One possible correction is adding an additional equal sign. This correction changes the assignment to a comparison. The if condition compares whether `alpha` and `beta` are equal.

```
#include <stdio.h>

void equality_test(int alpha, int beta)
{
    if(alpha == beta)
    {
        printf("Equal\n");
    }
}
```

#### Correction — Assignment and Comparison Inside the `if` Condition

If an assignment must be made inside the predicate, a possible correction is adding an explicit comparison. This correction assigns the value of `beta` to `alpha`, then explicitly checks whether `alpha` is nonzero. The code is clearer.

```
#include <stdio.h>

int assignment_not_zero(int alpha, int beta)
{
    if((alpha = beta) != 0)
    {
        return alpha;
    }
    else
    {
        return 0;
    }
}
```

#### Correction — Move Assignment Outside the `if` Statement

If the assignment can be made outside the control statement, one possible correction is to separate the assignment and comparison. This correction assigns the value of `beta` to `alpha` before the if. Inside the if-condition, only `alpha` is given to test if `alpha` is nonzero or not NULL.

```
#include <stdio.h>
```

```
void assign_and_print(int alpha, int beta)
{
    alpha = beta;
    if(alpha)
    {
        printf("%d", alpha);
    }
}
```

Do not use a bitwise operator with a Boolean-like operand

## Description

### Rule Definition

*Do not use a bitwise operator with a Boolean-like operand.*

### Polyspace Implementation

The rule checker checks for **Use of bitwise operator with a Boolean-like operand**.

## Examples

### Use of bitwise operator with a Boolean-like operand

#### Issue

**Use of bitwise operator with a Boolean-like operand** occurs when you use bitwise operators, such as:

- Bitwise AND (&, &=)
- Bitwise OR (|, |=)
- Bitwise XOR (^, ^=)
- Bitwise NOT(~)

with:

- Boolean type variables
- Outputs of relational or equality expressions

Using Boolean type variables as array indices, in Boolean arithmetic expression, and in shifting operations does not raise this defect.

#### Risk

Boolean-like operands, such as variables of type `bool` and outputs of relational operators typically appear in logical expressions. Using a bitwise operator in an expression containing Boolean variables and relational operators might be a sign of logic error. Because bitwise operators and logical operators look similar, you might inadvertently use a bitwise operator instead of a logical operator. Such logic errors do not raise any compilation error and can introduce bugs in your code that are difficult to find.

#### Fix

Use logical operators in expressions that contain Boolean variables and relational operator. To indicate that you intend to use a bitwise operator in such an expression, use parentheses.

#### Example — Possible Bug Due to Using Bitwise Operator

```
class User{
    //...
    int uid;
    int euid;
public:
    int getuid();
    int geteuid();
};
void Noncompliant ()
{
    User nU;
    if (nU.getuid () & nU.geteuid () == 0) {   //Noncompliant
        //...
    }else{
        //...
    }
}
```

In this example, the `if-else` block is executed conditionally. The conditional statement uses the bitwise AND (&) instead of the logical AND (&&), perhaps by mistake. Consider when the function `nU.geteuid()` evaluates to 0, and `nU.getuid()` evaluates to 2. In this case, the `else` block of code executes if you use & because `2&1` evaluates to `false`. Conversely, the `if` block of code executes when you use && because `2&&1` evaluates to `true`. Using & instead of && might introduce logic errors and bugs in your code that are difficult to find. Polyspace flags the use of bitwise operators in these kinds of expressions where relational operators are also used.

#### Correction — Use Logical Operators with Boolean-Like Operands

One possible correction is to use logical operators in expressions that contain relational operators and Boolean variables.

```
class User{
    //...
    int uid;
    int euid;
public:
    int getuid();
    int geteuid();
};
void Noncompliant ()
{
    User nU;
    if (nU.getuid () && nU.geteuid () == 0) {   //Compliant
        //...
    }else{
        //...
    }
}
```

Do not call va_arg with an argument of the incorrect type

## Description

### Rule Definition

*Do not call va_arg with an argument of the incorrect type.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Incorrect data type passed to va_arg**.
- **Too many va_arg calls for current argument list**.

## Examples

### Incorrect data type passed to va_arg

#### Issue

**Incorrect data type passed to va_arg** when the data type in a va_arg call does not match the data type of the variadic function argument that va_arg reads.

For instance, you pass an unsigned char argument to a variadic function func. Because of default argument promotion, the argument is promoted to int. When you use a va_arg call that reads an unsigned char argument, a type mismatch occurs.

```
void func (int n, ...) {
   ...
   va_list args;
   va_arg(args, unsigned char);
   //...
}

void main(void) {
   unsigned char c;
   func(1,c);
}
```

#### Risk

In a variadic function (function with variable number of arguments), you use va_arg to read each argument from the variable argument list (va_list). The va_arg use does not guarantee that there actually exists an argument to read or that the argument data type matches the data type in the va_arg call. You have to make sure that both conditions are true.

Reading an incorrect type with a va_arg call can result in undefined behavior. Because function arguments reside on the stack, you might access an unwanted area of the stack.

#### Fix

Make sure that the data type of the argument passed to the variadic function matches the data type in the `va_arg` call.

Arguments of a variadic function undergo default argument promotions. The argument data types of a variadic function cannot be determined from a prototype. The arguments of such functions undergo default argument promotions (see Sec. 6.5.2.2 and 7.15.1.1 in the C99 Standard). Integer arguments undergo integer promotion and arguments of type `float` are promoted to `double`. For integer arguments, if a data type can be represented by an `int`, for instance, `char` or `short`, it is promoted to an `int`. Otherwise, it is promoted to an `unsigned int`. All other arguments do not undergo promotion.

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for `MISRA C:2012 Rule 17.1` or `MISRA C++:2008 Rule 8-4-1` to detect use of variadic functions.

#### Example - `char` Used as Function Argument Type and va_arg argument

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, unsigned char); //Noncompliant
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

In this example, `func` takes an `unsigned char` argument, which undergoes default argument promotion to `int`. The data type in the `va_arg` call is still `unsigned char`, which does not match the `int` argument type.

#### Correction — Use `int` as va_arg Argument

One possible correction is to read an `int` argument with `va_arg`.

```
#include <stdarg.h>
#include <stdio.h>

unsigned char func(size_t count, ...) {
    va_list ap;
    unsigned char result = 0;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
    }
    va_end(ap);
    return result;
}

void func_caller(void) {
    unsigned char c = 0x12;
    (void)func(1, c);
}
```

### Too many va_arg calls for current argument list

#### Issue

**Too many va_arg calls for current argument list** occurs when the number of calls to va_arg exceeds the number of arguments passed to the corresponding variadic function. The analysis raises a defect only when the variadic function is called.

**Too many va_arg calls for current argument list** does not raise a defect when:

- The number of calls to va_arg inside the variadic function is indeterminate. For example, if the calls are from an external source.
- The va_list used in va_arg is invalid.

#### Risk

When you call va_arg and there is no next argument available in va_list, the behavior is undefined. The call to va_arg might corrupt data or return an unexpected result.

#### Fix

Ensure that you pass the correct number of arguments to the variadic function.

#### Example - No Argument Available When Calling va_arg

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/
int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {
/* No further argument available
* in va_list when calling va_arg
*/

            result += va_arg(ap, int); //Noncompliant
        }
    }
    va_end(ap);
    return result;
}
```

```
void func(void) {

    (void)variadic_func(2, 100);

}
```

In this example, the named argument and only one variadic argument are passed to `variadic_func()` when it is called inside `func()`. On the second call to `va_arg`, no further variadic argument is available in `ap` and the behavior is undefined.

**Correction — Pass Correct Number of Arguments to Variadic Function**

One possible correction is to ensure that you pass the correct number of arguments to the variadic function.

```
#include <stdarg.h>
#include <stddef.h>
#include <math.h>

/* variadic function defined with
* one named argument 'count'
*/

int variadic_func(int count, ...) {
    int result = -1;
    va_list ap;
    va_start(ap, count);
    if (count > 0) {
        result = va_arg(ap, int);
        count --;
        if (count > 0) {

/* The correct number of arguments is
* passed to va_list when variadic_func()
* is called inside func()
*/
            result += va_arg(ap, int);
        }
    }
    va_end(ap);
    return result;
}

void func(void) {

    (void)variadic_func(2, 100, 200);

}
```

Do not depend on the order of evaluation for side effects

## Description

### Rule Definition

*Do not depend on the order of evaluation for side effects.*

### Polyspace Implementation

The rule checker checks for **Expression value depends on order of evaluation**.

## Examples

### Expression value depends on order of evaluation

#### Issue

The issue occurs when the value of an expression is not the same depending on the order of evaluation of the expression.

An expression can have different values under the following conditions:

- The same variable is modified more than once in the expression, or is both read and written.
- The expression allows more than one order of evaluation.

Therefore, the rule checker forbids expressions where a variable is modified more than once and can cause different results under different orders of evaluation. The rule checker also detects cases where a volatile variable is read more than once in an expression.

#### Risk

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

Do not delete an array through a pointer of the incorrect type

## Description

### Rule Definition

*Do not delete an array through a pointer of the incorrect type.*[9]

### Polyspace Implementation

The rule checker checks for the issue **Delete operator used to destroy downcast object of different type**.

## Examples

### Delete Operator Used to Destroy Downcast Object of Different Type

#### Issue

This issue occurs when an array object is deleted through a pointer type that is different from the pointer type of the object.

#### Risk

Deleting an array through the incorrect pointer type results in undefined behavior.

#### Fix

Match the static pointer type to the dynamic type of the object.

#### Example — Delete Downcast Object Through Different Static Pointer Type than Dynamic Object Type

```
struct Shape {
    virtual ~Shape() = default;
};

struct Rectangle : Shape {};

void example()
```

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

```
{
    Shape* r = new Rectangle[10];
    // do something
    delete[] r;        //Noncompliant
}
```

In this example, the pointer to the new `Rectangle` object is stored as the pointer type `Shape*`. As `Shape` and `Rectangle` are different types, when you attempt to delete the `Rectangle` array through `Shape*`, the result is undefined behavior.

**Correction — Delete Downcast Object Through Same Static Pointer Type as Dynamic Object Type**

```
struct Shape {
    virtual ~Shape() = default;
};

struct Rectangle : Shape {};

void example()
{
    Rectangle* r = new Rectangle[10];
    // do something
    delete[] r;
}
```

By changing the pointer type from `Shape*` to `Rectangle*`, you can avoid undefined behavior when deleting the array through the pointer. This is because the static type and dynamic type of the object are the same.

Do not rely on side effects in unevaluated operands

## Description

### Rule Definition

*Do not rely on side effects in unevaluated operands.*

### Polyspace Implementation

The rule checker checks for the following:

- **Logical operator operand with side effects**
- **`sizeof`, `alignof` or `decltype` operand with side effects**

## Examples

### Logical operator operand with side effects

#### Issue

The issue occurs when the right hand operand of a logical && or || operator contains side effects. When evaluated, an expression with side effect modifies at least one of the variables in the expression.

The checker does not consider volatile accesses and function calls as potential side effects.

#### Risk

When evaluated, an expression with side effect modifies at least one of the variables in the expression. For instance, `n++` is an expression with side effect.

The right-hand operand of a:

- Logical && operator is evaluated only if the left-hand operand evaluates to true.
- Logical `||` operator is evaluated only if the left-hand operand evaluates to false.

In other cases, the right-hand operands are not evaluated, so side effects of the expression do not take place. If your program relies on the side effects, you might see unexpected results in those cases.

#### Fix

If you want the expression in the right-hand operand evaluated, perform the evaluation in a separate statement.

For instance, instead of:

```
if(isOK && n++) {}
```

perform the operation in two steps:

```
n++;
if(isOK && n) {}
```

### `sizeof`, `alignof`, or `decltype` operand with side effects

#### Issue

This issue occurs when the `sizeof`, `alignof` or `decltype` operator operates on an expression with a side effect. When evaluated, an expression with side effect modifies at least one of the variables in the expression.

For instance, the defect checker does not flag `sizeof(n+1)` because `n+1` does not modify `n`. The checker flags `sizeof(n++)` because `n++` is intended to modify `n`.

#### Risk

Side effects in an `alignof` operator or `decltype` operator do not persist beyond the operation. The expression in a `sizeof` operator is evaluated only if it is required for calculating the size of a variable-length array, for instance, `sizeof(a[n++])`.

When an expression with a side effect is not evaluated, the variable modification from the side effect does not happen. If you rely on the modification, you can see unexpected results.

#### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result in a `sizeof`, `_Alignof`, or `_Generic` operator.

For instance, instead of:

```
a = sizeof(n++);
```

perform the operation in two steps:

```
n++;
a = sizeof(n);
```

The checker considers a function call as an expression with a side effect. Even if the function does not have side effects now, it might have side effects on later additions. The code is more maintainable if you call the function outside the `sizeof` operator. If you call a function in a `decltype`, for instance, to select the correct overload of a function and then determine its return type, the checker considers such a call as an exception.

#### Example – Increment Operator in `sizeof`

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    unsigned int b = (unsigned int)sizeof(++a); //Noncompliant
    printf ("%u, %u\n", a, b);
}
```

In this example, `sizeof` operates on `++a`, which is intended to modify `a`. Because the expression is not evaluated, the modification does not happen. The `printf` statement shows that `a` still has the value `1`.

#### Correction — Perform Increment Outside `sizeof`

One possible correction is to perform the increment first, and then provide the result to the `sizeof` operator.

```
#include <stdio.h>

void func(void) {
    unsigned int a = 1U;
    ++a;
    unsigned int b = (unsigned int)sizeof (a);
    printf ("%u, %u\n", a, b);
}
```

Do not read uninitialized memory

## Description

### Rule Definition

*Do not read uninitialized memory.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Non-initialized pointer**.
- **Non-initialized variable**.

### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See “Extend Checkers for Initialization to Check Function Arguments Passed by Pointers”.
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Non-initialized pointer

#### Issue

**Non-initialized pointer** occurs when a pointer is not assigned an address before dereference.

#### Risk

Unless a pointer is explicitly assigned an address, it points to an unpredictable location.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned an address to the pointer but the assignment is unreachable.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a pointer to NULL when declaring the pointer.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Non-initialized pointer error**

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
      {
        pi = new int(0);
        if (pi == NULL)
            return NULL;
      }

    *pi = j; //Noncompliant

    return pi;
}
```

If `prev` is not `NULL`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `NULL` or not. Because `pi` might be accessed without being initialized first, Polyspace flags it.

**Correction — Initialize Pointer on Every Execution Path**

One possible correction is to assign an address to `pi` in each branch of the execution path so that `pi` is not accessed before it is initialized.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
       {
        pi = new int(0);
        if (pi == NULL)
            return NULL;
       }
    /* Fix: Initialize pi in branches of if statement  */
    else
        pi = prev;

    *pi = j;//Compliant
    return pi;
}
```

### Non-initialized variable

#### Issue

**Non-initialized variable** occurs when a variable is not initialized before its value is read.

#### Risk

Unless a variable is explicitly initialized, the variable value is unpredictable. You cannot rely on the variable having a specific value.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned a value to the variable but the assignment is unreachable or you assigned a value to the variable in one of two branches of a conditional statement. Fix the unreachable code or missing assignment.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a variable at declaration.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Non-initialized variable error

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val; //Noncompliant

}
```

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

#### Correction — Initialize During Declaration

One possible correction is to initialize `val` during declaration so that the initialization is not bypassed on some execution paths.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    /* Fix: Initialize val */
    int val=0;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
 }
```

`val` is assigned an initial value of 0. When `command` is not equal to 2, the function `get_sensor_value` returns this value.

Do not access an object outside of its lifetime

## Description

### Rule Definition

*Do not access an object outside of its lifetime.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Non-initialized pointer**.
- **Non-initialized variable**.
- **Use of previously freed pointer**.
- **Pointer or reference to stack variable leaving scope**.
- **Accessing object with temporary lifetime**.

### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See “Extend Checkers for Initialization to Check Function Arguments Passed by Pointers”.
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Non-initialized pointer

#### Issue

**Non-initialized pointer** occurs when a pointer is not assigned an address before dereference.

#### Risk

Unless a pointer is explicitly assigned an address, it points to an unpredictable location.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned an address to the pointer but the assignment is unreachable.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below. It is a good practice to initialize a pointer to NULL when declaring the pointer.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Non-initialized pointer error

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == nullptr)
      {
        pi = new int;
        if (pi == nullptr) return NULL;
      }
    *pi = j;  //Noncompliant

    return pi;
}
```

If `prev` is not `nullptr`, the pointer `pi` is not assigned an address. However, `pi` is dereferenced on every execution paths, irrespective of whether `prev` is `nullptr` or not.

#### Correction — Initialize Pointer on Every Execution Path

One possible correction is to assign an address to `pi` when `prev` is not `nullptr`. Alternatively, initialize `pi` as a `nullptr` during its declaration.

```
#include <cstdlib>

int* assign_pointer(int* prev)
{
    int j = 42;
/*Fix: Initialize pointers by using nullptr during declaration*/
    int* pi = nullptr;

    if (prev == NULL)
       {
        pi = new int;
        if (pi == nullptr) return NULL;
       }
    /* Fix: Initialize pi in branches of if statement  */
    else
        pi = prev;
    *pi = j;
    return pi;
}
```

### Non-initialized variable

#### Issue

**Non-initialized variable** occurs when a variable is not initialized before its value is read.

#### Risk

Unless a variable is explicitly initialized, the variable value is unpredictable. You cannot rely on the variable having a specific value.

#### Fix

The fix depends on the root cause of the defect. For instance, you assigned a value to the variable but the assignment is unreachable or you assigned a value to the variable in one of two branches of a conditional statement. Fix the unreachable code or missing assignment.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below. It is a good practice to initialize a variable at declaration.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Non-initialized variable error

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val; //Noncompliant
}
```

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

#### Correction — Initialize During Declaration

One possible correction is to initialize `val` during declaration so that the initialization is not bypassed on some execution paths.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    /* Fix: Initialize val */
    int val=0;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val;
 }
```

`val` is assigned an initial value of 0. When `command` is not equal to 2, the function `get_sensor_value` returns this value.

### Use of previously freed pointer

#### Issue

**Use of previously freed pointer** occurs when you access a block of memory after deallocating the block, for instance, by using the `free` function or the `delete` operator.

#### Risk

When a pointer is allocated dynamic memory by using the functions `malloc`, `calloc`, `realloc` or the operator `new`, it points to a memory location on the heap. When you use the `free` function or the `delete` operator on this pointer, the associated block of memory is deallocated. Trying to access this block of memory can result in unpredictable behavior or even a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to deallocate the memory later or allocate another memory block to the pointer before access.

As a good practice, after you deallocate a memory block, assign the corresponding pointer to `nullptr`. Before dereferencing pointers, check if they are `nullptr` and handle the error. In this way, you are protected against accessing a deallocated block.

#### Example - Use of Previously Freed Pointer Error

```
#include <cstdlib>
int increment_content_of_address(int base_val, int shift)
   {
    int j;
    int* pi = new int;
    if (pi == NULL) return 0;

    *pi = base_val;
    delete pi;
    j = *pi + shift; //Noncompliant

    return j;
   }
```

The `delete` operator deallocates the block of memory that `pi` refers to. Therefore, dereferencing`pi` after the `delete pi;` statement is not valid.

**Correction — Deallocate Pointer After Use**

One possible correction is to deallocate the pointer `pi` only after the last instance where it is accessed.

```
#include <cstdlib>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = new int;
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is deallocated after its last use */
    delete pi;
    return j;
}
```

**Correction — Use `std::unique_ptr`**

Another possible correction is to use a `std::unique_ptr` instead of a raw pointer. Smart pointers such as `std::unique_ptr` manages their own resources. because you don't have to deallocate smart pointers explicitly, they are not inadvertently accessed after deallocation.

```
#include <cstdlib>
#include <memory>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    /* Fix: A smart pointer is used*/
    std::unique_ptr<int>   pi(new int(3));
    if (pi == nullptr) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;
    return j;
}
```

### Pointer or reference to stack variable leaving scope

#### Issue

**Pointer or reference to stack variable leaving scope** occurs when a pointer or reference to a local variable leaves the scope of the variable. For instance:

- A function returns a pointer to a local variable.
- A function performs the assignment `globPtr = &locVar`. `globPtr` is a global pointer variable and `locVar` is a local variable.
- A function performs the assignment `*paramPtr = &locVar`. `paramPtr` is a function parameter that is, for instance, an `int**` pointer and `locVar` is a local `int` variable.
- A C++ method performs the assignment `memPtr = &locVar`. `memPtr` is a pointer data member of the class the method belongs to. `locVar` is a variable local to the method.

The defect also applies to memory allocated using the `alloca` function. The defect does not apply to static, local variables. Polyspace assumes that the local objects within a function definition are in the same scope.

#### Risk

Local variables are allocated an address on the stack. Once the scope of a local variable ends, this address is available for reuse. Using this address to access the local variable value outside the variable scope can cause unexpected behavior.

If a pointer to a local variable leaves the scope of the variable, Polyspace Bug Finder highlights the defect. The defect appears even if you do not use the address stored in the pointer. For maintainable code, it is a good practice to not allow the pointer to leave the variable scope. Even if you do not use the address in the pointer now, someone else using your function can use the address, causing undefined behavior.

#### Fix

Do not allow a pointer or reference to a local variable to leave the variable scope.

#### Example - Pointer to Local Variable Returned from Function

```
void func2(int *ptr) {
    *ptr = 0;
}

int* func1(void) {
    int ret = 0; //Noncompliant
    return &ret ;
}
void main(void) {
    int* ptr = func1() ;
    func2(ptr) ;
}
```

In this example, `func1` returns a pointer to local variable `ret`.

In `main`, `ptr` points to the address of the local variable. When `ptr` is accessed in `func2`, the access is illegal because the scope of `ret` is limited to `func1`,

#### Example - Pointer to Local Variable Escapes Through Lambda Expression

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd; //Noncompliant
  auto adder = [&] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

In this example, the `createAdder` function defines a lambda expression `adder` that captures the local variable `addThis` by reference. The scope of `addThis` is limited to the `createAdder` function. When the object returned by `createAdder` is called, a reference to the variable `addThis` is accessed outside its scope. When accessed in this way, the value of `addThis` is undefined.

#### Correction – Capture Local Variables by Copy in Lambda Expression Instead of Reference

If a function returns a lambda expression object, avoid capturing local variables by reference in the lambda object. Capture the variables by copy instead.

Variables captured by copy have the same lifetime as the lambda object, but variables captured by reference often have a smaller lifetime than the lambda object itself. When the lambda object is used, these variables accessed outside scope have undefined values.

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;
  auto adder = [=] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

### Accessing object with temporary lifetime

#### Issue

**Accessing object with temporary lifetime** occurs when you attempt to read from or write to an object with temporary lifetime that is returned by a function call. In a structure or union returned by a function, and containing an array, the array members are temporary objects. The lifetime of temporary objects ends:

- When the full expression or full declarator containing the call ends, as defined in the C11 Standard.
- After the next sequence point, as defined in the C90 and C99 Standards. A sequence point is a point in the execution of a program where all previous evaluations are complete and no subsequent evaluation has started yet.

For C++ code, **Accessing object with temporary lifetime** raises a defect only when you write to an object with a temporary lifetime.

If the temporary lifetime object is returned by address, no defect is raised.

#### Risk

Modifying objects with temporary lifetime is undefined behavior and can cause abnormal program termination and portability issues.

#### Fix

Assign the object returned from the function call to a local variable. The content of the temporary lifetime object is copied to the variable. You can now modify it safely.

#### Example - Modifying Temporary Lifetime Object Returned by Function Call

```
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>

#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

/* func_temp() returns a struct value containing
* an array with a temporary lifetime.
*/
int func(void) {

/*Writing to temporary lifetime object is
 undefined behavior
 */
    return ++(func_temp().a[0]); //Noncompliant
}

void main(void) {
    (void)func();
}
```

In this example, `func_temp()` returns by value a structure with an array member `a`. This member has temporary lifetime. Incrementing it is undefined behavior.

#### Correction — Assign Returned Value to Local Variable Before Writing

One possible correction is to assign the return of the call to `func_temp()` to a local variable. The content of the temporary object `a` is copied to the variable, which you can safely increment.

```
 #include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <string.h>
```

```
#define SIZE6 6

struct S_Array
{
    int t;
    int a[SIZE6];
};

struct S_Array func_temp(void);

int func(void) {

/* Assign object returned by function call to
 *local variable
 */
    struct S_Array s = func_temp();

/* Local variable can safely be
 *incremented
 */
    ++(s.a[0]);
    return s.a[0];
}

void main(void) {
    (void)func();
}
```

Do not access a cv-qualified object through a cv-unqualified type

## Description

### Rule Definition

*Do not access a cv-qualified object through a cv-unqualified type.*

### Polyspace Implementation

The rule checker checks for **Cast removes cv-qualification of pointer**.

## Examples

### Cast removes cv-qualification of pointer

#### Issue

The issue occurs when a cast removes a `const` or `volatile` qualification from the type of a pointer or reference.

## Check Information

**Group:** 02. Expressions (EXP)

# Version History

**Introduced in R2019a**

Do not cast or delete pointers to incomplete classes

## Description

### Rule Definition

*Do not cast or delete pointers to incomplete classes.*

### Polyspace Implementation

The rule checker checks for **Conversion or deletion of incomplete class pointer**.

## Examples

### Conversion or deletion of incomplete class pointer

#### Issue

**Conversion or deletion of incomplete class pointer** occurs when you delete or cast to a pointer to an incomplete class. An incomplete class is one whose definition is not visible at the point where the class is used.

For instance, the definition of class `Body` is not visible when the `delete` operator is called on a pointer to `Body`:

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; }
  // ...
};
```

#### Risk

When you delete a pointer to an incomplete class, it is not possible to call any nontrivial destructor that the class might have. If the destructor performs cleanup activities such as memory deallocation, these activities do not happen.

A similar problem happens, for instance, when you downcast to a pointer to an incomplete class (downcasting is casting from a pointer to a base class to a pointer to a derived class). At the point of downcasting, the relationship between the base and derived class is not known. In particular, if the derived class inherits from multiple classes, at the point of downcasting, this information is not available. The downcasting cannot make the necessary adjustments for multiple inheritance and the resulting pointer cannot be dereferenced.

A similar statement can be made for upcasting (casting from a pointer to derived class to a pointer to a base class).

#### Fix

When you delete or downcast to a pointer to a class, make sure that the class definition is visible.

Alternatively, you can perform one of these actions:

- Instead of a regular pointer, use the `std::shared_ptr` type to point to the incomplete class.
- When downcasting, make sure that the result is valid. Write error-handling code for invalid results.

**Example - Deletion of Pointer to Incomplete Class**

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; } //Noncompliant
  // ...
};
```

In this example, the definition of class `Body` is not visible when the pointer to `Body` is deleted.

**Correction — Define Class Before Deletion**

One possible correction is to make sure that the class definition is visible when a pointer to the class is deleted.

```
class Handle {
  class Body *impl;
public:
  ~Handle();
  // ...
};

// Elsewhere
class Body { /* ... */ };

Handle::~Handle() {
  delete impl;
}
```

**Correction — Use `std::shared_ptr`**

Another possible correction is to use the `std::shared_ptr` type instead of a regular pointer.

```
#include <memory>

class Handle {
  std::shared_ptr<class Body> impl;
  public:
    Handle();
    ~Handle() {}
    // ...
};
```

**Example - Downcasting to Pointer to Incomplete Class**

`File1.h`:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

`File2.h`:

```
void funcprint(class Derived *);
class Base *get_derived();
```

`File1.cpp`:

```
#include "File1.h"
#include "File2.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(reinterpret_cast<class Derived *>(v)); //Noncompliant
}
```

`File2.cpp`:

```
#include "File2.h"
#include "File1.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;
public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
 };

void funcprint(Derived *d) {
  d->do_something();
}

Base *get_derived() {
  return new Derived;
}
```

In this example, the definition of class `Derived` is not visible in `File1.cpp` when a `Base*` pointer to downcast to a `Derived*` pointer.

In `File2.cpp`, class `Derived` derives from two classes, `Base` and `Base2`. This information about multiple inheritance is not available at the point of downcasting in `File1.cpp`. The result of downcasting is passed to the function `funcprint` and dereferenced in the body of `funcprint`. Because the downcasting was done with incomplete information, the dereference can be invalid.

#### Correction — Define Class Before Downcasting

One possible correction is to define the class `Derived` before downcasting a `Base*` pointer to a `Derived*` pointer.

In this corrected example, the downcasting is done in `File2.cpp` in the body of `funcprint` at a point where the definition of class `Derived` is visible. The downcasting is not done in `File1.cpp` where the definition of `Derived` is not visible. The changes from the previous incorrect example are highlighted.

`File1_corr.h`:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

`File2_corr.h`:

```
void funcprint(class Base *);
class Base *get_derived();
```

`File1.cpp`:

```
#include "File1_corr.h"
#include "File2_corr.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(v);
}
```

`File2.cpp`:

```
#include "File2_corr.h"
#include "File1_corr.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;

public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
};

void funcprint(Base *d) {
  Derived *temp = dynamic_cast<Derived*>(d);
  if(temp)  {
     d->do_something();
  }
  else {
      //Handle error
  }
}

Base *get_derived() {
  return new Derived;
}
```

Pass an object of the correct type to va_start

## Description

### Rule Definition

*Pass an object of the correct type to va_start.*

### Polyspace Implementation

The rule checker checks for **Incorrect type data passed to va_start**.

## Examples

### Incorrect type data passed to va_start

#### Issue

**Incorrect type data passed to va_start** occurs when the second argument of the `va_start` macro has one of these data types:

- A data type that changes when undergoing default argument promotion.

  For instance, `char` and `short` undergo promotion to `int` or `unsigned int` and `float` undergoes promotion to `double`. The types `int` and `double` do not change under default argument promotion.
- (C only) A register type or a data type declared with the `register` qualifier.
- (C++ only) A reference data type.
- (C++ only) A data type that has a nontrivial copy constructor or a nontrivial move constructor.

#### Risk

In a variadic function or function with variable number of arguments:

```
void multipleArgumentFunction(int someArg, short rightmostFixedArg, ...) {
    va_list myList;
    va_start(myList, rightmostFixedArg);
    ...
    va_end(myList);
}
```

The `va_start` macro initializes a variable argument list so that additional arguments to the variadic function after the fixed parameters can be captured in the list. According to the C11 and C++14 Standards, if you use one of the flagged data types for the second argument of the `va_start` macro (for instance, `rightmostFixedArg` in the preceding example), the behavior is undefined.

If the data type involves a nontrivial copy constructor, the behavior is implementation-defined. For instance, whether the copy constructor is invoked in the call to `va_start` depends on the compiler.

#### Fix

When using the `va_start` macro, try to use the types `int`, `unsigned int` or `double` for the rightmost named parameter of the variadic function. Then, use this parameter as the second argument of the `va_start` macro.

For instance, in this example, the rightmost named parameter of the variadic function has a supported data type `int`:

```
void multipleArgumentFunction(int someArg, int rightmostFixedArg, ...) {
    va_list myList;
    va_start(myList, rightmostFixedArg);
    ...
    va_end(myList);
}
```

To avoid undefined and implementation-defined behavior, minimize the use of variadic functions. Use the checkers for `MISRA C:2012 Rule 17.1` or `MISRA C++:2008 Rule 8-4-1` to detect use of variadic functions.

#### Example – Incorrect Data Types for Second Argument of va_start

```
#include <string>
#include <cstdarg>

double addVariableNumberOfDoubles(double* weight, short num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num); //Noncompliant
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}

double addVariableNumberOfFloats(float* weight, int num, std::string s, ...) {
    float sum=0.0;
    va_list list;
    va_start(list, s); //Noncompliant
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, float);
    }
    va_end(list);
    return sum;
}
```

In this example, the checker flags the call to `va_start` in:

- `addVariableNumberOfDoubles` because the argument has type `short`, which undergoes default argument promotion to `int`.
- `addVariableNumberOfFloats` because the argument has type `std::string`, which has a nontrivial copy constructor.

#### Correction — Fix Data Type for Second Argument of va_start

Make sure that the second argument of the `va_start` macro has a supported data type. In the following corrected example:

- In `addVariableNumberOfDoubles`, the data type of the last named parameter of the variadic function is changed to `int`.
- In `addVariableNumberOfFloats`, the second and third parameters of the variadic function are switched so that data type of the last named parameter is `int`.

```
#include <string>
#include <cstdarg>

double addVariableNumberOfDoubles(double* weight, int num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}

double addVariableNumberOfFloats(double* weight, std::string s, int num, ...) {
    double sum=0.0;
    va_list list;
    va_start(list, num);
    for(int i=0; i < num; i++) {
        sum+=weight[i]*va_arg(list, double);
    }
    va_end(list);
    return sum;
}
```

Use offsetof() on valid types and members

## Description

### Rule Definition

*Use offsetof() on valid types and members.*

### Polyspace Implementation

The rule checker checks for **Incorrect use of offsetof in C++**.

## Examples

### Incorrect use of offsetof in C++

#### Issue

This defect occurs when you pass arguments to the `offsetof` macro for which the behavior of the macro is not defined.

The `offsetof` macro:

```
offsetof(classType, aMember)
```

returns the offset in bytes of the data member `aMember` from the beginning of an object of type `classType`. For use in `offsetof`, `classType` and `aMember` have certain restrictions:

- `classType` must be a standard layout class.

  For instance, it must not have `virtual` member functions. For more information on the requirements for a standard layout class, see C++ named requirements: StandardLayoutType.
- `aMember` must not be static.
- `aMember` must not be a member function.

The checker flags uses of the `offsetof` macro where the arguments violate one or more of these restrictions.

#### Risk

Violating the restrictions on the arguments of the `offsetof` macro leads to undefined behavior.

#### Fix

Use the `offsetof` macro only on nonstatic data members of a standard layout class.

The result details state which restriction on the `offsetof` macro is violated. Fix the violation.

#### Example – Use of `offsetof` Macro with Nonstandard Layout Class

```
#include <cstddef>
```

```
class myClass {
     int privateData;
  public:
     int publicData;
};

void func() {
  size_t off = offsetof(myClass, publicData); //Noncompliant
  // ...
}
```

In this example, the class `myClass` has two data members with different access control, one private and the other public. Therefore, the class does not satisfy the requirements of a standard layout class and cannot be used with the `offsetof` macro.

**Correction — Use Uniform Access Control for All Data Members**

If the use of `offsetof` is important for the application, make sure that the first argument is a class with a standard layout. For instance, see if you can work around the need for a public data member.

```
#include <cstddef>

class myClass {
     int member1;
     int member2;
  public:
     int getMember2(void) { return member2;}
     friend void func(void);
};

void func() {
  size_t off = offsetof(myClass, member2);
  // ...
}
```

A lambda object must not outlive any of its reference captured objects

## Description

### Rule Definition

*A lambda object must not outlive any of its reference captured objects.*

### Polyspace Implementation

The rule checker checks for **Object Escapes Scope Through Lambda Expression**.

## Examples

### Object Escapes Scope Through Lambda Expression

#### Issue

The issue occurs when a lambda expression captures an object *by reference* and the lambda expression object outlives the captured object. For instance, the captured object is a local variable but the lambda expression object has a much larger scope.

#### Risk

If a lambda expression object outlives one of its reference captured objects, the captured object can be accessed outside its scope.

For instance, consider this function `createFunction`:

```
std::function<std::int32_t()> createFunction() {
   std::int32_t localVar = 0;
   return ([&localVar]() -> std::int32_t {
       localVar = 1;
       return localVar;
   });
}
```

`createFunction` returns a lambda expression object that captures the local variable `localVar` *by reference*. The scope of `localVar` is limited to `createFunction` but the lambda expression object returned has a much larger scope.

This situation can result in an attempt to access the local object `localVar` outside its scope. For instance, when you call `createFunction` and assign the returned lambda expression object to another object `aFunction`:

```
auto aFunction = createFunction();
```

and then invoke the new object `aFunction`:

```
std::int32_t someValue = aFunction();
```

the captured variable `localVar` is no longer in scope. Therefore, the value returned from `aFunction` is undefined.

#### Fix

If a function returns a lambda expression, to avoid accessing a captured object outside its scope, make sure that the lambda expression captures all objects by copy. For instance, you can rewrite `createFunction` as:

```
std::function<std::int32_t()> createFunction() {
   std::int32_t localVar = 0;
   return ([localVar]() mutable -> std::int32_t {
       localVar = 1;
       return localVar;
   });
}
```

#### Example – Pointer to Local Variable Escapes Through Lambda Expression

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd; //Noncompliant
  auto adder = [&] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

In this example, the `createAdder` function defines a lambda expression `adder` that captures the local variable `addThis` by reference. The scope of `addThis` is limited to the `createAdder` function. When the object returned by `createAdder` is called, a reference to the variable `addThis` is accessed outside its scope. When accessed in this way, the value of `addThis` is undefined.

#### Correction – Capture Local Variables by Copy in Lambda Expression Instead of Reference

If a function returns a lambda expression object, avoid capturing local variables by reference in the lambda object. Capture the variables by copy instead.

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd;
  auto adder = [=] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void func() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}
```

Do not access the bits of an object representation that are not part of the object's value representation

## Description

### Rule Definition

*Do not access the bits of an object representation that are not part of the object's value representation.*

### Polyspace Implementation

The rule checker checks for **Accessing padding and `vtable` bits**.

## Examples

### Accessing Padding and `vtable` Bits

#### Issue

This issue occurs when either of these conditions is true:

- You use the function `std::memcmp` on padding bits. For example:

  ```
  class A{char str; int size;}; //Padding beteen the fields.
  void foo(){
      A a1,a2;
      if(std::memcmp(&a1, &a2, sizeof(A))){/**/}//Noncompliant
  }
  ```
- You use the functions `memset` or `memcmp` on `vtable` bits. For example:

  ```
  class A{
  public:
      void virtual eval(){}
  }//Class contains a vtable
  void foo(){
      A *a = new A;
      //...
      std::memset(a,0,sizeof(A));//Noncompliant
      //...
      a->eval();
  }
  ```

The `vtable` holds pointers to different virtual functions available to an object. Padding bits might be inserted between members of an object. These bits are not part of the value representation of an object.

As an exception, this rule allows accessing `vtable` and padding bits if the code does not make assumptions about their values. This rule also allows overwriting the padding bits. For instance, you can use `memcpy()` to copy all object bits containing a bitfield into another object. For instance:

```
struct BF {
    int i : 10;
```

```
    int j;
};
void foo(const BF &a1)
{
    BF a2;
    std::memcpy(&a2, &a1, sizeof(BF));//Compliant
}
```

Depending on your environment and usage, unions might not have any padding bits. Violation of this rule is not reported on unions.

#### Risk

The C++ standard does not specify how the padding bit values and the `vtable` values are set. The values in these bits can vary depending on your hardware and software. Relying on such implementation-dependent values in your code might result in unexpected results that are difficult to diagnose.

#### Fix

Avoid accessing padding bits and `vtable` bits. In C++, the best practice is to avoid functions that directly access object bits, such as `std::memcmp()` and `std::memset()`.

#### Example — Avoid Comparing Padding Bits

```
#include <cstring>
class myString  {
    unsigned char buffer;
public:
    int size;
    void set(const char* );
    char* get();
};

void compmyString(const myString &s1, const myString &s2)
{
    if (!std::memcmp(&s1, &s2, sizeof(myString))) { //Noncompliant
        // ...
    }
}
```

This example implements a string type class `mystring`. The function `compmyString` compares two objects of this class. The comparison is performed by calling `std::memcmp()` to compare the bits of two objects, including the padding bits. Because the values of the padding bits are implementation-defined, using `std::memcmp()` makes the code nonportable and might yield unexpected results. Polyspace reports a violation of this rule.

#### Correction — Compare Value Representation of Objects

When you compare objects, the best practice is to implement appropriately overloaded operators that perform a field-by-field comparison. For instance, to check if two `myString` objects are equal, this code implements the `operator==`, which compares the fields `buffer` and `size`. Using the `operator==` avoids padding bits comparison.

```
#include <cstring>
class myString  {
    unsigned char buffer;
public:
    int size;
    void set(const char* );
    char* get();
    friend bool operator==(const myString &left, const myString &right)
    {
        return left.buffer == right.buffer &&
        left.size == right.size;
    }
};

void compmyString(const myString &s1, const myString &s2)
{
    if (s1==s2) { //Compliant
        // ...
    }
}
```

Do not rely on the value of a moved-from object

## Description

### Rule Definition

*Do not rely on the value of a moved-from object.*[10]

### Polyspace Implementation

The rule checker checks for **Reading the Value of a Moved-from Object**.

## Examples

### Reading the Value of a Moved-from Object

#### Issue

This issue occurs when the value of a source object is read after its content is moved to a destination object by calling the `std::move` function explicitly. Polyspace does not flag accessing the value of a moved-from object if:

- The source object of an explicit move operation is of these types:
  - `std::unique_ptr`
  - `std::shared_ptr`
  - `std::weak_ptr`
  - `std::basic_ios`
  - `std::basic_filebuf`
  - `std::thread`
  - `std::unique_lock`
  - `std::shared_lock`
  - `std::promise`

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

  - `std::future`
  - `std::shared_future`
  - `std::packaged_task`

  These objects do not remain in an unspecified state after their state is moved explicitly.
- The move operation is performed implicitly. For instance, the function `std::remove` might access the state of a source object after an implicit move operation. Polyspace does not flag it. A best practice is to avoid such operations and use safer alternatives that prevent accidental access, such as `std::erase`.
- The source object is of a built-in base type, such as: `int`, `enum`, `float`, `double`, pointer, `std::intptr_t`, `std::nullptr_t`.

**Risk**

Because the state of a source object is generally unspecified after a move operation, it is unsafe to perform operations that rely on the state of the source object after a move operation. Accessing the state of the source object after a move operation might result in a data integrity violation, an unexpected value, or an illegal dereferencing of a pointer.

**Fix**

Avoid operations that might read a source object after its content is moved.

**Example — Reading Value of Source Object After Calling `std::move`**

```
#include<string>
#include<iostream>
void F1()
{
    std::string s1{"string"};
    std::string s2{std::move(s1)};
    // ...
    std::cout
    <<  // Noncompliant
    s1
    << "\n";
    // value after move operation
}
void g(std::string v)
{
    std::cout << v << std::endl;
}

void F3()
{
    std::string s;
    for (unsigned i = 0; i < 10; ++i) {
        s.append(1, static_cast<char>('0' + i));  //Noncompliant
        g(std::move(s));
    }
}
```

- In the function `F1`, the string `s1` is explicitly moved to `s2` by calling `std::move`. After the move operation, the function attempts to read `s1`. Polyspace flags this attempt of reading a source object after an explicit move.

- In the function F3, the string s is explicitly moved and then it is read by the std::string::append function. Polyspace flags this attempt of reading a source object after an explicit move.

**Correction — Read Values of Source Objects in Specified State**

```
#include<string>
#include<iostream>
void F2()
{
    std::unique_ptr<std::int32_t> ptr1 = std::make_unique<std::int32_t>(0);
    std::unique_ptr<std::int32_t> ptr2{std::move(ptr1)};
    std::cout << ptr1.get() << std::endl; // Compliant by exception
}
void g(std::string v)
{
    std::cout << v << std::endl;
}
void F4()
{
    for (unsigned i = 0; i < 10; ++i) {
        std::string s(1, static_cast<char>('0' + i)); // Compliant
        g(std::move(s));
    }
}
```

- In the function F2, the unique pointer ptr1 is explicitly moved to ptr2. Because the state of std::unique_ptr remains in a specified state after the move, reading a source unique pointer after an explicit move is compliant.
- In the function F4, the string s is explicitly moved. In each iteration of the loop, s is initiated to specific content before the move operation is triggered. As a result, the state of s is specified before the object is accessed. This method of accessing the source object after a move operation is compliant with this rule.

Ensure that unsigned integer operations do not wrap

## Description

### Rule Definition

*Ensure that unsigned integer operations do not wrap.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Unsigned integer overflow**.
- **Unsigned integer constant overflow**.

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect an **Unsigned integer overflow** or **Unsigned integer constant overflow**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Unsigned integer overflow

#### Issue

**Unsigned integer overflow** occurs when an operation on unsigned integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

The C11 standard states that unsigned integer overflows result in wrap-around behavior. However, a wrap around behavior might not always be desirable. For instance, if the result of a computation is used as an array size and the computation overflows, the array size is much smaller than expected.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do

not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling. In the error handling code, you can override the default wrap-around behavior for overflows and implement saturation behavior, for instance.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Add One to Maximum Unsigned Integer

```
#include <limits.h>

unsigned int plusplus(void) {

    unsigned uvar = UINT_MAX;
    uvar++; //Noncompliant
    return uvar;
}
```

In the third statement of this function, the variable `uvar` is increased by 1. However, the value of `uvar` is the maximum unsigned integer value, so 1 plus the maximum integer value cannot be represented by an `unsigned int`. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `uvar` is reduced by modulo `UINT_MAX`. The result is `uvar = 1`.

#### Correction — Different Storage Type

One possible correction is to store the operation result in a larger data type. In this example, by returning an `unsigned long long` instead of an `unsigned int`, the overflow error is fixed.

```
#include <limits.h>

unsigned long long plusplus(void) {

    unsigned long long ullvar = UINT_MAX;
    ullvar++;
    return ullvar;
}
```

### Unsigned integer constant overflow

#### Issue

**Unsigned integer constant overflow** occurs when you assign a compile-time constant to a unsigned integer variable whose data type cannot accommodate the value. An `n`-bit unsigned integer holds values in the range `[0, 2^n-1]`.

For instance, `c` is an 8-bit unsigned `char` variable that cannot hold the value 256.

```
unsigned char c = 256;
```

To determine the sizes of fundamental types, Bug Finder uses your specification for `Target processor type (-target)`.

#### Risk

The C standard states that overflowing unsigned integers must be wrapped around (see, for instance, the C11 standard, section 6.2.5). However, the wrap-around behavior can be unintended and cause unexpected results.

#### Fix

Check if the constant value is what you intended. If the value is correct, use a wider data type for the variable.

#### Example - Overflowing Constant from Macro Expansion

```
#define MAX_UNSIGNED_CHAR 255 //Noncompliant
#define MAX_UNSIGNED_SHORT 65535 //Noncompliant

void main() {
    unsigned char c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned short c2 = MAX_UNSIGNED_SHORT + 1;
}
```

In this example, the defect appears on the macros because at least one use of the macro causes an overflow.

#### Correction — Use Wider Data Type

One possible correction is to use a wider data type for the variables that overflow.

```
#define MAX_UNSIGNED_CHAR 255
#define MAX_UNSIGNED_SHORT 65535

void main() {
    unsigned short c1 = MAX_UNSIGNED_CHAR + 1;
    unsigned int c2 = MAX_UNSIGNED_SHORT + 1;
}
```

Ensure that integer conversions do not result in lost or misinterpreted data

## Description

### Rule Definition

*Ensure that integer conversions do not result in lost or misinterpreted data.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer conversion overflow**.
- **Call to memset with unintended value**.
- **Sign change integer conversion overflow**.
- **Tainted sign change conversion**.
- **Unsigned integer conversion overflow**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer conversion overflow**, **Sign change integer conversion overflow**, or **Unsigned integer conversion overflow**. To check for these issues caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- A default Bug Finder analysis might not flag a **Tainted sign change conversion** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Integer conversion overflow

#### Issue

**Integer conversion overflow** occurs when converting an integer to a smaller integer type. If the variable does not have enough bytes to represent the original value, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer conversion overflows result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Converting from `int` to `char`

```
char convert(void) {

    int num = 1000000;

    return (char)num; //Noncompliant
}
```

In the return statement, the integer variable `num` is converted to a `char`. However, an 8-bit or 16-bit character cannot represent 1000000 because it requires at least 20 bits. So the conversion operation overflows.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number.

```
long convert(void) {

    int num = 1000000;

    return (long)num;
}
```

### Call to memset with unintended value

#### Issue

**Call to memset with unintended value** occurs when Polyspace Bug Finder detects a use of the `memset` or `wmemset` function with possibly incorrect arguments.

`void *memset (void *ptr, int value, size_t num)` fills the first `num` bytes of the memory block that `ptr` points to with the specified `value`. If the argument `value` is incorrect, the memory block is initialized with an unintended value.

The unintended initialization can occur in the following cases.

| Issue | Risk | Possible Fix |
|---|---|---|
| The second argument is `'0'` instead of `0` or `'\0'`. | The ASCII value of character `'0'` is `48` (decimal), `0x30` (hexadecimal), `069` (octal) but not `0` (or `'\0'`) . | If you want to initialize with `'0'`, use one of the ASCII values. Otherwise, use `0` or `'\0'`. |
| The second and third arguments are probably reversed. For instance, the third argument is a literal and the second argument is not a literal. | If the order is reversed, a memory block of unintended size is initialized with incorrect arguments. | Reverse the order of the arguments. |
| The second argument cannot be represented in a byte. | If the second argument cannot be represented in a byte, and you expect each byte of a memory block to be filled with that argument, the initialization does not occur as intended. | Apply a bit mask to the argument to produce a wrapped or truncated result that can be represented in a byte. When you apply a bit mask, make sure that it produces an expected result.<br>For instance, replace `memset(a, -13, sizeof(a))` with `memset(a, (-13) & 0xFF, sizeof(a))`. |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Value Cannot Be Represented in a Byte

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE];
    int c = -2;
    memset(buf, (char)c, sizeof(buf)); //Noncompliant
}
```

In this example, `(char)c` cannot be represented in a byte.

#### Correction — Apply Bit Mask

One possible correction is to apply a bit mask so that the result can be represented in a byte. However, check that the result is an acceptable initialization value.

```
#include <string.h>

#define SIZE 32
void func(void) {
    char buf[SIZE   ];
    int c = -2;
    memset(buf, c & 0xFF, sizeof(buf));
}
```

### Sign change integer conversion overflow

#### Issue

**Sign change integer conversion overflow** occurs when converting an unsigned integer to a signed integer. If the variable does not have enough bytes to represent both the original constant and the sign bit, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Convert from `unsigned char` to `char`

```
char sign_change(void) {
    unsigned char count = 255;

    return (char)count; //Noncompliant
}
```

In the return statement, the unsigned character variable `count` is converted to a signed character. However, `char` has 8 bits, 1 for the sign of the constant and 7 to represent the number. The conversion operation overflows because 255 uses 8 bits.

#### Correction — Change conversion types

One possible correction is using a larger integer type. By using an `int`, there are enough bits to represent the sign and the number value.

```
int sign_change(void) {
    unsigned char count = 255;

    return (int)count;
}
```

### Tainted sign change conversion

#### Issue

**Tainted sign change conversion** looks for values from unsecure sources that are converted, implicitly or explicitly, from signed to unsigned values.

For example, functions that use `size_t` as arguments implicitly convert the argument to an unsigned integer. Some functions that implicitly convert `size_t` are:

```
bcmp
memcpy
memmove
strncmp
strncpy
calloc
malloc
memalign
```

#### Risk

If you convert a small negative number to unsigned, the result is a large positive number. The large positive number can create security vulnerabilities. For example, if you use the unsigned value in:

- Memory size routines — causes allocating memory issues.
- String manipulation routines — causes buffer overflow.
- Loop boundaries — causes infinite loops.

#### Fix

To avoid converting unsigned negative values, check that the value being converted is within an acceptable range. For example, if the value represents a size, validate that the value is not negative and less than the maximum value size.

#### Example - Set Memory Value with Size Argument

```
#include <stdlib.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void bug_taintedsignchange(int size) {
    char str[SIZE128] = "";
    if (size<SIZE128) {
        memset(str, 'c', size); //Noncompliant
    }
}
```

In this example, a `char` buffer is created and filled using `memset`. The size argument to `memset` is an input argument to the function.

The call to `memset` implicitly converts `size` to unsigned integer. If `size` is a large negative number, the absolute value could be too large to represent as an integer, causing a buffer overflow.

#### Correction — Check Value of `size`

One possible correction is to check if `size` is inside the valid range. This correction checks if `size` is greater than zero and less than the buffer size before calling `memset`.

```
#include <stdlib.h>
#include <string.h>

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

void corrected_taintedsignchange(int size) {
    char str[SIZE128] = "";
    if (size>0 && size<SIZE128) {
        memset(str, 'c', size);
    }
}
```

### Unsigned integer conversion overflow

#### Issue

**Unsigned integer conversion overflow** occurs when converting an unsigned integer to a smaller unsigned integer type. If the variable does not have enough bytes to represent the original constant, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer conversion overflows result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.

- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller integer types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Converting from `int` to `char`

```
unsigned char convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned char)unum; //Noncompliant
}
```

In the return statement, the unsigned integer variable `unum` is converted to an unsigned character type. However, the conversion overflows because 1000000 requires at least 20 bits. The C programming language standard does not view unsigned overflow as an error because the program automatically reduces the result by modulo the maximum value plus 1. In this example, `unum` is reduced by modulo `2^8` because a character data type can only represent `2^8-1`.

#### Correction — Change Conversion Type

One possible correction is to convert to a different integer type that can represent the entire number. For example, `long`.

```
unsigned long convert(void) {
    unsigned int unum = 1000000U;

    return (unsigned long)unum;
}
```

Ensure that operations on signed integers do not result in overflow

## Description

### Rule Definition

*Ensure that operations on signed integers do not result in overflow.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer overflow**.
- **Tainted division operand**.
- **Tainted modulo operand**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer overflow**. To check for this issue when it is caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- A default Bug Finder analysis might not flag a **Tainted division operand** or **Tainted modulo operand** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Integer overflow

#### Issue

**Integer overflow** occurs when an operation on integer variables can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Integer overflows on signed integers result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the overflowing computation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

To avoid overflows in general, try one of these techniques:

- Keep integer variable values restricted to within half the range of signed integers.
- In operations that might overflow, check for conditions that can lead to the overflow and implement wrap around or saturation behavior depending on how the result of the operation is used. The result then becomes predictable and can be safely used in subsequent computations.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Addition of Maximum Integer

```
#include <limits.h>

int plusplus(void) {

    int var = INT_MAX;
    var++; //Noncompliant
    return var;
}
```

In the third statement of this function, the variable `var` is increased by one. But the value of `var` is the maximum integer value, so an `int` cannot represent one plus the maximum integer value.

#### Correction — Different Storage Type

One possible correction is to change data types. Store the result of the operation in a larger data type (Note that on a 32-bit machine, `int` and `long` has the same size). In this example, on a 32-bit machine, by returning a `long long` instead of an `int`, the overflow error is fixed.

```
#include <limits.h>

long long plusplus(void) {

    long long lvar = INT_MAX;
    lvar++;
    return lvar;
}
```

### Tainted division operand

#### Issue

**Tainted division operand** detects division operations where one or both of the integer operands is from an unsecure source.

#### Risk

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

#### Fix

Before performing the division, validate the values of the operands. Check for denominators of `0` or `-1`, and numerators of the minimum integer value.

#### Example - Division of Function Arguments

```
#include <limits.h>
#include <stdio.h>

extern void print_int(int);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    int r =  num/denum; //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include <limits.h>
#include <stdio.h>

extern void print_long(long);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    long res= 0;
    if (denum!=0 && !(num==INT_MIN && denum==-1)) {
        res = num/denum;
    }
    print_long(res);
    return res;
}
```

### Tainted modulo operand

#### Issue

**Tainted modulo operand** checks the operands of remainder `%` operations. Bug Finder flags modulo operations with one or more tainted operands.

#### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is `-1`, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

#### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of `0` and `-1`. Check both operands for negative values.

#### Example - Modulo with Function Arguments

```
#include <stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem =  128%userden; //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using an input argument. The argument is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem = 0;
    if (userden > 0 ) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

Ensure that division and remainder operations do not result in divide-by-zero errors

## Description

### Rule Definition

*Ensure that division and remainder operations do not result in divide-by-zero errors.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Integer division by zero**.
- **Tainted division operand**.
- **Tainted modulo operand**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Integer division by zero**. To check for this issue when it is caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".
- A default Bug Finder analysis might not flag a **Tainted division operand** or **Tainted modulo operand** issue for certain inputs that originate outside of the current analysis boundary. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Integer division by zero

#### Issue

**Integer division by zero** occurs when the denominator of a division or modulo operation can be a zero-valued integer.

#### Risk

A division by zero can result in a program crash.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the denominator variable acquires a zero value. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

It is a good practice to check for zero values of a denominator before division and handle the error. Instead of performing the division directly:

```
res = num/den;
```

use a library function that handles zero values of the denominator before performing the division:

```
res = div(num, den);
```

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Example - Dividing an Integer by Zero

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    result = num/denom; //Noncompliant

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

### Correction — Check Before Division

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    if (denom != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
int fraction(int num)
{
    int denom = 2;
    int result = 0;
    result = num/denom;

    return result;
}
```

#### Example - Modulo Operation with Zero

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        arr[i] = input % i; //Noncompliant
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

In this example, Polyspace flags the modulo operation as a division by zero. Because modulo is inherently a division operation, the divisor (right hand argument) cannot be zero. The modulo operation uses the `for` loop index as the divisor. However, the `for` loop starts at zero, which cannot be an iterator.

#### Correction — Check Divisor Before Operation

One possible correction is checking the divisor before the modulo operation. In this example, see if the index `i` is zero before the modulo operation.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        if(i != 0)
        {
             arr[i] = input % i;
        }
        else
        {
             arr[i] = input;
        }
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

#### Correction — Change Divisor

Another possible correction is changing the divisor to a nonzero integer. In this example, add one to the index before the `%` operation to avoid dividing by zero.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
         arr[i] = input % (i+1);
    }
    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

### Tainted division operand

#### Issue

**Tainted division operand** detects division operations where one or both of the integer operands is from an unsecure source.

#### Risk

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

#### Fix

Before performing the division, validate the values of the operands. Check for denominators of `0` or `-1`, and numerators of the minimum integer value.

#### Example - Division of Function Arguments

```
#include <limits.h>
#include <stdio.h>

extern void print_int(int);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    int r =  num/denum; //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include <limits.h>
#include <stdio.h>

extern void print_long(long);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    long res= 0;
    if (denum!=0 && !(num==INT_MIN && denum==-1)) {
        res = num/denum;
    }
    print_long(res);
    return res;
}
```

### Tainted modulo operand

#### Issue

**Tainted modulo operand** checks the operands of remainder % operations. Bug Finder flags modulo operations with one or more tainted operands.

#### Risk

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is -1, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

#### Fix

Before performing the modulo operation, validate the values of the operands. Check the second operand for values of 0 and -1. Check both operands for negative values.

#### Example - Modulo with Function Arguments

```
#include <stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem =  128%userden; //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using an input argument. The argument is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem = 0;
    if (userden > 0 ) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

Do not shift an expression by a negative number of bits or by greater than or equal to the number of bits that exist in the operand

## Description

### Rule Definition

*Do not shift an expression by a negative number of bits or by greater than or equal to the number of bits that exist in the operand.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Shift of a negative value**.
- **Shift operation overflow**.

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect a **Shift of a negative value** or **Shift operation overflow**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Shift of a negative value

#### Issue

**Shift of a negative value** occurs when a bit-wise shift is used on a variable that can have negative values.

#### Risk

Shifts on negative values overwrite the sign bit that identifies a number as negative. The shift operation can result in unexpected values.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being shifted acquires negative values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

To fix the defect, check for negative values before the bit-wise shift operation and perform appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Shifting a negative variable

```
int shifting(int val)
{
    int res = -1;
    return res << val; //Noncompliant
}
```

In the return statement, the variable `res` is shifted a certain number of bits to the left. However, because `res` is negative, the shift might overwrite the sign bit.

#### Correction — Change the Data Type

One possible correction is to change the data type of the shifted variable to unsigned. This correction eliminates the sign bit, so left shifting does not change the sign of the variable.

```
int shifting(int val)
{
    unsigned int res = -1;
    return res << val;
}
```

### Shift operation overflow

#### Issue

**Shift operation overflow** occurs when a shift operation can result in values that cannot be represented by the result data type. The data type of a variable determines the number of bytes allocated for the variable storage and constrains the range of allowed values.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Shift operation overflows can result in undefined behavior.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variables in the shift operation acquire their current values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

You can fix the defect by:

- Using a bigger data type for the result of the shift operation so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Left Shift of Integer

```
int left_shift(void) {

    int foo = 33;
    return 1 << foo; //Noncompliant
}
```

In the return statement of this function, bit-wise shift operation is performed shifting 1 `foo` bits to the left. However, an `int` has only 32 bits, so the range of the shift must be between 0 and 31. Therefore, this shift operation causes an overflow.

#### Correction — Different storage type

One possible correction is to store the shift operation result in a larger data type. In this example, by returning a `long long` instead of an `int`, the overflow defect is fixed.

```
long long left_shift(void) {

    int foo = 33;
    return 1LL << foo;
}
```

Use correct integer precisions

## Description

### Rule Definition

*Use correct integer precisions.*

### Polyspace Implementation

The rule checker checks for **Integer precision exceeded**.

## Examples

### Integer precision exceeded

#### Issue

**Integer precision exceeded** occurs when an integer expression uses the integer size in an operation that exceeds the integer precision. On some architectures, the size of an integer in memory can include sign and padding bits. On these architectures, the integer size is larger than the precision which is just the number of bits that represent the value of the integer.

#### Risk

Using the size of an integer in an operation on the integer precision can result in integer overflow, wrap around, or unexpected results. For instance, an unsigned integer can be stored in memory in 64 bits, but uses only 48 bits to represent its value. A 56 bits left-shift operation on this integer is undefined behavior.

Assuming that the size of an integer is equal to its precision can also result in program portability issues between different architectures.

#### Fix

Do not use the size of an integer instead of its precision. To determine the integer precision, implement a precision computation routine or use a builtin function such as `__builtin_popcount()`.

#### Example - Using Size of `unsigned int` for Left Shift Operation

```
#include <limits.h>

unsigned int func(unsigned int exp)
{
    if (exp >= sizeof(unsigned int) * CHAR_BIT) {
        /* Handle error */
    }
    return 1U << exp; //Noncompliant
}
```

In this example, the function uses a left shift operation to return the value of 2 raised to the power of `exp`. The operation shifts the bits of `1U` by `exp` positions to the left. The `if` statement ensures that the operation does not shift the bits by a number of positions `exp` greater than the size of an `unsigned int`. However, if `unsigned int` contains padding bits, the value returned by `sizeof()` is larger than the precision of `unsigned int`. As a result, some values of `exp` might be too large, and the shift operation might be undefined behavior.

#### Correction — Implement Function to Compute Precision of `unsigned int`

One possible correction is to implement a function `popcount()` that computes the precision of `unsigned int` by counting the number of set bits.

```
#include <stddef.h>
#include <stdint.h>
#include <limits.h>

size_t popcount(uintmax_t);
#define PRECISION(umax_value) popcount(umax_value)

unsigned int func(unsigned int exp)
{
    if (exp >= PRECISION(UINT_MAX)) {
        /* Handle error */
    }
    return 1 << exp;
}

size_t popcount(uintmax_t num)
{
    size_t precision = 0;
    while (num != 0) {
        if (num % 2 == 1) {
            precision++;
        }
        num >>= 1;
    }
    return precision;
}
```

Converting a pointer to integer or integer to pointer

## Description

### Rule Definition

*Converting a pointer to integer or integer to pointer.*

### Polyspace Implementation

The rule checker checks for **Conversion between pointer and integer**.

## Examples

### Conversion between pointer and integer

#### Issue

**Conversion between pointer and integer** is raised when any of these conditions is true:

- A pointer type is converted into an integral type with smaller size. When converting a pointer of the types `intptr_t` or `uintprt_t` into integral types `enum`, `ptrdiff_t`, or `pid_t`, Polyspace raises a defect if the size of pointers and integer types are different in your environment. In `i386` environment, both pointers and integer types have a size of 32 bits. In this environment, Polyspace does not flag conversion from a pointer to an integer of same size. But in `x86_64` environment where pointers are 64 bits and unsigned integers are 32 bits, Polyspace flags conversion from pointers to integers of different sizes.
- An integral type is converted into a raw pointer type. Polyspace flags conversion from integral types to raw pointers regardless of their sizes. For instance, if an integer originates from a pointer and then later, is cast into a pointer, Polyspace flags the conversion from integer to pointer. In this case, the integer and the pointer are of the same size, but the conversion is still flagged.

#### Risk

The mapping between pointers and integers is not always consistent with the addressing structure of the environment.

Converting from pointers to integers can create:

- Truncated or out of range integer values.
- Invalid integer types.

Converting from integers to pointers can create:

- Misaligned pointers or misaligned objects.
- Invalid pointer addresses.

#### Fix

Where possible, avoid pointer-to-integer or integer-to-pointer conversions. If you want to convert a `void` pointer to an integer, so that you do not change the value, use types:

- C99 — `intptr_t` or `uintptr_t`
- C90 — `size_t` or `ssize_t`

#### Example — Integer to Pointer Conversions

```
unsigned int* badintptrcast(void)
{
    int* ptr;
    unsigned long long int_same_as_ptr ;
    unsigned int int_smaller_than_ptr;

    unsigned int* ptr0 = (unsigned int*)0xdeadbeef; //Noncompliant
    /*int to ptr of same size*/
    ptr = (int*)int_same_as_ptr;  //Noncompliant

    /*int to ptr of different size*/
    ptr = (int*)int_smaller_than_ptr;  //Noncompliant

    return (unsigned int*)(ptr0 - (unsigned int*)ptr);  //Noncompliant
}
```

In this example, Polyspace flags the conversions that might be unsafe. For instance:

- The conversion of `0xdeadbeef` to `unsigned int*` causes alignment issues for the pointer. Polyspace flags the conversion.
- The conversion of the `int_same_as_ptr` and `int_smaller_than_ptr` to `int*` pointers might result in invalid pointer address. Polyspace flags these conversion.
- The `return` statement casts `ptrdiff_t` to a pointer. This pointer might not point to an invalid address. Polyspace flags the conversion.

#### Correction — Use `intptr_t`

One possible correction is to use `intptr_t` types to store addresses. When storing the result of subtracting two pointers, use the type `ptrdiff_t`.

```
#include<cstdint>
#include<stddef.h>
ptrdiff_t badintptrcast(void)
{
    intptr_t ptr;
    unsigned long long int_same_as_ptr ;
    unsigned int int_smaller_than_ptr;

    intptr_t ptr0 = (intptr_t)0xdeadbeef; //Compliant
    /*int to ptr of same size*/
    ptr = (intptr_t)int_same_as_ptr;  //Compliant

    /*int to ptr of different size*/
    ptr = (intptr_t)int_smaller_than_ptr;  //Compliant

    int offset = 0;
    return (ptrdiff_t)(ptr0 - offset);//Compliant
}
```

Do not form or use out-of-bounds pointers or array subscripts

## Description

### Rule Definition

*Do not form or use out-of-bounds pointers or array subscripts.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access out of bounds**.
- **Pointer access out of bounds**.
- **Array access with tainted index**.
- **Pointer dereference with tainted offset**.

### Extend Checker

A default Bug Finder analysis might not flag an **Array access out of bounds** issue when the input values are unknown and only a subset of inputs cause the issue. To check for the **Array access out of bounds** issue caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

A default Bug Finder analysis might not flag an **Array access with tainted index** or **Pointer dereference with tainted offset** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Array access out of bounds

#### Issue

**Array access out of bounds** occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.

- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Array Access Out of Bounds Error

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]); //Noncompliant

}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

#### Correction — Keep Array Index Within Array Bounds

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];

   for (i = 0; i < 10; i++)
    {
        if (i < 2)
            fib[i] = 1;
        else
            fib[i] = fib[i-1] + fib[i-2];
    }

    /* Fix: Print fib[9] instead of fib[10] */
    printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.

- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

#### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

#### Example - Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];//Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The function does not check to see if `num` is inside the range of `tab`.

#### Correction — Check Range Before Use

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

### Pointer dereference with tainted offset

#### Issue

**Pointer dereference with tainted offset** detects pointer dereferencing, either reading or writing, using an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

#### Fix

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

#### Example - Dereference Pointer Array

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = new int [SIZE10];
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset];//Noncompliant
        delete pint;
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `i`. The value of `i` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of the index. If the index is inside the valid range, continue with the pointer dereferencing.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

Do not add or subtract an integer to a pointer to a non-array object

## Description

### Rule Definition

*Do not add or subtract an integer to a pointer to a non-array object.*

### Polyspace Implementation

The rule checker checks for **Invalid assumptions about memory organization**.

## Examples

### Invalid assumptions about memory organization

#### Issue

**Invalid assumptions about memory organization** occurs when you compute the address of a variable in the stack by adding or subtracting from the address of another non-array variable.

#### Risk

When you compute the address of a variable in the stack by adding or subtracting from the address of another variable, you assume a certain memory organization. If your assumption is incorrect, accessing the computed address can be invalid.

#### Fix

Do not perform an access that relies on assumptions about memory organization.

#### Example - Reliance on Memory Organization

```
void func(void) {
    int var1 = 0x00000011, var2;
    *(&var1 + 1) = 0; //Noncompliant
}
```

In this example, the programmer relies on the assumption that `&var1 + 1` provides the address of `var2`. Therefore, an **Invalid assumptions about memory organization** appears on the `+` operation. In addition, a **Pointer access out of bounds** error also appears on the dereference.

#### Correction — Do Not Rely on Memory Organization

One possible correction is not perform direct computation on addresses to access separately declared variables.

Guarantee that library functions do not form invalid pointers

## Description

### Rule Definition

*Guarantee that library functions do not form invalid pointers.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Mismatch between data length and size**.
- **Invalid use of standard library memory routine**.
- **Possible misuse of sizeof**.
- **Buffer overflow from incorrect string format specifier**.
- **Invalid use of standard library string routine**.
- **Destination buffer overflow in string manipulation**.
- **Destination buffer underflow in string manipulation**.

## Examples

### Mismatch between data length and size

#### Issue

**Mismatch between data length and size** looks for memory copying functions such as `memcpy`, `memset`, or `memmove`. If you do not control the length argument and data buffer argument properly, Bug Finder raises a defect.

#### Risk

If an attacker can manipulate the data buffer or length argument, the attacker can cause buffer overflow by making the actual data size smaller than the length.

This mismatch in length allows the attacker to copy memory past the data buffer to a new location. If the extra memory contains sensitive information, the attacker can now access that data.

This defect is similar to the SSL Heartbleed bug.

#### Fix

When copying or manipulating memory, compute the length argument directly from the data so that the sizes match.

#### Example - Copy Buffer of Data

```
#include <stdlib.h>
#include <string.h>
```

```
typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    memcpy(&(beta.data[num]), os->data + 2, length); //Noncompliant

    return(1);
}
```

This function copies the buffer `alpha` into a buffer `beta`. However, the `length` variable is not related to `data+2`.

### Correction — Check Buffer Length

One possible correction is to check the length of your buffer against the maximum value minus 2. This check ensures that you have enough space to copy the data to the `beta` structure.

```
#include <stdlib.h>
#include <string.h>

typedef struct buf_mem_st {
    char *data;
    size_t max;     /* size of buffer */
} BUF_MEM;

extern BUF_MEM beta;

int cpy_data(BUF_MEM *alpha)
{
    BUF_MEM *os = alpha;
    int num, length;

    if (alpha == 0x0) return 0;
    num = 0;

    length = *(unsigned short *)os->data;
    if (length<(os->max -2)) {
        memcpy(&(beta.data[num]), os->data + 2, length);
    }

    return(1);

}
```

### Invalid use of standard library memory routine

#### Issue

**Invalid use of standard library memory routine** occurs when a memory library function is called with invalid arguments. For instance, the `memcpy` function copies to an array that cannot accommodate the number of bytes copied.

#### Risk

Use of a memory library function with invalid arguments can result in issues such as buffer overflow.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library Memory Routine Error

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
 {
  char str1[10],str2[5];

  printf("Enter string:\n");
  sscanf("%10c",str1);

  memcpy(str2,str1,6); //Noncompliant

  return str2;
 }
```

The size of string `str2` is 5, but six characters of string `str1` are copied into `str2` using the `memcpy` function.

#### Correction — Call Function with Valid Arguments

One possible correction is to adjust the size of `str2` so that it accommodates the characters copied with the `memcpy` function.

```
#include <string.h>
#include <stdio.h>

char* Copy_First_Six_Letters(void)
```

```
{
 /* Fix: Declare str2 with size 6 */
 char str1[12],str2[6];

 printf("Enter string:\n");
 sscanf("%12c",str1);

 memcpy(str2,str1,6);
 return str2;
}
```

### Possible misuse of sizeof

#### Issue

**Possible misuse of sizeof** occurs when Polyspace Bug Finder detects possibly unintended results from the use of `sizeof` operator. For instance:

- You use the `sizeof` operator on an array parameter name, expecting the array size. However, the array parameter name by itself is a pointer. The `sizeof` operator returns the size of that pointer.
- You use the `sizeof` operator on an array element, expecting the array size. However, the operator returns the size of the array element.
- The size argument of certain functions such as `strncmp` or `wcsncpy` is incorrect because you used the `sizeof` operator earlier with possibly incorrect expectations. For instance:
  - In a function call `strncmp(string1, string2, num)`, `num` is obtained from an incorrect use of the `sizeof` operator on a pointer.
  - In a function call `wcsncpy(destination, source, num)`, `num` is the not the number of wide characters but a size in bytes obtained by using the `sizeof` operator. For instance, you use `wcsncpy(destination, source, sizeof(destination) - 1)` instead of `wcsncpy(destination, source, (sizeof(desintation)/sizeof(wchar_t)) - 1)`.

#### Risk

Incorrect use of the `sizeof` operator can cause the following issues:

- If you expect the `sizeof` operator to return array size and use the return value to constrain a loop, the number of loop runs are smaller than what you expect.
- If you use the return value of `sizeof` operator to allocate a buffer, the buffer size is smaller than what you require. Insufficient buffer can lead to resultant weaknesses such as buffer overflows.
- If you use the return value of `sizeof` operator incorrectly in a function call, the function does not behave as you expect.

#### Fix

Possible fixes are:

- Do not use the `sizeof` operator on an array parameter name or array element to determine array size.

  The best practice is to pass the array size as a separate function parameter and use that parameter in the function body.
- Use the `sizeof` operator carefully to determine the number argument of functions such as `strncmp` or `wcsncpy`. For instance, for wide string functions such as `wcsncpy`, use the number of wide characters as argument instead of the number of bytes.

#### Example - sizeof Used Incorrectly to Determine Array Size

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < sizeof(a)/sizeof(int); i++) //Noncompliant
    {
        a[i] = i + 1;
    }
}
```

In this example, `sizeof(a)` returns the size of the pointer `a` and not the array size.

#### Correction — Determine Array Size in Another Way

One possible correction is to use another means to determine the array size.

```
#define MAX_SIZE 1024

void func(int a[MAX_SIZE]) {
    int i;

    for (i = 0; i < MAX_SIZE; i++)    {
        a[i] = i + 1;
    }
}
```

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf); //Noncompliant
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
 #include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text); //Noncompliant
  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>
```

```
void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string);  //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Destination buffer underflow in string manipulation

#### Issue

**Destination buffer underflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at a negative offset from the beginning of the buffer.

For instance, for the function `sprintf(char* buffer, const char* format)`, you obtain the `buffer` from an operation `buffer = (char*)arr; ... buffer += offset;`. `arr` is an array and `offset` is a negative value.

#### Risk

Buffer underflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer underflow also introduces the risk of code injection.

#### Fix

If the destination buffer argument results from pointer arithmetic, see if you are decrementing a pointer. Fix the pointer decrement by modifying either the original value before decrement or the decrement value.

#### Example - Buffer Underflow in `sprintf` Use

```
#include <stdio.h>
#define offset -2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";

    sprintf(&buffer[offset], fmt_string);  //Noncompliant
}
```

In this example, `&buffer[offset]` is at a negative offset from the memory allocated to `buffer`.

#### Correction — Change Pointer Decrementer

One possible correction is to change the value of `offset`.

```
#include <stdio.h>
#define offset 2

void func(void) {
    char buffer[20];
    char *fmt_string ="Text";

    sprintf(&buffer[offset], fmt_string);
}
```

Do not add or subtract a scaled integer to a pointer

## Description

### Rule Definition

*Do not add or subtract a scaled integer to a pointer.*

### Polyspace Implementation

The rule checker checks for **Incorrect pointer scaling**.

## Examples

### Incorrect Pointer Scaling

#### Issue

**Incorrect pointer scaling** occurs when you ignore the implicit scaling in pointer arithmetic.

For instance, the defect can occur in these situations.

| Situation | Risk | Possible Fix |
|---|---|---|
| You use the `sizeof` operator in arithmetic operations on a pointer. | The `sizeof` operator returns the size of a data type in number of bytes.<br>When you perform arithmetic operations on a pointer, the argument is implicitly scaled by the size of the data type of the pointed variable. The use of `sizeof` in pointer arithmetic produces unintended results. | Do not use `sizeof` operator in pointer arithmetic. |
| You perform arithmetic operations on a pointer, and then apply a cast. | The implicit scaling in pointer arithmetic depends on the type of an object. Performing these scaled arithmetic and then changing the pointer type by casting might produce unintended results. | Perform the pointer arithmetic after the casting operation. |

#### Fix

The fix depends on the root cause of the defect. Often, the **Result Details** pane shows a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the **Result Details** pane does not show the event history, investigate the root cause of the defect by checking previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example — Use of `sizeof` Operator**

```
#include <string.h>
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
#include <stdio.h>

enum { INTBUFSIZE = 80 };
extern int getdata (void);
int buf[INTBUFSIZE];
void foo (void)
{
  int *buf_ptr = buf;

  while (buf_ptr < (buf + sizeof (buf))) {  //Noncompliant
    *buf_ptr++ = getdata ();
  }
}
```

In this example, the operation `sizeof(buf)` is used for obtaining a pointer to the end of the array `buf`. The output of `sizeof(buf)` is scaled by `int`. Because pointer arithmetic is implicitly scaled, the output of `sizeof(buf)` is again scaled by `int` when it is added to `buf`, resulting in unexpected behavior. Polyspace flags the use of `sizeof` operator.

**Correction — Remove `sizeof` Operator**

One possible correction is to use unscaled numbers as offsets.

```
#include <string.h>
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
#include <stdio.h>

enum { INTBUFSIZE = 80 };
extern int getdata (void);
int buf[INTBUFSIZE];
void foo (void)
{
  int *buf_ptr = buf;

  while (buf_ptr < (buf + INTBUFSIZE)) {
    *buf_ptr++ = getdata ();
  }
}
```

### Example — Cast Following Pointer Arithmetic

```
int func(void) {
    int x = 0;
    char r = *(char *)(&x + 1); //Noncompliant
    return r;
}
```

In this example, the operation `&x + 1` offsets `&x` by `sizeof(int)`. Following the operation, the resulting pointer points outside the allowed buffer. When you dereference the pointer, a **Pointer access out of bounds** error appears on the `*` operation.

### Correction — Apply Cast Before Pointer Arithmetic

If you want to access the second byte of `x`, first cast `&x` to a `char*` pointer, and then perform the pointer arithmetic. The resulting pointer is offset by `sizeof(char)` bytes and still points within the allowed buffer, whose size is `sizeof(int)` bytes.

```
int func(void) {
    int x = 0;
    char r = *((char *)(&x )+ 1);
    return r;
}
```

### Example — Use of `sizeof` in Function Arguments

```
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
enum { WCHAR_BUF = 128 };
FILE* pFile;
//...
void func2_ko (void)
{
    wchar_t error_msg[WCHAR_BUF];
    wcscpy (error_msg, L"Error: ");
    fgetws (error_msg + wcslen (error_msg)   //Noncompliant
           * sizeof (wchar_t), WCHAR_BUF - 7, pFile);
}
```

In this example, an error message is read from the file pointer `pFile` stream and copied to `error_msg` after an offset. The intended offset here is `wcslen(error_msg)`, which is already implicitly scaled when it is added to the `wchar` pointer `error_msg`. Because the offset is then explicitly scaled again by using `sizeof`, Polyspace flags the incorrect scaling.

### Correction — Remove `sizeof` Operator

One possible correction is to remove the `sizeof` operator.

```
#include <stddef.h>
#include <stdlib.h>
#include <wchar.h>
enum { WCHAR_BUF = 128 };
const wchar_t ERROR_PREFIX[8] = L"Error: ";
FILE* pFile;
//...

void func2_ok (void)
{
  const size_t prefix_len = wcslen (ERROR_PREFIX);
  wchar_t error_msg[WCHAR_BUF];
  wcscpy (error_msg, ERROR_PREFIX);
  fgetws (error_msg + prefix_len, WCHAR_BUF - prefix_len, pFile);  //Compliant
  /* ... */
}
```

**Example — Implicitly Scaled Offset When Calling memset**

```
#include <string.h>
#include <stdlib.h>
#include <stddef.h>

#define bigNum unsigned long long

struct Collection {
    bigNum bn_A;
    bigNum bn_B;
    bigNum bn_C;
    int ci_1;
    int ci_2;
};

void foo(void) {
    size_t offset = offsetof(struct Collection, bn_B);
    struct Collection *s = (struct Collection *)malloc(sizeof(struct Collection));
    if (s == NULL) {
        /* Handle malloc() error */
    }

    memset(s + offset, 0, sizeof(struct Collection) - offset); //Noncompliant
    /* ... */
    free(s);
    s = NULL;
}
```

In this example, `offset` is calculated by calling `offsetof`, and then added to `s`. The variable `offset` is the byte offset of `bn_B` in `struct Collection`. When setting memory by using `memset`, instead of offsetting the location by bytes, `offset` is implicitly scaled by the size. The implicit scaling might cause unexpected results. Polyspace raises a violation.

**Correction — Calculate Offset by Using unsigned char***

The violation is caused by the fact that `offset` is scaled by the type of `s`. Avoid the violation by declaring `s` as `unsigned char*`, which is scaled by a factor of one.

```
#include <string.h>
#include <stdlib.h>
#include <stddef.h>

#define bigNum unsigned long long

struct Collection {
    bigNum bn_A;
    bigNum bn_B;
    bigNum bn_C;
    int ci_1;
    int ci_2;
};

void foo(void) {
    size_t offset = offsetof(struct Collection, bn_B);
    unsigned char *s = (unsigned char *)malloc(sizeof(struct Collection));
    if (s == NULL) {
        /* Handle malloc() error */
    }

    memset(s + offset, 0, sizeof(struct Collection) - offset); //Compliant
    /* ... */
    free(s);
    s = NULL;
}
```

## Check Information

Guarantee that container indices and iterators are within the valid range

## Description

### Rule Definition

*Guarantee that container indices and iterators are within the valid range.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access out of bounds**
- **Array access with tainted index**
- **Pointer dereference with tainted offset**
- **Potentially negative container index**

### Extend Checker

A default Bug Finder analysis might not flag an **Array access out of bounds** issue when the input values are unknown and only a subset of inputs cause the issue. To check for the **Array access out of bounds** issue caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

A default Bug Finder analysis might not flag an **Array access with tainted index** or **Pointer dereference with tainted offset** issue for certain inputs that originate outside of the current analysis boundary. See "Sources of Tainting in a Polyspace Analysis". To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Array access out of bounds

#### Issue

**Array access out of bounds** occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.

- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Array Access Out of Bounds Error

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);  //Noncompliant
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

#### Correction — Keep Array Index Within Array Bounds

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
```

```
    int fib[10];

    for (i = 0; i < 10; i++)
     {
         if (i < 2)
             fib[i] = 1;
         else
             fib[i] = fib[i-1] + fib[i-2];
     }

     /* Fix: Print fib[9] instead of fib[10] */
     printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

#### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

#### Example - Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];  //Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The index `num` is obtained from an unsecure source and the function `taintedarrayindex` does not check to see if `num` is inside the range of `tab`.

#### Correction — Check Range Before Use

One possible correction is to check that num is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

### Pointer dereference with tainted offset

#### Issue

**Pointer dereference with tainted offset** detects pointer dereferencing, either reading or writing, using an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

#### Fix

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

#### Example - Dereference Pointer Array

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);
```

```
int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset]; //Noncompliant
        free(pint);
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `offset`. The value of `offset` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of `offset`. Continue with the pointer dereferencing only if `offset` is inside the valid range.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

### Potentially negative container index

#### Issue

The issue **Potentially negative container index** occurs when:

- You use a potentially negative index to access a standard template library (STL) container that provides random access by using `operator[]`. For example:

```
std::vector v<int>;
int index;
//index becomes negative
v[index]; // index is implicitly cast into unsigned int(index)
```

- You explicitly cast a potentially negative value into an unsigned integer and use the converted value as the index of an STL container. For instance:

```
std::vector v<int>;
int index;
//index  becomes negative
v[static_cast<size_t>(index)]; // size_t has an unsigned type
```

This issue does not apply to associative containers.

**Risk**

STL containers expect an unsigned index. To use a signed integer as an index, the index must be cast to an unsigned integer type, either explicitly or implicitly.

If a negative index is cast to an unsigned index, the resulting unsigned value might be larger than the container expects. Using such a value as the index of an STL container results in an out-of-bounds access. For instance, in the preceding code, if `index` is `-1`, the index of the vector `v` might become `UINT_MAX` after an implicit or explicit cast. The unexpectedly large value of `index` makes the access to `v[index]`out of bounds.

**Fix**

To fix this issue, check the index of the STL container for negative values before accessing the container. Alternatively, use functions that perform range checking, such as the `at()` method of STL containers.

**Example — Potentially Negative Index Causes Out of Bound Access**

In this example, the function `insert_at()` obtains the value of `index` by calling the external function `getIndex()`. The function `insert_at()` checks if the value of `index` is greater than a valid size, but does not check for a negative `index` value. Polyspace reports two violations of this rule in this code:

```
#include <array>
typedef long long LL;
extern LL getIndex();
void insert_at(std::array<int,1024>& container, LL index, int value)
{
    index = getIndex();
    if (index >= container.size())
    {
        // Handle error
        return;
    }

    container[index] = value;  //Noncompliant- a negative index might be
                             // implicitly converted to size_t

    container[static_cast<size_t>(index)] = value; // Noncompliant - a negative
                                                 // index might be converted to size_t
}
```

#### Correction — Use Unsigned Types as Container Index

To fix this issue, declare `index` as an unsigned integer. Explicitly cast the value `getIndex()` returns into `size_t` and check for large values. In this code, if `getIndex()` returns a negative value, `index` becomes unexpectedly large because of the explicit cast. The large value triggers the `if()` condition and the function returns before the defect.

```
#include <array>
typedef long long LL;
typedef unsigned long long ULL;
extern LL getIndex();
void insert_at(std::array<int,1024>& container, ULL index, int value)
{
    index = static_cast<ULL>(getIndex());
    if (index >= container.size())
    {
        // Handle error
        return;
    }

    container[index] = value;  //Compliant
    container[static_cast<size_t>(index)] = value; //Compliant
}
```

#### Correction — Use `at()` Method

The `at()` method of STL containers performs bounds checking. In this code, if `index` becomes unexpectedly large after a cast from signed to unsigned integer, `container.at(index)` raises an `std::out_of_range` exception.

```
#include <array>
typedef long long LL;
extern LL getIndex();
void insert_at(std::array<int,1024>& container, LL index, int value)
{
    index = getIndex();
    if (index >= container.size())
    {
        // Handle error
        return;
    }
    try{
    container.at(index) = value;  //Compliant
    container.at(static_cast<size_t>(index)) = value; //Compliant
    }catch(std::exception& e){
        // check for std::out_of_range
    }
}
```

Use valid references, pointers, and iterators to reference elements of a container

## Description

### Rule Definition

*Use valid references, pointers, and iterators to reference elements of a container.*

### Polyspace Implementation

The rule checker checks for **Use of invalid iterator**.

## Examples

### Use of invalid iterator

#### Issue

**Use of invalid iterator** occurs when you use an iterator, pointer, or reference to a container element that has been invalidated by actions such as insertion or erasure. For instance, consider this code:

```
std::vector<int> v = {1,2,3,4,5,6,7};
std::vector<int>::iterator it = std::find(v.begin(), v.end(), 5);
v.push_back(-1);
std::cout<<*it;
```

If the `push_back()` operation causes the vector v to reallocate memory to accommodate a larger size, the iterator `it` is no longer valid. Polyspace flags the dereferencing of invalid iterators.

Certain erasure operations, such as `std::deque::pop_back()` or `std::forward_list::pop_front()` invalidate the iterators to the erased elements. After the erasure, whether any iterators pointed to the erased elements is unknown. If invalidated iterators that point to the erased elements exist in your code, Polyspace does not flag them.

Certain operations return iterators through an `std::pair`. Polyspace does not track iterators that are part of an `std::pair`.

#### Risk

Dereferencing the invalid iterator might produce unexpected results. If the invalidated iterator becomes a dangling pointer or an uninitialized pointer, you might not be able to dereference it safely.

#### Fix

The C++ standard defined which operations invalidate the iterators of the standard library containers. See Containers library. When performing actions that might invalidate an iterator, validate the iterator, for instance, by recalculating its position.

#### Example — Avoid Using Invalid Iterators

```
#include <deque>
```

```
void foo(const int *Value, std::size_t count)
{
  std::deque<int> DQ;
  auto It = DQ.begin();
  for (std::size_t i = 0; i < count; ++i, ++It) {
    DQ.insert(It, Value[i] + 42);//Noncompliant
  }
}
```

In this example, the first `DQ.insert()` operation invalidates the iterator `It`. Its subsequent use might result in undefined behavior. Polyspace flags the use of the invalid operator.

**Correction — Update the Iterator**

When using iterators after an insertion or erasure, update the iterator to avoid undefined behavior. For instance, in this code, `It` is updated after each insertion so that the iterator remains valid.

```
#include <deque>

void foo(const int *Value, std::size_t count)
{
  std::deque<int> DQ;
  auto It = DQ.begin();
  for (std::size_t i = 0; i < count; ++i, ++It) {
    It = DQ.insert(It, Value[i] + 41.0);//Compliant
  }
}
```

Guarantee that library functions do not overflow

## Description

### Rule Definition

*Guarantee that library functions do not overflow.*[11]

### Polyspace Implementation

The rule checker checks for **Library function overflows sequence container**.

## Examples

### Library Function Overflows Sequence Container

#### Issue

This issue occurs when you use library functions to copy data into a sequence container that might be too small to hold the data. Polyspace reports a violation of this rule when any of these conditions are true:

- The destination container might be too small.
- The size of the destination container might be unknown.

Functions from the C standard library, such as `std::memmove()` or `std::memset()`, overwrite a memory block even if the memory block is invalid. This issue might be prominent when using these functions. Many standard template library (STL) functions are also vulnerable to this issue.

The C++ standard defines vector, list, array, and double ended queue (deque) as sequence containers. See Containers library.

#### Risk

Copying data into a container that is too small results in buffer overflow. Buffer overflow might overwrite unexpected memory locations, resulting in incorrect results, or unexpected program termination.

[11] *This software has been created by MathWorks incorporating portions of: the "SEI CERT-C Website," © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, "SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition," © 2016 Carnegie Mellon University, and "SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition" © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

#### Fix

To prevent container overflow, validate the size of the destination container or the incoming data. For instance, restrict the data being copied to the size of the destination container. Alternatively, allocate sufficient memory for the destination container to safely accommodate the incoming data.

#### Example — Destination Container Too Small

```
#include <algorithm>
#include <vector>
#include <array>

// Destination container size unknown
void copy_vector(const std::vector<int> &src)
{
    std::vector<int> dest;
    std::copy(src.begin(), src.end(), dest.begin()); //Noncompliant
    // ...
}

//Container too small
void fill_vector()
{
    std::vector<int> v;
    std::fill_n(v.begin(), 10, 0x42);    //Noncompliant
}
//Container too small
void copy_array(const std::array<int,10>& src, std::array<int,5>& dest) {

    std::copy(src.begin(), src.end(), dest.begin());     //Noncompliant
}
```

In this example, Polyspace reports violations of this rule on operations that might result in container overflow. For instance:

- In the function `copy_vector`, the size of the destination container `dest` is unknown. Because `std::copy` does not check the bounds of the source container, calling this function to copy `dest` into `src` results in an overflow if `dest` is larger than `src`.
- In the function `fill_vector`, 10 elements are written into the vector `v` before sufficient memory is allocated for the elements. This operation results in an overflow.
- In the function `copy_array`, a container with 10 elements is copied into a container with five elements, resulting in an overflow.

#### Correction — Validate Destination Container Size

Verify that the destination container is large enough so that library functions do not overflow. For instance:

- In `copy_vector`, initialize `dest` with the same size as `src`.
- In `fill_vector`, allocate sufficient memory to `v` to accommodate 10 elements.
- In `copy_array`, use the same size for `src` and `dest`.

```
#include <algorithm>
#include <vector>
#include <array>
```

```
// Destination container size unknown
void copy_vector(const std::vector<int> &src)
{
    std::vector<int> dest(src.size());
    std::copy(src.begin(), src.end(), dest.begin()); //Compliant
    // ...
}

//Container too small
void fill_vector()
{
    std::vector<int> v(10);
    std::fill_n(v.begin(), 10, 0x42);    //Compliant
}
//Container too small

void copy_array(const std::array<int,10>& src, std::array<int,10>& dest) {

    std::copy(src.begin(), src.end(), dest.begin());     //Compliant
}
```

Use valid iterator ranges

## Description

### Rule Definition

*Use valid iterator ranges.*[12]

### Polyspace Implementation

The rule checker checks for **Invalid iterator usage**.

## Examples

### Invalid iterator usage

#### Issue

This issue occurs when the first and last iterators of a range do not correspond to the `begin` and `end` iterators of the same container. Consider this code:

```
std::vector v{0,1,2,3,4,5,6,7,8,9};
std::vector w{0,1,2,3,4,5,6,7,8,9};
//...
std::for_each(v.end(), v.begin(), [](int i){}); //Noncompliant
std::for_each(v.begin(), w.end(), [](int i){}); //Noncompliant
std::for_each(v.begin(), v.end(), [](int i){}); //Compliant
```

Polyspace reports a violation if the range does not begin and end with the `begin` and `end` iterator of the same container, such as `v.begin()` and `v.end()`. Polyspace checks for the invalid use of most iterators in the standard library. Invalid use of string iterators, such as `std::string` and `std::string_view` iterators are not reported.

#### Risk

- Using an iterator range where the first and last iterators do not refer to the `begin` and `end` iterators of the same container results in undefined behavior. For instance, using `v.begin()` and `w.end()` to delimit a range might result in undefined behavior.

[12] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

- When you use the end iterator as the first point of a range, the compiler might attempt to access memory that is not part of the container. Accessing memory past the end iterator might result in undefined behavior.

Using such invalid iterator ranges might allow an attacker to run arbitrary code.

**Fix**

To fix violations this rule:

- Use iterators from the same container when defining a range.
- Use the begin iterator as the first element and the end iterator as the last element of the range.

**Example — Invalid Iterator**

```
#include <iostream>
#include <algorithm>
#include <map>

void foo(const std::map<int,int> &a, const std::map<int,int> &b) {
    std::for_each(a.rend(), a.rbegin(), [](std::pair<int,int> i) {  //Noncompliant
    /*...*/});

    std::all_of(a.rbegin(), b.rend(), [](std::pair<int,int> i) {  //Noncompliant
        return 0;});
}
```

In this example, Polyspace reports the invalid use of iterators:

- In the call to the function std::for_each(), the range is delimited by using the a.rend() iterator first and a.rbegin() iterator next. The compiler might increment a.rend() and attempt to access memory that is not part of the container. Polyspace reports a violation.
- In the call to the function std::all_of, the iterators a.rbegin and b.rend() delimits the range. Defining ranges by using two unrelated iterators is undefined behavior. Polyspace reports a violation.

**Correction — Use Iterators From Same Container In Correct Order**

To fix this issue, use iterators from the same container in the correct order when defining a range.

```
#include <iostream>
#include <algorithm>
#include <map>

void foo(const std::map<int,int> &a, const std::map<int,int> &b) {
    std::for_each(a.rbegin(), a.rend(), [](std::pair<int,int> i) {  //Compliant
    /*...*/});

    std::all_of(b.rbegin(), b.rend(), [](std::pair<int,int> i) {  //Compliant
        return 0;});
}
```

Do not subtract iterators that do not refer to the same container

## Description

### Rule Definition

*Do not subtract iterators that do not refer to the same container.*[13]

### Polyspace Implementation

The rule checker checks for **Subtraction or comparison between iterators from different containers**.

## Examples

### Subtraction or Comparison between Iterators from Different Containers

#### Issue

This issue occurs when you subtract or compare iterators from different containers. For instance:

```
std::vector<int> v1,v2;
//...
std::less<std::vector<int>::iterator>()(v1.begin(), v2.end());
```

Polyspace reports a violation when you compare between iterators from `v1` and `v2`.

#### Risk

If the two iterators are not from the same container, performing subtraction or comparison between these two iterators might result in a nonportable code, undefined behavior, or an unexpected result. For instance:

- Subtracting iterators from different containers results in undefined behavior.
- Comparing iterators from different containers leads to unexpected, implementation-dependent results.

[13] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

### Fix

Before subtracting or comparing iterators, verify that they belong to the same container.

### Example — Compare or Subtract Pointers to Different Containers

```
#include <iostream>
#include <cassert>
#include <cstddef>
#include <cstdbool>
#include <vector>

template <typename T>
bool isWithinRange(const T *query, const T *begin, size_t span)
{
    return 0 < (query - begin) && ((query - begin) < (std::ptrdiff_t)span); // Noncompliant -unde
}
template <typename T>
bool isOutofRange(const T *query, const T *begin, size_t span)
{
    std::less<const T*> less;
    return less(query, begin) && query > (begin + span); //Noncompliant - unspecified behavior
}

template <typename Iter>
bool inContainerRange(Iter query, Iter begin, Iter end)
{
    return query >= begin && query < end; //Noncompliant - unspecified behavior
}

void foo()
{
    double set[10];
    double *first = &set[0];
    double test_case;
    std::cout << std::boolalpha << isWithinRange(&test_case, first, 10);
    std::cout << std::boolalpha << isOutofRange(&test_case, first, 10);
}
void func(){
    std::vector<double> v1(10);
    std::vector<double> v2(1);
    std::cout << std::boolalpha << inContainerRange(v2.begin(), v1.begin(), v1.end());
}
```

In this example, Polyspace flags comparison and subtraction between iterators or pointers belonging to different containers. For instance:

- In the function `foo()`, `isWithinRange()` is called in such a way that the iterators `query` and `begin` might not point to the same container. The operation `query-begin` might be undefined behavior. Polyspace reports a violation of this rule on the subtraction.
- Similarly, the function `isOutofRange()` is called in such a way that the iterators `query` and `begin` might not point to the same container. The operation `less(query, begin)` might be unspecified behavior. Depending on your hardware architecture and software environment, this comparison might result in an unexpected result or undefined behavior. Polyspace reports a violation of this rule on the comparison.

- In the function `inContainerRange()`, the iterators `query`, `begin`, and `end` might not belong to the same container. The operation `query >= begin` compares iterators from different containers when the function `inContainerRange` is improperly used, as shown in the function `func()`. Comparing iterators from different containers results in an unspecified behavior. Depending on your hardware architecture and software environment, this comparison might result in unexpected result or undefined behavior. Polyspace reports a violation of this rule on the comparison.

#### Correction —Do Not Compare or Subtract Iterators or Pointers to Different Containers

Avoid subtraction or comparison between pointers or iterators that might be from different containers. For instance, range checking is done in the function `isWithinRange()` by using the == operation, which has well-defined behavior even if the operands belong to different containers. While less efficient, this code avoids undefined or unexpected behavior.

```
#include <iostream>
#include <cassert>
#include <cstddef>
#include <cstdbool>
#include <vector>

template <typename T>
bool isWithinRange(const T *query, const T *begin, size_t span)
{
    auto *current = reinterpret_cast<const unsigned char *>(begin);
    auto *end = reinterpret_cast<const unsigned char *>(begin + span);
    auto *ptr = reinterpret_cast<const unsigned char *>(query);
    while(current!=end){
        if(current==ptr){
            return true;
        }
    }

    return false;
}
template <typename T>
bool isOutofRange(const T *query, const T *begin, size_t span)
{
    return !(isWithinRange(query, begin, span));
}

void foo()
{
    double set[10];
    double *first = &set[0];
    double test_case;
    std::cout << std::boolalpha << isWithinRange(&test_case, first, 10);
    std::cout << std::boolalpha << isOutofRange(&test_case, first, 10);
}
```

Do not use an additive operator on an iterator if the result would overflow

## Description

### Rule Definition

*Do not use an additive operator on an iterator if the result would overflow.*[14]

### Polyspace Implementation

The rule checker checks for **Possible iterator overflow**.

## Examples

### Possible Iterator Overflow

#### Issue

This issue occurs when:

- A constant other than `1`, `0`, or `-1` is added or subtracted from an iterator.
- A variable that is assigned a value other than `1`, `0`, or `-1` is added or subtracted from an iterator. The variable must be local in scope and unmodified before use.

Such operations might result in an iterator before the `begin` iterator or after the `end` iterator of a container. For instance:

```
void print_vec(const std::vector<int> &v) {
    auto end_it = v.begin()+20;//Noncompliant
    for (auto it = v.begin(); it != end_it; ++it) {
        //...
    }
}
```

The function `print_vec` does not check if the iterator `end_it` goes past `v.end()`. The operation `v.begin()+20` might result in an iterator overflow. Polyspace reports a violation on this operation.

[14] *This software has been created by MathWorks incorporating portions of: the "SEI CERT-C Website," © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, "SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition," © 2016 Carnegie Mellon University, and "SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition" © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

Polyspace raises this violation for sequence containers such as `std::vector`, `std::array`, and `std::deque`. As an exception, Polyspace does not report a violation if iterators are incremented or decremented by using the pre or post increment or decrement operators.

#### Risk

The C++ standard does not guarantee the dereferencibility of iterators that are beyond the bounds of the container. An addition or subtraction operation that results in a possible iterator overflow cause an undefined behavior. Often, such an iterator overflow leads to a buffer overflow or buffer underrun. These defects might be exploited by an attacker to execute malicious code.

#### Fix

Validate the addition and subtraction operations on iterators so that the resultant iterators do not overflow.

#### Example — Avoid Addition Operation That Might Overflow on Iterators

```
#include<vector>
#include<string>
#include<iostream>
//Template function that accepts any container and prints the first 20 values
template<typename C, typename T = typename C::value_type>
void checkFirst20(C const& container)
{

  for(auto it = container.begin(), last = it+20; it!=last;++it)//Noncompliant
  {std::cout<<*it<<'\n';}
}

void foo(){
    std::vector<float> v(20);
    checkFirst20(v);
}
```

In this example, the function `checkFirst20()` calculates the value of the iterator `last` adding `20` to another iterator `it`. The code does not verify if `last` remains within the bounds of `container`. Dereferencing such an iterator might result in undefined behavior. Polyspace reports a violation of this rule on this addition.

#### Correction — Validate Addition Operation

To fix this issue, validate the addition operation that defines `last` so that the iterator does not point beyond the bounds of `container`. For instance, in the addition operation that defines `last`, use the smaller of 20 and the value `container.size()` so that `last` is within the bounds of `container`.

```
#include<vector>
#include<string>
#include<iostream>
//Template function that accepts any container and prints the first 20 values
template<typename C, typename T = typename C::value_type>
void printFirst20(C const& container)
{
 typename C::size_type max = 20;
  for(auto it = container.begin(), last = it + std::min(max,container.size()); it!=last;++it)//Co
  {std::cout<<*it<<'\n';}
}
```

```
void foo(){
    std::vector<float> v(5);
    printFirst20(v);
}
```

Do not use pointer arithmetic on polymorphic objects

## Description

### Rule Definition

*Do not use pointer arithmetic on polymorphic objects.*[15]

### Polyspace Implementation

The rule checker checks for the issue **Pointer Arithmetic on Polymorphic Object**.

## Examples

### Pointer Arithmetic on Polymorphic Object

#### Issue

**Pointer Arithmetic on Polymorphic Object** occurs when you perform pointer arithmetic on a base class pointer pointing to a derived class object. Pointer arithmetic includes array subscripting.

#### Risk

Because the base class and derived class objects might not be the same size, when you attempt pointer arithmetic on a basic class type pointer and this pointer points to a derived class object, the result is undefined behavior.

#### Fix

Typically, the issue occurs when you try to access an array of derived class objects through a base class pointer. To fix this issue, iterate through an array of pointers to objects instead of an array of objects. Instead of a regular array, you can also use a standard template library container such as `std::vector`.

#### Example — Pointer Arithmetic with Polymorphic Objects

In this example, the `Triangle` class is derived from the `Shape` class. The function `example()` takes a `Shape *` pointer as first parameter. A pointer to an array of `Triangle` objects is passed to this

[15] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

parameter when the function is called from `main()`. The function body contains two instances of pointer arithmetic on the `Shape *` pointer:

- In the initialization statement of the `for` loop, `const Shape* end = exampleShape + count`.
- In the increment statement of the `for` loop, `++exampleShape`.

```
#include <iostream>

class Shape
{
public:
    int height, width;
};

class Triangle : public Shape
{
public:
    double height, width;
};

void example(const Shape* exampleShape, std::size_t count)
{
    for (const Shape* end = exampleShape + count; exampleShape != end; ++exampleShape) //Noncomp
      {
        std::cout << exampleShape->height << std::endl;
    }
}

int main()
{
    Triangle triforce[4] = {};
    example(triforce, 4);
}
```

**Correction — Use an Array of Pointers**

By switching the array of objects in the `for` loop for an array of pointers to objects, you are no longer performing the arithmetic on the objects, but rather on the pointers to the objects. This change avoids the undefined behavior with pointer arithmetic in the `for` loop.

```
#include <iostream>

class Shape
{
public:
    int height, width;
};

class Triangle : public Shape
{
public:
    double height, width;
};

void example(const Shape* const* exampleShape, std::size_t count)
{
    for (const Shape* const* end = exampleShape + count; exampleShape != end; ++exampleShape)
    {
        std::cout << (*exampleShape)->height << std::endl;
    }
}

void main()
{
    Shape* triforce[] = { new Triangle , new Triangle , new Triangle , new Triangle };
    example(triforce, 4);
}
```

**Correction — Use an STL Container**

Instead of an array of objects, the example uses the STL container `std::vector` and fills the vector with pointers to `Triangle` objects. `example()` takes two iterators as parameters, which are the beginning and end of the vector `triforce`. The `for` loop then cycles through the vector of pointers by performing arithmetic on the iterators instead of the polymorphic objects.

```
#include <iostream>
#include <vector>

class Shape
{
public:
    int height, width;
};

class Triangle : public Shape
{
public:
    double height, width;
};

template <typename Iter>

void example(Iter i, Iter e)
{
    for (; i != e; ++i)
    {
        std::cout << (*i)->height << std::endl;
    }
}

void main()
{
    std::vector<Shape*> triforce{ new Triangle , new Triangle , new Triangle , new Triangle };
    example(triforce.cbegin(), triforce.cend());

    for (auto v : triforce)
    {
        delete v;
    }
}
```

Provide a valid ordering predicate

## Description

### Rule Definition

*Provide a valid ordering predicate.*[16]

### Polyspace Implementation

The rule checker checks for **Use of predicate lacking strict weak ordering**

## Examples

### Use of predicate lacking strict weak ordering

#### Issue

**Use of predicate lacking strict weak ordering** occurs when you use one of these compare types as predicates in standard template library (STL) algorithms and containers:

- `std::less_equal`
- `std::greater_equal`
- `std::equal_to`
- `std::not_equal_to`
- `std::logical_or`
- `std::logical_and`

For a list of standard library algorithms that expect a predicate with strict weak ordering, see Compare.

If you use a user-defined predicate function, Polyspace does not check if the custom predicate adheres to strict weak ordering.

[16] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

#### Risk

Algorithms and containers of the standard template library use predicates to sort and compare their elements. The predicates must adhere to strict weak ordering. That is, the predicate must adhere to these requirements:

- Irreflexivity: For all x, comparing x to itself must always evaluate to false.
- Assymetry: Far all x, y: if comparing x to y evaluates to true, then comparing y to x must evaluate to false.
- Transitivity: For all x, y, z: if comparing x to y and y to z both evaluate to true, then comparing x to z must also evaluate to true.

These compare type methods violate at least one of these requirements:

- std::less_equal
- std::greater_equal
- std::equal_to
- std::not_equal_to
- std::logical_or
- std::logical_and

Using the preceding predicates with algorithms and containers from the standard library might result in infinite loops, erratic behavior, and bugs that are difficult to diagnose.

#### Fix

To resolve this defect, avoid using the preceding methods as predicates for algorithms and containers from the standard template library. Instead, use methods that adhere to strict weak ordering. For instance, use functions such as std::less or std::greater. The STL uses these functions or their equivalent operators as the default ordering predicate. Using the default predicate might be sufficient to resolve the defect.

#### Example — Avoid Using Predicates That Do Not Adhere to Strict Weak Ordering with STL Algorithms

```
#include <functional>
#include <iostream>
#include <set>
#include <map>

int main(void)
{
    // GE
    std::set<int, std::greater_equal<int>>//Noncompliant
        s1{2, 5, 8};
    auto r = s1.equal_range(5);
    //returns 0
    std::cout << std::distance(r.first, r.second) << std::endl;

    //LE
    std::map<int, std::string, std::less_equal<int>>//Noncompliant
        m1{{2, "AB"}, {5, "CD"}, {8, "EF"}};
    auto r3 = m1.equal_range(5);
    //returns 0
    std::cout << std::distance(r3.first, r3.second) << std::endl;
    return 0;
}
```

In this example, Polyspace flags the use of inappropriate predicates when declaring STL containers. For instance:

- The predicate `greater_equal` does not return false when comparing the same objects, violating the irreflexivity requirement.
- The predicate `less_equal` does not return false when comparing the same objects, violating the irreflexivity requirement.

Polyspace flags the use of these function as predicates when declaring containers such as `std::set` or `std::map`.

#### Correction — Use the Default Predicate

By default, these containers use the function `std::less` as the ordering predicate. Because this function adheres to strict weak ordering relation, Polyspace does not raise a violation when you declare the containers by using the default predicate.

```
#include <functional>
#include <iostream>
#include <set>
#include <map>

int main(void)
{
    std::set<int> s2{2, 5, 8}; //Compliant
    auto r2 = s2.equal_range(5);
    //returns 1
    std::cout << std::distance(r2.first, r2.second) << std::endl;

    std::map<int, std::string> m2{{2, "AB"}, {5, "CD"}, {8, "EF"}}; //Compliant
    auto r4 = m2.equal_range(5);
    //returns 1
    std::cout << std::distance(r4.first, r4.second) << std::endl;

    return 0;
}
```

Predicate function objects should not be mutable

## Description

### Rule Definition

*Predicate function objects should not be mutable.*[17]

### Polyspace Implementation

The rule checker checks for **Function object that modifies its state**.

## Examples

### Function object that modifies its state

#### Issue

This issue occurs when the following conditions are true:

- You use a STL algorithm that takes a predicate function object. For a full list of STL algorithms, see Algorithms library.
- The state of the function object is modified, where the state is one of the following:
  - The `this` pointer if the predicate object is an instance of a class that defines a function call operator `operator()`.
  - A captured-by-copy value if the predicate object is a lambda function. A lambda function that captures values by reference is compliant.

A function object state is modified if it is written to or if a non-const method is called on it. For example, in this code snippet, non-const method `increment()` modifies the state `elemPosition` of `operator()` :

```
#include <functional>
#include <vector>
#include <algorithm>
```

[17] *This software has been created by MathWorks incorporating portions of: the “SEI CERT-C Website,” © 2017 Carnegie Mellon University, the SEI CERT-C++ Web site © 2017 Carnegie Mellon University, ”SEI CERT C Coding Standard – Rules for Developing safe, Reliable and Secure systems – 2016 Edition,” © 2016 Carnegie Mellon University, and “SEI CERT C++ Coding Standard – Rules for Developing safe, Reliable and Secure systems in C++ – 2016 Edition” © 2016 Carnegie Mellon University, with special permission from its Software Engineering Institute.*

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

```
class myPred : public std::unary_function<int, bool> {
  public:
    myPred(): elemPosition(0) {}
    void increment() {++elemPosition;} // Non-const method
    bool operator()(const int&) // function call operator
    {
        increment(); // method called on state elemPosition
        return elemPosition == 3;
    }
  private:
    size_t elemPosition;
};

void func(std::vector<int> v) {
    std::remove_if(v.begin(), v.end(), myPred()); // Noncompliant
}
```

Polyspace flags function objects that modify their state even if the function object is not a predicate.

Polyspace does not flag function objects that are wrapped in these:

- `std::ref`
- `std::cref`
- `std::function`
- `std::bind`
- `std::not1`

**Risk**

Predicate function objects take a single argument and use that argument to return a value that is testable as a boolean (true or false). Standard Template Library (STL) algorithms that accept a predicate function object may, depending on the algorithm implementation, make a copy of the function object. The invocation of the copy might cause unexpected results.

For example, suppose that you use an algorithm to remove one element from a list. To determine the element to remove, the algorithm uses a predicate function object that modifies a state related to the function object identity each time the function object is called. You might expect the predicate object to return true only once. If the algorithm makes a copy of the predicate object, the state of the copy is also modified and the copy returns true a second time, removing a second element from the list.

**Fix**

To avoid unexpected results, consider one of the following:

- Wrap the predicate function object in a `std::reference_wrapper<T>` before you pass it to the algorithm. If the wrapper object is copied, all copies refer to the same underlying predicate function object.

  For example, in this code snippet, predicate function object `myObj` is wrapped in `std::ref` when passed to `std::remove_if`.

  ```
  class predObj {
      // Defines function object that modifies its state
  };
  void func() {
      std::vector<int> v{0, 1, 2, 3, 4, 5};
      //
      predObj myObj;
  ```

```
    v.erase(std::remove_if(v.begin(), v.end(), std::ref(myObj)), v.end());
    //....
}
```

- Implement a `const` function call operator that does not modify the state of the predicate object. For example, in this code snippet, `predModifies` defines a call operator that modifies `elemPosition` before checking the equality whereas `predDoesNotModify` checks only the equality of `var` without modifying it.

  ```
  #include <functional>
  #include <vector>
  #include <algorithm>

  class predModifies : public std::unary_function<int, bool>
  {
  public:
  predModifies() : elemPosition(0) {}
  bool operator()(const int &) const { return (++elemPosition) == 3; }
  //call operator modifies elemPosition
  private:
  mutable size_t elemPosition;
  };

  class predDoesNotModify: public std::unary_function<int, bool>
  {
  public:
  bool operator()(const int& var) const { return var == 3; }
  //call operator does not modify state of object
  };
  ```

**Example — Function Object that Modifies Its State**

```
#include <functional>
#include <vector>
#include <algorithm>

void lambdaDoesNotModify(std::vector<int> v)
{
  int elemPosition = 0;
  std::remove_if(v.begin(), v.end(),
    [elemPosition](const int & element) mutable {  //Compliant
      return elemPosition == 0 && element == 3;
    });
}

void lambdaCaptureByRef(std::vector<int> v)
{
  int elemPosition = 0;
  std::remove_if(v.begin(), v.end(),
    [&elemPosition](const int & i) { // Compliant
      return ++elemPosition == 3;
    });
}

class nonConstPred : public std::unary_function<int, bool>
{
  public:
    nonConstPred() : elemPosition(0) {}
    void increment() { ++elemPosition; }
```

```
    bool operator()(const int &)
    {
      increment();
      return elemPosition == 3;
    }
  private:
    size_t elemPosition;
};

void myFunc(std::vector<int> v)
{
  std::remove_if(v.begin(), v.end(), nonConstPred()); // Noncompliant
}
```

In this example, the use of predicate function object `nonConstPred()` inside function `myFunc` is not compliant. The call operator inside class `nonConstPred` uses a non-const method `increment()` that modifies `elemPosition`, the state of the predicate. If the algorithm `std::remove_if` makes a copy of the predicate function object, there might be two instances of `elemPosition == 3` being true, which might cause unexpected results.

The use of a lambda function as predicate function object in function `lambdaDoesNotModify` is compliant because the state of the function object is not modified. Similarly, the lambda function in `lambdaCaptureByRef` is compliant because the state of the function object is captured by reference.

### Correction — Wrap the Function Object in `std::ref`

```
#include <functional>
#include <vector>
#include <algorithm>

void lambdaDoesNotModify(std::vector<int> v)
{
  int elemPosition = 0;
  std::remove_if(v.begin(), v.end(),
    [elemPosition](const int & element) mutable {  //Compliant
      return elemPosition == 0 && element == 3;
    });
}

void lambdaCaptureByRef(std::vector<int> v)
{
  int elemPosition = 0;
  std::remove_if(v.begin(), v.end(),
    [&elemPosition](const int & i) { // Compliant
      return ++elemPosition == 3;
    });
}

class nonConstPred : public std::unary_function<int, bool>
{
  public:
    nonConstPred() : elemPosition(0) {}
    void increment() { ++elemPosition; }
    bool operator()(const int &)
    {
      increment();
      return elemPosition == 3;
    }
  private:
    size_t elemPosition;
};

void myFunc(std::vector<int> v)
{
  nonConstPred myPred;
  std::remove_if(v.begin(), v.end(), std::ref(myPred)); // Compliant
}
```

One possible correction is to wrap the function object in `std::ref`. All copies of the wrapper object refer to the same underlying function object and there is only one instance of the state `elemPosition`.

Do not attempt to modify string literals

## Description

### Rule Definition

*Do not attempt to modify string literals.*

### Polyspace Implementation

The rule checker checks for **Writing to const qualified object**.

## Examples

### Writing to const qualified object

#### Issue

**Writing to `const` qualified object** occurs when you do one of the following:

- Use a `const`-qualified object as the destination of an assignment.
- Pass a `const`-qualified object to a function that modifies the argument.

For instance, the defect can occur in the following situations:

- You pass a `const`-qualified object as first argument of one of the following functions:
  - `mkstemp`
  - `mkostemp`
  - `mkostemps`
  - `mkdtemp`
- You pass a `const`-qualified object as the destination argument of one of the following functions:
  - `strcpy`
  - `strncpy`
  - `strcat`
  - `memset`
- You perform a write operation on a `const`-qualified object.

#### Risk

The risk depends upon the modifications made to the `const`-qualified object.

| Situation | Risk |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | These functions replace the last six characters of their first argument with a string. Therefore, they expect a modifiable `char` array as their first argument. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | These functions modify their destination argument. Therefore, they expect a modifiable `char` array as their destination argument. |
| Writing to the object | The `const` qualifier implies an agreement that the value of the object will not be modified. By writing to a `const`-qualified object, you break the agreement. The result of the operation is undefined. |

#### Fix

The fix depends on the modification made to the `const`-qualified object.

| Situation | Fix |
|---|---|
| Passing to `mkstemp`, `mkostemp`, `mkostemps`, `mkdtemp`, and so on. | Pass a non-`const` object as first argument of the function. |
| Passing to `strcpy`, `strncpy`, `strcat`, `memset` and so on. | Pass a non-`const` object as destination argument of the function. |
| Writing to the object | Perform the write operation on a non-`const` object. |

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Writing to const-Qualified Object

```
#include <string.h>

const char* buffer = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string); //Noncompliant
}
```

In this example, because `buffer` is `const`-qualified, `strchr(buffer,'X')` returns a `const`-qualified `char*` pointer. When this `char*` pointer is used as the destination argument of `strcpy`, a **Writing to const qualified object** error appears.

### Correction — Copy `const`-Qualified Object to Non-`const` Object

One possible correction is to assign the constant string to a non-`const` object and use the non-`const` object as destination argument of `strchr`.

```
#include <string.h>

char buffer[] = "abcdeXXXXXXX";

void func(char* string) {
    char *ptr = (char*)strchr(buffer,'X');
    if(ptr)
        strcpy(ptr,string);
}
```

Guarantee that storage for strings has sufficient space for character data and the null terminator

## Description

### Rule Definition

*Guarantee that storage for strings has sufficient space for character data and the null terminator.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of dangerous standard function**.
- **Buffer overflow from incorrect string format specifier**.
- **Destination buffer overflow in string manipulation**.
- **Insufficient destination buffer size**.

## Examples

### Use of dangerous standard function

#### Issue

The **Use of dangerous standard function** check highlights uses of functions that are inherently dangerous or potentially dangerous given certain circumstances. The following table lists possibly dangerous functions, the risks of using each function, and what function to use instead.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `std::cin::operator>>` and `std::wcin::operator>>` | Inherently dangerous — You cannot control the length of input from the console. | Preface calls to `cin` by `cin.width` to control the input length. This method can result in truncated input.<br>To avoid potential buffer overflow and truncated input, use `std::string` objects as destinations for >> operator. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

**Risk**

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

**Fix**

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Using `sprintf`**

```
#include <stdio.h>
#include <string.h>
```

```
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1) //Noncompliant
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

#### Correction — Use `snprintf` with Buffer Size

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf); //Noncompliant
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string); //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Insufficient destination buffer size

#### Issue

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(input, str); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

#### Risk

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if `argv[0]` contains 100 or more characters, the `strcpy` operation results in a buffer overflow.

#### Fix

Before calling the function `strcpy()`, allocate sufficient memory dynamically. For instance, use the function `strlen()` to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value `strlen(source) + 1`.

#### Example — Destination Buffer Too Small

In this example, the size of the `source` buffer is unknown, while the size of the `destination` buffer is fixed at `128`. The size of the `destination` buffer might not be sufficient to accommodate the characters from the `source` buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <cstring>

int main(int argc, char *argv[]) {
    const char *const source = (argc && argv[0]) ? argv[0] : "";
    char destination[128];
    strcpy(const_cast<char*>(source), destination);//Noncompliant
    return 0;
}
```

#### Correction — Allocate Sufficient Memory for Destination Buffer

This violation is resolved by allocating sufficient memory for the `destination` buffer. For instance, use the function `strlen()` to calculate the size of the `source` buffer and allocate sufficient memory for the `destination` buffer so that it can accommodate all characters from the `source` buffer and the null terminator (`'\0'` ).

```
#include <cstring>
#include <cstdlib>

int main(int argc, char *argv[]) {
    const char *const source = (argc && argv[0]) ? argv[0] : "";
    char* destination = (char *)malloc(strlen(source)+ 1);
    if(destination!=NULL){
        strcpy(const_cast<char*>(source), destination);//Compliant
    }else{
        /*Handle Error*/
    }
    //...
    free(destination);
    return 0;
}
```

Do not pass a non-null-terminated character sequence to a library function that expects a string

## Description

### Rule Definition

*Do not pass a non-null-terminated character sequence to a library function that expects a string.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid use of standard library string routine**.
- **Tainted NULL or non-null-terminated string**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted NULL or non-null-terminated string** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Invalid use of standard library string routine

#### Issue

**Invalid use of standard library string routine** occurs when a string library function is called with invalid arguments.

#### Risk

The risk depends on the type of invalid arguments. For instance, using the `strcpy` function with a source argument larger than the destination argument can result in buffer overflows.

#### Fix

The fix depends on the standard library function involved in the defect. In some cases, you can constrain the function arguments before the function call. For instance, if the `strcpy` function:

```
char * strcpy(char * destination, const char* source);
```

tries to copy too many bytes into the destination argument compared to the available buffer, constrain the source argument before the call to `strcpy`. In some cases, you can use an alternative function to avoid the error. For instance, instead of `strcpy`, you can use `strncpy` to control the number of bytes copied. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Invalid Use of Standard Library String Routine Error

```
 #include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  char gbuffer[5],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);  //Noncompliant
  /* Error: Size of text is less than gbuffer */

  return(res);
 }
```

The string `text` is larger in size than `gbuffer`. Therefore, the function `strcpy` cannot copy `text` into `gbuffer`.

#### Correction — Use Valid Arguments

One possible correction is to declare the destination string `gbuffer` with equal or larger size than the source string `text`.

```
#include <string.h>
 #include <stdio.h>

 char* Copy_String(void)
 {
  char *res;
  /*Fix: gbuffer has equal or larger size than text */
  char gbuffer[20],text[20]="ABCDEFGHIJKL";

  res=strcpy(gbuffer,text);

  return(res);
 }
```

### Tainted NULL or non-null-terminated string

#### Issue

**Tainted NULL or non-null-terminated string** looks for strings from unsecure sources that are being used in string manipulation routines that implicitly dereference the string buffer. For example, `strcpy` or `sprintf`.

**Tainted NULL or non-null-terminated string** raises no defect for a string returned from a call to `scanf`-family variadic functions. Similarly, no defect is raised when you pass the string with a `%s` specifier to `printf`-family variadic functions.

**Note** If you reference a string using the form `ptr[i]`, `*ptr`, or pointer arithmetic, Bug Finder raises a **Use of tainted pointer** defect instead. The **Tainted NULL or non-null-terminated string** defect is raised only when the pointer is used as a string.

#### Risk

If a string is from an unsecure source, it is possible that an attacker manipulated the string or pointed the string pointer to a different memory location.

If the string is NULL, the string routine cannot dereference the string, causing the program to crash. If the string is not null-terminated, the string routine might not know when the string ends. This error can cause you to write out of bounds, causing a buffer overflow.

#### Fix

Validate the string before you use it. Check that:

- The string is not NULL.
- The string is null-terminated
- The size of the string matches the expected size.

#### Example - Getting String from Input Argument

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
void warningMsg(void)
{
      char userstr[MAX];
      read(0,userstr,MAX);
      char str[SIZE128] = "Warning: ";
      strncat(str, userstr, SIZE128-(strlen(str)+1)); //Noncompliant
      print_str(str);
}
```

In this example, the string `str` is concatenated with the argument `userstr`. The value of `userstr` is unknown. If the size of `userstr` is greater than the space available, the concatenation overflows.

#### Correction — Validate the Data

One possible correction is to check the size of `userstr` and make sure that the string is null-terminated before using it in `strncat`. This example uses a helper function, `sansitize_str`, to validate the string. The defects are concentrated in this function.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#define SIZE128 128
#define MAX 40
extern void print_str(const char*);
int sanitize_str(char* s) {
    int res = 0;
    if (s && (strlen(s) > 0)) { // Noncompliant
    //TAINTED_STRING confined to the sanitizer function.
        // - string is not null
        // - string has a positive and limited size
        // - TAINTED_STRING on strlen used as a firewall
        res = 1;
    }
    return res;
}
void warningMsg(void)
{
    char userstr[MAX];
    read(0,userstr,MAX);
    char str[SIZE128] = "Warning: ";
    if (sanitize_str(userstr))
        strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}
```

#### Correction — Validate the Data

Another possible correction is to call function `errorMsg` and `warningMsg` with specific strings.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

#define SIZE128 128

extern void print_str(const char*);

void warningMsg(char* userstr)
{
    char str[SIZE128] = "Warning: ";
    strncat(str, userstr, SIZE128-(strlen(str)+1));
    print_str(str);
}

void errorMsg(char* userstr)
{
  char str[SIZE128] = "Error: ";
  strncat(str, userstr, SIZE128-(strlen(str)+1));
  print_str(str);
}

int manageSensorValue(int sensorValue) {
  int ret = sensorValue;
  if ( sensorValue < 0 ) {
    errorMsg("sensor value should be positive");
    exit(1);
  } else if ( sensorValue > 50 ) {
    warningMsg("sensor value greater than 50 (applying threshold)...");
    sensorValue = 50;
  }

  return sensorValue;
}
```

## Check Information

**Group:** 05. Characters and Strings (STR)

# Version History

**Introduced in R2019a**

Cast characters to unsigned char before converting to larger integer sizes

## Description

### Rule Definition

*Cast characters to unsigned char before converting to larger integer sizes.*

### Polyspace Implementation

The rule checker checks for **Misuse of sign-extended character value**.

## Examples

### Misuse of sign-extended character value

#### Issue

**Misuse of sign-extended character value** occurs when you convert a signed or plain `char` data type to a wider integer data type with sign extension. You then use the resulting sign-extended value as array index, for comparison with EOF or as argument to a character-handling function.

#### Risk

*Comparison with EOF*: Suppose, your compiler implements the plain `char` type as signed. In this implementation, the character with the decimal form of 255 (–1 in two’s complement form) is stored as a signed value. When you convert a `char` variable to the wider data type `int` for instance, the sign bit is preserved (sign extension). This sign extension results in the character with the decimal form 255 being converted to the integer –1, which cannot be distinguished from EOF.

*Use as array index*: By similar reasoning, you cannot use sign-extended plain `char` variables as array index. If the sign bit is preserved, the conversion from `char` to `int` can result in negative integers. You must use positive integer values for array index.

*Argument to character-handling function*: By similar reasoning, you cannot use sign-extended plain `char` variables as arguments to character-handling functions declared in `ctype.h`, for instance, `isalpha()` or `isdigit()`. According to the C11 standard (Section 7.4), if you supply an integer argument that cannot be represented as `unsigned char` or EOF, the resulting behavior is undefined.

#### Fix

Before conversion to a wider integer data type, cast the signed or plain `char` value explicitly to `unsigned char`.

#### Example - Sign-Extended Character Value Compared with EOF

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];
```

```
static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = *buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {  //Noncompliant
        /* Handle error */
        fatal_error();
    }
}
```

In this example, the function `parser` can traverse a string input `buf`. If a character in the string has the decimal form 255, when converted to the `int` variable `c`, its value becomes –1, which is indistinguishable from `EOF`. The later comparison with `EOF` can lead to a false positive.

#### Correction — Cast to `unsigned char` Before Conversion

One possible correction is to cast the plain `char` value to `unsigned char` before conversion to the wider `int` type.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

extern char parsed_token_buffer[20];

static int parser(char *buf)
{
    int c = EOF;
    if (buf && *buf) {
        c = (unsigned char)*buf++;
    }
    return c;
}

void func()
{
    if (parser(parsed_token_buffer) == EOF) {
        /* Handle error */
        fatal_error();
    }
}
```

Arguments to character-handling functions must be representable as an unsigned char

## Description

### Rule Definition

*Arguments to character-handling functions must be representable as an unsigned char.*

### Polyspace Implementation

The rule checker checks for **Invalid arguments to character-handling functions**.

## Examples

### Invalid arguments to character-handling functions

#### Issue

**Invalid arguments to character-handling functions** occurs when you use a signed or plain `char` variable with a negative value as argument to a character-handling function declared in `<cctype>`, for instance, `isalpha()` or `isdigit()`.

#### Risk

You cannot use plain `char` variables as arguments to these character-handling functions. On certain platforms, plain `char` variables can have negative values that cannot be represented as `unsigned char` or EOF, resulting in undefined behavior.

#### Fix

To avoid unexpected results, explicitly cast plain `char` variables to unsigned `char` before passing to character-handling functions.

Do not confuse narrow and wide character strings and functions

## Description

### Rule Definition

*Do not confuse narrow and wide character strings and functions.*

### Polyspace Implementation

The rule checker checks for **Misuse of narrow or wide character string**.

## Examples

### Misuse of narrow or wide character string

#### Issue

**Misuse of narrow or wide character string** occurs when you pass a narrow character string to a wide string function, or a wide character string to a narrow string function.

**Misuse of narrow or wide character string** raises no defect on operating systems where narrow and wide character strings have the same size.

#### Risk

Using a narrow character string with a wide string function, or vice versa, can result in unexpected or undefined behavior.

If you pass a wide character string to a narrow string function, you can encounter these issues:

- Data truncation. If the string contains null bytes, a copy operation using `strncpy()` can terminate early.
- Incorrect string length. `strlen()` returns the number of characters of a string up to the first null byte. A wide string can have additional characters after its first null byte.

If you pass a narrow character string to a wide string function, you can encounter this issue:

- Buffer overflow. In a copy operation using `wcsncpy()`, the destination string might have insufficient memory to store the result of the copy.

#### Fix

Use the narrow string functions with narrow character strings. Use the wide string functions with wide character strings.

#### Example - Passing Wide Character Strings to `strncpy()`

```
#include <string.h>
#include <wchar.h>

void func(void)
```

```
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    strncpy(reinterpret_cast<char *>(wide_str2), reinterpret_cast<const char *>(wide_str1), 10);
}
```

In this example, `strncpy()` copies 10 wide characters from `wide_strt1` to `wide_str2`. If `wide_str1` contains null bytes, the copy operation can end prematurely and truncate the wide character string.

#### Correction — Use `wcsncpy()` to Copy Wide Character Strings

One possible correction is to use `wcsncpy()` to copy `wide_str1` to `wide_str2`.

```
#include <string.h>
#include <wchar.h>

void func(void)
{
    wchar_t wide_str1[]  = L"0123456789";
    wchar_t wide_str2[] =  L"0000000000";
    wcsncpy(wide_str2, wide_str1, 10);
}
```

Guarantee that storage for strings has sufficient space for character data and the null terminator

## Description

### Rule Definition

*Guarantee that storage for strings has sufficient space for character data and the null terminator.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Use of dangerous standard function**.
- **Buffer overflow from incorrect string format specifier**.
- **Destination buffer overflow in string manipulation**.
- **Insufficient destination buffer size**.
- **Input string not null-terminated**

## Examples

### Use of dangerous standard function

#### Issue

The **Use of dangerous standard function** check highlights uses of functions that are inherently dangerous or potentially dangerous given certain circumstances. The following table lists possibly dangerous functions, the risks of using each function, and what function to use instead.

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `gets` | Inherently dangerous — You cannot control the length of input from the console. | `fgets` |
| `std::cin::operator>>` and `std::wcin::operator>>` | Inherently dangerous — You cannot control the length of input from the console. | Preface calls to `cin` by `cin.width` to control the input length. This method can result in truncated input.<br>To avoid potential buffer overflow and truncated input, use `std::string` objects as destinations for >> operator. |
| `strcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `strncpy` |

| Dangerous Function | Risk Level | Safer Function |
|---|---|---|
| `stpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `stpncpy` |
| `lstrcpy` or `StrCpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `StringCbCopy`, `StringCchCopy`, `strncpy`, `strcpy_s`, or `strlcpy` |
| `strcat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `strncat`, `strlcat`, or `strcat_s` |
| `lstrcat` or `StrCat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `StringCbCat`, `StringCchCat`, `strncay`, `strcat_s`, or `strlcat` |
| `wcpcpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcpncpy` |
| `wcscat` | Possibly dangerous — If the concatenated result is greater than the destination, buffer overflow can occur. | `wcsncat`, `wcslcat`, or `wcncat_s` |
| `wcscpy` | Possibly dangerous — If the source length is greater than the destination, buffer overflow can occur. | `wcsncpy` |
| `sprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `snprintf` |
| `vsprintf` | Possibly dangerous — If the output length depends on unknown lengths or values, buffer overflow can occur. | `vsnprintf` |

#### Risk

These functions can cause buffer overflow, which attackers can use to infiltrate your program.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.

- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Example - Using `sprintf`

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (sprintf(dst, "%s", str) == 1) //Noncompliant
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

This example function uses `sprintf` to copy the string `str` to `dst`. However, if `str` is larger than the buffer, `sprintf` can cause buffer overflow.

### Correction — Use `snprintf` with Buffer Size

One possible correction is to use `snprintf` instead and specify a buffer size.

```
#include <stdio.h>
#include <string.h>
#include <iostream>

#define BUFF_SIZE 128

int dangerous_func(char *str)
{
    char dst[BUFF_SIZE];
    int r = 0;

    if (snprintf(dst, sizeof(dst), "%s", str) == 1)
    {
        r += 1;
        dst[BUFF_SIZE-1] = '\0';
    }

    return r;
}
```

### Buffer overflow from incorrect string format specifier

#### Issue

**Buffer overflow from incorrect string format specifier** occurs when the format specifier argument for functions such as `sscanf` leads to an overflow or underflow in the memory buffer argument.

#### Risk

If the format specifier specifies a precision that is greater than the memory buffer size, an overflow occurs. Overflows can cause unexpected behavior such as memory corruption.

#### Fix

Use a format specifier that is compatible with the memory buffer size.

#### Example - Memory Buffer Overflow

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%33c", buf); //Noncompliant
}
```

In this example, `buf` can contain 32 `char` elements. Therefore, the format specifier `%33c` causes a buffer overflow.

#### Correction — Use Smaller Precision in Format Specifier

One possible correction is to use a smaller precision in the format specifier.

```
#include <stdio.h>

void func (char *str[]) {
    char buf[32];
    sscanf(str[1], "%32c", buf);
}
```

### Destination buffer overflow in string manipulation

#### Issue

**Destination buffer overflow in string manipulation** occurs when certain string manipulation functions write to their destination buffer argument at an offset greater than the buffer size.

For instance, when calling the function `sprintf(char* buffer, const char* format)`, you use a constant string `format` of greater size than `buffer`.

#### Risk

Buffer overflow can cause unexpected behavior such as memory corruption or stopping your system. Buffer overflow also introduces the risk of code injection.

#### Fix

One possible solution is to use alternative functions to constrain the number of characters written. For instance:

- If you use `sprintf` to write formatted data to a string, use `snprintf`, `_snprintf` or `sprintf_s` instead to enforce length control. Alternatively, use `asprintf` to automatically allocate the memory required for the destination buffer.
- If you use `vsprintf` to write formatted data from a variable argument list to a string, use `vsnprintf` or `vsprintf_s` instead to enforce length control.
- If you use `wcscpy` to copy a wide string, use `wcsncpy`, `wcslcpy`, or `wcscpy_s` instead to enforce length control.

Another possible solution is to increase the buffer size.

#### Example - Buffer Overflow in `sprintf` Use

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    sprintf(buffer, fmt_string); //Noncompliant
}
```

In this example, `buffer` can contain 20 `char` elements but `fmt_string` has a greater size.

#### Correction — Use `snprintf` Instead of `sprintf`

One possible correction is to use the `snprintf` function to enforce length control.

```
#include <stdio.h>

void func(void) {
    char buffer[20];
    char *fmt_string = "This is a very long string, it does not fit in the buffer";

    snprintf(buffer, 20, fmt_string);
}
```

### Insufficient destination buffer size

#### Issue

**Insufficient destination buffer size** occurs when the destination buffer in a `strcpy` operation cannot accommodate the source buffer and a null terminator. This issue is reported if the size of the source buffer is unknown. Consider this code:

```
int main (int argc, char *argv[])
{
  const char *const input = ((argc && argv[0]) ? argv[0] : "");
  char str[100];
  strcpy(input, str); // Noncompliant
}
```

In this case, the size of the source buffer `input` is unknown. The size of the destination buffer `str` might be smaller than the value `(strlen(input)+1)`. Polyspace reports a violation on the `strcpy` operation.

#### Risk

Using a destination buffer of insufficient size might allow an attacker to cause a buffer overflow. In the preceding code example, if argv[0] contains 100 or more characters, the strcpy operation results in a buffer overflow.

#### Fix

Before calling the function strcpy(), allocate sufficient memory dynamically. For instance, use the function strlen() to determine the size of the source buffer and then allocate the destination buffer so that its size is greater than the value strlen(source) + 1.

#### Example — Destination Buffer Too Small

In this example, the size of the source buffer is unknown, while the size of the destination buffer is fixed at 128. The size of the destination buffer might not be sufficient to accommodate the characters from the source buffer and terminate the buffer with a null. Polyspace reports a violation of the rule.

```
#include <cstring>

int main(int argc, char *argv[]) {
    const char *const source = (argc && argv[0]) ? argv[0] : "";
    char destination[128];
    strcpy(const_cast<char*>(source), destination);//Noncompliant
    return 0;
}
```

#### Correction — Allocate Sufficient Memory for Destination Buffer

This violation is resolved by allocating sufficient memory for the destination buffer. For instance, use the function strlen() to calculate the size of the source buffer and allocate sufficient memory for the destination buffer so that it can accommodate all characters from the source buffer and the null terminator ('\0' ).

```
#include <cstring>
#include <cstdlib>

int main(int argc, char *argv[]) {
    const char *const source = (argc && argv[0]) ? argv[0] : "";
    char* destination = (char *)malloc(strlen(source)+ 1);
    if(destination!=NULL){
        strcpy(const_cast<char*>(source), destination);//Compliant
    }else{
        /*Handle Error*/
    }
    //...
    free(destination);
    return 0;
}
```

### Input string not null-terminated

#### Issue

The issue **Input string not null-terminated** occurs when both of these conditions are true:

- You obtain a string from an input function that does not necessarily terminates the string by a null character.

- You use the input string that does not have the terminating null character in places where a null-terminated string is expected.

For instance:

```
char str[10];
scanf("%10c", str);
std::string S(str);//Null-terminated string expected
```

Here, the constructor of `std::string` expects a string terminated by a null character, but `str` is not null-terminated. Polyspace reports a violation of this rule.

#### Risk

Functions in the C++ library assume that a valid string is terminated by a null character and apply this assumption string algorithms. Using these functions and algorithms with a string that lacks a terminating null character results in undefined behavior.

#### Fix

The fix for this issue depends on the context:

- You can fix this issue by terminating raw input strings by a null. For example, this code declares `str` with 11 elements. After filling the first 10 elements with the raw input, assign the last element the value `'\0'`. After manually terminating the input string with a null character, you can use the input string with standard template library (STL) string functions without violating this rule.

  ```
  char str[11];
  scanf("%10c", str);
  str[10] = '\0';
  std::string S(str);//Valid string
  ```
- Some C++ functions accepts character pointers or substrings as input. These functions can correctly handle a raw character array without a terminating null character. For instance, This code constructs the `std::string` object `S` by using a nondefault constructor. This constructor allows the use of `str`, which lacks a terminating null character. Such uses do not violate this rule.

  ```
  char str[10];
  scanf("%10c", str);
  std::string S(str,sizeof(str));//Valid use of substring
  ```

#### Example — Print Input String Without Terminating Null Character

In this example, the `read` function accepts an array of characters, which is then stored in the `char` array `buffer`. Because `buffer`does not have a terminating null character, using `buffer` with the function `printf()` results in undefined behavior. Polyspace reports a violation of this rule.

```
#include <iostream>
#include <string>
#include <fstream>
#include <cstdio>
void echo_instream(std::istream& instream) {
    //...
    char buffer[10];
    instream.read(buffer,sizeof(buffer));
    //...
    printf("%s", buffer); //Noncompliant
    //...
```

```
}
```

#### Correction — Terminate Input String with `'\0'`

To fix this issue, manually add the terminating null character at the end of `buffer`.

```
#include <iostream>
#include <string>
#include <fstream>
#include <cstdio>
void echo_instream(std::istream& instream) {
    //...
    char buffer[10];
    instream.read(buffer,sizeof(buffer)-1);
    buffer[9] = '\0';
    //...
    printf("%s", buffer); //Compliant
    //...
}
```

Do not attempt to create a `std::string` from a null pointer

## Description

### Rule Definition

*Do not attempt to create a `std::string` from a null pointer.*

### Polyspace Implementation

The rule checker checks for the issue **String operations on null pointer**.

## Examples

### String Operations On Null Pointer

#### Issue

This issue occurs when:

- You perform string operations that require calling `std::char_traits::length()` on `NULL`, 0, or `nullptr` . Examples of such string operations are creating, appending, assigning, inserting, or replacing the string. For a list of operations that results in call to `std::char_traits::length()`, see STR51-CPP.

  This issue is a specific instance of the issue **Null pointer**, which causes violations of `CERT C++: EXP34-C`. Consider this code:

  ```
  std::string getString(); //returns nullptr
  void foo(){
      std::string str{getString()};//Defect
  }
  ```

  Construction of `str` requires an implicit call to `std::char_traits::length()`. Polyspace reports a violation because `getString()` returns a `nullptr`, which results in calling `std::char_traits::length()` on `nullptr`.
- You perform certain string operations on a nonnull pointer to an uninitialized memory block. Consider this code:

  ```
  void foo() {

      const char* uninitialized = (const char*)std::malloc(size*sizeof(char) + 1);;
       std::string tmp(uninitialized);  //Noncompliant
  }
  ```

  Polyspace reports a violation of this rule when `tmp` is constructed by using the uninitialized memory in `uninitialized`.

A violation of this rule is not reported for stubbed functions.

#### Risk

Performing string operations that require calling `std::char_traits::length()` on `NULL`, 0, or `nullptr` might result in an undefined behavior. The function `std::char_traits::length()` dereferences the null pointer, which is an undefined behavior.

Performing string operations on uninitialized memory results in unexpected outcome and might result in bugs that are difficult to diagnose.

#### Fix

Check if the string object is a null pointer or an empty string before you perform string operations.

#### Example — String Operations Using Null Pointer

```
#include <cstdlib>
#include <string>

int status;
const char *getInput()
{
    return status == 0 ? std::getenv("TMP") : nullptr;

}

void foo()
{
    status=1;
    const char *data = getInput();
    //...
    std::string str(data);   // Noncompliant
    str.append(data);        // Noncompliant
    str.assign(data);        // Noncompliant
    str.insert(0, data);     // Noncompliant
    str.replace(0, 1, data); // Noncompliant
}
```

In this example, the `const char*` object `data` is created by calling `getInput()`, and then various string operations are performed by using `data`. Polyspace reports a violation of this rule for each string operation because the function `getInput()` returns a `nullptr` which is then assigned to `data`.

#### Correction — Avoid Performing String Operation on Null Pointers

Modify `getInput()` so that the function does not return a `nullptr`.

```
#include <cstdlib>
#include <string>

int status;
const char *getInput()
{
    return status == 0 ? std::getenv("TMP") : "";

}

void foo()
{
    status=1;
    const char *data = getInput();
    //...
    std::string str(data);   // Compliant
    str.append(data);        // Compliant
    str.assign(data);        // Compliant
    str.insert(0, data);     // Compliant
    str.replace(0, 1, data); // Compliant
}
```

Use valid references, pointers, and iterators to reference elements of a `basic_string`

## Description

### Rule Definition

*Use valid references, pointers, and iterators to reference elements of a `basic_string`.*

### Polyspace Implementation

The rule checker checks for the issue **Use of invalid string iterator**.

## Examples

### Use of Invalid String Iterator

#### Issue

This issue occurs when you use an iterator, pointer, or reference to an element of a `basic_string` object that has been invalidated by actions such as insertion or erasure. This issue is a specific instance of the issue **Use of invalid iterator**, which causes violations of `CERT C++: CTR51-CPP`. Consider this code:

```
std::string str = "Basic String";
auto it_begin = str.begin();
//...
str.replace(0,5,"Advanced");
str.insert(it_begin,'A'); // Violation
```

Here, the iterator `it_begin` is invalidated after the call to `string::replace`. Using this invalid iterator in `string::insert` causes a violation of this rule.

Functions that invalidate an STL iterator also invalidate `basic_string` iterators. In addition, these functions invalidate a `basic_string` iterator:

- `std::swap()`
- `Operator>>(std::basic_istream&, std::string&)`
- `std::getline()`

#### Risk

Dereferencing the invalid iterator might produce unexpected results. If the invalidated iterator becomes a dangling pointer or an uninitialized pointer, dereferencing it might cause sudden termination of the program.

#### Fix

The C++ standard defines which operations invalidate the iterators of the standard library containers. These operations also invalidate a string operator. See Containers library. When you perform actions that might invalidate an iterator, revalidate the iterator. For instance, recalculate the iterator after an insertion or erasure.

#### Example — Avoid Using Invalid Iterators

```
#include <string>

void foo(const std::string& raw, std::string& processed) {

  // Process the raw string and store in processed
  auto loc = processed.begin();
  for (auto i = raw.begin(); i != raw.end(); ++i, ++loc) {
    processed.insert(loc, *i != ';' ? *i : ' ');//Noncompliant
  }
}
```

In this example, the first `processed.insert` operation in the `for` loop invalidates the iterator `i`. The subsequent use of the iterator `i` might result in undefined behavior. Polyspace reports a violation of this rule.

#### Correction — Update the Iterator

When you use iterators after an insertion or erasure, update the iterator to avoid undefined behavior. For instance, in this code, the iterator `i` is updated after each insertion so that the iterator remains valid.

```
#include <string>

void foo(const std::string& raw, std::string& processed) {

  // Process the raw string and store in processed
  auto loc = processed.begin();
  for (auto i = raw.begin(); i != raw.end(); ++i, ++loc) {
    loc = processed.insert(loc, *i != ';' ? *i : ' ');//Compliant
  }
}
```

Range check element access

## Description

### Rule Definition

*Range check element access.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Array access out of bounds**.
- **Array access with tainted index**.
- **Pointer dereference with tainted offset**.

### Extend Checker

Extend this checker to run a stricter analysis:

- When the input values are unknown and only a subset of inputs causes an issue, a default Bug Finder analysis might not detect an **Array access out of bounds**. To check for this issue when it is caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- A default Bug Finder analysis might not flag a **Array access with tainted index** or **Pointer dereference with tainted offset** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Array access out of bounds

#### Issue

**Array access out of bounds** occurs when an array index falls outside the range `[0...array_size-1]` during array access.

#### Risk

Accessing an array outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you accessed an array inside a loop and one of these situations happened:

- The upper bound of the loop is too large.

- You used an array index that is the same as the loop index instead of being one less than the loop index.

To fix the issue, you have to modify the loop bound or the array index.

Another reason why an array index can exceed array bounds is a prior conversion from signed to unsigned integers. The conversion can result in a wrap around of the index value, eventually causing the array index to exceed the array bounds.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

**Example - Array Access Out of Bounds Error**

```
#include <stdio.h>

void fibonacci(void)
{
    int i;
    int fib[10];

    for (i = 0; i < 10; i++)
       {
        if (i < 2)
            fib[i] = 1;
         else
            fib[i] = fib[i-1] + fib[i-2];
       }

    printf("The 10-th Fibonacci number is %i .\n", fib[i]);    //Noncompliant
    /* Defect: Value of i is greater than allowed value of 9 */
}
```

The array `fib` is assigned a size of 10. An array index for `fib` has allowed values of `[0,1,2,...,9]`. The variable `i` has a value 10 when it comes out of the `for`-loop. Therefore, the `printf` statement attempts to access `fib[10]` through `i`.

**Correction — Keep Array Index Within Array Bounds**

One possible correction is to print `fib[i-1]` instead of `fib[i]` after the `for`-loop.

```
#include <stdio.h>

void fibonacci(void)
{
   int i;
   int fib[10];

   for (i = 0; i < 10; i++)
    {
        if (i < 2)
            fib[i] = 1;
        else
            fib[i] = fib[i-1] + fib[i-2];
    }

    /* Fix: Print fib[9] instead of fib[10] */
    printf("The 10-th Fibonacci number is %i .\n", fib[i-1]);
}
```

The `printf` statement accesses `fib[9]` instead of `fib[10]`.

### Array access with tainted index

#### Issue

**Array access with tainted index** detects reading or writing to an array by using a tainted index that has not been validated.

#### Risk

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite — writing to memory before the beginning of the buffer.
- Buffer overflow — writing to memory after the end of a buffer.
- Over-reading a buffer — accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write operation create to problems in your program.

#### Fix

Before using the index to access the array, validate the index value to make sure that it is inside the array range.

#### Example - Use Index to Return Buffer Value

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
  return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    return tab[num];   //Noncompliant
}
```

In this example, the index `num` accesses the array `tab`. The index `num` is obtained from an unsecure source and the function `taintedarrayindex` does not check to see if `num` is inside the range of `tab`.

**Correction — Check Range Before Use**

One possible correction is to check that `num` is in range before using it.

```
#include <stdlib.h>
#include <stdio.h>
#define SIZE100 100
extern int tab[SIZE100];
static int tainted_int_source(void) {
    return strtol(getenv("INDEX"),NULL,10);
}
int taintedarrayindex(void) {
    int num = tainted_int_source();
    if (num >= 0 && num < SIZE100) {
        return tab[num];
    } else {
        return -1;
    }
}
```

### Pointer dereference with tainted offset

**Issue**

**Pointer dereference with tainted offset** detects pointer dereferencing, either reading or writing, using an offset variable from an unknown or unsecure source.

This check focuses on dynamically allocated buffers. For static buffer offsets, see `Array access with tainted index`.

**Risk**

The index might be outside the valid array range. If the tainted index is outside the array range, it can cause:

- Buffer underflow/underwrite, or writing to memory before the beginning of the buffer.
- Buffer overflow, or writing to memory after the end of a buffer.
- Over reading a buffer, or accessing memory after the end of the targeted buffer.
- Under-reading a buffer, or accessing memory before the beginning of the targeted buffer.

An attacker can use an invalid read or write to compromise your program.

**Fix**

Validate the index before you use the variable to access the pointer. Check to make sure that the variable is inside the valid range and does not overflow.

**Example - Dereference Pointer Array**

```
#include <stdio.h>
#include <stdlib.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);
```

```
int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if(pint) {
        /* Filling array */
        read_pint(pint);
        c = pint[offset]; //Noncompliant
        free(pint);
    }
    return c;
}
```

In this example, the function initializes an integer pointer `pint`. The pointer is dereferenced using the input index `offset`. The value of `offset` could be outside the pointer range, causing an out-of-range error.

#### Correction — Check Index Before Dereference

One possible correction is to validate the value of `offset`. Continue with the pointer dereferencing only if `offset` is inside the valid range.

```
#include <stdlib.h>
#include <stdio.h>
enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};
extern void read_pint(int*);

int taintedptroffset(void) {
    int offset;
    scanf("%d",&offset);
    int* pint = (int*)calloc(SIZE10, sizeof(int));
    int c = 0;
    if (pint) {
        /* Filling array */
        read_pint(pint);
        if (offset>0 && offset<SIZE10) {
            c = pint[offset];
        }
        free(pint);
    }
    return c;
}
```

Do not access freed memory

## Description

### Rule Definition

*Do not access freed memory.*

### Polyspace Implementation

This checker checks for:

- **Accessing previously freed pointer**
- **Freeing previously freed pointer**

## Examples

### Accessing previously freed pointer

#### Issue

**Accessing previously freed pointer** occurs when you attempt to access a block of memory after freeing the block by using the `free` function.

#### Risk

When a pointer is allocated dynamic memory by using `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation and the pointer becomes a dangling pointer. Attempting to access this block of memory by dereferencing the dangling pointer can result in unpredictable behavior or a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. Determine if you intended to free the memory later or allocate another memory block to the pointer before access.

As a best practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

#### Example — Accessing Previously Freed Pointer Error

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   { 
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);

    j = *pi + shift; //Noncompliant

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing `pi` after the `free` statement is not valid.

#### Correction — Free Pointer After Last Use

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

### Freeing previously freed pointer

#### Issue

**Freeing previously freed pointer** occurs when you attempt to free the memory allocated to a pointer after already freeing the pointer by using the `free` function.

#### Risk

Attempting to free the memory associated with a previously freed pointer might corrupt the memory management of the program and cause a memory leak. This defect might allow an attacker to access the memory and execute arbitrary code.

#### Fix

To avoid this defect, assign pointers to NULL after freeing them. Check the pointers for NULL value before attempting to access the memory associated with the pointer. In this way, you are protected against accessing a freed block.

#### Example — Freeing Previously Freed Pointer

```
#include <stdlib.h>
#include <stdio.h>
int getStatus();
void double_deallocation(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == 0) return;

    *pi = 2;
    /*...*/
    if(getStatus()==1)
    {
        /*...*/
        free(pi);
    }
    free(pi); //Noncompliant
}
```

The second `free` statement attempts to release the block of memory that `pi` refers to, but the pointer `pi` might already be freed in the `if` block of code. This second `free` statement might cause a memory leak and security vulnerabilities in the code. Polyspace flags the second `free` statement.

**Correction — Check Pointers Before Calling `free`**

One possible correction is to assign freed pointers to NULL and to check pointers for NULL before freeing them.

```
#include <stdlib.h>
#include <stdio.h>
int getStatus();
void double_deallocation(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == 0) return;

    *pi = 2;
    /*...*/
    if(getStatus()==1)
    {
        /*...*/
        if(pi!=NULL)
        {
            free(pi);
            pi= NULL;
        }
    }
    /*...*/
    if(pi!=NULL)
    {
        free(pi);
        pi= NULL;
    } //Compliant
}
```

In this case, the memory allocated to pointer `pi` is freed only if it is not already freed.

Free dynamically allocated memory when no longer needed

## Description

### Rule Definition

*Free dynamically allocated memory when no longer needed.*

### Polyspace Implementation

The rule checker checks for **Memory leak**.

## Examples

### Memory leak

#### Issue

**Memory leak** occurs when you do not free a block of memory allocated through `malloc`, `calloc`, `realloc`, or `new`. If the memory is allocated in a function, the defect does not occur if:

- Within the function, you free the memory using `free` or `delete`.
- The function returns the pointer assigned by `malloc`, `calloc`, `realloc`, or `new`.
- The function stores the pointer in a global variable or in a parameter.

#### Risk

Dynamic memory allocation functions such as `malloc` allocate memory on the heap. If you do not release the memory after use, you reduce the amount of memory available for another allocation. On embedded systems with limited memory, you might end up exhausting available heap memory even during program execution.

#### Fix

Determine the scope where the dynamically allocated memory is accessed. Free the memory block at the end of this scope.

To free a block of memory, use the `free` function on the pointer that was used during memory allocation. For instance:

```
ptr = (int*)malloc(sizeof(int));
...
free(ptr);
```

It is a good practice to allocate and free memory in the same module at the same level of abstraction. For instance, in this example, `func` allocates and frees memory at the same level but `func2` does not.

```
void func() {
  ptr = (int*)malloc(sizeof(int));
  {
    ...
  }
  free(ptr);
}

void func2() {
  {
   ptr = (int*)malloc(sizeof(int));
   ...
  }
  free(ptr);
}
```

See CERT-C Rule MEM00-C.

#### Example - Dynamic Memory Not Released Before End of Function

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }

    *pi = 42;
    /* Defect: pi is not freed */
} //Noncompliant
```

In this example, `pi` is dynamically allocated by `malloc`. The function `assign_memory` does not free the memory, nor does it return `pi`.

#### Correction — Free Memory

One possible correction is to free the memory referenced by `pi` using the `free` function. The `free` function must be called before the function `assign_memory` terminates

```
#include<stdlib.h>
#include<stdio.h>

void assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
         printf("Memory allocation failed");
         return;
        }
    *pi = 42;

    /* Fix: Free the pointer pi*/
    free(pi);
}
```

#### Correction — Return Pointer from Dynamic Allocation

Another possible correction is to return the pointer `pi`. Returning `pi` allows the function calling `assign_memory` to free the memory block using `pi`.

```
#include<stdlib.h>
#include<stdio.h>

int* assign_memory(void)
{
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL)
        {
            printf("Memory allocation failed");
            return(pi);
        }
    *pi = 42;

    /* Fix: Return the pointer pi*/
    return(pi);
}
```

#### Example - Memory Leak with New/Delete

```
#define NULL '\0'

void initialize_arr1(void)
{
    int *p_scalar = new int(5);
} //Noncompliant

void initialize_arr2(void)
{
    int *p_array = new int[5];
} //Noncompliant
```

In this example, the functions create two variables, `p_scalar` and `p_array`, using the `new` keyword. However, the functions end without cleaning up the memory for these pointers. Because the functions used `new` to create these variables, you must clean up their memory by calling `delete` at the end of each function.

#### Correction — Add Delete

To correct this error, add a `delete` statement for every `new` initialization. If you used brackets `[]` to instantiate a variable, you must call delete with brackets as well.

```
#define NULL '\0'

void initialize_arrs(void)
{
    int *p_scalar = new int(5);
    int *p_array = new int[5];

    delete p_scalar;
    p_scalar = NULL;
    delete[] p_array;
    p_scalar = NULL;
}
```

Only free memory allocated dynamically

## Description

### Rule Definition

*Only free memory allocated dynamically.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid free of pointer**
- **Invalid reallocation of pointer**

## Examples

### Invalid free of pointer

#### Issue

**Invalid free of pointer** occurs when a block of memory released using the `free` function was not previously allocated using `malloc`, `calloc`, or `realloc`.

#### Risk

The `free` function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `free` function or a previous `malloc` function on a different pointer.

#### Fix

In most cases, you can fix the issue by removing the `free` statement. If the pointer is not allocated memory from the heap with `malloc` or `calloc`, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of `free` or `malloc` on the wrong pointer, correct the error.

If the issue occurs because you use the `free` function to free memory allocated with the `new` operator, replace the `free` function with the `delete` operator.

#### Example - Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
```

```
     *(p+i)=1;

  free(p);    //Noncompliant
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer `p` is deallocated using the `free` function. However, `p` points to a memory location that was not dynamically allocated.

#### Correction — Remove Pointer Deallocation

If the number of elements of the array `p` is known at compile time, one possible correction is to remove the deallocation of the pointer `p`.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

#### Correction — Introduce Pointer Allocation

If the number of elements of the array `p` is not known at compile time, one possible correction is to dynamically allocate memory to the array `p`.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

### Invalid reallocation of pointer

#### Issue

**Invalid reallocation of pointer** occurs when a block of memory reallocated using the `realloc` function was not previously allocated using `malloc` or `calloc`.

#### Risk

Reallocating a block of memory that was not allocated dynamically allocated can result in undefined behavior.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `realloc` function on a different pointer.

**Fix**

If you want to reallocate a block of memory, make sure that it was dynamically allocated in the first place.

**Example – Reallocation of Memory Allocated Statically**

```
#include <cstdlib>

#define SIZE 256

void reshape(int isSpaceAvailable) {
  char buf[SIZE];
  char *newBuf;
  newBuf = (char *)realloc(buf, 2 * SIZE); //Noncompliant

  if (newBuf == NULL) {
    /* Handle error */
  }
}
```

In this example, the buffer `buf` is not allocated dynamically. Therefore, the reallocation of `buf` results in undefined behavior.

**Example – Reallocation of Memory Allocated Statically**

Make sure that a buffer that you reallocate was previous allocated memory dynamically.

```
#include <cstdlib>

#define SIZE 256

void reshape(void){
  char *buf;
  char *newBuf;
  buf = (char*)malloc(SIZE *sizeof(char));
  newBuf = (char *)realloc(buf, 2 * SIZE);

  if (newBuf == NULL) {
    /* Handle error */
  }
  free(newBuf);
}
```

Allocate sufficient memory for an object

## Description

### Rule Definition

*Allocate sufficient memory for an object.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Pointer access out of bounds**.
- **Memory allocation with tainted size**.
- **Insufficient memory allocation**

### Extend Checker

A default Bug Finder analysis might not flag a **Memory allocation with tainted size** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example — Pointer access out of bounds error

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

#### Correction — Check Pointer Stays Within Bounds

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Memory allocation with tainted size

#### Issue

**Memory allocation with tainted size** checks memory allocation functions, such as `calloc` or `malloc`, for size arguments from unsecured sources.

#### Risk

Uncontrolled memory allocation can cause your program to request too much system memory. This consequence can lead to a crash due to an out-of-memory condition, or assigning too many resources.

#### Fix

Before allocating memory, check the value of your arguments to check that they do not exceed the bounds.

#### Example — Allocate Memory Using Input Argument

```
#include<stdio.h>
#include <stdlib.h>

int* bug_taintedmemoryallocsize(void) {
    size_t size;
    scanf("%zu", &size);
    int* p = (int*)malloc(size); //Noncompliant
    return p;
}
```

In this example, `malloc` allocates `size` amount of memory for the pointer `p`. `size` comes from the user of the program and its value is not checked. If the size is larger than the amount of memory you have available, your program could crash.

#### Correction — Check Size of Memory to be Allocated

One possible correction is to check the size of the memory that you want to allocate before performing the `malloc` operation. This example checks to see if the size is positive and less than the maximum size.

```
#include "stdlib.h"

enum {
    SIZE10  =  10,
    SIZE100 = 100,
    SIZE128 = 128
};

int* corrected_taintedmemoryallocsize(int size) {
    int* p = NULL;
          /* Fix: Check entry range before use */
    if (size>0 && size<SIZE128) {
        p = (int*)malloc((unsigned int)size);
    }
    return p;
}
```

### Insufficient memory allocation

#### Issue

**Insufficient memory allocation** occurs when the allocated memory is not sufficient to hold the target object. Consider this code:

```
#include <stdlib.h>

typedef struct S {
    int a;
    int b;
    int c;
}S;

void foo(){
    S* a;
    a = (S*)malloc(sizeof(S*)*2);//Noncompliant
}
void bar(){
    S* a;
    a = (S*)malloc(sizeof(S*)*3); //Compliant
}
```

Objects of type `S` must accommodate three integers, which typically requires 12 bytes of memory. In `foo()` the allocated memory size for the `S` type object is eight bytes. Because the allocated memory is insufficient to hold the target object, Polyspace reports a violation of this rule. In `bar()`, the allocated memory is 12 bytes, which is sufficient. Polyspace does not report a violation.

#### Risk

Insufficient memory allocation results in buffer overflow and unexpected termination of the program.

#### Fix

When allocating memory blocks, allocate sufficient memory.

#### Example — Allocate Memory for Objects by Calling `malloc()`

In this example, the function `foo()` allocates memory for pointers `a` and `b`:

- When allocating memory for `a`, the argument of `sizeof()` is `S*`, which is a pointer. In a 64 bit system, all pointer types are 8 bytes in size. The `malloc()` statement allocates 24 bytes, which is sufficient to accommodate an object of `S` type. Because the allocated memory can hold the `a` object, Polyspace does not report a violation. This statement causes a `Wrong type used in sizeof` defect.

  From the context of the `malloc()` statement, the object `a` is intended to be a three element array of `S` type objects. Clearly, the `malloc()` statement does not allocate sufficient memory for the entire array. In the `for` loop, when you access the elements of the array, the insufficient memory causes a violation of this rule. This way, the `Wrong type used in sizeof` defect in the `malloc()` statement causes a violation of this rule when you use `a` as an array. If you use `a` as an object instead of an array, this rule is not violated.
- When allocating memory for `b`, the `malloc()` statement allocates enough memory to accommodate two integers. Because objects of type `S` require enough memory to accommodate three integers, the allocated memory is insufficient. Polyspace reports a violation of this rule.

```
#include <stdlib.h>

typedef struct S
{
  int a;
  int b;
  int c;
} S;

void setS (S * a, int x, int y, int z)
{
  a->a = x;            //Noncompliant: pointer access out of bounds
  a->b = y;
  a->c = z;
}

void foo ()
{
  S *a, *b;
  a = (S *) malloc (3 * sizeof (S *));    //Compliant but causes PTR_SIZEOF_MISMATCH defect/
  setS(a,22,32,45); //Compliant
  for (int i = 1; i < 3; ++i)
    {
      setS (a + i, i, i * i, i * i * i);

    }
  b = (S *) malloc (2 * sizeof (int));    //Noncompliant

}
```

**Correction — Allocate Sufficient Memory**

To fix this issue, allocate sufficient memory. The best practice is to use the `sizeof()` function with correct argument type and a correct multiplier to calculate how much memory is required.

```
#include <stdlib.h>

typedef struct S
{
  int a;
  int b;
  int c;
} S;

void setS (S * a, int x, int y, int z)
{
  a->a = x;            //Compliant: pointer access out of bounds
  a->b = y;
  a->c = z;
}

void foo ()
{
  S *a, *b;
  a = (S *) malloc (3 * sizeof (S));    //No violations of PTR_SIZEOF_MISMATCH*/
  setS(a,22,32,45); //Compliant
  for (int i = 1; i < 3; ++i)
    {
      setS (a + i, i, i * i, i * i * i);

    }
  b = (S *) malloc (1 * sizeof (S));    //Compliant
  //...
  free(a);
  free (b);
}
```

Do not modify the alignment of objects by calling realloc()

## Description

### Rule Definition

*Do not modify the alignment of objects by calling realloc().*

### Polyspace Implementation

The rule checker checks for **Alignment changed after memory reallocation**.

## Examples

### Alignment changed after memory reallocation

#### Issue

**Alignment changed after memory reallocation** occurs when you use `realloc()` to modify the size of objects with strict memory alignment requirements.

#### Risk

The pointer returned by `realloc()` can be suitably assigned to objects with less strict alignment requirements. A misaligned memory allocation can lead to buffer underflow or overflow, an illegally dereferenced pointer, or access to arbitrary memory locations. In processors that support misaligned memory, the allocation impacts the performance of the system.

#### Fix

To reallocate memory:

1. Resize the memory block.
   - In Windows, use `_aligned_realloc()` with the alignment argument used in `_aligned_malloc()` to allocate the original memory block.
   - In UNIX/Linux, use the same function with the same alignment argument used to allocate the original memory block.
2. Copy the original content to the new memory block.
3. Free the original memory block.

**Note** This fix has implementation-defined behavior. The implementation might not support the requested memory alignment and can have additional constraints for the size of the new memory.

#### Example - Memory Reallocated Without Preserving the Original Alignment

```
#include <stdio.h>
#include <stdlib.h>
```

```
#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;
    int *ptr1;

    /* Allocate memory with 4096 bytes alignment */

    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
      }

    /*Reallocate memory without using the original alignment.
    ptr1 may not be 4096 bytes aligned. */

    ptr1 = (int *)realloc(ptr, sizeof(int) * resize); //Noncompliant

    if (ptr1 == NULL)
    {
        /* Handle error */
    }

    /* Processing using ptr1 */

    /* Free before exit */
    free(ptr1);
}
```

In this example, the allocated memory is 4096-bytes aligned. `realloc()` then resizes the allocated memory. The new pointer `ptr1` might not be 4096-bytes aligned.

**Correction — Specify the Alignment for the Reallocated Memory**

When you reallocate the memory, use `posix_memalign()` and pass the alignment argument that you used to allocate the original memory.

```
#include <stdio.h>
#include <stdlib.h>

#define SIZE1024 1024

void func(void)
{
    size_t resize = SIZE1024;
    size_t alignment = 1 << 12; /* 4096 bytes alignment */
    int *ptr = NULL;

    /* Allocate memory with 4096 bytes alignment */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int)) != 0)
    {
        /* Handle error */
    }

    /* Reallocate memory using the original alignment. */
    if (posix_memalign((void **)&ptr, alignment, sizeof(int) * resize) != 0)
    {
        /* Handle error */
        free(ptr);
        ptr = NULL;
    }

    /* Processing using ptr */

    /* Free before exit */
    free(ptr);
}
```

Do not access freed memory

## Description

### Rule Definition

*Do not access freed memory.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Pointer access out of bounds**.
- **Deallocation of previously deallocated pointer**.
- **Use of previously freed pointer**.

## Examples

### Pointer access out of bounds

#### Issue

**Pointer access out of bounds** occurs when a pointer is dereferenced outside its bounds.

When a pointer is assigned an address, a block of memory is associated with the pointer. You cannot access memory beyond that block using the pointer.

#### Risk

Dereferencing a pointer outside its bounds is undefined behavior. You can read an unpredictable value or try to access a location that is not allowed and encounter a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. For instance, you dereferenced a pointer inside a loop and one of these situations happened:

- The upper bound of the loop is too large.
- You used pointer arithmetic to advance the pointer with an incorrect value for the pointer increment.

To fix the issue, you have to modify the loop bound or the pointer increment value.

Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Pointer access out of bounds error**

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
   {
    ptr++;
    *ptr=i; //Noncompliant
    /* Defect: ptr out of bounds for i=9 */
   }

 return(arr);
}
```

`ptr` is assigned the address `arr` that points to a memory block of size `10*sizeof(int)`. In the `for`-loop, `ptr` is incremented 10 times. In the last iteration of the loop, `ptr` points outside the memory block assigned to it. Therefore, it cannot be dereferenced.

**Correction — Check Pointer Stays Within Bounds**

One possible correction is to reverse the order of increment and dereference of `ptr`.

```
int* Initialize(void)
{
 int arr[10];
 int *ptr=arr;

 for (int i=0; i<=9;i++)
     {
      /* Fix: Dereference pointer before increment */
      *ptr=i;
      ptr++;
     }

 return(arr);
}
```

After the last increment, even though `ptr` points outside the memory block assigned to it, it is not dereferenced more.

### Deallocation of previously deallocated pointer

**Issue**

**Deallocation of previously deallocated pointer** occurs when a block of memory is freed more than once using the `free` function without an intermediate allocation.

#### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to free this block of memory can result in a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to allocate a memory block to the pointer between the first deallocation and the second. Otherwise, remove the second `free` statement.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before freeing pointers, check them for NULL values and handle the error. In this way, you are protected against freeing an already freed block.

#### Example - Deallocation of Previously Deallocated Pointer Error

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    free (pi);        //Noncompliant
    /* Defect: pi has already been freed */
}
```

The first `free` statement releases the block of memory that `pi` refers to. The second `free` statement on `pi` releases a block of memory that has been freed already.

#### Correction — Remove Duplicate Deallocation

One possible correction is to remove the second `free` statement.

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    /* Fix: remove second deallocation */
 }
```

### Use of previously freed pointer

#### Issue

**Use of previously freed pointer** occurs when you access a block of memory after freeing the block using the `free` function.

**Risk**

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to access this block of memory can result in unpredictable behavior or even a segmentation fault.

**Fix**

The fix depends on the root cause of the defect. See if you intended to free the memory later or allocate another memory block to the pointer before access.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before dereferencing pointers, check them for NULL values and handle the error. In this way, you are protected against accessing a freed block.

**Example - Use of Previously Freed Pointer Error**

```
#include <stdlib.h>
#include <stdio.h>
 int increment_content_of_address(int base_val, int shift)
   {
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;
    free(pi);

    j = *pi + shift; //Noncompliant
    /* Defect: Reading a freed pointer */

    return j;
   }
```

The `free` statement releases the block of memory that `pi` refers to. Therefore, dereferencing`pi` after the `free` statement is not valid.

**Correction — Free Pointer After Use**

One possible correction is to free the pointer `pi` only after the last instance where it is accessed.

```
#include <stdlib.h>

int increment_content_of_address(int base_val, int shift)
{
    int j;
    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return 0;

    *pi = base_val;

    j = *pi + shift;
    *pi = 0;

    /* Fix: The pointer is freed after its last use */
    free(pi);
    return j;
}
```

Properly deallocate dynamically allocated resources

## Description

### Rule Definition

*Properly deallocate dynamically allocated resources.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Invalid deletion of pointer**.
- **Invalid free of pointer**.
- **Deallocation of previously deallocated pointer**.

## Examples

### Invalid deletion of pointer

#### Issue

**Invalid deletion of pointer** occurs when:

- You release a block of memory with the `delete` operator but the memory was previously not allocated with the `new` operator.
- You release a block of memory with the `delete` operator using the single-object notation but the memory was previously allocated as an array with the `new` operator.

This defect applies only to C++ source files.

#### Risk

The risk depends on the cause of the issue:

- The `delete` operator releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.
- If you use the single-object notation for `delete` on a pointer that is previously allocated with the array notation for `new`, the behavior is undefined.

The issue can also highlight other coding errors. For instance, you perhaps wanted to use the `delete` operator or a previous `new` operator on a different pointer.

#### Fix

The fix depends on the cause of the issue:

- In most cases, you can fix the issue by removing the `delete` statement. If the pointer is not allocated memory from the heap with the `new` operator, you do not need to release the pointer with `delete`. You can simply reuse the pointer as required or let the object be destroyed at the end of its scope.

- In case of mismatched notation for `new` and `delete`, correct the mismatch. For instance, to allocate and deallocate a single object, use this notation:

  ```
  classType* ptr = new classType;
  delete ptr;
  ```

  To allocate and deallocate an array objects, use this notation:

  ```
  classType* p2 = new classType[10];
  delete[] p2;
  ```

If the issue highlights a coding error such as use of `delete` or `new` on the wrong pointer, correct the error.

**Example - Deleting Static Memory**

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;

    delete[] ptr;    //Noncompliant
}
```

The pointer `ptr` is released using the `delete` operator. However, `ptr` points to a memory location that was not dynamically allocated.

**Correction: Remove Pointer Deallocation**

If the number of elements of the array `ptr` is known at compile time, one possible correction is to remove the deallocation of the pointer `ptr`.

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;
}
```

**Correction — Add Pointer Allocation**

If the number of array elements is not known at compile time, one possible correction is to dynamically allocate memory to the array `ptr` using the `new` operator.

```
void assign_ones(int num)
{
    int *ptr = new int[num];

    for(int i=0; i < num; i++)
        *(ptr+i) = 1;

    delete[] ptr;
   }
```

**Example - Mismatched `new` and `delete`**

```
int main (void)
{
```

```
    int *p_scale = new int[5];

    //more code using scal

    delete p_scale; //Noncompliant
}
```

In this example, `p_scale` is initialized to an array of size 5 using `new int[5]`. However, `p_scale` is deleted with `delete` instead of `delete[]`. The `new`-`delete` pair does not match. Do not use `delete` without the brackets when deleting arrays.

#### Correction — Match delete to new

One possible correction is to add brackets so the `delete` matches the `new []` declaration.

```
int main (void)
{
    int *p_scale = new int[5];

    //more code using p_scale

    delete[] p_scale;
}
```

#### Correction — Match new to delete

Another possible correction is to change the declaration of `p_scale`. If you meant to initialize `p_scale` as 5 itself instead of an array of size 5, you must use different syntax. For this correction, change the square brackets in the initialization to parentheses. Leave the `delete` statement as it is.

```
int main (void)
{
    int *p_scale = new int(5);

    //more code using p_scale

    delete p_scale;
}
```

### Invalid free of pointer

#### Issue

**Invalid free of pointer** occurs when a block of memory released using the `free` function was not previously allocated using `malloc`, `calloc`, or `realloc`.

#### Risk

The `free` function releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.

The issue can highlight coding errors. For instance, you perhaps wanted to use the `free` function or a previous `malloc` function on a different pointer.

#### Fix

In most cases, you can fix the issue by removing the `free` statement. If the pointer is not allocated memory from the heap with `malloc` or `calloc`, you do not need to free the pointer. You can simply reuse the pointer as required.

If the issue highlights a coding error such as use of `free` or `malloc` on the wrong pointer, correct the error.

If the issue occurs because you use the `free` function to free memory allocated with the `new` operator, replace the `free` function with the `delete` operator.

### Example - Invalid Free of Pointer Error

```
#include <stdlib.h>

void Assign_Ones(void)
{
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;

  free(p);    //Noncompliant
  /* Defect: p does not point to dynamically allocated memory */
}
```

The pointer `p` is deallocated using the `free` function. However, `p` points to a memory location that was not dynamically allocated.

### Correction — Remove Pointer Deallocation

If the number of elements of the array `p` is known at compile time, one possible correction is to remove the deallocation of the pointer `p`.

```
#include <stdlib.h>

void Assign_Ones(void)
 {
  int p[10];
  for(int i=0;i<10;i++)
     *(p+i)=1;
  /* Fix: Remove deallocation of p */
 }
```

### Correction — Introduce Pointer Allocation

If the number of elements of the array `p` is not known at compile time, one possible correction is to dynamically allocate memory to the array `p`.

```
#include <stdlib.h>

void Assign_Ones(int num)
{
  int *p;
  /* Fix: Allocate memory dynamically to p */
  p=(int*) calloc(10,sizeof(int));
  for(int i=0;i<10;i++)
     *(p+i)=1;
  free(p);
}
```

### Deallocation of previously deallocated pointer

#### Issue

**Deallocation of previously deallocated pointer** occurs when a block of memory is freed more than once using the `free` function without an intermediate allocation.

#### Risk

When a pointer is allocated dynamic memory with `malloc`, `calloc` or `realloc`, it points to a memory location on the heap. When you use the `free` function on this pointer, the associated block of memory is freed for reallocation. Trying to free this block of memory can result in a segmentation fault.

#### Fix

The fix depends on the root cause of the defect. See if you intended to allocate a memory block to the pointer between the first deallocation and the second. Otherwise, remove the second `free` statement.

As a good practice, after you free a memory block, assign the corresponding pointer to NULL. Before freeing pointers, check them for NULL values and handle the error. In this way, you are protected against freeing an already freed block.

#### Example - Deallocation of Previously Deallocated Pointer Error

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    free (pi);        //Noncompliant
    /* Defect: pi has already been freed */
}
```

The first `free` statement releases the block of memory that `pi` refers to. The second `free` statement on `pi` releases a block of memory that has been freed already.

#### Correction — Remove Duplicate Deallocation

One possible correction is to remove the second `free` statement.

```
#include <stdlib.h>

void allocate_and_free(void)
{

    int* pi = (int*)malloc(sizeof(int));
    if (pi == NULL) return;

    *pi = 2;
    free(pi);
    /* Fix: remove second deallocation */
 }
```

Detect and handle memory allocation errors

## Description

### Rule Definition

*Detect and handle memory allocation errors.*

### Polyspace Implementation

The rule checker checks for **Unprotected dynamic memory allocation**.

## Examples

### Unprotected dynamic memory allocation

#### Issue

**Unprotected dynamic memory allocation** occurs when you do not check after dynamic memory allocation whether the memory allocation succeeded.

#### Risk

When memory is dynamically allocated using `malloc`, `calloc`, or `realloc`, it returns a value `NULL` if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this `NULL` value, this access is not protected from failures.

#### Fix

Check the return value of `malloc`, `calloc`, or `realloc` for NULL before accessing the allocated memory location.

```
int *ptr = malloc(size * sizeof(int));

if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

#### Example - Unprotected dynamic memory allocation error

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));

  *p = 2;   //Noncompliant
  /* Defect: p is not checked for NULL value */

  free(p);
}
```

If the memory allocation fails, the function `calloc` returns `NULL` to `p`. Before accessing the memory through `p`, the code does not check whether `p` is `NULL`

#### Correction — Check for NULL Value

One possible correction is to check whether `p` has value `NULL` before dereference.

```
#include <stdlib.h>

void Assign_Value(void)
 {
   int* p = (int*)calloc(5, sizeof(int));

   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;

   free(p);
 }
```

Explicitly construct and destruct objects when manually managing object lifetime

## Description

### Rule Definition

*Explicitly construct and destruct objects when manually managing object lifetime.*

### Polyspace Implementation

The rule checker checks for **Object allocated but not initialized**. Polyspace does not look for explicit destruction of manually managed objects.

## Examples

### Object Allocated But Not Initialized

#### Issue

This issue occurs when a nontrivially constructible object is created by calling functions such as `std::malloc()` or `std::allocator<T>::allocate()`. These functions allocate memory for objects but do not initialize them. To check if a class is trivially constructible, use the function `std::is_trivially_constructible`. See https://en.cppreference.com/w/cpp/types/is_constructible.

Polyspace checks for this issue in classes that has a defined constructor. If a class lacks a defined constructor, Polyspace does not report violations of this rule.

#### Risk

Calling the function `malloc()` or `std::allocator<T>::allocate()` allocates the memory necessary for an object, but does not start the lifetime of the allocated object. Using these functions to construct an object might cause you to access class members before their lifetime starts. Accessing objects before their lifetime is an undefined behavior. For instance:

```
class myObj {
    myObj();

    void myFunc();
};

void foo() {
    //Allocating sufficient memory
    myObj* obj = static_cast<myObj*>(std::malloc(sizeof(myObj)));
    // Accessing myObj::myFunc
    obj->myFunc();

}
```

The code allocates sufficient memory for the object `obj` by calling the function `std::malloc()`. The function `malloc()` does not initiate the lifetime of `obj` and its members. In `obj->myFunc`, you access `muFunc()` before its lifetime, which is an undefined behavior.

**Fix**

When using the function `std::malloc()` or `std::allocator<T>::allocate()` to construct an object, explicitly complete the construction by using the placement-`new` operator. This step starts the lifetime of the object and prevent the undefined behavior resulting from accessing objects before their lifetime.

**Example — Accessing Objects Before Lifetime**

```
#include <memory>
template <typename T, typename Allocator = std::allocator<T>>
class customManager{
    T* memChunk;
public:
    void Allocate(){
        Allocator alloc;
        T* p = alloc.allocate(1);
        memChunk = p;
    }

    void Deallocate(){
        //...
    }
    T* access(){
        //..
        return memChunk;
    }
};

class myClass{
public:
    myClass(){}
    int num;
    void getNum(){};//Noncompliant

};
void foo(){
    customManager<myClass> managedObj;
    managedObj.Allocate();
    (managedObj.access())->getNum();}
```

In this example, the template `customManager` manages memory for a class. In the function `foo`, this template is used to manage a `myClass` object. The function `CustomManager::Allocate` allocates memory but does not initiate the lifetime of its client objects. Accessing `myClass::getnum()` after allocating `managedObj` results in accessing an object before its lifetime, which is undefined behavior. Polyspace reports a violation of this rule.

**Correction — Explicitly Initiate Object Lifetime**

Explicitly start the lifetime of the objects after allocating memory for them. For instance, after calling `alloc.allocate()`, initiate the lifetime of the client objects by calling the placement `new` operator.

```
#include <memory>
template <typename T, typename Allocator = std::allocator<T>>
```

```
class customManager{
    T* memChunk;
public:
    void Allocate(){
        Allocator alloc;
        T* p = alloc.allocate(1);
        memChunk = new (p) T;//Lifetime of the object starts
    }

    void Deallocate(){
        //...
    }
    T* access(){
        //..
        return memChunk;
    }
};

class myClass{
public:
    myClass(){}
    int num;
    void getNum(){};
};
void foo(){
    customManager<myClass> managedObj;
    managedObj.Allocate();
    (managedObj.access())->getNum();
}
```

Provide placement new with properly aligned pointers to sufficient storage capacity

## Description

### Rule Definition

*Provide placement new with properly aligned pointers to sufficient storage capacity*

### Polyspace Implementation

The rule checker checks for **Placement new used with insufficient storage or misaligned pointers**.

## Examples

### Placement new used with insufficient storage or misaligned pointers

#### Issue

**Placement new used with insufficient storage or misaligned pointers** occurs when the pointer passed to a placement `new` operator does not have sufficient storage for the memory allocation or is not properly aligned.

Suppose that a pointer `ptr` is preallocated `m` bytes of memory on the stack and has alignment `n`. For instance, if `ptr` is an array:

```
uint8_t ptr[5];
```

the allocated storage is `sizeof(uint8_t) * 5` and the alignment is `alignof(uint8_t)`. If you allocate more than `m` bytes to this pointer in a placement `new` expression or if the alignment required for the allocation is greater than `n`, the checker raises a violation. When determining the pointer alignment, the checker takes into account explicit alignments such as with `std::align`.

The checker does not consider pointers that are preallocated memory on the heap since the available storage depends on the memory availability, which is known only at run time.

#### Risk

The `new` operator allocates the required amount of memory for storing an object on the heap and constructs a new object in the allocated memory in a single operation. If you want to separate the allocation and the construction and place an object in preallocated memory on either the stack or the heap, you use placement `new`. Placement `new` has advantages over `new` in certain situations, for example, when you need to place the object at a known memory location.

The `new` operator automatically allocates the correct amount of aligned memory that the object requires. But when using placement `new`, you must manually make sure that the pointer you pass has sufficient allocated storage capacity and is properly aligned. Violating these constraints results in the construction of an object at a misaligned location or memory initialization outside of allocated bounds, which might lead to unexpected or implementation-dependent behavior.

#### Fix

Make sure that the pointer used in the placement new operation has sufficient memory for the allocation and the alignments match.

**Example — Placement new Used with Insufficient Storage Capacity and Misaligned Pointers**

```
#include <new>
#include<memory>
#include <cstdint>

void Foo()
{
  uint8_t c;
  uint64_t* ptr =
      new    // Non-compliant (insufficient storage, misaligned)
      (&c) uint64_t;
}

void Bar()
{
  uint8_t buf[sizeof(uint64_t)];
  uint64_t* ptr =
      new            // Non-compliant (sufficient storage, misaligned)
      (buf) uint64_t;
}

void Baz()
{
  void* buf;
  std::size_t sp = 64;
  std::align(alignof(uint64_t), sizeof(uint64_t), buf, sp);
  uint64_t* ptr =
      new            // Compliant (sufficient storage, aligned)
      (buf) uint64_t;
}
```

In the function Foo, the &c points to an uint8_t value and has one byte memory in stack with one-byte alignment. The pointer is passed to placement new, which constructs an instance of uint64_t that requires 8 bytes of memory and a 4-byte alignment. This usage violates the rule.

In the function Bar, the pointer buf is properly allocated and has sufficient storage capacity. But, because it points to the uint8_t data type, it has one-byte alignment. This usage still violates the rule.

The function Baz calls the std::align function to create a pointer with correct storage capacity (8 byte) and alignment (4-byte) for uint64_t. This usage complies with the rule.

Honor replacement dynamic storage management requirements

## Description

### Rule Definition

*Honor replacement dynamic storage management requirements.*

### Polyspace Implementation

The rule checker checks for **Replacement allocation/deallocation functions that do not meet requirements of the Standard**.

## Examples

### Replacement allocation/deallocation functions that do not meet requirements of the Standard

#### Issue

The issue occurs when you provide these replacement implementations of dynamic allocation and deallocation functions in the global namespace:

- Replacement `operator new` that returns `nullptr`.

  The expected behavior is to throw a `bad_alloc` exception on failure.
- Replacement `operator new` or `operator delete` that throws directly or indirectly on failure.

  The expected behavior is that dynamic allocation or deallocation functions must not throw. Polyspace also highlights the location of the throw in your code.

#### Risk

The C++ Standard (*[new.delete]*) specifies certain required behaviors for the dynamic allocation and deallocation functions. If you implement a global replacement allocation or deallocation function that does not meet these semantic requirements, other functions that rely on the required behaviors might behave in an undefined manner.

For instance, `void* operator new ( std::size_t count )` is expected to throw a `bad_alloc` exception if it fails to allocate the requested amount of memory. If you implement a replacement allocation function that returns `nullptr` instead of throwing, a function that expect the memory allocation to throw on failure might try to dereference a null pointer instead.

#### Fix

If you provide global replacements for dynamic allocation/deallocation functions, implement the semantic requirements specified by the standard in the corresponding required behavior paragraphs.

#### Non-Throwing `operator new` That Throws

```
#include<cstdlib>
#include<new>
```

```
extern void* custom_alloc(std::size_t);

void* operator new (std::size_t count, const std::nothrow_t& tag) //Non-compliant
{
    if (void* ret = custom_alloc(count)) {
        return ret;
    }
    throw std::bad_alloc();
}

void func()
{
    int* ptr1 = new int;
    if (ptr1) {
        //Use ptr1
    }

}
```

In this example, the replacement dynamic allocation function is specified as non-throwing (`std::nothrow_t`) but throws a `bad_alloc` exception on failure. Function `func`, which expects `operator new` to return a null pointer on failure, does not handle the exception and this might result in an abrupt program termination.

#### Correction

One possible correction is to provide a replacement `operator new` function that does not throw.

```
#include<cstdlib>
#include<new>

extern void* custom_alloc(std::size_t);

void* operator new (std::size_t count, const std::nothrow_t& tag)
{
    return custom_alloc(count);
}

void func()
{
    int* ptr1 = new int;
    if (ptr1) {
        //Use ptr1
    }

}
```

Do not store an already-owned pointer value in an unrelated smart pointer

## Description

### Rule Definition

*Do not store an already-owned pointer value in an unrelated smart pointer.*[18]

### Polyspace Implementation

The rule checker checks for **Use of already-owned pointers**

## Examples

### Use of already-owned pointers

#### Issue

This issue occurs when you use an already-owned pointer as the argument of:

- A smart pointer constructor. For instance, in this code snippet, `raw_ptr` is already owned by `s_ptr1` and is used to initialize `s_ptr2`:

```
char *raw_ptr = new char;
std::shared_ptr<char> s_ptr1(raw_ptr);
std::shared_ptr<char> s_ptr2(raw_ptr); //raw_ptr is already owned by s_ptr1
```

- A smart pointer reset operation. For instance, in this code snippet, the reset of `s_ptr2` replaces `raw_ptr2` with already-owned `raw_ptr1`:

```
char *raw_ptr1 = new char;
char *raw_ptr2 = new char;

std::shared_ptr<char> s_ptr1(raw_ptr1);
std::shared_ptr<char> s_ptr2(raw_ptr2);

s_ptr2.reset(raw_ptr1); // s_ptr2 releases raw_ptr2 and owns already owned raw_ptr1
```

Polyspace checks only smart pointer types `std::shared_ptr` and `std::unique_ptr` and considers that user-defined allocators and deleters have standard allocation and deallocation behavior.

A pointer is already owned by a smart pointer if the pointer type is not `std::nullptr_t` and either:

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

- The pointer was used to initialize the smart pointer.
- The pointer was used as an argument to the smart pointer `reset()` member function.
- The pointer is the return value of the smart pointer `get()` member function.
- The pointer is the return value of the smart pointer `operator->` member function.

**Risk**

You use smart pointers to ensure that the memory a pointer points to is automatically deallocated when the pointer is destroyed, for example if the pointer goes out of scope. When unrelated smart pointers manage the same pointer value, one of the smart pointers might attempt to deallocate memory that was already deallocated by the other smart pointer. This results in a double free vulnerability, which corrupts your program's memory management data structure.

**Fix**

Use `std::make_shared` to create a smart pointer and then use copy construction to create a related smart pointer. The underlying pointer value is managed by both smart pointers and the memory pointed to is not deallocated until all the smart pointers are destroyed.

If you do not intend to allow multiple smart pointers to manage the same pointer value, use `std::make_unique` to construct a `std::unique_ptr` smart pointer. A `std::unique_ptr` can only be moved, which relinquishes ownership of the underlying managed pointer value.

**Example — Use of an Already-Owned Pointer**

```
#include <memory>
#include <string>

struct Profile
{
    virtual ~Profile()=default;
};

struct Player : public Profile
{
    std::string name;
    std::int8_t rank;

    Player();
    Player(const std::string& name_, const std::int8_t& rank_) :
        name{ name_ }, rank{ rank_ } {}
};

void func(){

    Player * player = new Player("Richard Roll",1);
    std::shared_ptr<Player> player1(player);
    std::shared_ptr<Player> top_rank(player); //Non-compliant

}
```

In this example, the use of pointer value `player` to construct smart pointer `top_rank` in function `func` is non-compliant. `player` is already owned by smart pointer `player1`. When `player1` is destroyed, it might attempt to delete pointer value `player` which was already deleted by `top_rank`.

#### Correction — Use `std::make_shared` and Copy Construction to Create Related Smart Pointers

```
#include <memory>
#include <string>

struct Profile
{
    virtual ~Profile()=default;
};

struct Player : public Profile
{
    std::string name;
    std::int8_t rank;

    Player();
    Player(const std::string& name_, const std::int8_t& rank_) :
        name{ name_ }, rank{ rank_ } {}
};

void func2(){

    std::shared_ptr<Player> player1_shared =
        std::make_shared<Player>("Richard Roll",1);
    std::shared_ptr<Player> top_rank_shared(player1_shared); //Compliant

}
```

One possible correction is to use `std::make_shared` to declare `player1_shared`, and then use copy construction to create related smart pointer `top_rank_shared`. The underlying pointer value is not deleted until all smart pointers are destroyed.

Avoid using default operator new for over-aligned types

## Description

### Rule Definition

*Avoid using default operator new for over-aligned types.*

### Polyspace Implementation

The rule checker checks for **Operator new not overloaded for possibly overaligned class**.

## Examples

### Operator new not overloaded for possibly overaligned class

#### Issue

**Operator new not overloaded for possibly overaligned class** occurs when you do not adequately overload operator `new/new[]` and you use this operator to create an object with an alignment requirement specified with `alignas`. The checker raises a defect for these versions of throwing and non-throwing operator `new/new[]`.

- `void* operator new(std::size_t size)`
- `void* operator new(std::size_t size, const std::nothrow_t&)`
- `void* operator new[](std::size_t size)`
- `void* operator new[](std::size_t size, const std::nothrow_t&)`

The use of `alignas` indicates that you do not expect the default operator `new/new[]` to satisfy the alignment requirement or the object, and that the object is possibly over aligned. A type is over aligned if you use `alignas` to make the alignment requirement of the type larger than `std::max_align_t`. For instance, `foo` is over aligned in this code snippet because its alignment requirement is 32 bytes, but `std::max_align_t` has an alignment of 16 bytes in most implementations.

```
struct alignas(32) foo {
  char elems[32];
};
```

**Operator new not overloaded for possibly overaligned class** raises no defect if you do not overload the operator `new/new[]` and you use version C++17 or later of the Standard. The default operator `new/new[]` in C++17 or later supports over alignment by passing the alignment requirement as an argument of type `std::align_val_t`, for instance `void* operator new(std::size_t size, std::align_val_t alignment)`.

#### Risk

The default operator `new/new[]` allocates storage with the alignment requirement of `std::align_val_t` at most. If you do not overload the operator when you create an object with over aligned type, the resulting object may be misaligned. Accessing this object might cause illegal access errors or abnormal program terminations.

#### Fix

If you use version C++14 or earlier of the Standard, pass the alignment requirement of over aligned types to the operator `new/new[]` by overloading the operator.

#### Example - Allocated Memory Is Smaller Than Alignment Requirement of Type `foo`

```
#include <new>
#include <cstdlib>
#include <iostream>

struct alignas(64) foo {
    char elems[32];
};

foo*  func()
{
    foo*  bar = 0x0;
    try {
        bar =  new  foo ; //Noncompliant
    } catch (...) { return nullptr; }
    delete bar;
}
```

In this example, structure `foo` is declared with an alignment requirement of 32 bytes. When you use the default operator `new` to create object `bar`, the allocated memory for `bar` is smaller than the alignment requirement of type `foo` and `bar` might be misaligned.

#### Correction — Define Overloaded Operator `new` to Handle Alignment Requirement of Type `foo`

One possible correction, if you use C11 `stdlib.h` or POSIX-C `malloc.h`, is to define an overloaded operator `new` that uses `aligned_alloc()` or `posix_memalign()` or to obtain storage with the correct alignment.

```
#include <new>
#include <cstdlib>
#include <iostream>

struct alignas(64) foo {
    char elems[32];
    static void* operator new (size_t nbytes)
    {
        if (void* p =
                ::aligned_alloc(alignof(foo), nbytes)) {
            return p;
        }
        throw std::bad_alloc();
    }
    static void operator delete(void *p) {
        free(p);
    }
};

foo*  func()
{
    foo*  bar = 0x0;
    try {
        bar =  new  foo ;
    } catch (...) { return nullptr; }
    delete bar;
}
```

Exclude user input from format strings

## Description

### Rule Definition

*Exclude user input from format strings.*

### Polyspace Implementation

The rule checker checks for **Tainted string format**.

### Extend Checker

A default Bug Finder analysis might not flag a **Tainted string format** issue for certain inputs that originate outside of the current analysis boundary. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

## Examples

### Tainted string format

#### Issue

**Tainted string format** detects string formatting with `printf`-style functions that contain elements from unsecure sources.

#### Risk

If you use externally controlled elements to format a string, you can cause buffer overflow or data-representation problems. An attacker can use these string formatting elements to view the contents of a stack using `%x` or write to a stack using `%n`.

#### Fix

Pass a static string to format string functions. This fix ensures that an external actor cannot control the string.

Another possible fix is to allow only the expected number of arguments. If possible, use functions that do not support the vulnerable `%n` operator in format strings.

#### Example - Get Elements from User Input

```
#include <stdio.h>
#include <unistd.h>
#define MAX 40
void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf(userstr); //Noncompliant
}
```

This example prints the input argument `userstr`. The string is unknown. If it contains elements such as `%`, `printf` can interpret `userstr` as a string format instead of a string, causing your program to crash.

#### Correction — Print as String

One possible correction is to print `userstr` explicitly as a string so that there is no ambiguity.

```
#include "stdio.h"
#include <unistd.h>
#define MAX 40

void taintedstringformat(void) {
    char userstr[MAX];
    read(0,userstr,MAX);
    printf("%.20s", userstr);
}
```

Do not perform operations on devices that are only appropriate for files

## Description

### Rule Definition

*Do not perform operations on devices that are only appropriate for files.*

### Polyspace Implementation

The rule checker checks for **Inappropriate I/O operation on device files**.

## Examples

### Inappropriate I/O operation on device files

#### Issue

**Inappropriate I/O operation on device files** occurs when you do not check whether a file name parameter refers to a device file before you pass it to these functions:

- `fopen()`
- `fopen_s()`
- `freopen()`
- `remove()`
- `rename()`
- `CreateFile()`
- `CreateFileA()`
- `CreateFileW()`
- `_wfopen()`
- `_wfopen_s()`

Device files are files in a file system that provide an interface to device drivers. You can use these files to interact with devices.

**Inappropriate I/O operation on device files** does not raise a defect when:

- You use `stat` or `lstat`-family functions to check the file name parameter before calling the previously listed functions.
- You use a string comparison function to compare the file name against a list of device file names.

#### Risk

Operations appropriate only for regular files but performed on device files can result in denial-of-service attacks, other security vulnerabilities, or system failures.

### Fix

Before you perform an I/O operation on a file:

- Use `stat()`, `lstat()`, or an equivalent function to check whether the file name parameter refers to a regular file.
- Use a string comparison function to compare the file name against a list of device file names.

### Example - Using `fopen()` Without Checking `file_name`

```
#include <stdio.h>
#include <string.h>

#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";

    if ((f = fopen(file_name, "w")) == NULL) { //Noncompliant
        /*handle error */
    };
    /*operate on file */
}
```

In this example, `func()` operates on the file `file_name` without checking whether it is a regular file. If `file_name` is a device file, attempts to access it can result in a system failure.

### Correction — Check File with `lstat()` Before Calling `fopen()`

One possible correction is to use `lstat()` and the `S_ISREG` macro to check whether the file is a regular file. This solution contains a `TOCTOU` race condition that can allow an attacker to modify the file after you check it but before the call to fopen(). To prevent this vulnerability, ensure that `file_name` refers to a file in a secure folder.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include <sys/stat.h>

#define SIZE1024 1024

FILE* func()
{

    FILE* f;
    const char file_name[SIZE1024] = "./tmp/file";
    struct stat orig_st;
    if ((lstat(file_name, &orig_st) != 0) ||
        (!S_ISREG(orig_st.st_mode))) {
        exit(0);
    }
    if ((f = fopen(file_name, "w")) == NULL) {
        /*handle error */
    };
    /*operate on file */
}
```

Distinguish between characters read from a file and EOF or WEOF

## Description

### Rule Definition

*Distinguish between characters read from a file and EOF or WEOF.*

### Polyspace Implementation

The rule checker checks for **Character value absorbed into EOF**.

## Examples

### Character value absorbed into EOF

#### Issue

**Character value absorbed into EOF** occurs when you perform a data type conversion that makes a valid character value indistinguishable from `EOF` (End-of-File). Bug Finder flags the defect in one of the following situations:

- *End-of-File*: You perform a data type conversion such as from `int` to `char` that converts a non-EOF character value into `EOF`.

  ```
  char ch = (char)getchar()
  ```

  You then compare the result with EOF.

  ```
  if((int)ch == EOF)
  ```

  The conversion can be explicit or implicit.
- *Wide End-of-File*: You perform a data type conversion that can convert a non-WEOF wide character value into WEOF, and then compare the result with WEOF.

#### Risk

The data type `char` cannot hold the value `EOF` that indicates the end of a file. Functions such as `getchar` have return type `int` to accommodate `EOF`. If you convert from `int` to `char`, the values `UCHAR_MAX` (a valid character value) and `EOF` get converted to the same value -1 and become indistinguishable from each other. When you compare the result of this conversion with `EOF`, the comparison can lead to false detection of `EOF`. This rationale also applies to wide character values and `WEOF`.

#### Fix

Perform the comparison with `EOF` or `WEOF` before conversion.

#### Example - Return Value of `getchar` Converted to `char`

```
#include <stdio.h>
#include <stdlib.h>
```

```
#define fatal_error() abort()

char func(void)
{
    char ch;
    ch = getchar();
    if (EOF == (int)ch) { //Noncompliant
        fatal_error();
    }
    return ch;
}
```

In this example, the return value of `getchar` is implicitly converted to `char`. If `getchar` returns `UCHAR_MAX`, it is converted to -1, which is indistinguishable from EOF. When you compare with EOF later, it can lead to a false positive.

#### Correction — Perform Comparison with EOF Before Conversion

One possible correction is to first perform the comparison with EOF, and then convert from `int` to `char`.

```
#include <stdio.h>
#include <stdlib.h>
#define fatal_error() abort()

char func(void)
{
    int i;
    i = getchar();
    if (EOF == i) {
        fatal_error();
    }
    else {
        return (char)i;
    }
}
```

Do not assume that fgets() or fgetws() returns a nonempty string when successful

## Description

### Rule Definition

*Do not assume that fgets() or fgetws() returns a nonempty string when successful.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate string**.

## Examples

### Use of indeterminate string

#### Issue

**Use of indeterminate string** occurs when you do not check the validity of the buffer returned from `fgets`-family functions. The checker raises a defect when such a buffer is used as:

- An argument in standard functions that print or manipulate strings or wide strings.
- A return value.
- An argument in external functions with parameter type `const char *` or `const wchar_t *`.

#### Risk

If an `fgets`-family function fails, the content of its output buffer is indeterminate. Use of such a buffer has undefined behavior and can result in a program that stops working or other security vulnerabilities.

#### Fix

Reset the output buffer of an `fgets`-family function to a known string value when the function fails.

#### Example - Output of `fgets()` Passed to External Function

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func(void) {
    char buf[SIZE20];

    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* 'buf' may contain an indeterminate string.  */
        ;
    }
    /* 'buf passed to external function */
    display_text(buf); //Noncompliant
}
```

In this example, the output `buf` is passed to the external function `display_text()`, but its value is not reset if `fgets()` fails.

#### Correction — Reset `fgets()` Output on Failure

If `fgets()` fails, reset `buf` to a known value before you pass it to an external function.

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func1(void) {
    char buf[SIZE20];
    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* value of 'buf' reset after fgets() failure. */
        buf[0] = '\0';
    }
    /* 'buf' passed to external function */
    display_text(buf);
}
```

Do not copy a FILE object

## Description

### Rule Definition

*Do not copy a FILE object.*

### Polyspace Implementation

The rule checker checks for **Misuse of a FILE object**.

## Examples

### Misuse of a FILE object

#### Issue

**Misuse of a FILE object** occurs when:

- You dereference a pointer to a FILE object, including indirect dereference by using `memcmp()`.
- You modify an entire FILE object or one of its components through its pointer.
- You take the address of FILE object that was not returned from a call to an `fopen`-family function. No defect is raised if a macro defines the pointer as the address of a built-in FILE object, such as `#define ptr (&__stdout)`.

#### Risk

In some implementations, the address of the pointer to a FILE object used to control a stream is significant. A pointer to a copy of a FILE object is interpreted differently than a pointer to the original object, and can potentially result in operations on the wrong stream. Therefore, the use of a copy of a FILE object can cause the software to stop responding, which an attacker might exploit in denial-of-service attacks.

#### Fix

Do not make a copy of a FILE object. Do not use the address of a FILE object that was not returned from a successful call to an `fopen`-family function.

#### Example - Copy of FILE Object Used in `fputs()`

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /*'stdout' dereferenced and contents
        copied to 'my_stdout'. */
    FILE my_stdout = *stdout;  //Noncompliant

    /* Address of 'my_stdout' may not point to correct stream. */
    if (fputs("Hello, World!\n", &my_stdout) == EOF)  //Noncompliant
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

In this example, FILE object `stdout` is dereferenced and its contents are copied to `my_stdout`. The contents of `stdout` might not be significant. `fputs()` is then called with the address of `my_stdout` as an argument. Because no call to `fopen()` or a similar function was made, the address of `my_stdout` might not point to the correct stream.

**Correction — Copy the FILE Object Pointer**

Declare `my_stdout` to point to the same address as `stdout` to ensure that you write to the correct stream when you call `fputs()`.

```
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
#include <string.h>
#include <strings.h>

void fatal_error(void);

int func(void)
{
    /* 'my_stdout' and 'stdout' point to the same object. */
    FILE *my_stdout = stdout;
    if (fputs("Hello, World!\n", my_stdout) == EOF)
    {
        /* Handler error */
        fatal_error();
    }
    return 0;
}
```

Do not alternately input and output from a stream without an intervening flush or positioning call

## Description

### Rule Definition

*Do not alternately input and output from a stream without an intervening flush or positioning call.*

### Polyspace Implementation

The rule checker checks for **Alternating input and output from a stream without flush or positioning call**.

## Examples

### Alternating input and output from a stream without flush or positioning call

#### Issue

**Alternating input and output from a stream without flush or positioning call** occurs when:

- You do not perform a flush or function positioning call between an output operation and a following input operation on a file stream in update mode.
- You do not perform a function positioning call between an input operation and a following output operation on a file stream in update mode.

#### Risk

Alternating input and output operations on a stream without an intervening flush or positioning call is undefined behavior.

#### Fix

Call `fflush()` or a file positioning function such as `fseek()` or `fsetpos()` between output and input operations on an update stream.

Call a file positioning function between input and output operations on an update stream.

#### Example - Read After Write Without Intervening Flush

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;
    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Read operation after write without
    intervening flush. */
    if (fread(data, 1, SIZE20, file) < SIZE20) //Noncompliant
      {
          (void)fclose(file);
          /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

In this example, the file `demo.txt` is opened for reading and appending. After the call to `fwrite()`, a call to `fread()` without an intervening flush operation is undefined behavior.

**Correction — Call `fflush()` Before the Read Operation**

After writing data to the file, before calling `fread()`, perform a flush call.

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
```

```
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Buffer flush after write and before read */
    if (fflush(file) != 0)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

Reset strings on fgets() or fgetws() failure

## Description

### Rule Definition

*Reset strings on fgets() or fgetws() failure.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate string**.

## Examples

### Use of indeterminate string

#### Issue

**Use of indeterminate string** occurs when you do not check if a write operation using an `fgets`-family function such as:

```
char * fgets(char* buf, int n, FILE *stream)
```

succeeded and the buffer written has valid content, or you do not reset the buffer on failure. You then perform an operation that assumes a buffer with valid content. For instance, if the buffer with possibly indeterminate content is `buf` (as shown above), the checker raises a defect if:

- You pass `buf` as argument to standard functions that print or manipulate strings or wide strings.
- You return `buf` from a function.
- You pass `buf` as argument to external functions with parameter type `const char *` or `const wchar_t *`.
- You read `buf` as `buf[index]` or `*(buf + offset)`, where `index` or `offset` is a numerical value representing the distance from the beginning of the buffer.

#### Risk

If an `fgets`-family function fails, the content of its output buffer is indeterminate. Use of such a buffer has undefined behavior and can result in a program that stops working or other security vulnerabilities.

#### Fix

Reset the output buffer of an `fgets`-family function to a known string value when the function fails.

#### Example - Output of `fgets()` Passed to External Function

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>
```

```
#define SIZE20 20

extern void display_text(const char *txt);

void func(void) {
    char buf[SIZE20];

    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* 'buf' may contain an indeterminate string.  */
        ;
    }
    /* 'buf passed to external function */
    display_text(buf); //Noncompliant
}
```

In this example, the output `buf` is passed to the external function `display_text()`, but its value is not reset if `fgets()` fails.

#### Correction — Reset `fgets()` Output on Failure

If `fgets()` fails, reset `buf` to a known value before you pass it to an external function.

```
#include <stdio.h>
#include <wchar.h>
#include <string.h>
#include <stdlib.h>

#define SIZE20 20

extern void display_text(const char *txt);

void func1(void) {
    char buf[SIZE20];
    /* Check fgets() error */
    if (fgets (buf, sizeof (buf), stdin) == NULL)
    {
        /* value of 'buf' reset after fgets() failure. */
        buf[0] = '\0';
    }
    /* 'buf' passed to external function */
    display_text(buf);
}
```

Do not call getc(), putc(), getwc(), or putwc() with a stream argument that has side effects

## Description

### Rule Definition

*Do not call getc(), putc(), getwc(), or putwc() with a stream argument that has side effects.*

### Polyspace Implementation

The rule checker checks for **Stream argument with possibly unintended side effects**.

## Examples

### Stream argument with possibly unintended side effects

#### Issue

**Stream argument with possibly unintended side effects** occurs when you call `getc()`, `putc()`, `getwc()`, or `putwc()` with a stream argument that has side effects.

**Stream argument with possibly unintended side effects** considers the following as stream side effects:

- Any assignment of a variable of a stream, such as `FILE *`, or any assignment of a variable of a deeper stream type, such as an array of `FILE *`.
- Any call to a function that manipulates a stream or a deeper stream type.

The number of defects raised corresponds to the number of side effects detected. When a stream argument is evaluated multiple times in a function implemented as a macro, a defect is raised for each evaluation that has a side effect.

A defect is also raised on functions that are not implemented as macros but that can be implemented as macros on another operating system.

#### Risk

If the function is implemented as an unsafe macro, the stream argument can be evaluated more than once, and the stream side effect happens multiple times. For instance, a stream argument calling `fopen()` might open the same file multiple times, which is unspecified behavior.

#### Fix

To ensure that the side effect of a stream happens only once, use a separate statement for the stream argument.

#### Example - Stream Argument of `getc()` Has Side Effect `fopen()`

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
```

```
#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;
    /* getc() has stream argument fptr with
    * 2 side effects: call to fopen(), and assignment
    * of fptr
    */
     c = getc(fptr = fopen(myfile, "r"));//Noncompliant
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

In this example, `getc()` is called with stream argument `fptr`. The stream argument has two side effects: the call to `fopen()` and the assignment of `fptr`. If `getc()` is implemented as an unsafe macro, the side effects happen multiple times.

#### Correction — Use Separate Statement for `fopen()`

One possible correction is to use a separate statement for `fopen()`. The call to `fopen()` and the assignment of `fptr` happen in this statement so there are no side effects when you pass `fptr` to `getc()`.

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

#define fatal_error() abort()

const char* myfile = "my_file.log";

void func(void)
{
    int c;
    FILE* fptr;

    /* Separate statement for fopen()
    * before call to getc()
    */
    fptr = fopen(myfile, "r");
    if (fptr == NULL) {
        /* Handle error */
        fatal_error();
    }
    c = getc(fptr);
    if (c == EOF) {
        /* Handle error */
        (void)fclose(fptr);
        fatal_error();
    }
    if (fclose(fptr) == EOF) {
        /* Handle error */
        fatal_error();
    }
}

void main(void)
{
    func();

}
```

Close files when they are no longer needed

## Description

### Rule Definition

*Close files when they are no longer needed.*

### Polyspace Implementation

The rule checker checks for **Resource leak**.

## Examples

### Resource leak

#### Issue

**Resource leak** occurs when you open a file stream by using a `FILE` pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

#### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

#### Fix

Close a `FILE` pointer before the end of its scope, or before you assign the pointer to another stream.

#### Example - FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" ); //Noncompliant
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer `fp1` is pointing to a file `data1.txt`. Before `fp1` is explicitly dissociated from the file stream of `data1.txt`, it is used to access another file `data2.txt`.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate `fp1` from the file stream of `data1.txt`.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

Only use values for fsetpos() that are returned from fgetpos()

## Description

### Rule Definition

*Only use values for fsetpos() that are returned from fgetpos().*

### Polyspace Implementation

The rule checker checks for **Invalid file position**.

## Examples

### Invalid file position

#### Issue

**Invalid file position** occurs when the file position argument of `fsetpos()` uses a value that is not obtained from `fgetpos()`.

#### Risk

The function `fgetpos(FILE *stream, fpos_t *pos)` gets the current file position of the stream. When you use any other value as the file position argument of `fsetpos(FILE *stream, const fpos_t *pos)`, you might access an unintended location in the stream.

#### Fix

Use the value returned from a successful call to `fgetpos()` as the file position argument of `fsetpos()`.

#### Example - `memset()` Sets File Position Argument

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset' */
    (void)memset(&offset, 0, sizeof(offset));

    /* Read data from file */

    /* Return to the initial position. offset was not
    returned from a call to fgetpos()    */
    if (fsetpos(file, &offset) != 0) //Noncompliant
    {
        /* Handle error */
    }
    return file;
}
```

In this example, `fsetpos()` uses `offset` as its file position argument. However, the value of `offset` is set by `memset()`. The preceding code might access the wrong location in the stream.

#### Correction — Use a File Position Returned From `fgetpos()`

Call `fgetpos()`, and if it returns successfully, use the position argument in your call to `fsetpos()`.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

FILE *func(FILE *file)
{
    fpos_t offset;
    if (file == NULL)
    {
        /* Handle error */
    }
    /* Store initial position in variable 'offset'
    using fgetpos() */
    if (fgetpos(file, &offset) != 0)
    {
        /* Handle error */
    }

    /* Read data from file */

    /* Back to the initial position */
    if (fsetpos(file, &offset) != 0)
    {
        /* Handle error */
    }
    return file;
}
```

Avoid TOCTOU race conditions while accessing files

## Description

### Rule Definition

*Avoid TOCTOU race conditions while accessing files.*

### Polyspace Implementation

The rule checker checks for **File access between time of check and use (TOCTOU)**.

## Examples

### File access between time of check and use (TOCTOU)

#### Issue

**File access between time of check and use (TOCTOU)** detects race condition issues between checking the existence of a file or folder, and using a file or folder.

#### Risk

An attacker can access and manipulate your file between your check for the file and your use of a file. Symbolic links are particularly risky because an attacker can change where your symbolic link points.

#### Fix

Before using a file, do not check its status. Instead, use the file and check the results afterward.

#### Example - Check File Before Using

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    if (access(log_path, W_OK)==0) {
        FILE* f = fopen(log_path, "w"); //Noncompliant
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

In this example, before opening and using the file, the function checks if the file exists. However, an attacker can change the file between the first and second lines of the function.

#### Correction — Open Then Check

One possible correction is to open the file, and then check the existence and contents afterward.

```
#include <stdio.h>
#include <fcntl.h>
#include <unistd.h>

extern void print_tofile(FILE* f);

void toctou(char * log_path) {
    int fd = open(log_path, O_WRONLY);
    if (fd!=-1) {
        FILE *f = fdopen(fd, "w");
        if (f) {
            print_tofile(f);
            fclose(f);
        }
    }
}
```

Do not access a closed file

## Description

### Rule Definition

*Do not access a closed file.*

### Polyspace Implementation

The rule checker checks for **Use of previously closed resource**.

## Examples

### Use of previously closed resource

#### Issue

**Use of previously closed resource** occurs when a function operates on a stream that you closed earlier in your code.

#### Risk

The standard states that the value of a `FILE*` pointer is indeterminate after you close the stream associated with it. Operations using the `FILE*` pointer can produce unintended results.

#### Fix

One possible fix is to close the stream only at the end of operations. Another fix is to reopen the stream before using it again.

#### Example - Use of `FILE*` Pointer After Closing Stream

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fclose(fp);
        fprintf(fp,"text"); //Noncompliant
    }
}
```

In this example, `fclose` closes the stream associated with `fp`. When you use `fprintf` on `fp` after `fclose`, the **Use of previously closed resource** defect appears.

#### Correction — Close Stream After All Operations

One possible correction is to reverse the order of the `fprintf` and `fclose` operations.

```
#include <stdio.h>

void func(void) {
    FILE *fp;
    void *ptr;

    fp = fopen("tmp","w");
    if(fp != NULL) {
        fprintf(fp,"text");
        fclose(fp);
    }
}
```

Use valid format strings

## Description

### Rule Definition

*Use valid format strings.*

### Polyspace Implementation

The rule checker checks for **Format string specifiers and arguments mismatch**.

## Examples

### Format string specifiers and arguments mismatch

#### Issue

**Format string specifiers and arguments mismatch** occurs when the format specifiers in the formatted output functions such as `printf` do not match their corresponding arguments. For example, an argument of type `unsigned long` must have a format specification of `%lu`.

#### Risk

Mismatch between format specifiers and the corresponding arguments result in undefined behavior.

#### Fix

Make sure that the format specifiers match the corresponding arguments. For instance, in this example, the `%d` specifier does not match the string argument `message` and the `%s` specifier does not match the integer argument `err_number`.

```
const char *message = "License not available";
int err_number = -4;
printf("Error: %d (error type %s)\n", message, err_number);
```

Switching the two format specifiers fixes the issue. See the specifications for the printf function for more information about format specifiers.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Printing a Float

```
#include <stdio.h>

void string_format(void) {
    unsigned long fst = 1;

    printf("%d\n", fst); //Noncompliant
}
```

In the `printf` statement, the format specifier, `%d`, does not match the data type of `fst`.

**Correction — Use an Unsigned Long Format Specifier**

One possible correction is to use the `%lu` format specifier. This specifier matches the `unsigned` integer type and `long` size of `fst`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%lu\n", fst);
}
```

**Correction — Use an Integer Argument**

One possible correction is to change the argument to match the format specifier. Convert `fst` to an integer to match the format specifier and print the value `1`.

```
#include <stdio.h>

void string_format(void) {

    unsigned long fst = 1;

    printf("%d\n", (int)fst);
}
```

Do not alternately input and output from a file stream without an intervening positioning call

## Description

### Rule Definition

*Do not alternately input and output from a file stream without an intervening positioning call.*

### Polyspace Implementation

The rule checker checks for **Alternating input and output from a stream without flush or positioning call**.

## Examples

### Alternating input and output from a stream without flush or positioning call

#### Issue

**Alternating input and output from a stream without flush or positioning call** occurs when:

- You do not perform a flush or function positioning call between an output operation and a following input operation on a file stream in update mode.
- You do not perform a function positioning call between an input operation and a following output operation on a file stream in update mode.

#### Risk

Alternating input and output operations on a stream without an intervening flush or positioning call is undefined behavior.

#### Fix

Call `fflush()` or a file positioning function such as `fseek()` or `fsetpos()` between output and input operations on an update stream.

Call a file positioning function between input and output operations on an update stream.

#### Example - Read After Write Without Intervening Flush

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;
    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Read operation after write without
    intervening flush. */
    if (fread(data, 1, SIZE20, file) < SIZE20) //Noncompliant
      {
          (void)fclose(file);
          /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

In this example, the file `demo.txt` is opened for reading and appending. After the call to `fwrite()`, a call to `fread()` without an intervening flush operation is undefined behavior.

### Correction — Call `fflush()` Before the Read Operation

After writing data to the file, before calling `fread()`, perform a flush call.

```
#include <stdio.h>
#define SIZE20 20

void initialize_data(char* data, size_t s) {};
const char *temp_filename = "/tmp/demo.txt";

void func()
{
    char data[SIZE20];
    char append_data[SIZE20];
    FILE *file;

    file = fopen(temp_filename, "a+");
    if (file == NULL)
      {
        /* Handle error. */;
      }

    initialize_data(append_data, SIZE20);

    if (fwrite(append_data, 1, SIZE20, file) != SIZE20)
```

```
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    /* Buffer flush after write and before read */
    if (fflush(file) != 0)
      {
        (void)fclose(file);
        /* Handle error. */;
      }
    if (fread(data, 1, SIZE20, file) < SIZE20)
      {
        (void)fclose(file);
        /* Handle error. */;
      }

    if (fclose(file) == EOF)
      {
        /* Handle error. */;
      }
}
```

Close files when they are no longer needed

## Description

### Rule Definition

*Close files when they are no longer needed.*

### Polyspace Implementation

The rule checker checks for **Resource leak**.

## Examples

### Resource leak

#### Issue

**Resource leak** occurs when you open a file stream by using a `FILE` pointer but do not close it before:

- The end of the pointer’s scope.
- Assigning the pointer to another stream.

#### Risk

If you do not release file handles explicitly as soon as possible, a failure can occur due to exhaustion of resources.

#### Fix

Close a `FILE` pointer before the end of its scope, or before you assign the pointer to another stream.

#### Example - FILE Pointer Not Released Before End of Scope

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );

    fp1 = fopen ( "data2.txt", "w" ); //Noncompliant
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

In this example, the file pointer `fp1` is pointing to a file `data1.txt`. Before `fp1` is explicitly dissociated from the file stream of `data1.txt`, it is used to access another file `data2.txt`.

#### Correction — Release FILE Pointer

One possible correction is to explicitly dissociate `fp1` from the file stream of `data1.txt`.

```
#include <stdio.h>

void func1( void ) {
    FILE *fp1;
    fp1 = fopen ( "data1.txt", "w" );
    fprintf ( fp1, "*" );
    fclose(fp1);

    fp1 = fopen ( "data2.txt", "w" );
    fprintf ( fp1, "!" );
    fclose ( fp1 );
}
```

Set errno to zero before calling a library function known to set errno, and check errno only after the function returns a value indicating failure

## Description

### Rule Definition

*Set errno to zero before calling a library function known to set errno, and check errno only after the function returns a value indicating failure.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Misuse of errno**.
- **Errno not reset**.

## Examples

### Misuse of errno

#### Issue

**Misuse of errno** occurs when you check `errno` for error conditions in situations where checking `errno` does not guarantee the absence of errors. In some cases, checking `errno` can lead to false positives.

For instance, you check `errno` following calls to the functions:

- `fopen`: If you follow the ISO Standard, the function might not set `errno` on errors.
- `atof`: If you follow the ISO Standard, the function does not set `errno`.
- `signal`: The `errno` value indicates an error only if the function returns the `SIG_ERR` error indicator.

#### Risk

The ISO C Standard does not enforce that these functions set `errno` on errors. Whether the functions set `errno` or not is implementation-dependent.

To detect errors, if you check `errno` alone, the validity of this check also becomes implementation-dependent.

In some cases, the `errno` value indicates an error only if the function returns a specific error indicator. If you check `errno` before checking the function return value, you can see false positives.

#### Fix

For information on how to detect errors, see the documentation for that specific function.

Typically, the functions return an out-of-band error indicator to indicate errors. For instance:

- fopen returns a null pointer if an error occurs.
- signal returns the SIG_ERR error indicator and sets errno to a positive value. Check errno only after you have checked the function return value.

**Example - Incorrectly Checking for errno After fopen Call**

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    errno = 0;
    fileptr = fopen(temp_filename, "w+b");
    if (errno != 0) { //Noncompliant
        if (fileptr != NULL) {
            (void)fclose(fileptr);
        }
        /* Handle error */
        fatal_error();
    }
    return fileptr;
}
```

In this example, errno is the first variable that is checked after a call to fopen. You might expect that fopen changes errno to a nonzero value if an error occurs. If you run this code with an implementation of fopen that does not set errno on errors, you might miss an error condition. In this situation, fopen can return a null pointer that escapes detection.

**Correction — Check Return Value of fopen After Call**

One possible correction is to only check the return value of fopen for a null pointer.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>

#define fatal_error() abort()

const char *temp_filename = "/tmp/demo.txt";

FILE *func()
{
    FILE *fileptr;
    fileptr = fopen(temp_filename, "w+b");
    if (fileptr == NULL) {
        fatal_error();
    }
    return fileptr;
}
```

### Errno not reset

#### Issue

**Errno not reset** occurs when you do not reset `errno` before calling a function that sets `errno` to indicate error conditions. However, you check `errno` for those error conditions after the function call.

#### Risk

The `errno` is not clean and can contain values from a previous call. Checking `errno` for errors can give the false impression that an error occurred.

`errno` is set to zero at program startup but subsequently, `errno` is not reset by a C standard library function. You must explicitly set `errno` to zero when required.

#### Fix

Before calling a function that sets `errno` to indicate error conditions, reset `errno` to zero explicitly.

#### Example - `errno` Not Reset Before Call to `strtod`

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>

#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    f1 = strtod (s1, NULL);
    if (0 == errno) {  //Noncompliant
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
                  {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

In this example, `errno` is not reset to 0 before the first call to `strtod`. Checking `errno` for 0 later can lead to a false positive.

#### Correction — Reset `errno` Before Call

One possible correction is to reset `errno` to 0 before calling `strtod`.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <float.h>
```

```
#define fatal_error() abort()

double func(const char *s1, const char *s2)
{
    double f1;
    errno = 0;
    f1 = strtod (s1, NULL);
    if (0 == errno) {
      double f2 = strtod (s2, NULL);
        if (0 == errno) {
            long double result = (long double)f1 + f2;
            if ((result <= (long double)DBL_MAX) && (result >= (long double)-DBL_MAX))
              {
                return (double)result;
            }
        }
    }
    fatal_error();
    return 0.0;
}
```

Do not rely on indeterminate values of errno

## Description

### Rule Definition

*Do not rely on indeterminate values of errno.*

### Polyspace Implementation

The rule checker checks for **Misuse of errno in a signal handler**.

## Examples

### Misuse of errno in a signal handler

#### Issue

**Misuse of errno in a signal handler** occurs when you call one of these functions in a signal handler:

- `signal`: You call the `signal` function in a signal handler and then read the value of `errno`.

  For instance, the signal handler function `handler` calls `signal` and then calls `perror`, which reads `errno`.

  ```
  void handler(int signum) {
    pfv old_handler = signal(signum, SIG_DFL);
    if (old_handler == SIG_ERR) {
      perror("SIGINT handler");
    }
  }
  ```
- `errno`-setting POSIX function: You call an `errno`-setting POSIX function in a signal handler but do not restore `errno` when returning from the signal handler.

  For instance, the signal handler function `handler` calls `waitpid`, which changes `errno`, but does not restore `errno` before returning.

  ```
  void handler(int signum) {
    int rc = waitpid(-1, NULL, WNOHANG);
    if (ECHILD != errno) {
    }
  }
  ```

#### Risk

In each case that the checker flags, you risk relying on an indeterminate value of `errno`.

- `signal`: If the call to `signal` in a signal handler fails, the value of `errno` is indeterminate (see C11 Standard, Sec. 7.14.1.1). If you rely on a specific value of `errno`, you can see unexpected results.

- errno-setting POSIX function: An errno-setting function sets errno on failure. If you read errno after a signal handler is called and the signal handler itself calls an errno-setting function, you can see unexpected results.

**Fix**

Avoid situations where you risk relying on an indeterminate value of errno.

- signal: After calling the signal function in a signal handler, do not read errno or use a function that reads errno.
- errno-setting POSIX function: Before calling an errno-setting function in a signal handler, save errno to a temporary variable. Restore errno from this variable before returning from the signal handler.

**Example - Reading errno After signal Call in Signal Handler**

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()

void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        perror("SIGINT handler");
    }
} //Noncompliant

int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

In this example, the function handler is called to handle the SIGINT signal. In the body of handler, the signal function is called. Following this call, the value of errno is indeterminate. The checker raises a defect when the perror function is called because perror relies on the value of errno.

**Correction — Avoid Reading errno After signal Call**

One possible correction is to not read errno after calling the signal function in a signal handler. The corrected code here calls the abort function via the fatal_error macro instead of the perror function.

```
#include <signal.h>
#include <stdlib.h>
#include <stdio.h>

#define fatal_error() abort()
```

```
void handler(int signum) {
    if (signal(signum, SIG_DFL) == SIG_ERR) {
        fatal_error();
    }
}

int func(void) {
    if (signal(SIGINT, handler) == SIG_ERR) {
        /* Handle error */
        fatal_error();
    }
    /* Program code */
    if (raise(SIGINT) != 0) {
        /* Handle error */
        fatal_error();
    }
    return 0;
}
```

Detect and handle standard library errors

## Description

### Rule Definition

*Detect and handle standard library errors.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Errno not checked**.
- **Returned value of a sensitive standard function not checked**.
- **Unprotected dynamic memory allocation**.

## Examples

### Errno not checked

#### Issue

**Errno not checked** occurs when you call a function that sets errno to indicate error conditions, but do not check errno after the call. For these functions, checking errno is the only reliable way to determine if an error occurred.

Functions that set errno on errors include:

- fgetwc, strtol, and wcstol.

  For a comprehensive list of functions, see documentation about errno.
- POSIX errno-setting functions such as encrypt and setkey.

#### Risk

To see if the function call completed without errors, check errno for error values.

The return values of these errno-setting functions do not indicate errors. The return value can be one of the following:

- void
- Even if an error occurs, the return value can be the same as the value from a successful call. Such return values are called in-band error indicators.

You can determine if an error occurred only by checking errno.

For instance, strtol converts a string to a long integer and returns the integer. If the result of conversion overflows, the function returns LONG_MAX and sets errno to ERANGE. However, the function can also return LONG_MAX from a successful conversion. Only by checking errno can you distinguish between an error and a successful conversion.

#### Fix

Before calling the function, set `errno` to zero.

After the function call, to see if an error occurred, compare `errno` to zero. Alternatively, compare `errno` to known error indicator values. For instance, `strtol` sets `errno` to `ERANGE` to indicate errors.

The error message in the Polyspace result shows the error indicator value that you can compare to.

#### Example - `errno` Not Checked After Call to `strtol`

```
#include<stdio.h>
#include<stdlib.h>
#include<errno.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    long val = strtol(str, &endptr, base); //Noncompliant
    printf("Return value of strtol() = %ld\n", val);
}
```

You are using the return value of `strtol` without checking `errno`.

#### Correction — Check `errno` After Call

Before calling `strtol`, set `errno` to zero . After a call to `strtol`, check the return value for `LONG_MIN` or `LONG_MAX` and `errno` for `ERANGE`.

```
#include<stdlib.h>
#include<stdio.h>
#include<errno.h>
#include<limits.h>

int main(int argc, char *argv[]) {
    char *str, *endptr;
    int base;

    str = argv[1];
    base = 10;

    errno = 0;
    long val = strtol(str, &endptr, base);
    if((val == LONG_MIN || val == LONG_MAX) && errno == ERANGE) {
         printf("strtol error");
         exit(EXIT_FAILURE);
    }
    printf("Return value of strtol() = %ld\n", val);
}
```

### Returned value of a sensitive standard function not checked

#### Issue

**Returned value of a sensitive standard function not checked** occurs when you call sensitive standard functions, but you:

- Ignore the return value.
- Use an output or a return value without testing the validity of the return value.

For this defect, two type of functions are considered: ***sensitive*** and ***critical sensitive***.

A ***sensitive*** function is a standard function that can encounter:

- Exhausted system resources (for example, when allocating resources)
- Changed privileges or permissions
- Tainted sources when reading, writing, or converting data from external sources
- Unsupported features despite an existing API

A ***critical sensitive*** function is a sensitive function that performs one of these critical or vulnerable tasks:

- Set privileges (for example, `setuid`)
- Create a jail (for example, `chroot`)
- Create a process (for example, `fork`)
- Create a thread (for example, `thrd_create`)
- Lock or unlock memory segments (for example, `mlock`)

#### Risk

If you do not check the return value of functions that perform sensitive or critical sensitive tasks, your program can behave unexpectedly. Errors from these functions can propagate throughout the program causing incorrect output, security vulnerabilities, and possibly system failures.

#### Fix

Before continuing with the program, test the return value of *critical sensitive* functions.

For *sensitive functions*, you can explicitly ignore a return value by casting the function to `void`. Polyspace does not raise this defect for sensitive functions cast to void. This resolution is not accepted for *critical sensitive functions* because they perform more vulnerable tasks.

#### Example - Sensitive Function Return Ignored

```
#include<cstdlib>
#include<cstdio>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    scanf("%d",&n); //Noncompliant
    setlocale (LC_CTYPE, "en_US.UTF-8");   //Noncompliant
    *size = mbstowcs (wcs, utf8, n);
}
```

This example shows a call to the sensitive function `scanf()`. The return value of `scanf()` is ignored, causing a defect. Similarly, the pointer returned by `setlocale` is not checked. When `setlocal` returns a `NULL` pointer, the call to `mbstowcs` might fail or produce unexpected results. Polyspace flags these calls to sensitive functions when their returns are not checked.

#### Correction — Cast Function to `(void)`

One possible correction is to cast the functions to void. This fix informs Polyspace and any reviewers that you are explicitly ignoring the return value of these sensitive functions.

```
#include<cstdlib>
#include<cstdio>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    (void)scanf("%d",&n); //Compliant
    (void)setlocale (LC_CTYPE, "en_US.UTF-8");   //Compliant
    *size = mbstowcs (wcs, utf8, n);
}
```

#### Correction — Test Return Value

One possible correction is to test the return value of `scanf` and `setlocale` to check for errors.

```
#include<cstdlib>
#include<cstdio>
#include <wchar.h>
#include <locale.h>
void initialize(size_t n, size_t* size, wchar_t *wcs, const char *utf8) {

    int flag = scanf("%d",&n);
    if(flag>0){ //Compliant
        // action
    }
    char* status = setlocale (LC_CTYPE, "en_US.UTF-8");
    if(status!=NULL){//Compliant
        *size = mbstowcs (wcs, utf8, n);
    }

}
```

#### Example — Unchecked Dynamic Memory Allocation

```
#include <stddef.h>
#include <stdlib.h>

void unchecked_memory_allocation(void) {
  int * p = (int*)calloc(5, sizeof(int));// C-style allocation
  *p = 2;                                  //Noncompliant
  //...
  delete[] p;
}
```

In this example, memory is dynamically allocated for the pointer `*p`. The pointer is then used without checking the output of the dynamic memory allocation operation. Polyspace raises this defect when pointers are used after an unchecked dynamic memory allocation operation.

#### Correction — Check Output of Dynamic Memory Allocation

The correction for this defect is to check the return value of the operation `new` to verify that the function performed as expected.

```
#include <stddef.h>
#include <stdlib.h>

void checked_memory_allocation(void) {
    int * p = new int[5];
    if(p==NULL){// Check output of new
        //Handle memory allocation error
    }else{
        *p = 2; //Compliant
        //...
        delete[] p;
    }

}
```

### Unprotected dynamic memory allocation

#### Issue

**Unprotected dynamic memory allocation** occurs when you do not check after dynamic memory allocation whether the memory allocation succeeded.

#### Risk

When memory is dynamically allocated using `malloc`, `calloc`, or `realloc`, it returns a value `NULL` if the requested memory is not available. If the code following the allocation accesses the memory block without checking for this `NULL` value, this access is not protected from failures.

#### Fix

Check the return value of `malloc`, `calloc`, or `realloc` for NULL before accessing the allocated memory location.

```
#DEFINE SIZE 8;

int *ptr = malloc(SIZE * sizeof(int));

if(ptr) /* Check for NULL */
{
   /* Memory access through ptr */
}
```

#### Example - Unprotected Dynamic Memory Allocation Error

```
#include <stdlib.h>

void Assign_Value(void)
{
  int* p = (int*)calloc(5, sizeof(int));
  *p = 2;  //Noncompliant
  /* Defect: p is not checked for NULL value */
  free(p);
} /*Defect: p is not checked for NULL before deallocating*/
```

If the memory allocation fails, the function `calloc` returns `NULL` to `p`. Before accessing the memory through `p` or freeing `p`, the code does not check whether `p` is `NULL`. These operations might result in memory leaks.

#### Correction — Check for NULL Value

One possible correction is to check whether `p` has value `NULL` before dereference.

```
#include <stdlib.h>

void Assign_Value(void)
 {
   int* p = (int*)calloc(5, sizeof(int));
   /* Fix: Check if p is NULL */
   if(p!=NULL) *p = 2;
   free(p);
 }
```

### Pointer overwritten during reallocation

#### Issue

**Pointer overwritten during reallocation** occurs when you overwrite the original pointer by the return value of `realloc()`. For instance:

```
p = realloc(p,SIZE);
```

#### Risk

The function `realloc()` returns a `NULL` value when memory allocation fails. In the preceding code, because you overwrite `p` by the return of `realloc()`, it becomes `NULL` when the reallocation operation fails. You lose the connection between the original memory block and `p`, resulting in a memory leak.

#### Fix

When reallocating pointers, preserve the original pointer. For instance, you might use a temporary variable to store the reallocated memory.

#### Example — Avoid Overwriting Original Pointer When Reallocating Memory

```
#include <stdlib.h>

void foo (int* ptrI, size_t new_size)
{

  if (new_size == 0) {
    /* Handle error */
    return;
  }

  ptrI = (int*)realloc (ptrI, new_size);   //Noncompliant

  if (ptrI == NULL) {
    /* Handle error */
    return;
  }
}
```

Overwriting the pointer ptrI by the pointer returned by realloc destroys the association between ptrI and the original memory block. If realloc fails, such overwriting might cause a memory leak and data loss.

#### Correction — Store Reallocated Memory in Temporary Variable

When reallocating a pointer, use a temporary variable to hold the reallocated memory. Before assigning the temporary variable to ptrI, check it for NULL value to avoid memory leaks and data loss.

```
#include <stdlib.h>

void foo (int* ptrI, size_t new_size)
{
int* temp;
  if (new_size == 0) {
    /* Handle error */
    return;
  }

  temp = (int*)realloc (ptrI, new_size);   //Compliant

  if (temp == NULL) {
    /* Handle error */
    return;
  }else{
      ptrI = temp;
  }
}
```

Detect errors when converting a string to a number

## Description

### Rule Definition

*Detect errors when converting a string to a number.*

### Polyspace Implementation

The rule checker checks for **Unsafe conversion from string to numerical value**.

## Examples

### Unsafe conversion from string to numerical value

#### Issue

**Unsafe conversion from string to numerical value** detects conversions from strings to integer or floating-point values. If your conversion method does not include robust error handling, a defect is raised.

#### Risk

Converting a string to numerical value can cause data loss or misinterpretation. Without validation of the conversion or error handling, your program continues with invalid values.

#### Fix

- Add additional checks to validate the numerical value.
- Use a more robust string-to-numeric conversion function such as `strtol`, `strtoll`, `strtoul`, or `strtoull`.

#### Example - Conversion With `atoi`

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char* argv1)
{
    int s = 0;
    if (demo_check_string_not_empty(argv1))
    {
        s = atoi(argv1); //Noncompliant
    }
    return s;
}
```

In this example, `argv1` is converted to an integer with `atoi`. `atoi` does not provide errors for an invalid integer string. The conversion can fail unexpectedly.

**Correction — Use `strtol` instead**

One possible correction is to use `strtol` to validate the input string and the converted integer.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <limits.h>
#include <errno.h>

static int demo_check_string_not_empty(char *s)
{
    if (s != NULL)
        return strlen(s) > 0; /* check string null-terminated and not empty */
    else
        return 0;
}

int unsafestrtonumeric(char *argv1)
{
    char *c_str = argv1;
    char *end;
    long sl;

    if (demo_check_string_not_empty(c_str))
    {
        errno = 0; /* set errno for error check */
        sl = strtol(c_str, &end, 10);
        if (end == c_str)
        {
            (void)fprintf(stderr, "%s: not a decimal number\n", c_str);
        }
        else if ('\0' != *end)
        {
            (void)fprintf(stderr, "%s: extra characters: %s\n", c_str, end);
        }
        else if ((LONG_MIN == sl || LONG_MAX == sl) && ERANGE == errno)
        {
            (void)fprintf(stderr, "%s out of range of type long\n", c_str);
        }
        else if (sl > INT_MAX)
        {
            (void)fprintf(stderr, "%ld greater than INT_MAX\n", sl);
        }
        else if (sl < INT_MIN)
        {
            (void)fprintf(stderr, "%ld less than INT_MIN\n", sl);
        }
        else
        {
            return (int)sl;
        }
    }
    return 0;
}
```

Do not abruptly terminate the program

## Description

### Rule Definition

*Do not abruptly terminate the program.*

### Polyspace Implementation

The rule checker checks for **Implicit call to terminate() function**.

## Examples

### Implicit call to `terminate()` function

#### Issue

The checker flags situations that might result in calling the function `std::terminate()` implicitly. These situations might include:

- An exception remains unhandled. For instance:
  - While handling an exception, it escapes through another function that raises an unhandled exception. For instance, a catch statement or exception handler invokes another function that raises an unhandled exception.
  - An empty `throw` statement raises an unhandled exception again.
- A class destructor raises an exception.
- A termination handler that is passed to `std::atexit` raises an unhandled exception.

#### Risk

Depending on the hardware and software that you use, calling `terminate()` implicitly might result in a call to `std::abort()`, which aborts program execution without deleting the variables in the stack. Such an abnormal termination results in memory leaks and security vulnerabilities.

#### Fix

To avoid implicit calls to `terminate()`:

- Avoid unhandled exceptions. For instance, execute the operations of `main()` or task main functions in a `try-catch` block. In the catch blocks:
  - Handle exceptions of type `std::exception` explicitly in appropriate catch blocks.
  - Handle the base class of exceptions arising from third-party libraries.
  - Handle unexpected exceptions in a `catch(...)` block.
- Declare destructors as `noexcept` and handle the exceptions in destructors.
- Handle all exceptions in termination handlers.

#### Example — Implicit Call to `terminate`

```
#include <stdexcept>
int main(){   // Noncompliant
  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }
  return 0;
}
```

In this example, `main()` handles specific types of exceptions. An unexpected exception remains unhandled, resulting in an implicit call to the function `terminate` that terminates the program abruptly. Because `main()` calls `terminate` implicitly, Polyspace raises this defect.

#### Correction — Handle Unexpected Exceptions

One possible correction is to include a `catch(...)` block to handle unexpected exceptions so that the program can exit gracefully.

```
#include <stdexcept>
[[noreturn]] void gracefulExit(){
    // unwind stack and report errors
    std::terminate();
}
int main()   // Compliant
{
  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }
  catch(...){
      //Exit gracefully
      gracefulExit();
  }
  return 0;
}
```

#### Example — Unhandled Exceptions in Termination Handlers

The termination handler `atexit_handler` raises an uncaught exception. The function `atexit_handler` executes after the main finishes execution. Unhandled exceptions in this function cannot be handled elsewhere, leading to an implicit call to `std::terminate()`. Polyspace flags the function.

```
#include <stdexcept>
void atexit_handler(){//Noncompliant
    throw std::runtime_error("Error in atexit function");
}
void main(){
    try{
        //...
        std::atexit(atexit_handler);
    }catch(...){

    }
}
```

**Correction — Handle All Exceptions in Termination Handlers**

To correct the issue, use a `catch(...)` block to handle all exceptions in the termination handler `atexit_handler`.

```
#include <stdexcept>
void atexit_handler(){
    try{
        //..
        throw std::runtime_error("Error in atexit function");
    }catch(...){
        //...
    }
}
void main(){
    try{
        //...
        std::atexit(atexit_handler);
    }catch(...){

    }
}
```

Handle all exceptions

## Description

### Rule Definition

*Handle all exceptions.*

### Polyspace Implementation

The rule checker checks for **Unhandled exception not caught**.

## Examples

### Unhandled exception not caught

#### Issue

The checker shows a violation if there is no `try`/`catch` in the `main` function or the `catch` block does not handle all exceptions by using a `catch(...)` block. The rule is not checked if a `main` function does not exist.

The checker does not determine if an exception of an unhandled type actually propagates to `main`.

#### Risk

Depending on the hardware and software that you use, unhandled exceptions might result in a call to `std::abort()`, which aborts program execution without deleting the variables in the stack. Such an abnormal termination results in memory leaks and security vulnerabilities.

#### Fix

Avoid unhandled exceptions. For instance, execute the operations of `main()` or task main functions in a `try-catch` block. In the catch blocks:

- Handle exceptions of type `std::exception` explicitly in appropriate catch blocks.
- Handle the base class of exceptions arising from third-party libraries.
- Handle unexpected exceptions in a `catch(...)` block.

#### Example — Exceptions Might Remain Unhandled

```
#include <stdexcept>
int main(){   // Noncompliant
  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }
  return 0;
}
```

In this example, `main()` handles specific types of exceptions, but lacks a `catch(...)` block. An unexpected exception remains unhandled. Because `main()` does not handle *all* exceptions, Polyspace raises this defect.

#### Correction

One possible correction is to include a `catch(...)` block to handle unexpected exceptions.

```
#include <stdexcept>
int main(){   // Compliant
  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }
  catch(...){
      //Exit gracefully
  }
  return 0;
}
```

Do not use setjmp() or longjmp()

## Description

### Rule Definition

*Do not use setjmp() or longjmp().*

### Polyspace Implementation

The rule checker checks for **Use of setjmp/longjmp**.

## Examples

### Use of setjmp/longjmp

#### Issue

**Use of setjmp/longjmp** occurs when you use a combination of `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` to deviate from normal control flow and perform non-local jumps in your code.

#### Risk

Using `setjmp` and `longjmp`, or `sigsetjmp` and `siglongjmp` has the following risks:

- Nonlocal jumps are vulnerable to attacks that exploit common errors such as buffer overflows. Attackers can redirect the control flow and potentially execute arbitrary code.
- Resources such as dynamically allocated memory and open files might not be closed, causing resource leaks.
- If you use `setjmp` and `longjmp` in combination with a signal handler, unexpected control flow can occur. POSIX does not specify whether `setjmp` saves the signal mask.
- Using `setjmp` and `longjmp` or `sigsetjmp` and `siglongjmp` makes your program difficult to understand and maintain.

#### Fix

Perform nonlocal jumps in your code using `setjmp/longjmp` or `sigsetjmp/siglongjmp` only in contexts where such jumps can be performed securely. Alternatively, use POSIX threads if possible.

In C++, to simulate throwing and catching exceptions, use standard idioms such as `throw` expressions and `catch` statements.

#### Example - Use of `setjmp` and `longjmp`

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

static jmp_buf env;
```

```
void sighandler(int signum) {
    longjmp(env, signum); //Noncompliant
}
void func_main(int i) {
    signal(SIGINT, sighandler);
    if (setjmp(env)==0) { //Noncompliant
        while(1) {
            /* Main loop of program, iterates until SIGINT signal catch */
            i = update(i);
        }
    } else {
        /* Managing longjmp return */
        i = -update(i);
    }

    print_int(i);
    return;
}
```

In this example, the initial return value of `setjmp` is 0. The `update` function is called in an infinite `while` loop until the user interrupts it through a signal.

In the signal handling function, the `longjmp` statement causes a jump back to `main` and the return value of `setjmp` is now 1. Therefore, the `else` branch is executed.

### Correction — Use Alternative to `setjmp` and `longjmp`

To emulate the same behavior more securely, use a `volatile` global variable instead of a combination of `setjmp` and `longjmp`.

```
#include <setjmp.h>
#include <signal.h>

extern int update(int);
extern void print_int(int);

volatile sig_atomic_t eflag = 0;

void sighandler(int signum) {
     eflag = signum;                   /* Fix: using global variable */
}

void func_main(int i) {
      /* Fix: Better design to avoid use of setjmp/longjmp */
    signal(SIGINT, sighandler);
    while(!eflag) {                   /* Fix: using global variable */
        /* Main loop of program, iterates until eflag is changed */
        i = update(i);
    }

    print_int(i);
    return;
}
```

Do not reference base classes or class data members in a constructor or destructor function-try-block handler

## Description

### Rule Definition

*Do not reference base classes or class data members in a constructor or destructor function-try-block handler.*

### Polyspace Implementation

The rule checker checks for **Constructor or destructor function-try-block handler references base classes or class data members**.

## Examples

### Constructor or destructor function-try-block handler references base classes or class data members

#### Issue

The issue occurs when handlers of a function-try-block implementation of a class constructor or destructor references non-static members from this class or its bases.

Catch handlers should order their parameter types from most derived to least derived

## Description

### Rule Definition

*Catch handlers should order their parameter types from most derived to least derived.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Exception handlers not ordered from most-derived to base class**.
- **Incorrect order of ellipsis handler**.

## Examples

### Exception handlers not ordered from most-derived to base class

#### Issue

The issue occurs when you provide multiple handlers in a single try-catch statement or function-try-block for a derived class and some or all of its bases, and the handlers are not ordered from most-derived to base class.

### Incorrect order of ellipsis handler

#### Issue

The issue occurs when you provide multiple handlers in a single try-catch statement or function-try-block, and the ellipsis (catch-all) handler does not occur last.

Honor exception specifications

## Description

### Rule Definition

*Honor exception specifications*

### Polyspace Implementation

The rule checker checks for **Noexcept functions exiting with exception**.

## Examples

### Noexcept functions exiting with exception

#### Issue

This defect occurs when a `noexcept` entity might exit with an exception. The compiler omits the exception handing process for `noexcept` entities. When such an entity exits with an exception, the exception becomes unhandled, leading to abnormal program termination.

When a `noexcept` entity invokes other callable entities, Polyspace makes certain assumptions to calculate whether there might be unhandled exceptions.

- Function: When a `noexcept` function calls another function, Polyspace checks whether the called function might raise an exception only if it is specified as `noexcept(<false>)`. If the called function is specified as `noexcept`, Polyspace assumes that it does not raise an exception. Some standard library functions, such as the constructor of `std::string`, use pointers to functions to perform memory allocation, which might raise exceptions. Because these functions are not specified as `noexcept(<false>)`, Polyspace does not flag a function that calls these standard library functions.
- External function: When a `noexcept` function calls an external function, Polyspace flags the function declaration if the external function is specified as `noexcept(<false>)`.
- Virtual function: When a function calls a virtual function, Polyspace flags the function declaration if the virtual function is specified as `noexcept(<false>)` in a derived class. For instance, if a `noexcept` function calls a virtual function that is declared as `noexcept(<true>)` in the base class, and `noexcept(<false>)` in a subsequent derived class, Polyspace flags the declaration of the `noexcept` function.
- Pointers to function: When a `noexcept` function invokes a pointer to a function, Polyspace assumes that the pointer to the function does not raise exceptions.

When analyzing whether a function raises unhandled exceptions, Polyspace ignores:

- Exceptions raised in destructors
- Exceptions raised in `atexit()` operations

Polyspace also ignores the dynamic context when checking for exceptions. For instance, a function might raise unhandled exceptions only in certain dynamic contexts. Polyspace flags such a function even if the exception might not be raised.

#### Risk

If a `noexcept` function exits with an exception, the compiler invokes `std::terminate()` implicitly. The function `std::terminate()` terminates the program execution in an implementation-defined manner. That is, the exact process of program termination depends on the particular set of software and hardware that you use. For instance, `std:terminate()` might invoke `std::abort()` to abnormally abort the execution without unwinding the stack, leading to resource leak and security vulnerabilities.

#### Fix

Specify a function as `noexcept` or `noexcept(true)` only when you know that the function does not exit with an exception. If you are not sure, specify it by using `noexcept(false)`

#### Example

Consider this code where two functions are specified as `noexcept`. Polyspace statically analyzes these functions and the functions that they call.

```
#include <stdexcept>
#include <typeinfo>
bool f(bool flag){
    if(flag==true)
    throw flag;
    return flag;

}
void LibraryFunc_noexcept_false() noexcept(false);
void SpecFalseCT() noexcept  // Noncompliant
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}
bool flag = false;
void Caller() noexcept {          //Noncompliant
    try {
        if(f(flag)){
            //...
        }
    } catch (int i) {
        //...
    }
}
```

- Polyspace flags the `noexcept` function `SpecFaleCT()` because this function calls the `noexcept(false)` external function `LibraryFunc_noexcept_false()` without handling any exceptions that can be raised from it. These exceptions can cause the `noexcept` function to exit with an exception.

- Polyspace flags the noexcept function Caller because this function calls the noexcept(false) function f(), which contains an explicit throw statement. Even though the throw statement is not executed when flag is false, Polyspace ignores the dynamic context and flags Caller.

**Correction**

When defining functions, specify them as noexcept only when all possible exceptions are handled within the function. Otherwise, specify them as noexcept(false). In cases where an exception is not raised in the dynamic context, justify this defect by using comments.

```
#include <stdexcept>
#include <typeinfo>
bool f(bool flag){
    if(flag==true)
    throw flag;
    return flag;

}
void LibraryFunc_noexcept_false() noexcept(false);
void SpecFalseCT() noexcept(false)// Compliant
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}
bool flag = false;
void Caller() noexcept{//Noncompliant // polyspace CERT-CPP:ERR55-CPP
//[Justified:Unset] "Exception is not thrown when flag is false"
    try {
        if(f(flag)){
            //...
        }
    } catch (int i) {
        //...
    }
}
```

- The function SpecFalseCT is now specified as noexcept(false) because it calls an external function that can raise exceptions. This function is compliant with this rule.
- The function f() does not raise an exception when flag is false. The function Caller honors its exception specification, but Polyspace flags it because Polyspace ignores dynamic context. This defect is justified by using a comment.

Guarantee exception safety

## Description

### Rule Definition

*Guarantee exception safety*

### Polyspace Implementation

The rule checker checks for **Exception violating class invariant**.

## Examples

### Exception violating class invariant

#### Issue

This defect occurs when a non-`noexcept` member function attempts to raise an exception after modifying any of the fields of the class. For instance, Polyspace flags a `throw()` statement or a `new` statement if they are used after modifying the internal state of a class.

#### Risk

To facilitate recovery from an exception while preserving the invariant of the relevant objects, you must design programs to have exception safety. The C++ standard allows These levels of exception safety:

- Basic Exception Safety: This level of exception safety requires that after raising an exception, the basic invariants of all objects are maintained in a valid state and no memory is leaked. If an operation has basic exception safety, then you can destroy or assign to an object after the operations, even if an exception has been raised. The operations in standard library offers at least basic exception safety.
- Strong Exception Safety: This level of exception safety requires that after raising an exception, the state of the program remains as it was before the exception. Operations with strong exception safety either succeed or exit with an exception and have no effects on the program.
- `nothrow`: This level of safety requires that an exception cannot occur in an operation.

Without at least the basic exception safety, exceptions might corrupt the state of a program, leave the program in an invalid state, or create memory leaks. Code that does not provide at least the basic exception safety guarantee is unsafe and defective.

#### Fix

To provide at least the basic exception safety in a function, modify the class invariant only when there can be no exceptions. When performing actions that might raise exceptions, use temporary objects that do not modify the original objects invariant.

#### Example

```
#include <cstdint>
#include <cstring>
```

```
template<typename T=int>
class myArray
{
public:
    myArray(){/*...*/}
    myArray(const myArray& rhs)
    {
        DeepCopyNC(rhs);
    }
    ~myArray()
    {
        delete[] array;
    }
    void DeepCopyNC(const myArray& rhs) // Noncompliant
    {
        if (this != &rhs) {
            delete[] array;
            array = nullptr;
            len = rhs.len;

            if (len > 0) {

                array = new T[len];
                std::memcpy(array, rhs.array, len * sizeof(T));
            }
        }
    }

private:
    T* array;
    std::size_t len;
};
extern     myArray<> c1{};
void foo(){

    myArray<> c2{c1};

}
```

This example shows a generic class template `myArray` that manages a raw array. The copy constructor of this class shows two implementation of deep copy. In the function `DeepCopyNC()`, the memory operations are performed after modifying the `this->array` and `this->len` fields. If the memory operation exits with an exception, the invariant of the original class is violated. Because the class invariant is violated by an exception, the function `DeepCopyNC()` cannot guarantee basic exception safety. Polyspace flags it.

#### Correction

To guarantee basic exception safety, modify the class invariant only when the memory operation succeeds with no exceptions, as shown in `DeepCopy`.

```
#include <cstdint>
#include <cstring>
template<typename T=int>
class myArray
{
public:
    myArray(){/*...*/}
    myArray(const myArray& rhs)
    {
        DeepCopy(rhs);
    }
    ~myArray()
    {
        delete[] array;
    }
    void DeepCopy(const myArray& rhs) // Compliant
    {
        T* eTmp = nullptr;

        if (rhs.len > 0) {
            eTmp = new T[rhs.len];
            std::memcpy(eTmp, rhs.array, rhs.len * sizeof(T));
        }

        delete[] array;
        array = eTmp;
        len = rhs.len;
    }

private:
    T* array;
    std::size_t len;
};
extern     myArray<> c1{};
void foo(){

    myArray<> c2{c1};

}
```

Do not leak resources when handling exceptions

## Description

### Rule Definition

*Do not leak resources when handling exceptions.*[19]

### Polyspace Implementation

The rule checker checks for these issues:

- **Resource leak caused by exception**
- **Object left in partially initialized state**
- **Bad allocation in constructor**

## Examples

### Resource leak caused by exception

#### Issue

**Resource leak caused by exception** occurs when a function raises an unhandled exception by using a `throw` statement but does not deallocate the resources that were allocated before the exception.

#### Risk

When a function raises an unhandled exception it immediately goes out of scope. If the function manages resources and they are not deallocated prior to raising the exception, the resource is leaked. Consider this code:

```
FILE* FilePtr;
//...
void foo(){
    FilePtr = fopen("some_file.txt", "r");
```

```
//...
    if(/*error condition*/)
    throw ERROR_CODE;
    //...
    fclose(FilePtr);
}
```

The allocated file pointer is intended to be deallocated before the function finishes execution. When an exception takes place, the function exits without deleting the pointer, which results in a resource leak.

**Fix**

To fix this defect, a function must set all resources that it allocates to a valid state before it goes out of scope. In the preceding code example, the function must delete the pointer `FilePtr` before the `throw` statement.

Instead of manually tracking the allocation and deallocation of resources, the best practice is to follow either the Resource Acquisition Is Initialization (RAII) or the Constructor Acquires, Destructor Releases (CADre) design patterns. Resource allocation is performed in constructors and resource deallocation is performed in destructors. The lifecycle of resources are controlled by scope-bound objects. When functions reach the end of their scope, the acquired resources are properly released. Consider this code:

```
void releaseFile(std::FILE* fp) { std::fclose(fp); }
std::unique_ptr<std::FILE, decltype(&releaseFile)> FilePtr;
//...
void foo(){
    FilePtr(std::fopen("some_file.txt"),&releaseFile);
//...
    if(/*error condition*/)
    throw ERROR_CODE;
}
```

The unique pointer `FilePTR` invokes the function `releaseFile` to delete the allocated resource once the function `foo` reaches the end of its scope. Whether the function exits normally with an unhandled exception, the allocated resources are deallocated.

C++ smart pointers such as `std::unique_ptr` and `std::shared_ptr` follow the RAII pattern. They simplify managing the lifecycle of resources during exception handling. Whenever possible, avoid using raw pointers.

**Example — Resource Leak Caused by Exception**

```
#include <cstdint>
#include <memory>
#include <stdexcept>
extern int sensorFlag() noexcept;
namespace Noncompliant{
    void func(){
        int* intPtr = new int;
        int data = sensorFlag();
        if(data==-1)//Error
        throw std::runtime_error("Unexpected value");//Noncompliant
        //...
        delete intPtr;
    }
}
```

In this example, the function `Noncompliant::func()` manages the raw pointer `inPtr`. The function allocates memory for it, and then releases the memory after some operations. The function exits with an exception when `data` is `-1`. In this case, the function exits before releasing the allocated memory, resulting in a memory leak. Polyspace flags the `throw` statement.

#### Correction — Deallocate Resources Before `throw` Statements

To prevent memory leak, the allocated memory must be released before raising the exception, as shown in `Compliant::func`.

The best practice is to follow the RAII design pattern. For instance, when C++14 is available, use `unique_ptr` instead of a raw pointer. `BestPractice::func` shows an implementation of `func` that follows the RAII pattern. The memory lifecycle is managed by the object itself. That is, once `func` is out of scope, the smart pointer `intPtr` deletes itself and releases the memory. Because the memory management is performed correctly by the smart pointer, `BestPractice::func` is simpler and safer.

```
#include <cstdint>
#include <memory>
#include <stdexcept>

extern int sensorFlag() noexcept;
 namespace Compliant{
    void func(){
        int* intPtr = new int;
        int data = sensorFlag();
        if(data==-1){//Error
            delete intPtr;
            throw std::runtime_error("Unexpected value");//Compliant
        }
        //...
        delete intPtr;
    }
}
namespace BestPractice{// C++14
    void func(){
        std::unique_ptr<int> intPtr = std::make_unique<int>();
        int data = sensorFlag();
        if(data==-1){//Error
            throw std::runtime_error("Unexpected value");//Compliant
        }
        //...

    }
}
```

### Object left in partially initialized state

#### Issue

**Object left in partially initialized state** occurs when a `noexcept(false)` constructor raises an unhandled exception but does not deallocate the resources that were allocated before the exception. This issue is detected only in classes that your code uses.

#### Risk

A constructor goes out of scope when it raises an unhandled exception. If the constructor manages resources and they are not deallocated prior to raising the exception, the object is left in a partially initialized state. This behavior is undefined and can produce unexpected results.

#### Fix

To fix this defect, keep track of the allocated resources and deallocate them before raising exception.

Instead of manually tracking the allocation and deallocation of resources, the best practice is to follow either the Resource Acquisition Is Initialization (RAII) or the Constructor Acquires, Destructor Releases (CADre) design patterns. Resource allocation is performed in constructors and resource deallocation is performed in destructors. The lifecycle of resources are controlled by scope-bound objects. When functions reach the end of their scope, the acquired resources are properly released. Consider this code:

```
class complex_ptr{
    complex_ptr() = default;
    ~complex_ptr() = default;
    private:
    std::unique_ptr<std::complex<double> > z;

};
```

The class `complex_ptr` uses the implicit default constructor because the resource management is performed by the smart pointer class `unique_ptr`. The default constructor does not raise exceptions and the object is not left in a partially initialized state.

C++ smart pointers such as `std::unique_ptr` and `std::shared_ptr` follow the RAII pattern. They simplify managing the lifecycle of resources during exception handling. Whenever possible, avoid using raw pointers.

#### Example — Partially Constructed Object Caused by Exceptions

```
##include<cstdlib>
#include<exception>

class complex_ptr{

    complex_ptr(){
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            throw std::exception(); //Noncompliant
        }
    }
    ~complex_ptr(){
        free(real);
        free(imag);
    }
    private:
    double* real;
    double* imag;

};
```

```
void foo(void){
    complex_ptr Z;
    //...
}
```

In this example, the class `complex_ptr` is responsible for allocating and deallocating two raw pointers to `double`. The constructor `complex_ptr::complex_ptr()` terminates with an exception when a memory allocation operation fails. The constructor exits without deallocating the allocated resources, resulting in a partially constructed object. Polyspace flags the `throw` statement in the constructor.

#### Correction — Deallocate Resources Before raising Exceptions in Constructors

To correct this defect, deallocate the allocated resources before raising exceptions in constructor. In this code, before raising the exception, the constructor deallocates the allocated memory by calling `deallocate()`. This constructor is compliant with this rule.

```
#include<cstdlib>
#include<exception>

class complex_ptr{

    complex_ptr(){
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            deallocate();
            throw std::exception();  //Compliant
        }
    }
    void deallocate(){
        free(real);
        free(imag);
    }
    ~complex_ptr(){
        deallocate();
    }
    private:
    double* real;
    double* imag;

};

void foo(void){
    complex_ptr Z;
    //...
}
```

### Bad allocation in constructor

#### Issue

**Bad allocation in constructor** occurs when a `new` operation is performed in a constructor without using the argument `std::nothrow` or outside exception handling blocks such as `try` or `function-try`.

**Risk**

The new operations might fail and raise a std::bad_alloc exception. If these statements are not enclosed in a try or function-try block, the exception might cause an abrupt termination of a constructor. Such an abrupt termination might leave the object in a partially constructed state, which is undefined behavior in the C++ standard.

**Fix**

When using the new operator, enclose it in a try or function-try block.

**Example — Bad Allocation in Constructors**

```
#include<cstdlib>
#include <stdexcept>
#include <new>
 class complex_ptr{

    complex_ptr(): real(new double), imag(new double){ //Noncompliant

    }
    ~complex_ptr(){
        delete real;
        delete imag;
    }
    private:
    double* real;
    double* imag;

};
void foo(void){
    complex_ptr Z;
    //...
}
```

In this example, the constructor of complex_ptr performs new operations that might raise exceptions. Because the constructor has no mechanism for handling these exceptions, they might cause the constructor to abruptly terminate. Such termination might leave the object in partially defined state because the allocated resources are not deallocated. Polyspace flags the constructor.

**Correction — Handle Exceptions Arising from new Operations in Constructors**

To correct this defect, perform the new operation in a try or function-try block.

```
#include<cstdlib>
#include <stdexcept>
#include <new>
 class complex_ptr{

    complex_ptr()try: real(new double), imag(new double){    //Compliant

    }catch(std::bad_alloc){
        //...
    }
    ~complex_ptr(){
        delete real;
        delete imag;
    }
    private:
```

```
    double* real;
    double* imag;

};
void foo(void){
    complex_ptr Z;
    //...
}
```

Handle all exceptions thrown before main() begins executing

## Description

### Rule Definition

*Handle all exceptions thrown before main() begins executing.*

### Polyspace Implementation

The rule checker checks for **Exceptions raised during program startup.**

## Examples

### Exceptions raised during program startup

#### Issue

This issue occurs when an exception might arise during the construction of global and static variables before `main()` begins executing. If an exception is raised during the startup phase, you cannot write an exception handler that the compiler can execute to handle the raised exception. This exception becomes an unhandled exception. For instance, you might implement `main()` as a `function-try-catch` block to handle exceptions. None of the `catch` blocks can handle exceptions raised during the startup phase and these raised exceptions become unhandled exceptions.

When you invoke callable entities to initialize or declare global or static variables, these entities are executed during program startup. Polyspace checks whether these entities might raise exceptions during program startup by making certain assumptions.

- Function: When you call an initializer function or constructor directly to initialize a global or static variable, Polyspace checks whether the function raises an exception and flags the variable declaration if the function might raise an exception. Polyspace deduces whether a function might raise an exception regardless of its exception specification. For instance, if a `noexcept` constructor raises an exception, Polyspace flags it. If the initializer or constructor calls another function, Polyspace assumes the called function might raise an exception only if it is specified as `noexcept(<false>)`. Some standard library functions, such as the constructor of `std::string`, use pointers to functions to perform memory allocation, which might raise exceptions. Polyspace does not flag the variable declaration when these functions are used.
- External function: When you call external functions to initialize a global or static variable, Polyspace flags the declaration if the external function is specified as `noexcept(<false>)`.
- Virtual function: When you call a virtual function to initialize a global or static variable, Polyspace flags it if the virtual function is specified as `noexcept(<false>)` in any derived class. For instance, if you use a virtual initializer function that is declared as `noexcept(<true>)` in the base class, and `noexcept(<false>)` in a subsequent derived class, Polyspace flags it.
- Pointers to function: When you use a pointer to a function to initialize a global or static variable, Polyspace assumes that pointer to a function do not raise exceptions.

Polyspace ignores:

- Exceptions raised in destructors
- Exceptions raised in `atexit()` operations

Polyspace also ignores the dynamic context when checking for exceptions. For instance, you might initialize a global or static variable by using a function that raises exceptions only in a certain dynamic context. Polyspace flags such a declaration even if the exception might never be raised. You can justify such a violation by using comments in Polyspace.

**Risk**

When exceptions are not handled, the compiler might abnormally terminate the code execution without unwinding the stack depending on the set of hardware and software that you use. Consider this code where the construction of the static object `obj` might cause an exception.

```
class A{
    A(){throw(0);}
};

static A obj;

main(){
    //...
}
```

The static object `obj` is constructed by calling `A()` before `main()` starts. When `A()` raises an exception, a handler cannot be matched with the raised exception. Based on the set of software and hardware that you use, such an exception can result in program termination without stack unwinding, leading to memory leak and security vulnerabilities.

**Fix**

Avoid operations that might raise an exception in the parts of your code that might be executed before startup or after termination of the program. For instance, avoid operations that might raise exceptions in the constructor and destructor of static or global objects.

**Example**

Consider this code where the construction of the global pointer `arr` requires dynamic memory allocation.

```
#include <stdexcept>
void* alloc(size_t s) noexcept {
    return new int[s];
}
int* arr = (int*)alloc(5);//Noncompliant
int main(){
    //..
    return 0;
}
```

Dynamic memory allocation by using the `new` operator can raise an exception. Because constructing `arr` can raise an exception before `main()` begins execution, Polyspace flags the declaration.

**Correction**

Avoid operations that might raise exception when constructing global objects. For instance, you can initialize the global pointer `arr` by using a `nullptr`. Then allocate memory for `arr` in `main()` in a `try-catch` code block.

```
#include <stdexcept>
#include<vector>
void* alloc(size_t s) noexcept {
    return new int[s];
}
int* arr =nullptr;
int main(){
    try{
        arr =  (int*)alloc(5);
    }
    catch(std::bad_alloc e){
        //..
    }
    //..
    return 0;
}
```

In this case, the dynamic memory allocation operation raises the `std::bad_alloc` exception in `main()` where it can be handled by the catch blocks of code.

Do not throw an exception across execution boundaries

## Description

### Rule Definition

*Do not throw an exception across execution boundaries.*

### Polyspace Implementation

The rule checker checks for **Exceptions raised from library interface**.

## Examples

### Exceptions raised from library interface

#### Issue

This issue occurs when both of these conditions are met:

- A function is specified to be across an execution boundary.
- The function raises an exception.

Polyspace assumes that library interface functions are across an execution boundary. A violation is not raised if a `new` operator in a library interface function raises a `std::bad_alloc` exception.

To use this checker correctly, specify the library interface functions in your. Declare a function *`foo()`* as a library interface function by setting their `visibility` attribute. For instance:

- GNU and Clang compiler: `void __attribute__((visibility("default"))) foo(){/*...*/}`
- Visual Studio: `void __declspec(dllexport) foo(){/**.../}`

If you do not explicitly specify a function as visible, Polyspace assumes that it is not part of a library interface.

#### Risk

Exception handling requires interoperability between the functions that raise the exception and the functions that handle the raised exceptions. Library functions might implement exception handling by using incompatible interfaces. For instance:

```
// lib.h
void foo() noexcept(false);
//lib.cpp
void foo() noexcept(false){
  //...
  throw 42;
}
//App.cpp
#include"lib.h"
```

```
int main(){
  try{
    foo();
  }catch(int& e){
    //handle exception
  }
}
```

Say you use the library interface `lib.cpp` that has been compiled by using a GCC 4.9 compiler. Then you compile the application `App.cpp` by using Microsoft Visual Studio. These two portions of your code use incompatible exception-handling interfaces. If the library interface function raises an exception, it is not handled and terminates the application unexpectedly.

**Fix**

Avoid raising exceptions in library interfaces. Instead of raising exceptions, return different error codes to handle unexpected situations.

**Example — Exception Arising from Visible Function**

```
#include<exception>

void __attribute__((visibility("default"))) foo(int rd) noexcept(false) { //Noncompliant
    if (rd==-1)
        throw std::exception();
}
```

In this example, the `visibility` attribute of the function `foo()` is set to `default`. Because `foo()` might be used in modules that have different exception handling mechanisms, exceptions raised by `foo()` might remain unhandled. Avoid raising exceptions from visible functions functions.

**Correction — Use Other Methods to Handle Errors**

Use other methods for handling errors. For instance, set an error flag and return an error code when a logic error occurs in the code.

```
#include<exception>
int FLAG;

int __attribute__((visibility("default"))) foo(bool rd) noexcept(true) {
    if (rd==-1){
        FLAG = 52;
        return -1;//Compliant
    }
}
```

Catch exceptions by lvalue reference

## Description

### Rule Definition

*Catch exceptions by lvalue reference.*

### Polyspace Implementation

The rule checker checks for **Exception object initialized by copy in catch statement**.

## Examples

### Exception object initialized by copy in `catch` statement

#### Issue

The issue occurs when a `catch` statement

```
catch (exceptionType customExc) {
  //...
}
```

initializes the exception object `customExc` by copy.

#### Risk

If *`exceptionType`* has a nontrivial copy constructor or if the exception thrown belongs to a class derived from *`exceptionType`*, the copying can produce object slicing or undefined behavior.

#### Fix

Catch the exception by reference or `const` reference.

```
catch (exceptionType &customExc) {
  //...
}
```

#### Example - Derived Class Exception Caught by Value

```
#include <exception>
#include <string>
#include <typeinfo>
#include <iostream>

// Class declarations
class BaseExc {
public:
    explicit BaseExc();
    virtual ~BaseExc() {};
protected:
    BaseExc(const std::string& type);
private:
    std::string _id;
};

class IOExc: public BaseExc {
public:
    explicit IOExc();
};

//Class method declarations
BaseExc::BaseExc():_id(typeid(this).name()) {
}
BaseExc::BaseExc(const std::string& type): _id(type) {
}
IOExc::IOExc(): BaseExc(typeid(this).name()) {
}

int input(void);

int main(void) {
    int rnd = input();
    try {
        if (rnd==0) {
            throw IOExc();
        } else {
            throw BaseExc();
        }
    }

    catch(BaseExc exc) {  //Noncompliant
        std::cout << "Intercept BaseExc" << std::endl;
    }
    return 0;
}
```

In this example, the `catch` statement takes a `BaseExc` object by value. Catching exceptions by value causes copying of the object. The copying can cause:

- Undefined behavior of the exception if it fails.
- Object slicing if an exception of the derived class `IOExc` is caught.

**Correction — Catch Exceptions by Reference**

One possible correction is to catch exceptions by reference.

```
#include <exception>
#include <string>
#include <typeinfo>
#include <iostream>

// Class declarations
class BaseExc {
public:
    explicit BaseExc();
    virtual ~BaseExc() {};
protected:
    BaseExc(const std::string& type);
private:
    std::string _id;
};

class IOExc: public BaseExc {
public:
    explicit IOExc();
};

//Class method declarations
BaseExc::BaseExc():_id(typeid(this).name()) {
}
BaseExc::BaseExc(const std::string& type): _id(type) {
}
IOExc::IOExc(): BaseExc(typeid(this).name()) {
}

int input(void);

int main(void) {
    int rnd = input();
    try {
        if (rnd==0) {
            throw IOExc();
        } else {
            throw BaseExc();
        }
    }

    catch(BaseExc& exc) {
        std::cout << "Intercept BaseExc" << std::endl;
    }
    return 0;
}
```

Do not invoke virtual functions from constructors or destructors

## Description

### Rule Definition

*Do not invoke virtual functions from constructors or destructors.*[20]

### Polyspace Implementation

The rule checker checks for **Virtual function call from constructors and destructors**.

## Examples

### Virtual function call from constructors and destructors

#### Issue

**Virtual function call from constructors and destructors** occurs when you invoke virtual functions in a constructor or a destructor with possibly unexpected results.

When you call virtual functions in the constructor or destructor of a class in a hierarchy, it is not clear which instance of the virtual function you intend to invoke. Calls to virtual functions in a constructor or a destructor resolves to the implementation of the virtual function in the currently executing class instead of the most derived override.

There are two cases where calling virtual functions from a constructor or destructor does not raise this defect.

- When you use the explicitly qualified ID to call the virtual function. Consider this code:

  ```
  Base(){
      Base::foo();
  }
  ```

  The call to `Base::foo` uses the explicitly qualified ID of the function. This call is compliant with this rule because it explicitly states that the implementation of `foo` belonging to `Base` is invoked.

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

- When the you specify the called virtual function as `final` in the currently executing class. Consider this code:

  ```
  Base(){
      foo();
  }
  //...
  void foo() override final{
  //...
  }
  ```

  In this case, a call to `foo` implies a call to `Base::foo` because the function is specified as the final override.

**Risk**

When you call a virtual function, you expect the compiler to resolve the call to the most derived override of the virtual function at runtime. Unlike in other functions, virtual function calls in constructors and destructors are resolved differently, resulting in unexpected behavior. Invoking virtual functions in constructor and destructors might cause undefined behavior, resulting in a memory leak and security vulnerabilities. Consider this code:

```
#include <iostream>

class Base
{
public:
    Base() { foo(); }  //Noncompliant
    ~Base(){bar();}    //Noncompliant
    virtual void foo() {
        std::cout<<"Base Constructor\n";
    }
    virtual void bar(){
        std::cout<<"Base Destructor\n";
    }

};
class Derived : public Base
{
public:
    Derived() : Base() {}
    ~Derived() = default;
    virtual void foo() {
        std::cout<<"Derived constructor\n";
    }
    virtual void bar() {
        std::cout<<"Derived Constructor\n";
    }
};
int main(){
    Derived d;
    return 1;
}
```

The constructor of `d` calls the constructor for `Base` class, which invokes the virtual function `foo`. Because the derived class is not constructed yet, the compiler cannot invoke `Derived::foo`. Only the function `Base::foo()` is invoked. Similarly, when the virtual function `bar` is invoked in the destructor of `Base`, the derived class `Derived` is already destroyed. The compiler cannot invoke `Derived::bar`. Only the function `Base::bar` is invoked. The output of this code is:

```
Base Constructor
Base Destructor
```

instead of:

```
Base Constructor
Derived constructor
Derived Constructor
Base Destructor
```

The portion of `d` belonging to the class `Derived` is neither allocated nor deallocated. This behavior might result in memory leaks or security vulnerabilities.

**Fix**

To fix this issue, avoid calling virtual functions in constructors and destructors. For typical constructor or destructor tasks such as memory allocation and deallocation, initialization, or message logging, use functions that are specific to each class in a hierarchy.

**Example — Class-Specific Memory Management**

```
#include <iostream>

class Base {
public:
    Base()
    {
        allocator();  //Noncompliant
    }
    virtual ~Base()
    {
        deallocator();  //Noncompliant
    }

    virtual void allocator(){
        //...
    }
    virtual void deallocator(){
        //...
    }
};

class Derived : public Base {
public:
    Derived() : Base() {}
    virtual ~Derived() = default;
protected:
    void allocator() override
    {
        Base::allocator();
        // Get derived resources...
    }
    void deallocator() override
    {
        // Release derived resources...
        Base::deallocator();
    }
};

int main(){
    Derived dObj;
    //...
    return 1;
}
```

In this example, the code attempts class-specific memory management by implementing the functions `allocator` and `deallocator` as virtual. A call to these functions does not resolve to the most derived override.

- During the construction of the `Derived` object `dObj`, only the function `Base::allocator()` is invoked. Because the `Derived` class is not constructed yet, the function `Derived::allocator` is not invoked.
- During the destruction of `dObj`, only the function `Base::deallocator` is invoked because the class `Derived` is already destroyed.

Because of the use of virtual functions in the constructor and destructor of `dObj`, the `Derived` portion of `dObj` is neither allocated nor deallocated. This behavior is unexpected and might lead to memory leaks and security vulnerabilities.

#### Correction — Class-Specific Memory Management

One possible correction is to use class-specific nonvirtual functions for tasks that are commonly performed in constructors and destructors. In this code, allocation and deallocation tasks are performed by class-specific nonvirtual functions.

```
#include <iostream>

class Base {
public:
    Base()
    {
        allocator_base();
    }
    virtual ~Base()
    {
        deallocator_base();
    }
protected:
    void allocator_base(){
        // Allocate base resources
    }
    void deallocator_base(){
        // Deallocate base resources
    }
};

class Derived : public Base {
public:
    Derived(){
        allocator_derived();
    }
    virtual ~Derived(){
        deallocator_derived();
    }
protected:
    void allocator_derived()
    {
        // Allocate derived resources...
    }
    void deallocator_derived()
    {
        // Deallocate derived resources...
    }
};

int main(){
    Derived dObj;
    //...
    return 1;
}
```

Do not slice derived objects

## Description

### Rule Definition

*Do not slice derived objects.*

### Polyspace Implementation

The rule checker checks for **Object slicing**.

## Examples

### Object slicing

#### Issue

**Object slicing** occurs when you pass a derived class object by value to a function, but the function expects a base class object as parameter.

#### Risk

If you pass a derived class object *by value* to a function, you expect the derived class copy constructor to be called. If the function expects a base class object as parameter:

- The base class copy constructor is called.
- In the function body, the parameter is considered as a base class object.

In C++, `virtual` methods of a class are resolved at run time according to the actual type of the object. Because of object slicing, an incorrect implementation of a `virtual` method can be called. For instance, the base class contains a `virtual` method and the derived class contains an implementation of that method. When you call the `virtual` method from the function body, the base class method is called, even though you pass a derived class object to the function.

#### Fix

One possible fix is to pass the object by reference or pointer. Passing by reference or pointer does not cause invocation of copy constructors. If you do not want the object to be modified, use a `const` qualifier with your function parameter.

Another possible fix is to overload the function with another function that accepts the derived class object as parameter.

#### Example - Function Call Causing Object Slicing

```
#include <iostream>

class Base {
public:
    explicit Base(int b) {
        _b = b;
    }
    virtual ~Base() {}
    virtual int update() const;
protected:
    int _b;
};

class Derived: public Base {
public:
    explicit Derived(int b):Base(b) {}
    int update() const;
};

//Class methods definition

int Base::update() const {
    return (_b + 1);
}

int Derived::update() const {
    return (_b -1);
}

//Other function definitions
void funcPassByValue(const Base bObj) {
    std::cout << "Updated _b=" << bObj.update() << std::endl;
}

int main() {
    Derived dObj(0);
    funcPassByValue(dObj);       //Function call slices object //Noncompliant
    return 0;
 }
```

In this example, the call `funcPassByValue(dObj)` results in the output `Updated _b=1` instead of the expected `Updated _b=-1`. Because `funcPassByValue` expects a `Base` object parameter, it calls the `Base` class copy constructor.

Therefore, even though you pass the `Derived` object `dObj`, the function `funcPassByValue` treats its parameter `b` as a `Base` object. It calls `Base::update()` instead of `Derived::update()`.

**Correction — Pass Object by Reference or Pointer**

One possible correction is to pass the `Derived` object `dObj` by reference or by pointer. In the following, corrected example, `funcPassByReference` and `funcPassByPointer` have the same objective as `funcPassByValue` in the preceding example. However, `funcPassByReference` expects a reference to a `Base` object and `funcPassByPointer` expects a pointer to a `Base` object.

Passing the `Derived` object `d` by a pointer or by reference does not slice the object. The calls `funcPassByReference(dObj)` and `funcPassByPointer(&dObj)` produce the expected result `Updated _b=-1`.

```
#include <iostream>

class Base {
```

```
public:
    explicit Base(int b) {
        _b = b;
    }
    virtual ~Base() {}
    virtual int update() const;
protected:
    int _b;
};

class Derived: public Base {
public:
    explicit Derived(int b):Base(b) {}
    int update() const;
};

//Class methods definition

int Base::update() const {
    return (_b + 1);
}

int Derived::update() const {
    return (_b -1);
}

//Other function definitions
void funcPassByReference(const Base& bRef) {
    std::cout << "Updated _b=" << bRef.update() << std::endl;
}

void funcPassByPointer(const Base* bPtr) {
    std::cout << "Updated _b=" << bPtr->update() << std::endl;
}

int main() {
    Derived dObj(0);
    funcPassByReference(dObj);       //Function call does not slice object
    funcPassByPointer(&dObj);       //Function call does not slice object
    return 0;
 }
```

**Note** If you pass by value, because a copy of the object is made, the original object is not modified. Passing by reference or by pointer makes the object vulnerable to modification. If you are concerned about your original object being modified, add a `const` qualifier to your function parameter, as in the preceding example.

Do not delete a polymorphic object without a virtual destructor

## Description

### Rule Definition

*Do not delete a polymorphic object without a virtual destructor.*

### Polyspace Implementation

The rule checker checks for **Base class destructor not virtual**.

## Examples

### Base class destructor not virtual

#### Issue

**Base class destructor not virtual** occurs when a class has `virtual` functions but not a `virtual` destructor.

#### Risk

The presence of `virtual` functions indicates that the class is intended for use as a base class. However, if the class does not have a `virtual` destructor, it cannot behave polymorphically for deletion of derived class objects.

If a pointer to this class refers to a derived class object, and you use the pointer to delete the object, only the base class destructor is called. Additional resources allocated in the derived class are not released and can cause a resource leak.

#### Fix

One possible fix is to always use a `virtual` destructor in a class that contains `virtual` functions.

#### Example - Base Class Destructor Not Virtual

```
class Base {         //Noncompliant
        public:
                Base(): _b(0) {};
                virtual void update() {_b += 1;};
        private:
                int _b;
};

class Derived: public Base {
        public:
                Derived(): _d(0) {};
                ~Derived() {_d = 0;};
                virtual void update() {_d += 1;};
        private:
                int _d;
};
```

In this example, the class `Base` does not have a `virtual` destructor. Therefore, if a `Base*` pointer points to a `Derived` object that is allocated memory dynamically, and the `delete` operation is performed on that `Base*` pointer, the `Base` destructor is called. The memory allocated for the additional member `_d` is not released.

The defect appears on the base class definition. Following are some tips for navigating in the source code:

- To find classes derived from the base class, right-click the base class name and select **Search For All References**. Browse through each search result to find derived class definitions.
- To find if you are using a pointer or reference to a base class to point to a derived class object, right-click the base class name and select **Search For All References**. Browse through search results that start with `Base*` or `Base&` to locate pointers or references to the base class. You can then see if you are using a pointer or reference to point to a derived class object.

#### Correction — Make Base Class Destructor Virtual

One possible correction is to declare a `virtual` destructor for the class `Base`.

```
class Base {
        public:
                Base(): _b(0) {};
                virtual ~Base() {_b = 0;};
                virtual void update() {_b += 1;};
        private:
                int _b;
};

class Derived: public Base {
        public:
                Derived(): _d(0) {};
                ~Derived() {_d = 0;};
                virtual void update() {_d += 1;};
        private:
                int _d;
};
```

Write constructor member initializers in the canonical order

## Description

### Rule Definition

*Write constructor member initializers in the canonical order.*

### Polyspace Implementation

The rule checker checks for **Members not initialized in canonical order**.

## Examples

### Members not initialized in canonical order

#### Description

**Members not initialized in canonical order** occurs when the initializer list of a class constructor:

- Does not initialize data members of the class in the order in which they are declared.

  For instance:

  ```
  class aClass {
     int var1;
     int var2;
  public:
     aClass(int val): var2(val), var1(val) {}
  };
  ```
- Does not call base class constructors in the order in which they appear in the base-specifier list.

  For instance:

  ```
  class aClass: baseClass1, baseClass2 {
     aClass(int val): baseClass2(val), baseClass1(val) {}
  }
  ```

#### Risk

The order in which data members or base class constructors appear in the initializer list does not reflect the actual order of initialization. Data members are initialized in the order of declaration and base class constructors are called in the order in which they appear in the base-specifier list.

However, you or another developer can mistake the order in the initializer list as the actual initialization order. As a result, you might introduce dependencies between the initializations that results in reading an uninitialized region of memory. For instance, this initializer list might indicate that `bVar` is first initialized with the constructor argument `x` and then `aVar` is initialized with `bVar`:

```
class aClass {
```

```
   int aVar;
   int bVar;
public:
   aClass(int x): bVar(x), aVar(bVar) {}
};
```

However, the initialization happens in the order of declaration and an uninitialized `bVar` is read first.

#### Fix

In the initializer list of a class constructor:

- Specify class data members in the same order as you declare them in the class

  For instance:

  ```
  class aClass {
     int var1;
     int var2;
  public:
     aClass(int val): var1(val), var2(val) {}
  };
  ```
- Call base constructors in the same order as you specify them in the base-specifier list.

  For instance:

  ```
  class aClass: baseClass1, baseClass2 {
     aClass(int val): baseClass1(val), baseClass2(val) {}
  }
  ```

Gracefully handle self-copy assignment

## Description

### Rule Definition

*Gracefully handle self-copy assignment.*

### Polyspace Implementation

The rule checker checks for **Self assignment not tested in operator**.

## Examples

### Self assignment not tested in operator

#### Issue

**Self assignment not tested in operator** occurs when you do not test if the argument to the copy assignment operator of an object is the object itself.

#### Risk

Self-assignment causes unnecessary copying. Though it is unlikely that you assign an object to itself, because of aliasing, you or users of your class cannot always detect a self-assignment.

Self-assignment can cause subtle errors if a data member is a pointer and you allocate memory dynamically to the pointer. In your copy assignment operator, you typically perform these steps:

1. Deallocate the memory originally associated with the pointer.

   ```
   delete ptr;
   ```
2. Allocate new memory to the pointer. Initialize the new memory location with contents obtained from the operator argument.

   ```
    ptr = new ptrType(*(opArgument.ptr));
   ```

If the argument to the operator, `opArgument`, is the object itself, after your first step, the pointer data member in the operator argument, `opArgument.ptr`, is not associated with a memory location. `*opArgument.ptr` contains unpredictable values. Therefore, in the second step, you initialize the new memory location with unpredictable values.

#### Fix

Test for self-assignment in the copy assignment operator of your class. Only after the test, perform the assignments in the copy assignment operator.

#### Example - Missing Test for Self-Assignment

```
class MyClass1 { };
class MyClass2 {
public:
```

```
    MyClass2()                : p_(new MyClass1())      { }
    MyClass2(const MyClass2& f)   : p_(new MyClass1(*f.p_)) { }
    ~MyClass2()                {
        delete p_;
    }
    MyClass2& operator= (const MyClass2& f) //Noncompliant
    {
        delete p_;
        p_ = new MyClass1(*f.p_);
        return *this;
    }
private:
    MyClass1* p_;
};
```

In this example, the copy assignment operator in `MyClass2` does not test for self-assignment. If the parameter `f` is the current object, after the statement `delete p_`, the memory allocated to pointer `f.p_` is also deallocated. Therefore, the statement `p_ = new MyClass1(*f.p_)` initializes the memory location that `p_` points to with unpredictable values.

#### Correction — Test for Self-Assignment

One possible correction is to test for self-assignment in the copy assignment operator.

```
class MyClass1 { };
class MyClass2 {
public:
    MyClass2()                : p_(new MyClass1())      { }
    MyClass2(const MyClass2& f)   : p_(new MyClass1(*f.p_)) { }
    ~MyClass2()                {
        delete p_;
    }
    MyClass2& operator= (const MyClass2& f)
    {
        if(&f != this) {
           delete p_;
           p_ = new MyClass1(*f.p_);
        }
        return *this;
    }
private:
    MyClass1* p_;
};
```

Do not use pointer-to-member operators to access nonexistent members

## Description

### Rule Definition

*Do not use pointer-to-member operators to access nonexistent members.*[21]

### Polyspace Implementation

The rule checker checks for **Pointer to member accessing non-existent class members**

## Examples

### Pointer to Member Accessing Non-Existent Class Members

#### Issue

This issue occurs when you use of pointer-to-member operators in these instances:

- You cast a pointer-to-member type to another pointer-to-member type which does not contain the class member pointed to. For instance, in this code snippet, pointer-to-member `ptrToMember` is obtained from `myObj::f` but is then upcast to `baseObj::*` which does not contain a method `f`.

```
class baseObj {
  public:
    virtual ~baseObj() = default;
};

class myObj : public baseObj {
  public:
    void f();
};

void func() {
    baseObj* foo = new baseObj();
```

*ANY MATERIAL OF CARNEGIE MELLON UNIVERSITY AND/OR ITS SOFTWARE ENGINEERING INSTITUTE CONTAINED HEREIN IS FURNISHED ON AN "AS-IS" BASIS. CARNEGIE MELLON UNIVERSITY MAKES NO WARRANTIES OF ANY KIND, EITHER EXPRESSED OR IMPLIED, AS TO ANY MATTER INCLUDING, BUT NOT LIMITED TO, WARRANTY OF FITNESS FOR PURPOSE OR MERCHANTABILITY, EXCLUSIVITY, OR RESULTS OBTAINED FROM USE OF THE MATERIAL. CARNEGIE MELLON UNIVERSITY DOES NOT MAKE ANY WARRANTY OF ANY KIND WITH RESPECT TO FREEDOM FROM PATENT, TRADEMARK, OR COPYRIGHT INFRINGEMENT.*

*This software and associated documentation has not been reviewed nor is it endorsed by Carnegie Mellon University or its Software Engineering Institute.*

```
    void (baseObj::*ptrToMember)() =
        static_cast<void (baseObj::*)()>(&myObj::f); //Noncompliant
    (foo->*ptrToMember)();
}
```

Polyspace does not flag the casting operation if the type being cast to inherits from the other type. For example, in the preceding code, if `baseObj` inherits from `myObj`.

- The second operand of the pointer-to-member operator is a null pointer. For instance, in this code snippet, `ptrToMember` is declared but not initialized and defaults to a null pointer.

```
class baseObj {
  public:
    virtual ~baseObj() = default;
};
static void (baseObj::*ptrToMember)(); //Not initialized

void func() {
    baseObj* foo = new baseObj();

    (foo->*ptrToMember)(); //Noncompliant
}
```

#### Risk

The use of pointer-to-member operators results in undefined behavior in these cases:

- The dynamic type of the first operand does not contain the member referred to by the second operand.
- The second operand pointer is null.

#### Fix

Do not cast a pointer-to-member to a type that does not contain the class member pointed to, and do not use a null pointer as the second operand of the pointer to member operator.

#### Example — Pointer-to-Member Accesses Non-Existent Class Member

```
class Base {
  public:
    void f() {
    }
};

class Derived : public Base {
  public:
    int myVar;
};

void func() {
    Base myObj;
    auto ptrToMethod =
        static_cast<void (Base::*)()>(&Derived::f); // Compliant
    auto ptrToMember =
        static_cast<int(Base::*)>(&Derived::myVar); // Noncompliant

    (myObj.*ptrToMethod)(); // OK, equivalent to myObj.f()
    myObj.*ptrToMember;     // Undefined behavior
}
```

In this example, Polyspace flags the casting of `ptrToMember`, which is obtained from `Derived::myVar`, to `Base::*` because this class does not contain a member `myVar`. If you execute the code, the call `myObj.*ptrToMember;` results in undefined behavior.

Polyspace does not flag the casting of `ptrToMethod` to `Base::*` because class `Derived` inherits method `f` from `Base`.

**Correction — Use Correct Type for Underlying Object**

```
class Base {
  public:
    void f() {
    }
};

class Derived : public Base {
  public:
    int myVar;
};

void func() {
    Derived myObj;
    auto ptrToMethod =
        static_cast<void (Base::*)()>(&Derived::f); // Compliant
    int (Derived::*ptrToMember) = &Derived::myVar;

    (myObj.*ptrToMethod)(); // OK, equivalent to myObj.f()
    myObj.*ptrToMember; // Compliant
}
```

One possible correction is to use the correct type for the object that you use as the first operator of the pointer-to-member operator. In the preceding code, `myObj` is of type `Derived` and the casting is no longer necessary in the declaration of `ptrToMember`.

Prefer special member functions and overloaded operators to C Standard Library functions

## Description

### Rule Definition

*Prefer special member functions and overloaded operators to C Standard Library functions.*

### Polyspace Implementation

The rule checker checks for **Bytewise operations on nontrivial class object**.

## Examples

### Bytewise operations on nontrivial class object

#### Issue

**Bytewise operations on nontrivial class object** occurs when you use C Standard library functions to perform bytewise operation on non-trivial or non-standard layout class type objects. For definitions of trivial and standard layout classes, see the C++ Standard, [class], paragraphs 6 and 7 respectively.

The checker raises a defect you initialize or copy non-trivial class type objects using these functions:

- `std::memset`
- `std::memcpy`
- `std::strcpy`
- `std::memmove`

Or when you compare non-standard layout class type objects using these functions:

- `std::memcmp`
- `std::strcmp`

**Bytewise operations on nontrivial class object** raises no defect if the bytewise operation is performed through an alias. For example no defect is raised in the bytewise comparison and copy operations in this code. The bytewise operations use `dptr` and `sptr`, the aliases of non-trivial or non-standard layout class objects `d` and `s`.

```
void func(NonTrivialNonStdLayout *d, const NonTrivialNonStdLayout *s)
{
   void* dptr = (void*)d;
   const void* sptr = (void*)s;
   // ...
   // ...
   // ...
   if (!std::memcmp(dptr, sptr, sizeof(NonTrivialNonStdLayout))) {
     (void)std::memcpy(dptr, sptr, sizeof(NonTrivialNonStdLayout));
      // ...
   }
}
```

### Risk

Performing bytewise comparison operations by using C Standard library functions on non-trivial or non-standard layout class type object might result in unexpected values due to implementation details. The object representation depends on the implementation details, such as the order of private and public members, or the use of virtual function pointer tables to represent the object.

Performing bytewise setting operations by using C Standard library functions on non-trivial or non-standard layout class type object can change the implementation details. The operation might result in abnormal program behavior or a code execution vulnerability. For instance, if the address of a member function is overwritten, the call to this function invokes an unexpected function.

### Fix

To perform bytewise operations non-trivial or non-standard layout class type object, use these C++ special member functions instead of C Standard library functions.

| C Standard Library Functions | C++ Member Functions |
|---|---|
| `std::memset` | Class constructor |
| `std::memcpy`<br>`std::strcpy`<br>`std::memmove` | Class copy constructor<br>Class move constructor<br>Copy assignment operator<br>Move assignment operator |
| `std::memcmp`<br>`std::strcmp` | `operator<()`<br>`operator>()`<br>`operator==()`<br>`operator!=()` |

### Example - Using `memset` with non-trivial class object

```
#include <cstring>
#include <iostream>
#include <utility>

class nonTrivialClass
{
    int scalingFactor;
    int otherData;
public:
    nonTrivialClass() : scalingFactor(1) {}
    void set_other_data(int i);
    int f(int i)
    {
        return i / scalingFactor;
    }
    // ...
};

void func()
{
    nonTrivialClass c;
    // ... Code that mutates c ...
    std::memset(&c, 0, sizeof(nonTrivialClass)); //Noncompliant
    std::cout << c.f(100) << std::endl;
}
```

In this example, `func()` uses `std::memset` to reinitialize non-trivial class object `c` after it is first initialized with its default constructor. This bytewise operation might not properly initialize the value representation of `c`.

#### Correction — Define Function Template That Uses `std::swap`

One possible correction is to define a function template `clear()` that uses `std::swap` to perform a swap operation. The call to `clear()`properly reinitializes object `c` by swapping the contents of `c` and default initialized object `empty`.

```
 #include <cstring>
#include <iostream>
#include <utility>

class nonTrivialClass
{
    int scalingFactor;
    int otherData;
public:
    nonTrivialClass() : scalingFactor(1) {}
    void set_other_data(int i);
    int f(int i)
    {
        return i / scalingFactor;
    }
    // ...
};

template <typename T>
T& clear(T& o)
{
    using std::swap;
    T empty;
    swap(o, empty);
    return o;
}

void func()
{
    nonTrivialClass c;
    // ... Code that mutates c ...

    clear(c);
    std::cout << c.f(100) << std::endl;
}
```

Copy operations must not mutate the source object

## Description

### Rule Definition

*Copy operations must not mutate the source object.*

### Polyspace Implementation

The rule checker checks for **Copy operation modifying source operand**.

## Examples

### Copy operation modifying source operand

#### Issue

**Copy operation modifying source operand** occurs when a copy constructor or copy assignment operator modifies a mutable data member of its source operand.

For instance, this copy constructor A modifies the data member m of its source operand other:

```
class A {
  mutable int m;

public:
 ...
  A(const A &other) : m(other.m) {
    other.m = 0; //Modification of source
  }
}
```

#### Risk

A copy operation with a copy constructor (or copy assignment operator):

```
className new_object = old_object; //Calls copy constructor of className
```

copies its source operand old_object to its destination operand new_object. After the operation, you expect the destination operand to be a copy of the unmodified source operand. If the source operand is modified during copy, this assumption is violated.

#### Fix

Do not modify the source operand in the copy operation.

If you are modifying the source operand in a copy constructor to implement a move operation, use a move constructor instead. Move constructors are defined in the C++11 standard and later.

#### Example - Copy Constructor Modifying Source

```
#include <algorithm>
```

```
#include <vector>

class A {
  mutable int m;

public:
  A() : m(0) {}
  explicit A(int m) : m(m) {}

  A(const A &other) : m(other.m) {
    other.m = 0; //Noncompliant
  }

  A& operator=(const A &other) {
    if (&other != this) {
      m = other.m;
      other.m = 0; //Noncompliant //Noncompliant
    }
    return *this;
  }

  int get_m() const { return m; }
};

void f() {
  std::vector<A> v{10};
  A obj(12);
  std::fill(v.begin(), v.end(), obj);
}
```

In this example, a vector of ten objects of type `A` is created. The `std::fill` function copies an object of type `A`, which has a data member with value 12, to each of the ten objects. After this operation, you might expect that all ten objects in the vector have a data member with value 12.

However, the first copy modifies the data member of the source to the value 0. The remaining nine copies copy this value. After the `std::fill` call, the first object in the vector has a data member with value 12 and the remaining objects have data members with value 0.

**Correction — Use Move Constructor for Modifying Source**

Do not modify data members of the source operand in a copy constructor or copy assignment operator. If you want your class to have a move operation, use a move constructor instead of a copy constructor.

In this corrected example, the copy constructor and copy assignment operator of class `A` do not modify the data member `m`. A separate move constructor modifies the source operand.

```
#include <algorithm>
#include <vector>

class A {
  int m;

public:
  A() : m(0) {}
  explicit A(int m) : m(m) {}
  A(const A &other) : m(other.m) {}
  A(A &&other) : m(other.m) { other.m = 0; }

  A& operator=(const A &other) {
    if (&other != this) {
      m = other.m;
    }
    return *this;
  }

  //Move constructor
  A& operator=(A &&other) {
    m = other.m;
    other.m = 0;
    return *this;
  }

  int get_m() const { return m; }
};

void f() {
  std::vector<A> v{10};
  A obj(12);
  std::fill(v.begin(), v.end(), obj);
}
```

Avoid race conditions when using library functions

## Description

### Rule Definition

*Avoid race conditions when using library functions.*

### Polyspace Implementation

The rule checker checks for **Data race through standard library function call**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

## Examples

### Data race through standard library function call

#### Issue

**Data race through standard library function call** occurs when:

- Multiple tasks call the same standard library function.

  For instance, multiple tasks call the `strerror` function.
- The calls are not protected using a common protection.

  For instance, the calls are not protected by the same critical section.

Functions flagged by this defect are not guaranteed to be reentrant. A function is reentrant if it can be interrupted and safely called again before its previous invocation completes execution. If a function is not reentrant, multiple tasks calling the function without protection can cause concurrency issues. For the list of functions that are flagged, see CON33-C: Avoid race conditions when using library functions.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

#### Risk

The functions flagged by this defect are nonreentrant because their implementations can use global or static variables. When multiple tasks call the function without protection, the function call from one task can interfere with the call from another task. The two invocations of the function can concurrently access the global or static variables and cause unpredictable results.

The calls can also cause more serious security vulnerabilities, such as abnormal termination, denial-of-service attack, and data integrity violations.

#### Fix

To fix this defect, do one of the following:

- Use a reentrant version of the standard library function if it exists.

  For instance, instead of `strerror()`, use `strerror_r()` or `strerror_s()`. For alternatives to functions flagged by this defect, see the documentation for CON33-C.
- Protect the function calls using common critical sections or temporal exclusion.

  See `Critical section details (-critical-section-begin -critical-section-end)` and `Temporally exclusive tasks (-temporal-exclusions-file)`.

  To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

#### Example - Unprotected Call to Standard Library Function from Multiple Tasks

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno); //Noncompliant
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
    end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| `Configure multitasking manually` | ☑ | |
| `Tasks (-entry-points)` | `task1`<br>`task2`<br>`task3` | |
| `Critical section details (-critical-section-begin -critical-section-end)` | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

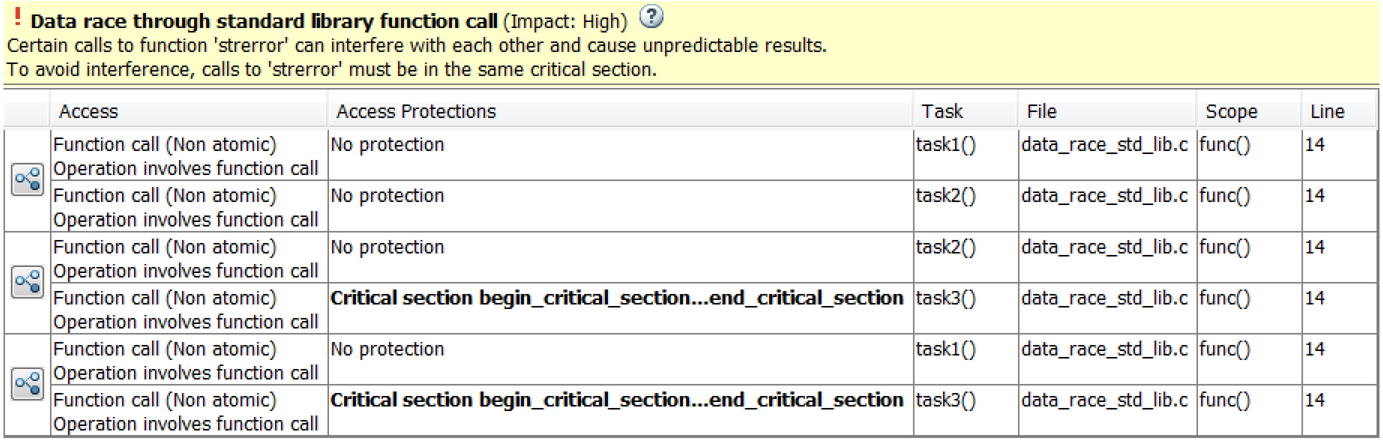
On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2,task3
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

In this example, the tasks, `task1`, `task2` and `task3`, call the function `func`. `func` calls the nonreentrant standard library function, `strerror`.

Though `task3` calls `func` inside a critical section, other tasks do not use the same critical section. Operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

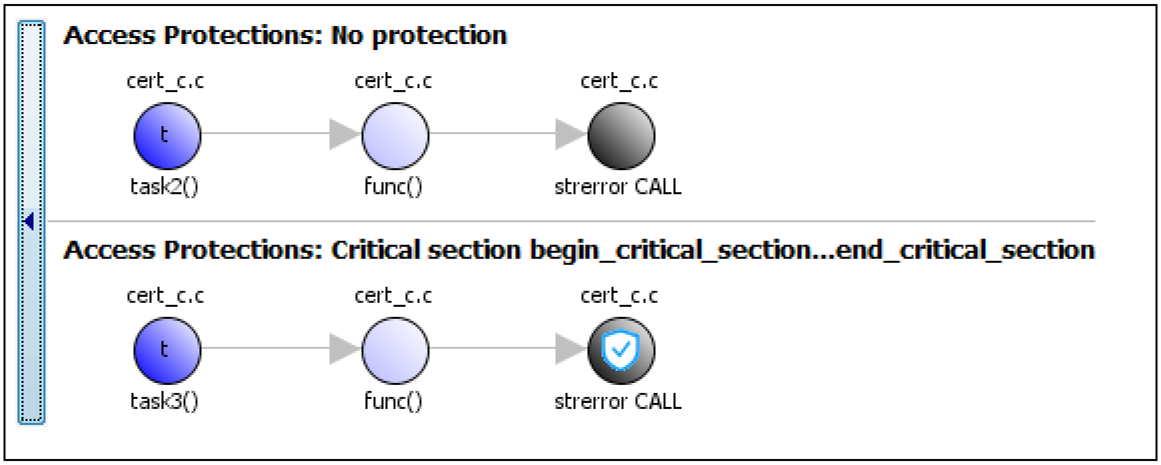
These three tasks are calling a nonreentrant standard library function without common protection. In your result details, you see each pair of conflicting function calls.



! **Data race through standard library function call** (Impact: High)
Certain calls to function 'strerror' can interfere with each other and cause unpredictable results.
To avoid interference, calls to 'strerror' must be in the same critical section.

| | Access | Access Protections | Task | File | Scope | Line |
|---|---|---|---|---|---|---|
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task2() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | No protection | task1() | data_race_std_lib.c | func() | 14 |
| | Function call (Non atomic)<br>Operation involves function call | **Critical section begin_critical_section...end_critical_section** | task3() | data_race_std_lib.c | func() | 14 |

If you click the icon, you see the function call sequence starting from the entry point to the standard library function call. You also see that the call starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



Access Protections: No protection
cert_c.c
t
task2()
cert_c.c
func()
cert_c.c
strerror CALL
Access Protections: Critical section begin_critical_section...end_critical_section
cert_c.c
t
task3()
cert_c.c
func()
cert_c.c
strerror CALL

**Correction — Use Reentrant Version of Standard Library Function**

One possible correction is to use a reentrant version of the standard library function `strerror`. You can use the POSIX version `strerror_r` which has the same functionality but also guarantees thread-safety.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);
enum { BUFFERSIZE = 64 };

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char errmsg[BUFFERSIZE];
    if (strerror_r(errno, errmsg, BUFFERSIZE) != 0) {
      /* Handle error */
    }
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    func(fptr1);
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     func(fptr2);
}
```

```
void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
     end_critical_section();
}
```

**Correction — Place Function Call in Critical Section**

One possible correction is to place the call to `strerror` in critical section. You can implement the critical section in multiple ways.

For instance, you can place the call to the intermediate function `func` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `func` and therefore the calls to `strerror` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `func` between calls to `begin_critical_section` and `end_critical_section`.

```
#include <errno.h>
#include <stdio.h>
#include <string.h>

void begin_critical_section(void);
void end_critical_section(void);

FILE *getFilePointer(void);

void func(FILE *fp) {
  fpos_t pos;
  errno = 0;
  if (0 != fgetpos(fp, &pos)) {
    char *errmsg = strerror(errno);
    printf("Could not get the file position: %s\n", errmsg);
  }
}

void task1(void) {
    FILE* fptr1 = getFilePointer();
    begin_critical_section();
    func(fptr1);
    end_critical_section();
}

void task2(void) {
     FILE* fptr2 = getFilePointer();
     begin_critical_section();
     func(fptr2);
     end_critical_section();
}

void task3(void) {
     FILE* fptr3 = getFilePointer();
     begin_critical_section();
     func(fptr3);
    end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| `Temporally exclusive tasks (-temporal-exclusions-file)` | `task1 task2 task3` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
     -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

Do not call signal() in a multithreaded program

## Description

### Rule Definition

*Do not call signal() in a multithreaded program.*

### Polyspace Implementation

The rule checker checks for **Signal call in multithreaded program**.

## Examples

### Signal call in multithreaded program

#### Issue

**Signal call in multithreaded program** occurs when you use the `signal()` function in a program with multiple threads.

#### Risk

According to the C11 standard (Section 7.14.1.1), use of the `signal()` function in a multithreaded program is undefined behavior.

#### Fix

Depending on your intent, use other ways to perform an asynchronous action on a specific thread.

#### Example - Use of `signal()` Function to Terminate Loop in Thread

```
#include <signal.h>
#include <stddef.h>
#include <thread>

volatile sig_atomic_t flag = 0;

void handler(int signum) {
    flag = 1;
}

/* Runs until user sends SIGUSR1 */
int func(int data) {
    while (!flag) {
        /* ... */
    }
    return 0;
}

int main(void) {
    signal(SIGINT, handler); //Noncompliant
    int data;
    //...
    std::thread th1(func, data);

    return 0;
}
```

In this example, the `signal` function is used to terminate a `while` loop in the thread.

#### Correction — Use `atomic_bool` Variable to Terminate Loop

One possible correction is to use an `std::atomic` variable of `bool` type that multiple threads can access. In the corrected example, the `std::atomic<bool>` variable `flag` can be accessed by both the main thread and the child thread `th1`. Before every loop iteration, the child thread checks `flag`. After completing the program, you can modify this variable so that the child thread exits the loop.

```
#include <thread>
#include <atomic>
std::atomic<bool> flag(false);

int func(int data) {
    while (!flag) {
        /* ... */
    }
    return 0;
}

int main(void) {
    int data;
    //...
    std::thread th1(func, data);
    th1.join();
    flag = true;
    return 0;
}
```

Do not refer to an atomic variable twice in an expression

## Description

### Rule Definition

*Do not refer to an atomic variable twice in an expression.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Atomic variable accessed twice in an expression**.
- **Atomic load and store sequence not atomic**.

## Examples

### Atomic variable accessed twice in an expression

#### Issue

**Atomic variable accessed twice in an expression** occurs when C atomic types or C++ `std::atomic` class variables appear twice in an expression and there are:

- Two atomic read operations on the variable.
- An atomic read and a distinct atomic write operation on the variable.

The C standard defines certain operations on atomic variables that are thread safe and do not cause data race conditions. Unlike individual operations, a pair of operations on the same atomic variable in an expression is not thread safe.

#### Risk

A thread can modify the atomic variable between the pair of atomic operations, which can result in a data race condition.

#### Fix

Do not reference an atomic variable twice in the same expression.

#### Example - Referencing Atomic Variable Twice in an Expression

To run this example, use these options:

- `-cpp-version cpp11`
- -compiler gnu4.9

```
#include <atomic>
std::atomic<int> n(5);
int compute_sum(void)
{
    return n * (n + 1) / 2; //Noncompliant
}
```

In this example, the global variable `n` is referenced twice in the return statement of `compute_sum()`. The value of `n` can change between the two distinct read operations. `compute_sum()` can return an incorrect value.

#### Correction — Pass Variable as Function Argument

One possible correction is to pass the variable as a function argument `n`. The variable is copied to memory and the read operations on the copy guarantee that `compute_sum()` returns a correct result. If you pass a variable of type `int` instead of type `atomic_int`, the correction is still valid.

```
#include <atomic>
int compute_sum(std::atomic<int> n)
{
    return n * (n + 1) / 2;
}
```

### Atomic load and store sequence not atomic

#### Issue

**Atomic load and store sequence not atomic** occurs when you use these functions to load, and then store an atomic variable.

- C functions:
  - `atomic_load()`
  - `atomic_load_explicit()`
  - `atomic_store()`
  - `atomic_store_explicit()`
- C++ functions:
  - `std::atomic_load()`
  - `std::atomic_load_explicit()`
  - `std::atomic_store()`
  - `std::atomic_store_explicit()`
  - `std::atomic::load()`
  - `std::atomic::store()`

A thread cannot interrupt an atomic load or an atomic store operation on a variable, but a thread can interrupt a store, and then load sequence.

#### Risk

A thread can modify a variable between the load and store operations, resulting in a data race condition.

#### Fix

To read, modify, and store a variable atomically, use a compound assignment operator such as +=, `atomic_compare_exchange()` or `atomic_fetch_*`-family functions.

### Example - Loading Then Storing an Atomic Variable

To run this example, use these options:

- `-cpp-version cpp11`
- -compiler gnu4.9

```
#include <atomic>
#include <stdbool.h>
using namespace std;
static atomic<bool> flag(false);

void init_flag(void)
{
    atomic_init(&flag, false);
}

void toggle_flag(void)
{
    bool temp_flag = atomic_load(&flag);
    temp_flag = !temp_flag;
    atomic_store(&flag, temp_flag); //Noncompliant
}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

In this example, variable `flag` of type `atomic_bool` is referenced twice inside the `toggle_flag()` function. The function loads the variable, negates its value, then stores the new value back to the variable. If two threads call `toggle_flag()`, the second thread can access `flag` between the load and store operations of the first thread. `flag` can end up in an incorrect state.

#### Correction — Use Compound Assignment to Modify Variable

One possible correction is to use the function `atomic_compare_exchange_weak` to perform a safe and atomic compare-and-exchange. When you use this function, the changes to `flag` are visible to other threads, and the expected result is stored in `flag`.

```
#include <atomic>
#include <stdbool.h>
using namespace std;
static atomic<bool> flag(false);

void toggle_flag(void)
{
  bool old_flag = atomic_load(&flag);
  bool new_flag;
  do {
    new_flag = !old_flag;
  } while (!atomic_compare_exchange_weak(&flag, &old_flag, new_flag));

}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

Wrap functions that can fail spuriously in a loop

## Description

### Rule Definition

*Wrap functions that can fail spuriously in a loop.*

### Polyspace Implementation

The rule checker checks for **Function that can spuriously fail not wrapped in loop**.

## Examples

### Function that can spuriously fail not wrapped in loop

#### Issue

**Function that can spuriously fail not wrapped in loop** occurs when the following atomic compare and exchange functions that can fail spuriously are called from outside a loop.

- C atomic functions:
  - `atomic_compare_exchange_weak()`
  - `atomic_compare_exchange_weak_explicit()`
- C++ atomic functions:
  - `std::atomic<T>::compare_exchange_weak(T* expected, T desired)`
  - `std::atomic<T>::compare_exchange_weak_explicit(T* expected, T desired, std::memory_order succ, std::memory_order fail)`
  - `std::atomic_compare_exchange_weak(std::atomic<T>* obj, T* expected, T desired)`
  - `std::atomic_compare_exchange_weak_explicit(volatile std::atomic<T>* obj, T* expected, T desired, std::memory_order succ, std::memory_order fail)`

The functions compare the memory contents of the object representations pointed to by `obj` and `expected`. The comparison can spuriously return false even if the memory contents are equal. This spurious failure makes the functions faster on some platforms.

#### Risk

An atomic compare and exchange function that spuriously fails can cause unexpected results and unexpected control flow.

#### Fix

Wrap atomic compare and exchange functions that can spuriously fail in a loop. The loop checks the failure condition after a possible spurious failure.

### Example — `atomic_compare_exchange_weak()` Not Wrapped in Loop

```
#include <atomic>
#include <stdbool.h>
using namespace std;
static atomic<bool> flag(false);
void toggle_flag(void)
{
    bool old_flag = atomic_load(&flag);
    bool new_flag;
    if (!atomic_compare_exchange_weak(&flag, &old_flag, new_flag)){//Noncompliant
        new_flag = !old_flag;
    }

}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

In this example, the function`toggle_flag` uses `atomic_compare_exchange_weak()` to compare `flag` and `old_flag`. If the variables are identical, `flag` is toggles to `new_flag`. When `atomic_compare_exchange_weak()` fails spuriously, the flag is toggled unnecessarily.

### Correction — Wrap `atomic_compare_exchange_weak()` in a `do-while` Loop

One possible correction is to wrap the call to `atomic_compare_exchange_weak()` in a `while` loop. The loop checks the failure condition after a possible spurious failure.

```
#include <atomic>
#include <stdbool.h>
using namespace std;
static atomic<bool> flag(false);

void toggle_flag(void)
{
  bool old_flag = atomic_load(&flag);
  bool new_flag;
  do {
    new_flag = !old_flag;
  } while (!atomic_compare_exchange_weak(&flag, &old_flag, new_flag));

}

bool get_flag(void)
{
    return atomic_load(&flag);
}
```

Do not allow data races in multithreaded code

## Description

### Rule Definition

*Do not allow data races in multithreaded code.*

### Polyspace Implementation

The rule checker checks for **Data race**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

You can also extend this checker in the following ways:

- Map your multithreading functions to their known POSIX equivalents. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.
- Detect all data races including ones involving atomic operations.

  Polyspace assumes that certain operations are atomic and excludes them from data race checks. See “Define Atomic Operations in Multitasking Code”. These assumptions might not apply to your environment. To extend the data race checkers to include these operations, use the option `-detect-atomic-data-race`. See “Extend Data Race Checkers to Atomic Operations”.

## Examples

### Data race

#### Issue

Data race occurs when:

- Multiple tasks perform unprotected operations on a shared variable.
- At least one task performs a write operation.
- At least one operation is nonatomic. To detect data race on both atomic and nonatomic operations, use the options `-detect-atomic-data-race`. See “Extend Data Race Checkers to Atomic Operations”.

  See “Define Atomic Operations in Multitasking Code”.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

### Risk

Data race can result in unpredictable values of the shared variable because you do not control the order of the operations in different tasks.

Data races between two write operations are more serious than data races between a write and read operation. Two write operations can interfere with each other and result in indeterminate values. To identify write-write conflicts, use the filters on the **Detail** column of the **Results List** pane. For these conflicts, the **Detail** column shows the additional line:

```
 Variable value may be altered by write-write concurrent access.
```

See “Filter and Group Results in Polyspace Desktop User Interface” or “Filter and Sort Results in Polyspace Access Web Interface”.

### Fix

To fix this defect, protect the operations on the shared variable using critical sections, temporal exclusion or another means. See “Protections for Shared Variables in Multitasking Code”.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon. For an example, see below.

### Example - Unprotected Operation on Global Variable from Multiple Tasks

```
int var; //Noncompliant
void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
    var++;
}

void task1(void)  {
      increment();
}

void task2(void)  {
      increment();
}

void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify the following options:

| Option | Specification | |
|---|---|---|
| `Configure multitasking manually` | ☑ | |
| `Tasks (-entry-points)` | `task1`<br>`task2`<br>`task3` | |
| `Critical section details (-critical-section-begin -critical-section-end)` | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

On the command-line, you can use the following:

```
 polyspace-bug-finder
   -entry-points task1,task2,task3
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

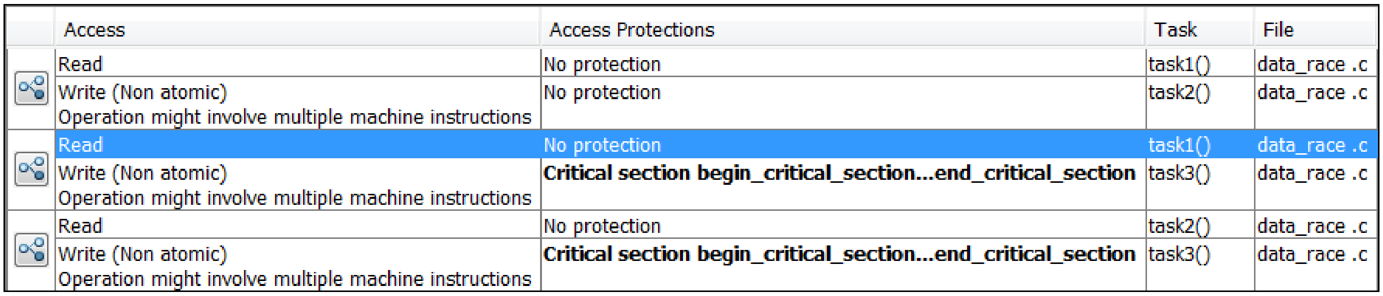
In this example, the tasks `task1`, `task2`, and `task3` call the function `increment`. `increment` contains the operation `var++` that can involve multiple machine instructions including:

- Reading `var`.
- Writing an increased value to `var`.

These machine instructions, when executed from `task1` and `task2`, can occur concurrently in an unpredictable sequence. For example, reading `var` from `task1` can occur either before or after writing to `var` from `task2`. Therefore the value of `var` can be unpredictable.

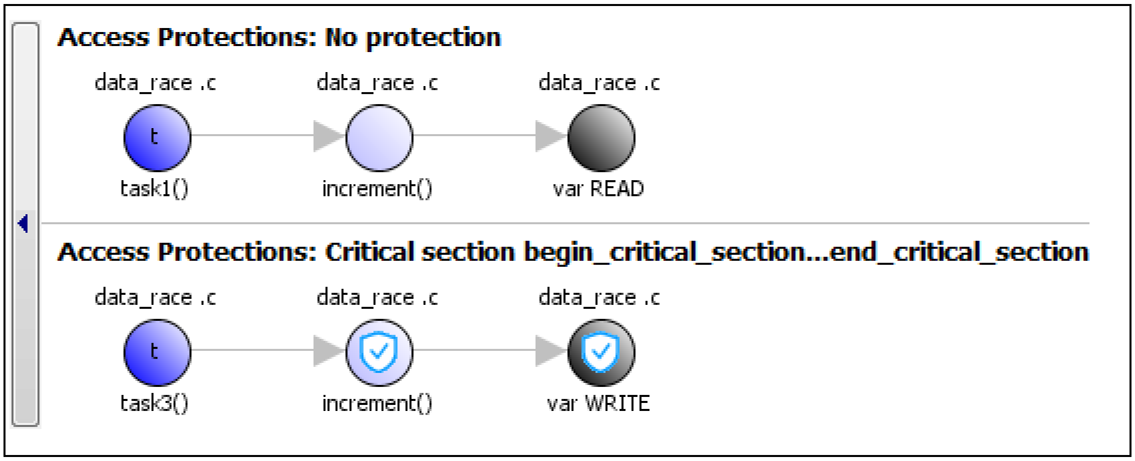
Though `task3` calls `increment` inside a critical section, other tasks do not use the same critical section. The operations in the critical section of `task3` are not mutually exclusive with operations in other tasks.

Therefore, the three tasks are operating on a shared variable without common protection. In your result details, you see each pair of conflicting function calls.



| Access | Access Protections | Task | File |
|---|---|---|---|
| Read | No protection | task1() | data_race .c |
| Write (Non atomic)<br>Operation might involve multiple machine instructions | No protection | task2() | data_race .c |
| Read | No protection | task1() | data_race .c |
| Write (Non atomic)<br>Operation might involve multiple machine instructions | **Critical section begin_critical_section...end_critical_section** | task3() | data_race .c |
| Read | No protection | task2() | data_race .c |
| Write (Non atomic)<br>Operation might involve multiple machine instructions | **Critical section begin_critical_section...end_critical_section** | task3() | data_race .c |

If you click the icon, you see the function call sequence starting from the entry point to the read or write operation. You also see that the operation starting from `task3` is in a critical section. The **Access Protections** entry shows the lock and unlock function that begin and end the critical section. In this example, you see the functions `begin_critical_section` and `end_critical_section`.



**Access Protections: No protection**

**Access Protections: Critical section begin_critical_section...end_critical_section**

**Correction — Place Operation in Critical Section**

One possible correction is to place the operation in critical section. You can implement the critical section in multiple ways. For instance:

- You can place `var++` in a critical section. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The operation `var++` from the three tasks cannot interfere with each other.

  To implement the critical section, in the function `increment`, place the operation `var++` between calls to `begin_critical_section` and `end_critical_section`.

  ```
  int var;

  void begin_critical_section(void);
  void end_critical_section(void);

  void increment(void) {
        begin_critical_section();
        var++;
        end_critical_section();
  }

  void task1(void)  {
        increment();
  }

  void task2(void)  {
        increment();
  }

  void task3(void)  {
        increment();
  }
  ```
- You can place the call to `increment` in the same critical section in the three tasks. When `task1` enters its critical section, the other tasks cannot enter their critical sections until `task1` leaves its critical section. The calls to `increment` from the three tasks cannot interfere with each other.

To implement the critical section, in each of the three tasks, call `increment` between calls to `begin_critical_section` and `end_critical_section`.

```
int var;

void begin_critical_section(void);
void end_critical_section(void);

void increment(void) {
      var++;
}

void task1(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task2(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}

void task3(void)  {
     begin_critical_section();
     increment();
     end_critical_section();
}
```

#### Correction — Make Tasks Temporally Exclusive

Another possible correction is to make the tasks, `task1`, `task2` and `task3`, temporally exclusive. Temporally exclusive tasks cannot execute concurrently.

On the **Configuration** pane, specify the following additional options:

| Option | Value |
|---|---|
| Temporally exclusive tasks (-temporal-exclusions-file) | task1 task2 task3 |

On the command-line, you can use the following:

```
 polyspace-bug-finder
     -temporal-exclusions-file "C:\exclusions_file.txt"
```

where the file `C:\exclusions_file.txt` has the following line:

```
task1 task2 task3
```

#### Example - Unprotected Operation in Threads Created with `pthread_create`

```
#include <pthread.h>
```

```
pthread_mutex_t count_mutex;
long long count; //Noncompliant

void* increment_count(void* args)
{
    count = count + 1;
    return NULL;
}

void* set_count(void *args)
{
    long long c;
    c = count;
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

In this example, Bug Finder detects the creation of separate threads with `pthread_create`. The **Data race** defect is raised because the operation `count = count + 1` in the thread with id `thread_increment` conflicts with the operation `c = count` in the thread with id `thread_get`. The variable `count` is accessed in multiple threads without a common protection.

The two conflicting operations are nonatomic. The operation `c = count` is nonatomic on 32-bit targets. See “Define Atomic Operations in Multitasking Code”.

#### Correction — Protect Operations with `pthread_mutex_lock` and `pthread_mutex_unlock` Pair

To prevent concurrent access on the variable `count`, protect operations on `count` with a critical section. Use the functions `pthread_mutex_lock` and `pthread_mutex_unlock` to implement the critical section.

```
#include <pthread.h>

pthread_mutex_t count_mutex;
long long count;

void* increment_count(void* args)
{
    pthread_mutex_lock(&count_mutex);
    count = count + 1;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}
```

```
void* set_count(void *args)
{
    long long c;
    pthread_mutex_lock(&count_mutex);
    c = count;
    pthread_mutex_unlock(&count_mutex);
    return NULL;
}

int main(void)
{
    pthread_t thread_increment;
    pthread_t thread_get;

    pthread_create(&thread_increment, NULL, increment_count, NULL);
    pthread_create(&thread_get, NULL, set_count, NULL);

    pthread_join(thread_get, NULL);
    pthread_join(thread_increment, NULL);

    return 1;
}
```

Do not destroy a mutex while it is locked

## Description

### Rule Definition

*Do not destroy a mutex while it is locked.*

### Polyspace Implementation

The rule checker checks for **Destruction of locked mutex**.

## Examples

### Destruction of locked mutex

#### Issue

**Destruction of locked mutex** occurs when a task destroys a mutex after it is locked (and before it is unlocked). The locking and destruction can happen in the same task or different tasks.

#### Risk

A mutex is locked to protect shared variables from concurrent access. If a mutex is destroyed in the locked state, the protection does not apply.

#### Fix

To fix this defect, destroy the mutex only after you unlock it. It is a good design practice to:

- Initialize a mutex *before* creating the threads where you use the mutex.
- Destroy a mutex *after* joining the threads that you created.

On the **Result Details** pane, you see two events, the locking and destruction of the mutex, and the tasks that initiated the events. To navigate to the corresponding line in your source code, click the event.

#### Example - Locking and Destruction in Different Tasks

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
  pthread_mutex_unlock (&lock3);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);
  pthread_mutex_destroy (&lock3); //Noncompliant
  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

In this example, after task `t0` locks the mutex `lock3`, task `t1` can destroy it. The destruction occurs if the following events happen in sequence:

1. `t0` acquires `lock3`.
2. `t0` releases `lock2`.
3. `t0` releases `lock1`.
4. `t1` acquires the lock `lock1` released by `t0`.
5. `t1` acquires the lock `lock2` released by `t0`.
6. `t1` destroys `lock3`.

For simplicity, this example uses a mix of automatic and manual concurrency detection. The tasks `t0` and `t1` are manually specified as entry points by using the option `Tasks (-entry-points)`.The critical sections are implemented through primitives `pthread_mutex_lock` and `pthread_mutex_unlock` that the software detects automatically. In practice, for entry point specification (thread creation), you will use primitives such as `pthread_create`. The next example shows how the defect can appear when you use `pthread_create`.

**Correction — Place Lock-Unlock Pair Together in Same Critical Section as Destruction**

The locking and destruction of `lock3` occurs inside the critical section imposed by `lock1` and `lock2`, but the unlocking occurs outside. One possible correction is to place the lock-unlock pair in the same critical section as the destruction of the mutex. Use one of these critical sections:

- Critical section imposed by `lock1` alone.
- Critical section imposed by `lock1` and `lock2`.

In this corrected code, the lock-unlock pair and the destruction is placed in the critical section imposed by `lock1` and `lock2`. When `t0` acquires `lock1` and `lock2`, `t1` has to wait for their release before it executes the instruction `pthread_mutex_destroy (&lock3);`. Therefore, `t1` cannot destroy mutex `lock3` in the locked state.

```
#include <pthread.h>

pthread_mutex_t lock1;
pthread_mutex_t lock2;
pthread_mutex_t lock3;

void t0 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_lock (&lock3);
  pthread_mutex_unlock (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}

void t1 (void) {
  pthread_mutex_lock (&lock1);
  pthread_mutex_lock (&lock2);

  pthread_mutex_destroy (&lock3);

  pthread_mutex_unlock (&lock2);
  pthread_mutex_unlock (&lock1);
}
```

**Example - Locking and Destruction in Start Routine of Thread**

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_exit((void*) 0);
}

void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_destroy(&lock);//Noncompliant
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Thread that initializes mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use mutex for atomic operation*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   pthread_exit(NULL);
}
```

In this example, four threads are created. The threads are assigned different actions.

- The first thread `callThd[0]` initializes the mutex `lock`.
- The second and third threads, `callThd[1]` and `callThd[2]`, perform an atomic operation protected by the mutex `lock`.
- The fourth thread `callThd[3]` destroys the mutex `lock`.

The threads can interrupt each other. Therefore, immediately after the second or third thread locks the mutex, the fourth thread can destroy it.

#### Correction — Initialize and Destroy Mutex Outside Start Routine

One possible correction is to initialize and destroy the mutex in the `main` function outside the start routine of the threads. The threads perform only the atomic operation. You need two fewer threads because the mutex initialization and destruction threads are not required.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 2
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
void atomic_operation(void);

void *do_work(void *arg) {
   pthread_mutex_lock (&lock);
   atomic_operation();
   pthread_mutex_unlock (&lock);
   pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize mutex */
   pthread_mutex_init(&lock, NULL);

   for(i=0; i<NUMTHREADS; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy mutex */
   pthread_mutex_destroy(&lock);

   pthread_exit(NULL);
}
```

#### Correction — Use A Second Mutex To Protect Lock-Unlock Pair and Destruction

Another possible correction is to use a second mutex and protect the lock-unlock pair from the destruction. This corrected code uses the mutex `lock2` to achieve this protection. The second mutex is initialized in the `main` function outside the start routine of the threads.

```
#include <pthread.h>

/* Define globally accessible variables and a mutex */
#define NUMTHREADS 4
pthread_t callThd[NUMTHREADS];
pthread_mutex_t lock;
pthread_mutex_t lock2;
void atomic_operation(void);

void *do_create(void *arg) {
    /* Creation thread */
    pthread_mutex_init(&lock, NULL);
    pthread_exit((void*) 0);
}

void *do_work(void *arg) {
    /* Worker thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_lock (&lock);
    atomic_operation();
    pthread_mutex_unlock (&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}
```

```
void *do_destroy(void *arg) {
    /* Destruction thread */
    pthread_mutex_lock (&lock2);
    pthread_mutex_destroy(&lock);
    pthread_mutex_unlock (&lock2);
    pthread_exit((void*) 0);
}

int main (int argc, char *argv[]) {
   int i;
   void *status;
   pthread_attr_t attr;

   /* Create threads */
   pthread_attr_init(&attr);
   pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

   /* Initialize second mutex */
   pthread_mutex_init(&lock2, NULL);

   /* Thread that initializes first mutex */
   pthread_create(&callThd[0], &attr, do_create, NULL);

   /* Threads that use first mutex for atomic operation */
   /* The threads use second mutex to protect first from destruction in locked state*/
   for(i=0; i<NUMTHREADS-1; i++) {
      pthread_create(&callThd[i], &attr, do_work, (void *)i);
   }

   /* Thread that destroys first mutex */
   /* The thread uses the second mutex to prevent destruction of locked mutex */
   pthread_create(&callThd[NUMTHREADS -1], &attr, do_destroy, NULL);

   pthread_attr_destroy(&attr);

   /* Join threads */
   for(i=0; i<NUMTHREADS; i++) {
      pthread_join(callThd[i], &status);
   }

   /* Destroy second mutex */
   pthread_mutex_destroy(&lock2);

   pthread_exit(NULL);
}
```

Prevent data races when accessing bit-fields from multiple threads

## Description

### Rule Definition

*Prevent data races when accessing bit-fields from multiple threads.*

### Polyspace Implementation

The rule checker checks for **Data race on adjacent bit fields**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

## Examples

### Data race on adjacent bit fields

#### Issue

This defect occurs when:

- Multiple tasks perform unprotected operations on bit fields that are part of the same structure.

  For instance, a task operates on field `errorFlag1` and another task on field `errorFlag2` in a variable of this type:

  ```
  struct errorFlags {
     unsigned int errorFlag1 : 1;
     unsigned int errorFlag2 : 1;
     ...
  }
  ```

  Suppose that the operations are not atomic with respect to each other. In other words, you have not implemented protection mechanisms to ensure that one operation is completed before another operation begins.
- At least one of the unprotected operations is a write operation.

To find this defect, before analysis, you must specify the multitasking options. To specify these options, on the **Configuration** pane, select **Multitasking**. For more information, see “Configuring Polyspace Multitasking Analysis Manually”.

#### Risk

Adjacent bit fields that are part of the same structure might be stored in one byte in the same memory location. Read or write operations on all variables including bit fields occur one byte or word at a time. To modify only specific bits in a byte, steps similar to these steps occur in sequence:

1. The byte is loaded into RAM.
2. A mask is created so that only specific bits are modified to the intended value and the remaining bits remain unchanged.
3. A bitwise OR operation is performed between the copy of the byte in RAM and the mask.
4. The byte with specific bits modified is copied back from RAM.

When you access two different bit fields, these four steps have to be performed for each bit field. If the accesses are not protected, all four steps for one bit field might not be completed before the four steps for the other bit field begin. As a result, the modification of one bit field might undo the modification of an adjacent bit field. For instance, in the preceding example, the modification of `errorFlag1` and `errorFlag2` can occur in the following sequence. Steps 1,2 and 5 relate to modification of `errorFlag1` and while steps 3,4 and 6 relate to that of `errorFlag2`.

1. The byte with both `errorFlag1` and `errorFlag2` unmodified is copied into RAM, for purposes of modifying `errorFlag1`.
2. A mask that modifies only `errorFlag1` is bitwise OR-ed with this copy.
3. The byte containing both `errorFlag1` and `errorFlag2` unmodified is copied into RAM a second time, for purposes of modifying `errorFlag2`.
4. A mask that modifies only `errorFlag2` is bitwise OR-ed with this second copy.
5. The version with `errorFlag1` modified is copied back. This version has `errorFlag2` unmodified.
6. The version with `errorFlag2` modified is copied back. This version has `errorFlag1` unmodified and overwrites the previous modification.

#### Fix

To fix this defect, protect the operations on bit fields that are part of the same structure by using critical sections, temporal exclusion, or another means. See “Protections for Shared Variables in Multitasking Code”.

To identify existing protections that you can reuse, see the table and graphs associated with the result. The table shows each pair of conflicting calls. The **Access Protections** column shows existing protections on the calls. To see the function call sequence leading to the conflicts, click the icon.

#### Example - Unprotected Operation on Global Variable from Multiple Tasks

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12; //Noncompliant

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

In this example, `task1` and `task2` access different bit fields `IOFlag` and `SetupFlag`, which belong to the same structured variable `InterruptConfigbitsProc12`.

To emulate multitasking behavior, specify the options listed in this table.

| Option | Specification |
|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ |
| **Tasks** on page 2-121 | `task1`<br>`task2` |

At the command-line, use:

```
 polyspace-bug-finder
   -entry-points task1,task2
```

**Correction – Use Critical Sections**

One possible correction is to wrap the bit field access in a critical section. A critical section lies between a call to a lock function and an unlock function. In this correction, the critical section lies between the calls to functions `begin_critical_section` and `end_critical_section`.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void begin_critical_section(void);
void end_critical_section(void);

void task1 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.IOFlag = 0;
    end_critical_section();
}

void task2 (void) {
    begin_critical_section();
    InterruptConfigbitsProc12.SetupFlag = 0;
    end_critical_section();
}
```

In this example, to emulate multitasking behavior, specify options listed in this table.

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** on page 2-117 | ☑ | |
| **Tasks** on page 2-121 | `task1`<br>`task2` | |
| **Critical section details** on page 2-133 | **Starting routine** | **Ending routine** |
| | `begin_critical_section` | `end_critical_section` |

At the command-line, use:

```
 polyspace-bug-finder
   -entry-points task1,task2
   -critical-section-begin begin_critical_section:cs1
   -critical-section-end end_critical_section:cs1
```

#### Correction – Avoid Bit Fields

If you do not have memory constraints, use the `char` data type instead of bit fields. The `char` variables in a structure occupy at least one byte and do not have the thread-safety issues that come from bit manipulations in a byte-sized operation. Data races do not result from unprotected operations on different `char` variables that are part of the same structure.

```
typedef struct
{
   unsigned char IOFlag;
   unsigned char InterruptFlag;
   unsigned char Register1Flag;
   unsigned char SignFlag;
   unsigned char SetupFlag;
   unsigned char Register2Flag;
   unsigned char ProcessorFlag;
   unsigned char GeneralFlag;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

Though the checker does not flag this correction, do not use this correction for C99 or earlier. Only from C11 and later does the C Standard mandate that distinct `char` variables cannot be accessed using the same word.

#### Correction – Insert Bit Field of Size 0

You can enter a non-bit field member or an unnamed bit field member of size 0 between two adjacent bit fields that might be accessed concurrently. A non-bit field member or size 0 bit field member ensures that the subsequent bit field starts from a new memory location. In this corrected example, the size 0 bit field member ensures that `IOFlag` and `SetupFlag` are stored in distinct memory locations.

```
typedef struct
{
   unsigned int IOFlag :1;
   unsigned int InterruptFlag :1;
   unsigned int Register1Flag :1;
   unsigned int SignFlag :1;
   unsigned int : 0;
   unsigned int SetupFlag :1;
   unsigned int Register2Flag :1;
   unsigned int ProcessorFlag :1;
   unsigned int GeneralFlag :1;
} InterruptConfigbits_t;

InterruptConfigbits_t InterruptConfigbitsProc12;

void task1 (void) {
    InterruptConfigbitsProc12.IOFlag = 0;
}

void task2 (void) {
    InterruptConfigbitsProc12.SetupFlag = 0;
}
```

Avoid deadlock by locking in a predefined order

## Description

### Rule Definition

*Avoid deadlock by locking in a predefined order.*

### Polyspace Implementation

The rule checker checks for **Deadlock**.

### Extend Checker

For the rule checker to detect issues, your code must use one of the concurrency primitives recognized by Polyspace for thread creation and shared variable protection. Otherwise, you must explicitly specify tasks, interrupts, critical sections, and other multitasking options in your project configuration. See “Multitasking”.

You can also extend this checker by mapping your multithreading functions to their known POSIX equivalents. See “Extend Concurrency Defect Checkers to Unsupported Multithreading Environments”.

## Examples

### Deadlock

#### Issue

**Deadlock** occurs when multiple tasks are stuck in their critical sections (CS) because:

- Each CS waits for another CS to end.
- The critical sections (CS) form a closed cycle. For example:
  - CS #1 waits for CS #2 to end, and CS #2 waits for CS #1 to end.
  - CS #1 waits for CS #2 to end, CS #2 waits for CS #3 to end and CS #3 waits for CS #1 to end.

Polyspace expects critical sections of code to follow a specific format. A critical section lies between a call to a lock function and a call to an unlock function. When a task `my_task` calls a lock function `my_lock`, other tasks calling `my_lock` must wait until `my_task` calls the corresponding unlock function. Both lock and unlock functions must have the form `void func(void)`.

To find this defect, you must specify the multitasking options before analysis. To specify these options, on the **Configuration** pane, select **Multitasking**.

#### Risk

Each task waits for a critical section in another task to end and is unable to proceed. The program can freeze indefinitely.

#### Fix

The fix depends on the root cause of the defect. You can try to break the cyclic order between the tasks in one of these ways:

- Write down all critical sections involved in the deadlock in a certain sequence. Whenever you call the lock functions of the critical sections within a task, respect the order in that sequence. See an example below.
- If one of the critical sections involved in a deadlock occurs in an interrupt, try to disable all interrupts during critical sections in all tasks. See `Disabling all interrupts (-routine-disable-interrupts -routine-enable-interrupts)`.

Reviewing this defect is an opportunity to check if all operations in your critical section are really meant to be executed as an atomic block. It is a good practice to keep critical sections at a bare minimum.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

#### Example - Deadlock with Two Tasks

```
void task1(void);
void task2(void);

int var;
void perform_task_cycle(void) {
 var++;
}

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2(); //Noncompliant
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_2();
    begin_critical_section_1();
    perform_task_cycle();
    end_critical_section_1();
    end_critical_section_2();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | task1<br>task2 | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | begin_critical_section_1 | end_critical_section_1 |
| | begin_critical_section_2 | end_critical_section_2 |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. task1 calls begin_critical_section_1.
2. task2 calls begin_critical_section_2.
3. task1 reaches the instruction begin_critical_section_2();. Since task2 has already called begin_critical_section_2, task1 waits for task2 to call end_critical_section_2.
4. task2 reaches the instruction begin_critical_section_1();. Since task1 has already called begin_critical_section_1, task2 waits for task1 to call end_critical_section_1.

#### Correction-Follow Same Locking Sequence in Both Tasks

One possible correction is to follow the same sequence of calls to lock and unlock functions in both task1 and task2.

```
void task1(void);
void task2(void);
void perform_task_cycle(void);

void begin_critical_section_1(void);
void end_critical_section_1(void);

void begin_critical_section_2(void);
void end_critical_section_2(void);

void task1() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}

void task2() {
 while(1) {
    begin_critical_section_1();
    begin_critical_section_2();
    perform_task_cycle();
    end_critical_section_2();
    end_critical_section_1();
 }
}
```

**Example - Deadlock with More Than Two Tasks**

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2(); //Noncompliant
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock3();
    lock1();
    performTaskCycle();
    unlock1();
    unlock3();
 }
}
```

In this example, to emulate multitasking behavior, you must specify the following options:

| Option | Specification | |
|---|---|---|
| **Configure multitasking manually** | ☑ | |
| **Entry points** | task1<br>task2<br>task3 | |
| **Critical section details** | **Starting routine** | **Ending routine** |
| | lock1 | unlock1 |
| | lock2 | unlock2 |
| | lock3 | unlock3 |

A **Deadlock** occurs because the instructions can execute in the following sequence:

1. `task1` calls `lock1`.
2. `task2` calls `lock2`.
3. `task3` calls `lock3`.
4. `task1` reaches the instruction `lock2();`. Since `task2` has already called `lock2`, `task1` waits for call to `unlock2`.
5. `task2` reaches the instruction `lock3();`. Since `task3` has already called `lock3`, `task2` waits for call to `unlock3`.
6. `task3` reaches the instruction `lock1();`. Since `task1` has already called `lock1`, `task3` waits for call to `unlock1`.

#### Correction — Break Cyclic Order

To break the cyclic order between critical sections, note every lock function in your code in a certain sequence, for example:

1. `lock1`
2. `lock2`
3. `lock3`

If you use more than one lock function in a task, use them in the order in which they appear in the sequence. For example, you can use `lock1` followed by `lock2` but not `lock2` followed by `lock1`.

```
int var;
void performTaskCycle() {
 var++;
}

void lock1(void);
void lock2(void);
void lock3(void);

void unlock1(void);
void unlock2(void);
void unlock3(void);

void task1() {
 while(1) {
    lock1();
    lock2();
    performTaskCycle();
    unlock2();
    unlock1();
 }
}

void task2() {
 while(1) {
    lock2();
    lock3();
    performTaskCycle();
    unlock3();
    unlock2();
 }
}

void task3() {
 while(1) {
    lock1();
    lock3();
    performTaskCycle();
    unlock3();
    unlock1();
 }
}
```

Wrap functions that can spuriously wake up in a loop

## Description

### Rule Definition

*Wrap functions that can spuriously wake up in a loop.*

### Polyspace Implementation

The rule checker checks for **Function that can spuriously wake up not wrapped in loop**.

## Examples

### Function that can spuriously wake up not wrapped in loop

#### Issue

**Function that can spuriously wake up not wrapped in loop** occurs when the following wait-on-condition functions are called from outside a loop:

- C functions:
  - `cnd_wait()`
  - `cnd_timedwait()`
- POSIX functions:
  - `pthread_cond_wait()`
  - `pthread_cond_timedwait()`
- C++ `std::condition_variable` and `std::condition_variable_any` class member functions:
  - `wait()`
  - `wait_until()`
  - `wait_for()`

Wait-on-condition functions pause the execution of the calling thread when a specified condition is met. The thread wakes up and resumes once another thread notifies it with `cnd_broadcast()` or an equivalent function. The wake-up notification can be spurious or malicious.

#### Risk

If a thread receives a spurious wake-up notification and the condition of the wait-on-condition function is not checked, the thread can wake up prematurely. The wake-up can cause unexpected control flow, indefinite blocking of other threads, or denial of service.

#### Fix

Wrap wait-on-condition functions that can wake up spuriously in a loop. The loop checks the wake-up condition after a possible spurious wake-up notification.

**Example - `std::condition_variable::wait` Not Wrapped in Loop**

```
#include <stdio.h>
#include <stddef.h>
#include <thread>
#include <mutex>

#define THRESHOLD 100

std::mutex myMutex;
std::condition_variable cv;

void func(int input)
{
    std::unique_lock<std::mutex> lk(myMutex);
    // test condition to pause thread
    if (input > THRESHOLD) {
    //pause current thread
        cv.wait(lk);//Noncompliant
    }
}
```

In this example, the thread uses `std::condition_variable::wait` to pause execution when `input` is greater than `THRESHOLD`. The paused thread can resume if another thread uses `std::condition_variable::notify_all`, which notifies all the threads. This notification causes the thread to wake up even if the pause condition is still true.

**Correction — Wrap `std::condition_variable::wait` in a `while` Loop Explicitly**

One possible correction is to wrap the call to `std::condition_variable::wait` in a `while` loop. The loop checks the pause condition after the thread receives a possible spurious wake-up notification.

```
#include <stdio.h>
#include <stddef.h>
#include <thread>
#include <mutex>

#define THRESHOLD 100

std::mutex myMutex;
std::condition_variable cv;

void func(int input)
{
    std::unique_lock<std::mutex> lk(myMutex);
    // test condition to pause thread
    while (input > THRESHOLD) {
    //pause current thread
        cv.wait(lk);
    }
}
```

**Correction — Wrap `std::condition_variable::wait` in a Loop Implicitly**

The `std::condition_variable::wait` function has an overload that accepts a lambda function as a second argument. The predicate of the Lambda function indicates when it is safe to stop waiting and proceed with the code execution. This overload of the `std::condition_variable::wait` function behaves as if it is implicitly wrapped in a loop. In this code, the function`std::condition_variable::wait` is invoked by using a Lambda function. Here, unwanted waking of the thread is prevented because the thread wakes up when the predicate of the Lambda function is true.

```
#include <stdio.h>
#include <stdio.h>
#include <stddef.h>
#include <thread>
#include <mutex>
#define THRESHOLD 100

std::mutex myMutex;
std::condition_variable cv;

void func(int input)
{
    std::unique_lock<std::mutex> lk(myMutex);
    cv.wait(lk,[&input]{ return !(input>THRESHOLD); });

}
```

Do not modify the object referenced by the return value of certain functions

## Description

### Rule Definition

*Do not modify the object referenced by the return value of certain functions.*

### Polyspace Implementation

The rule checker checks for **Modification of internal buffer returned from nonreentrant standard function**.

## Examples

### Modification of internal buffer returned from nonreentrant standard function

**Issue**

**Modification of internal buffer returned from nonreentrant standard function** occurs when the following happens:

- A nonreentrant standard function returns a pointer.
- You attempt to write to the memory location that the pointer points to.

Nonreentrant standard functions that return a non `const`-qualified pointer to an internal buffer include `getenv`, `getlogin`, `crypt`, `setlocale`, `localeconv`, `strerror` and others.

**Risk**

Modifying the internal buffer that a nonreentrant standard function returns can cause the following issues:

- It is possible that the modification does not succeed or alters other internal data.

  For instance, `getenv` returns a pointer to an environment variable value. If you modify this value, you alter the environment of the process and corrupt other internal data.
- Even if the modification succeeds, it is possible that a subsequent call to the same standard function does not return your modified value.

  For instance, you modify the environment variable value that `getenv` returns. If another process, thread, or signal handler calls `setenv`, the modified value is overwritten. Therefore, a subsequent call to `getenv` does not return your modified value.

**Fix**

Avoid modifying the internal buffer using the pointer returned from the function.

**Example - Modification of `getenv` Return Value**

```
#include <stdlib.h>
#include <string.h>
```

```
void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        strncpy(env, "C", 1); //Noncompliant
        printstr(env);
    }
}
```

In this example, the first argument of `strncpy` is the return value from a nonreentrant standard function `getenv`. The behavior can be undefined because `strncpy` modifies this argument.

#### Correction - Copy Return Value of getenv and Modify Copy

One possible solution is to copy the return value of `getenv` and pass the copy to the `strncpy` function.

```
#include <stdlib.h>
#include <string.h>
enum {
    SIZE20 = 20
};

void printstr(const char*);

void func() {
    char* env = getenv("LANGUAGE");
    if (env != NULL) {
        char env_cp[SIZE20];
        strncpy(env_cp, env, SIZE20);
        strncpy(env_cp, "C", 1);
        printstr(env_cp);
    }
}
```

Do not rely on an environment pointer following an operation that may invalidate it

## Description

### Rule Definition

*Do not rely on an environment pointer following an operation that may invalidate it.*

### Polyspace Implementation

The rule checker checks for **Environment pointer invalidated by previous operation**.

## Examples

### Environment pointer invalidated by previous operation

#### Issue

**Environment pointer invalidated by previous operation** occurs when you use the third argument of *main()* in a hosted environment to access the environment after an operation modifies the environment. In a hosted environment, many C implementations support the nonstandard syntax:

```
main (int argc, char *argv[], char *envp[])
```

A call to a `setenv` or `putenv` family function modifies the environment pointed to by `*envp`.

#### Risk

When you modify the environment through a call to a `setenv` or `putenv` family function, the environment memory can potentially be reallocated. The hosted environment pointer is not updated and might point to an incorrect location. A call to this pointer can return unexpected results or cause an abnormal program termination.

#### Fix

Do not use the hosted environment pointer. Instead, use global external variable `environ` in Linux, `_environ` or `_wenviron` in Windows, or their equivalent. When you modify the environment, these variables are updated.

#### Example - Access Environment Through Pointer envp

```
#include <stdio.h>
#include <stdlib.h>

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

/* envp is from main function */
int func(char **envp)
{
    /* Call to setenv may cause environment
     *memory to be reallocated
     */
    if (setenv(("MY_NEW_VAR"),("new_value"),1) != 0)
    {
        /* Handle error */
        return -1;
    }
    /* envp not updated after call to setenv, and may
     *point to incorrect location.
     **/
    if (envp != ((void *)0)) { //Noncompliant
        use_envp(envp);
/* No defect on second access to
*envp because defect already raised */
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func(envp);
    }
}
```

In this example, `envp` is accessed inside `func()` after a call to `setenv` that can reallocate the environment memory. `envp` can point to an incorrect location because it is not updated after `setenv` modifies the environment. No defect is raised when `use_envp()` is called because the defect is already raised on the previous line of code.

**Correction — Use Global External Variable `environ`**

One possible correction is to access the environment by using a variable that is always updated after a call to `setenv`. For instance, in the following code, the pointer `envp` is still available from `main()`, but the environment is accessed in `func()` through the global external variable `environ`.

```
#include <stdio.h>
#include <stdlib.h>
extern char **environ;

extern int check_arguments(int argc, char **argv, char **envp);
extern void use_envp(char **envp);

int func(void)
{
    if (setenv(("MY_NEW_VAR"), ("new_value"),1) != 0) {
        /* Handle error */
        return -1;
    }
  /* Use global external variable environ
   *which is always updated after a call to setenv */

    if (environ != NULL) {
        use_envp(environ);
    }
    return 0;
}

void  main(int argc, char **argv, char **envp)
```

```
{
    if (check_arguments(argc, argv, envp))
    {
        (void)func();
    }
}
```

All exit handlers must return normally

## Description

### Rule Definition

*All exit handlers must return normally.*

### Polyspace Implementation

The rule checker checks for **Abnormal termination of exit handler**.

## Examples

### Abnormal termination of exit handler

#### Issue

**Abnormal termination of exit handler** looks for registered exit handlers. Exit handlers are registered with specific functions such as `atexit`, (WinAPI) `_onexit`, or `at_quick_exit()`. If the exit handler calls a function that interrupts the program's expected termination sequence, Polyspace raises a defect. Some functions that can cause abnormal exits are `exit`, `abort`, `longjmp`, or (WinAPI) `_onexit`.

#### Risk

If your exit handler terminates your program, you can have undefined behavior. Abnormal program termination means other exit handlers are not invoked. These additional exit handlers may do additional clean up or other required termination steps.

#### Fix

In inside exit handlers, remove calls to functions that prevent the exit handler from terminating normally.

#### Example - Exit Handler With Call to exit

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        exit(0);  //Noncompliant
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() performs additional cleanup */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

In this example, `demo_install_exitabnormalhandler` registers two exit handlers, `demo_exit1` and `exitabnormalhandler`. Exit handlers are invoked in the reverse order of which they are registered. When the program ends, `exitabnormalhandler` runs, then `demo_exit1`. However, `exitabnormalhandler` calls `exit` interrupting the program exit process. Having this `exit` inside an exit handler causes undefined behavior because the program is not finished cleaning up safely.

#### Correction — Remove exit from Exit Handler

One possible correction is to let your exit handlers terminate normally. For this example, `exit` is removed from `exitabnormalhandler`, allowing the exit termination process to complete as expected.

```
#include <stdlib.h>

volatile int some_condition = 1;
void demo_exit1(void)
{
    /* ... Cleanup code ... */
    return;
}
void exitabnormalhandler(void)
{
    if (some_condition)
    {
        /* Clean up */
        /* Return normally */
    }
    return;
}

int demo_install_exitabnormalhandler(void)
{

    if (atexit(demo_exit1) != 0) /* demo_exit1() continues clean up */
    {
        /* Handle error */
    }
    if (atexit(exitabnormalhandler) != 0)
    {
        /* Handle error */
    }
    /* ... Program code ... */
    return 0;
}
```

Do not call system()

## Description

### Rule Definition

*Do not call system().*

### Polyspace Implementation

The rule checker checks for **Unsafe call to a system function**.

## Examples

### Unsafe call to a system function

#### Issue

**Unsafe call to a system function** occurs when you use a function that invokes an implementation-defined command processor. These functions include:

- The C standard `system()` function.
- The POSIX `popen()` function.
- The Windows `_popen()` and `_wpopen()` functions.

#### Risk

If the argument of a function that invokes a command processor is not sanitized, it can cause exploitable vulnerabilities. An attacker can execute arbitrary commands or read and modify data anywhere on the system.

#### Fix

Do not use a `system`-family function to invoke a command processor. Instead, use safer functions such as POSIX `execve()` and WinAPI `CreateProcess()`.

#### Example - system() Called

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
    char buf[SIZE512];
    int retval=sprintf(buf, "/usr/bin/any_cmd %s", arg);
    if (retval<=0 || retval>SIZE512){
        /* Handle error */
        abort();
    }
    /* Use of system() to pass any_cmd with
    unsanitized argument to command processor */

    if (system(buf) == -1) { //Noncompliant
    /* Handle error */
  }
}
```

In this example, `system()` passes its argument to the host environment for the command processor to execute. This code is vulnerable to an attack by command-injection.

**Correction — Sanitize Argument and Use execve()**

In the following code, the argument of `any_cmd` is sanitized, and then passed to `execve()` for execution. `exec`-family functions are not vulnerable to command-injection attacks.

```
# include <string.h>
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>

enum {
SIZE512=512,
SIZE3=3};

void func(char *arg)
{
  char *const args[SIZE3] = {"any_cmd", arg, NULL};
  char  *const env[] = {NULL};

  /* Sanitize argument */

  /* Use execve() to execute any_cmd. */

  if (execve("/usr/bin/time", args, env) == -1) {
    /* Handle error */
  }
}
```

Do not store pointers returned by certain functions

## Description

### Rule Definition

*Do not store pointers returned by certain functions.*

### Polyspace Implementation

The rule checker checks for **Misuse of return value from nonreentrant standard function**.

## Examples

### Misuse of return value from nonreentrant standard function

#### Issue

**Misuse of return value from nonreentrant standard function** occurs when these events happen in this sequence:

1. You point to the buffer returned from a nonreentrant standard function such as `getenv` or `setlocale`.

   ```
   user = getenv("USER");
   ```
2. You call that nonreentrant standard function again.

   ```
   user2 = getenv("USER2");
   ```
3. You use or dereference the pointer from the first step expecting the buffer to remain unmodified since that step. In the meantime, the call in the second step has modified the buffer.

   For instance:

   ```
   var=*user;
   ```

In some cases, the defect might appear even if you do not call the `getenv` function a second time but simply return the pointer. For instance:

```
char* func() {
     user=getenv("USER");
     .
     .
     return user;
}
```

For information on which functions are covered by this defect, see documentation on nonreentrant standard functions.

#### Risk

The C Standard allows nonreentrant functions such as `getenv` to return a pointer to a *static* buffer. Because the buffer is static, a second call to `getenv` modifies the buffer. If you continue to use the

pointer returned from the first call past the second call, you can see unexpected results. The buffer that it points to no longer has values from the first call.

The defect appears even if you do not call `getenv` a second time but simply return the pointer. The reason is that someone calling your function might use the returned pointer *after* a second call to `getenv`. By returning the pointer from your call to `getenv`, you make your function unsafe to use.

The same rationale is true for other nonreentrant functions covered by this defect.

#### Fix

After the first call to `getenv`, make a copy of the buffer that the returned pointer points to. After the second call to `getenv`, use this copy. Even if the second call modifies the buffer, your copy is untouched.

#### Example - Return from getenv Used After Second Call to getenv

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");   /* First call */
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');

        if (user_name_from_home != NULL) {
            user = getenv("USER");   /* Second call */
            if ((user != NULL) &&
                (strcmp(user, user_name_from_home) == 0)) //Noncompliant
            {
                result = 1;
            }
        }
    }
    return result;
}
```

In this example, the pointer `user_name_from_home` is derived from the pointer `home`. `home` points to the buffer returned from the first call to `getenv`. Therefore, `user_name_from_home` points to a location in the same buffer.

After the second call to `getenv`, the buffer is modified. If you continue to use `user_name_from_home`, you can get unexpected results.

#### Correction — Make Copy of Buffer Before Second Call

If you want to access the buffer from the first call to `getenv` past the second call, make a copy of the buffer after the first call. One possible correction is to use the `strdup` function to make the copy.

```
#include <stdlib.h>
#include <string.h>

int func()
{
    int result = 0;

    char *home = getenv("HOME");
    if (home != NULL) {
        char *user = NULL;
        char *user_name_from_home = strrchr(home, '/');
        if (user_name_from_home != NULL) {
            /* Make copy before second call */
            char *saved_user_name_from_home = strdup(user_name_from_home);
            if (saved_user_name_from_home != NULL) {
                user = getenv("USER");
                if ((user != NULL) &&
                    (strcmp(user, saved_user_name_from_home) == 0))
                {
                    result = 1;
                }
                free(saved_user_name_from_home);
            }
        }
    }
    return result;
}
```

Do not use floating-point variables as loop counters

## Description

### Rule Definition

*Do not use floating-point variables as loop counters.*

### Polyspace Implementation

The rule checker checks for **Use of float variable as loop counter**.

## Examples

### Use of float variable as loop counter

#### Issue

The issue occurs when a loop counter has a floating type.

If the `for` index is a variable symbol, Polyspace checks that it is not a float.

#### Risk

When using a floating-point loop counter, accumulation of rounding errors can result in a mismatch between the expected and actual number of iterations. This rounding error can happen when a loop step that is not a power of the floating point radix is rounded to a value that can be represented by a float.

Even if a loop with a floating-point loop counter appears to behave correctly on one implementation, it can give a different number of iteration on another implementation.

#### Example - `for` Loop Counters

In this example, the three `for` loops show three different loop counters. The first and second `for` loops use float variables as loop counters, and therefore are not compliant. The third loop uses the integer `count` as the loop counter. Even though `count` is used as a float inside the loop, the variable remains an integer when acting as the loop index. Therefore, this `for` loop is compliant.

```
int main(void){
    unsigned int counter = 0u;
    int result = 0;
    float foo;

    // Float loop counters
    for(float foo = 0.0f; foo < 1.0f; foo +=0.001f){ /*Non-compliant*/
        /*counter = 1000 at the end of the loop */
        ++counter;
    }

    float fff = 0.0f;
    for(fff = 0.0f; fff <12.0f; fff += 1.0f){    /* Non-compliant*/
        result++;
    }

    // Integer loop count
    for(unsigned int count = 0u; count < 1000u; ++count){ /* Compliant */
        foo = (float) count * 0.001f;
    }
}
```

### `while` Loop Counters

This example shows two `while` loops both of which use floating point variables in the `while`-loop conditions:

- The first `while` loop uses the floating point variable `foo` in the condition and inside the loop. Because `foo` changes, floating-point rounding errors can cause unexpected behavior. Polyspace reports a violation.
- In the second while loop, the floating point array `buffer` is used in the loop condition. Polyspace identifies `iter1` and `iter2` as the loop variable. Because the loop variables are not floating point variables, a violation is not reported.

```
int main(void){
    unsigned int iter1 =0;
    int iter2;
    float foo;
    double buffer[2];
    double tmp;

    foo = 0.0f;
    while (foo < 1.0f){/* Non-compliant - foo used as a loop counter */
        foo += 0.001f;
    }

    //...
    while((iter1+1 < 2)&& (buffer[iter1]<buffer[iter2])){ //Compliant - loop counter is integer
        // swap buffer[iter1] and buffer[iter2]
        tmp = buffer[iter2];
        buffer[iter2] = buffer[iter1];
        buffer[iter1] = tmp;
        iter2 = iter1;
        iter1++;
    }

    return 1;
}
```

Prevent or detect domain and range errors in math functions

## Description

### Rule Definition

*Prevent or detect domain and range errors in math functions.*

### Polyspace Implementation

The rule checker checks for **Invalid use of standard library floating point routine**.

### Extend Checker

Extend this checker to check for defects caused by specific values and invalid use of functions from a custom library. For instance:

- You might be using a custom library of mathematical floating point functions. If a custom library function have the same domain and range as another function from the standard library, you can extend this checker to check the custom library function. See "Extend Bug Finder Checkers for Standard Library Functions to Custom Libraries".
- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See "Extend Bug Finder Checkers to Find Defects from Specific System Input Values".

## Examples

### Invalid use of standard library floating point routine

#### Issue

**Invalid use of standard library floating point routine** occurs when you use invalid arguments with a floating point function from the standard library. This defect picks up:

- Rounding and absolute value routines

  `ceil, fabs, floor, fmod`
- Fractions and division routines

  `fmod, modf`
- Exponents and log routines

  `frexp, ldexp, sqrt, pow, exp, log, log10`
- Trigonometry function routines

  `cos, sin, tan, acos, asin, atan, atan2, cosh, sinh, tanh, acosh, asinh, atanh`

### Risk

Domain errors on standard library floating point functions result in implementation-defined values. If you use the function return value in subsequent computations, you can see unexpected results.

### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the function argument acquires invalid values. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

It is a good practice to handle for domain errors before using a standard library floating point function. For instance, before calling the `acos` function, check if the argument is in [-1.0, 1.0] and handle the error.

See examples of fixes below.

If you do not want to fix the issue, for instance, when you handle infinities in your code, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

### Example - Arc Cosine Operation

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    return acos(degree); //Noncompliant
}
```

The input value to `acos` must be in the interval `[-1,1]`. This input argument, `degree`, is outside this range.

### Correction — Change Input Argument

One possible correction is to change the input value to fit the specified range. In this example, change the input value from degrees to radians to fix this defect.

```
#include <math.h>

double arccosine(void) {
    double degree = 5.0;
    double radian = degree * 3.14159 / 180.;
    return acos(radian);
}
```

Ensure that floating-point conversions are within range of the new type

## Description

### Rule Definition

*Ensure that floating-point conversions are within range of the new type.*

### Polyspace Implementation

This checker checks for:

- **Float conversion overflow**
- **Floating point to integer conversion overflow**

### Extend Checker

When the input values are unknown and only a subset of inputs cause an issue, Bug Finder might not detect a **Float conversion overflow** or **Floating point to integer conversion overflow**. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

## Examples

### Float conversion overflow

#### Issue

**Float conversion overflow** occurs when converting a floating point number to a smaller floating point data type. If the variable does not have enough memory to represent the original number, the conversion overflows.

The exact storage allocation for different floating point types depends on your processor. See `Target processor type (-target)`.

#### Risk

Overflows can result in unpredictable values from computations. The result can be infinity or the maximum finite value depending on the rounding mode used in the implementation. If you use the result of an overflowing conversion in subsequent computations and do not account for the overflow, you can see unexpected results.

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. Use this event list to determine how the variable being converted acquires its current value You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

In general, avoid conversions to smaller floating point types.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

**Example - Converting from `double` to `float`**

```
float convert(void) {

    double diam = 1e100;
    return (float)diam; //Noncompliant
}
```

In the return statement, the variable `diam` of type double (64 bits) is converted to a variable of type float (32 bits). However, the value 1^100 requires more than 32 bits to be precisely represented.

### Floating point to integer conversion overflow

**Issue**

**Floating point to integer conversion overflow** occurs when converting a floating-point value to an integer data type. If the integer part of the value cannot be represented within the storage available for the integer data type, the conversion overflows.

**Risk**

When converting from floating point to integer types, if the floating point value is outside the range that can be represented by the integer type, the behavior is undefined.

**Fix**

You can fix the defect by:

- Using a bigger data type for the result of the conversion so that all values can be accommodated.
- Checking for values that lead to the overflow and performing appropriate error handling.

  A check for overflowing values on a `float` variable `var` can be like this:

```
if  isnan(var)
    || popcount(INT_MAX) < log2f(fabsf(var))
    || (var != 0.0F && fabsf(var) < FLT_MIN)){
    // Handle error
```

```
}
else {
    // Perform operations on var
}
```

The check determines if the floating point value is representable within an integer type:

- The value is not NaN.
- The number of bits required to store the value is less than the number of bits in `INT_MAX` (the largest integer that the `int` type can represent). The `popcount` function (not defined here) counts the number of 1's (or set bits) in a number.
- The floating point value is not lower than the smallest representable value.

**Example – Floating Point Value Converted to Integer Without Handling Overflows**

```
void func(float fVar) {
  int iVar;
  iVar = fVar; //Noncompliant
}
```

In this example, the floating point value of `fVar` is not checked for overflows before converting to an integer type. Since the argument `fVar` can contain values that are not representable within the `int` data type, the analysis flags a potential overflow.

Note that `func` is not called in this example, and the overflow is only a possibility. To see issues of these types, add the analysis option `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

Preserve precision when converting integral values to floating-point type

## Description

### Rule Definition

*Preserve precision when converting integral values to floating-point type.*

### Polyspace Implementation

The rule checker checks for **Precision loss in integer to float conversion**.

## Examples

### Precision loss in integer to float conversion

#### Issue

**Precision loss from integer to float conversion** occurs when you cast an integer value to a floating-point type that cannot represent the original integer value.

For instance, the `long int` value `1234567890L` is too large for a variable of type `float` .

#### Risk

If the floating-point type cannot represent the integer value, the behavior is undefined (see C11 standard, 6.3.1.4, paragraph 2). For instance, least significant bits of the variable value can be dropped leading to unexpected results.

#### Fix

Convert to a floating-point type that can represent the integer value.

For instance, if the `float` data type cannot represent the integer value, use the `double` data type instead.

When writing a function that converts an integer to floating point type, before the conversion, check if the integer value can be represented in the floating-point type. For instance, `DBL_MANT_DIG * log2(FLT_RADIX)` represents the number of base-2 digits in the type `double`. Before conversion to the type `double`, check if this number is greater than or equal to the precision of the integer that you are converting. To determine the precision of an integer `num`, use this code:

```
size_t precision = 0;
while (num != 0) {
   if (num % 2 == 1) {
     precision++;
   }
   num >>= 1;
}
```

Some implementations provide a builtin function to determine the precision of an integer. For instance, GCC provides the function `__builtin_popcount`.

#### Example - Conversion of Large Integer to Floating-Point Type

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  float approx = big;//Noncompliant
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

In this example, the `long int` variable `big` is converted to `float`.

#### Correction — Use a Wider Floating-Point Type

One possible correction is to convert to the `double` data type instead of `float`.

```
#include <stdio.h>

int main(void) {
  long int big = 1234567890L;
  double approx = big;
  printf("%ld\n", (big - (long int)approx));
  return 0;
}
```

Do not use object representations to compare floating-point values

## Description

### Rule Definition

*Do not use object representations to compare floating-point values.*

### Polyspace Implementation

The rule checker checks for **Memory comparison of float-point values**.

## Examples

### Memory comparison of float-point values

#### Issue

**Memory comparison of float-point values** occurs when you compare the object representation of floating-point values or the object representation of structures containing floating-point members. When you use the functions `memcmp`, `bcmp`, or `wmemcmp` to perform the bit pattern comparison, the defect is raised.

#### Risk

The object representation of floating-point values uses specific bit patterns to encode those values. Floating-point values that are equal, for instance `-0.0` and `0.0` in the IEC 60559 standard, can have different bit patterns in their object representation. Similarly, floating-point values that are not equal can have the same bit pattern in their object representation.

#### Fix

When you compare structures containing floating-point members, compare the structure members individually.

To compare two floating-point values, use the `==` or `!=` operators. If you follow a standard that discourages the use of these operators, such as MISRA, ensure that the difference between the floating-point values is within an acceptable range.

#### Example - Using `memcmp` to Compare Structures with Floating-Point Members

```
#include <string.h>

typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

int func_cmp(myStruct *s1, myStruct *s2) {
/* Comparison between structures containing
* floating-point members */
    return memcmp //Noncompliant
        ((const void *)s1, (const void *)s2, sizeof(myStruct));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

In this example, `func_cmp()` calls `memcmp()` to compare the object representations of structures `s1` and `s2`. The comparison might be inaccurate because the structures contain floating-point members.

#### Correction — Compare Structure Members Individually

One possible correction is to compare the structure members individually and to ensure that the difference between the floating-point values is within an acceptable range defined by `ESP`.

```
 #include <string.h>
#include <math.h>
typedef struct {
    int i;
    float f;
} myStruct;

extern void initialize_Struct(myStruct *);

#define ESP 0.00001

int func_cmp(myStruct *s1, myStruct *s2) {

/*Structure members are compared individually */
    return ((s1->i == s2->i) &&
            (fabsf(s1->f - s2->f) <= ESP));
}

void func(void) {
    myStruct s1, s2;
    initialize_Struct(&s1);
    initialize_Struct(&s2);
    (void)func_cmp(&s1, &s2);
}
```

Do not use the rand() function for generating pseudorandom numbers

## Description

### Rule Definition

*Do not use the rand() function for generating pseudorandom numbers.*

### Polyspace Implementation

The rule checker checks for **Vulnerable pseudo-random number generator**.

## Examples

### Vulnerable pseudo-random number generator

#### Issue

The **Vulnerable pseudo-random number generator** identifies the use of cryptographically weak pseudo-random number generator (PRNG) routine, `rand`.

#### Risk

The `rand` function has a predictable output and must not be used for security purposes. When a predictable random value controls the execution flow, your program is vulnerable to malicious attacks.

#### Fix

Use more cryptographically sound random number generators, such as `CryptGenRandom` (Windows), `OpenSSL/RAND_bytes`(Linux/UNIX).

#### Example - Random Loop Numbers

```
#include <stdio.h>
#include <stdlib.h>

volatile int rd = 1;
int main(int argc, char *argv[])
{
    int j, r, nloops;
    struct random_data buf;
    int i = 0;

    nloops = rand(); //Noncompliant

    for (j = 0; j < nloops; j++) {
        if (random_r(&buf, &i))
            exit(1);
        printf("random_r: %ld\n", (long)i);
    }
    return 0;
}
```

This example uses `rand` and `random_r` to generate random numbers. If you use these functions for security purposes, these PRNGs can be the source of malicious attacks. The CERT C checker flags the use of the `rand` function.

#### Correction — Use Stronger PRNG

One possible correction is to replace the vulnerable PRNG with a stronger random number generator.

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/rand.h>

volatile int rd = 1;
int main(int argc, char* argv[])
{
    int j, r, nloops;
    unsigned char buf;
    unsigned int seed;
    int i = 0;

    if (argc != 3)
    {
        fprintf(stderr, "Usage: %s <seed> <nloops>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    seed = atoi(argv[1]);
    nloops = atoi(argv[2]);

    for (j = 0; j < nloops; j++) {
        if (RAND_bytes(&buf, i) != 1)
            exit(1);
        printf("RAND_bytes: %u\n", (unsigned)buf);
    }
    return 0;
}
```

Properly seed pseudorandom number generators

## Description

### Rule Definition

*Properly seed pseudorandom number generators.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Deterministic random output from constant seed**.
- **Predictable random output from predictable seed**.

## Examples

### Deterministic random output from constant seed

#### Issue

**Deterministic random output from constant seed** detects random standard functions that when given a constant seed, have deterministic output.

#### Risk

When some random functions, such as `srand`, `srandom`, and `initstate`, have constant seeds, the results produce the same output every time that your program is run. A hacker can disrupt your program if they know how your program behaves.

#### Fix

Use a different random standard function or use a nonconstant seed.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Random Number Generator Initialization

```
#include <stdlib.h>

void random_num(void)
{
    srand(12345U); //Noncompliant
    /* ... */
}
```

This example initializes a random number generator using `srand` with a constant seed. The random number generation is deterministic, making this function cryptographically weak.

#### Correction — Use Different Random Number Generator

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S
#include <stdlib.h>
#include <stdio.h>

unsigned int random_num_time(void)
{

    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

### Predictable random output from predictable seed

#### Issue

**Predictable random output from predictable seed** looks for random standard functions that use a nonconstant but predictable seed. Examples of predictable seed generators are `time`, `gettimeofday`, and `getpid`.

#### Risk

When you use predictable seed values for random number generation, your random numbers are also predictable. A hacker can disrupt your program if they know how your program behaves.

#### Fix

You can use a different function to generate less predictable seeds.

You can also use a different random number generator that does not require a seed. For example, the Windows API function `rand_s` seeds itself by default. It uses information from the entire system, for example, system time, thread ids, system counter, and memory clusters. This information is more random and a user cannot access this information.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Seed as an Argument

```
#include <stdlib.h>
#include <time.h>

void seed_rng(int seed)
```

```
{
    srand(seed); //Noncompliant
}

int generate_num(void)
{
    seed_rng(time(NULL) + 3);
    /* ... */
}
```

This example uses `srand` to start the random number generator with `seed` as the seed. However, `seed` is predictable because the function `time` generates it. So, an attacker can predict the random numbers generated by `srand`.

**Correction — Use Different Random Number Generator**

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S

#include <stdlib.h>
#include <stdio.h>
#include <errno.h>

int generate_num(void)
{
    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

Do not pass invalid data to the asctime() function

## Description

### Rule Definition

*Do not pass invalid data to the asctime() function.*

### Polyspace Implementation

The rule checker checks for **Use of obsolete standard function**.

## Examples

### Use of obsolete standard function

#### Issue

**Use of obsolete standard function** detects calls to standard function routines that are considered legacy, removed, deprecated, or obsolete by C/C++ coding standards.

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `asctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |
| `asctime_r` | Deprecated in POSIX.1-2008 | Implementation based on unsafe function `sprintf`. | `strftime` or `asctime_s` |
| `bcmp` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcmp` |
| `bcopy` | Deprecated in 4.3BSD<br>Marked as legacy in POSIX.1-2001. | Returns from function after finding the first differing byte, making it vulnerable to timing attacks. | `memcpy` or `memmove` |
| `brk` and `sbrk` | Marked as legacy in SUSv2 and POSIX.1-2001. | | `malloc` |
| `bsd_signal` | Removed in POSIX.1-2008 | | `sigaction` |
| `bzero` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | `memset` |
| `ctime` | Deprecated in POSIX.1-2008 | Not thread-safe. | `strftime` or `asctime_s` |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| ctime_r | Deprecated in POSIX.1-2008 | Implementation based on unsafe function sprintf. | strftime or asctime_s |
| cuserid | Removed in POSIX.1-2001. | Not reentrant. Precise functionality not standardized causing portability issues. | getpwuid |
| ecvt and fcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | Not reentrant | snprintf |
| ecvt_r and fcvt_r | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008 | | snprintf |
| ftime | Removed in POSIX.1-2008 | | time, gettimeofday, clock_gettime |
| gamma, gammaf, gammal | Function not specified in any standard because of historical variations | Portability issues. | tgamma, lgamma |
| gcvt | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | snprintf |
| getcontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| getdtablesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_OPEN_MAX ) |
| gethostbyaddr | Removed in POSIX.1-2008 | Not reentrant | getaddrinfo |
| gethostbyname | Removed in POSIX.1-2008 | Not reentrant | getnameinfo |
| getpagesize | BSD API function not included in POSIX.1-2001 | Portability issues. | sysconf( _SC_PAGESIZE ) |
| getpass | Removed in POSIX.1-2001. | Not reentrant. | getpwuid |
| getw | Not present in POSIX.1-2001. | | fread |
| getwd | Marked legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | getcwd |
| index | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | strchr |
| makecontext | Removed in POSIX.1-2008. | Portability issues. | Use POSIX thread instead. |
| memalign | Appears in SunOS 4.1.3. Not in 4.4 BSD or POSIX.1-2001 | | posix_memalign |
| mktemp | Removed in POSIX.1-2008. | Generated names are predictable and can cause a race condition. | mkstemp removes race risk |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| `pthread_attr_getstackaddr` and `pthread_attr_setstackaddr` | | Ambiguities in the specification of the `stackaddr` attribute cause portability issues | `pthread_attr_getstack` and `pthread_attr_setstack` |
| `putw` | Not present in POSIX.1-2001. | Portability issues. | `fwrite` |
| `qecvt` and `qfcvt` | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | `snprintf` |
| `qecvt_r` and `qfcvt_r` | Marked as legacy in POSIX.1-2001, removed in POSIX.1-2008 | | `snprintf` |
| `rand_r` | Marked as obsolete in POSIX.1-2008 | | |
| `re_comp` | BSD API function | Portability issues | `regcomp` |
| `re_exes` | BSD API function | Portability issues | `regexec` |
| `rindex` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | | `strrchr` |
| `scalb` | Removed in POSIX.1-2008 | | `scalbln`, `scalblnf`, or `scalblnl` |
| `sigblock` | 4.3BSD signal API whose origin is unclear | | `sigprocmask` |
| `sigmask` | 4.3BSD signal API whose origin is unclear | | `sigprocmask` |
| `sigsetmask` | 4.3BSD signal API whose origin is unclear | | `sigprocmask` |
| `sigstack` | Interface is obsolete and not implemented on most platforms. | Portability issues. | `sigaltstack` |
| `sigvec` | 4.3BSD signal API whose origin is unclear | | `sigaction` |
| `swapcontext` | Removed in POSIX.1-2008 | Portability issues. | Use POSIX threads. |
| `tmpnam` and `tmpnam_r` | Marked as obsolete in POSIX.1-2008. | This function generates a different string each time it is called, up to TMP_MAX times. If it is called more than TMP_MAX times, the behavior is implementation-defined. | `mkstemp`, `tmpfile` |
| `ttyslot` | Removed in POSIX.1-2001. | | |
| `ualarm` | Marked as legacy in POSIX.1-2001. Removed in POSIX.1-2008. | Errors are under-specified | `setitimer` or POSIX `timer_create` |
| `usleep` | Removed in POSIX.1-2008. | | `nanosleep` |
| `utime` | SVr4, POSIX.1-2001. POSIX.1-2008 marks as obsolete. | | |

| Obsolete Function | Standards | Risk | Replacement Function |
|---|---|---|---|
| valloc | Marked as obsolete in 4.3BSD.<br>Marked as legacy in SUSv2.<br>Removed from POSIX.1-2001 | | posix_memalign |
| vfork | Removed from POSIX.1-2008 | Under-specified in previous standards. | fork |
| wcswcs | This function was not included in the final ISO/IEC 9899:1990/ Amendment 1:1995 (E). | | wcsstr |
| WinExec | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |
| LoadModule | WinAPI provides this function only for 16-bit Windows compatibility. | | CreateProcess |

#### Fix

The fix depends on the root cause of the defect. Often the result details show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface”.

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

#### Example - Printing Out Time

```
#include <stdio.h>
#include <time.h>

void timecheck_bad(int argc, char *argv[])
{
    time_t ticks;

    ticks = time(NULL);
    printf("%.24s\r\n", ctime(&ticks)); //Noncompliant
}
```

In this example, the function `ctime` formats the current time and prints it out. However, `ctime` was removed after C99 because it does not work on multithreaded programs.

#### Correction — Different Time Function

One possible correction is to use `strftime` instead because this function uses a set buffer size.

```
#include <stdio.h>
#include <string.h>
#include <time.h>

void timecheck_good(int argc, char *argv[])
{
    char outBuff[1025];
    time_t ticks;
    struct tm * timeinfo;

    memset(outBuff, 0, sizeof(outBuff));

    ticks = time(NULL);
    timeinfo = localtime(&ticks);
    strftime(outBuff,sizeof(outBuff),"%I:%M%p.",timeinfo);
    fprintf(stdout, outBuff);
}
```

Ensure that control never reaches the end of a non-void function

## Description

### Rule Definition

*Ensure that control never reaches the end of a non-void function.*

### Polyspace Implementation

The rule checker checks for **Missing return statement**.

## Examples

### Missing return statement

#### Issue

**Missing return statement** occurs when a function does not return a value along at least one execution path. If the return type of the function is `void`, this error does not occur.

#### Risk

If a function has a non-`void` return value in its signature, it is expected to return a value. The return value of this function can be used in later computations. If the execution of the function body goes through a path where a `return` statement is missing, the function return value is indeterminate. Computations with this return value can lead to unpredictable results.

#### Fix

In most cases, you can fix this defect by placing the `return` statement at the end of the function body.

Alternatively, you can identify which execution paths through the function body do not have a `return` statement and add a `return` statement on those paths. Often the result details show a sequence of events that indicate this execution path. You can add a `return` statement at an appropriate point in the path. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Missing or invalid return statement error**

```
int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }
 }  //Noncompliant
/* Defect: No return value if n is not 0*/
```

If `n` is equal to 0, the code does not enter the `if` statement. Therefore, the function `AddSquares` does not return a value if `n` is 0.

**Correction — Place Return Statement on Every Execution Path**

One possible correction is to return a value in every branch of the `if...else` statement.

```
 int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }

   /*Fix: Place a return statement on branches of if-else */
   else
     return 0;
  }
```

Do not treat a predefined identifier as an object if it might only be implemented as a macro

## Description

### Rule Definition

*Do not treat a predefined identifier as an object if it might only be implemented as a macro.*

### Polyspace Implementation

The rule checker checks for **Predefined macro used as an object**.

## Examples

### Predefined macro used as an object

#### Issue

**Predefined macro used as an object** occurs when you use certain identifiers in a way that requires an underlying object to be present. These identifiers are defined as macros. The C Standard does not allow you to redefine them as objects. You use the identifiers in such a way that macro expansion of the identifiers cannot occur.

For instance, you refer to an external variable `errno`:

```
extern int errno;
```

However, `errno` does not occur as a variable but a macro.

The defect applies to these macros: `assert`, `errno`, `math_errhandling`, `setjmp`, `va_arg`, `va_copy`, `va_end`, and `va_start`. The checker looks for the defect only in source files (not header files).

#### Risk

The C11 Standard (Sec. 7.1.4) allows you to redefine most macros as objects. To access the object and not the macro in a source file, you do one of these:

- Redeclare the identifier as an external variable or function.
- For function-like macros, enclose the identifier name in parentheses.

If you try to use these strategies for macros that cannot be redefined as objects, an error occurs.

#### Fix

Do not use the identifiers in such a way that a macro expansion is suppressed.

- Do not redeclare the identifiers as external variables or functions.
- For function-like macros, do not enclose the macro name in parentheses.

#### Example - Use of `assert` as Function

```
#include<assert.h>
typedef void (*err_handler_func)(int);

extern void demo_handle_err(err_handler_func, int);

void func(int err_code) {
    extern void assert(int);    //Noncompliant
    demo_handle_err(&(assert), err_code); //Noncompliant
}
```

In this example, the `assert` macro is redefined as an external function. When passed as an argument to `demo_handle_err`, the identifier `assert` is enclosed in parentheses, which suppresses use of the `assert` macro.

#### Correction — Use `assert` as Macro

One possible correction is to directly use the `assert` macro from `assert.h`. A different implementation of the function `demo_handle_err` directly uses the `assert` macro instead of taking the address of an `assert` function.

```
#include<assert.h>
void demo_handle_err(int err_code) {
    assert(err_code == 0);
}

void func(int err_code) {
    demo_handle_err(err_code);
}
```

Do not call va_arg() on a va_list that has an indeterminate value

## Description

### Rule Definition

*Do not call va_arg() on a va_list that has an indeterminate value.*

### Polyspace Implementation

The rule checker checks for **Use of indeterminate va_list values**.

## Examples

### Use of indeterminate va_list values

#### Issue

This issue occurs when:

- You use a local `va_list` without initializing it first using `va_start` or `va_copy`.

  You might be using the local `va_list` in `va_arg` or a `vprintf`-like function (function that takes variable number of arguments).
- You use a `va_list` (variable argument list) from a function parameter directly instead of making a copy using `va_copy` and using the copy.

Note that the checker works on a per-function basis. If you initialize a `va_list` with `va_start` within a block, the checker considers the list as initialized beyond the block for the remainder of the function. Likewise, if you end the list with `va_end` within a block, the checker considers the list as ended beyond the block for the remainder of the function.

#### Risk

If you use a local `va_list` without initializing it first, the behavior is undefined.

If you pass a `va_list` to another function and use it there, the `va_list` has indeterminate values in the original calling function. Using the `va_list` in the calling function following the function call can produce unexpected results.

#### Fix

Initialize a local `va_list` with `va_start` or `va_copy` before using it.

Pass a `va_list` by reference. In the called function, make a copy of the passed `va_list` and use the copy. You can then continue to access the original `va_list` in the calling function.

#### Example – Direct Use of `va_list` From Another Function

```
#include <cstdarg>
#include <cstdio>
#include <climits>
```

```
int containsOutliers(size_t count, va_list ap) {
  for (size_t i = 1; i < count; ++i) {
    if (va_arg(ap, int) > INT_MAX) { //Noncompliant
      return 1;
    }
  }
  return 0;
}

int printList(size_t count, ...) {
  va_list ap;
  va_start(ap, count);

  if (containsOutliers(count, ap)) {
    va_end(ap);
    return 1;
  }

  for (size_t i = 0; i < count; ++i) {
    printf("%d", va_arg(ap, int));
  }

  va_end(ap);
  return 0;
}
```

In this example, the checker flags the direct use of the `va_list` variable `ap` obtained as argument in the `containsOutliers` function.

**Correction – Copy `va_list` Obtained from Another Function**

To avoid the violation, pass the `va_list` by reference and make a copy of the variable in the `containsOutliers` function. Perform further operations on the copy.

```
#include <cstdarg>
#include <cstdio>
#include <climits>

int containsOutliers(size_t count, va_list* ap) {
  va_list copiedAp;
  va_copy (copiedAp, *ap);

  for (size_t i = 1; i < count; ++i) {
    if (va_arg(copiedAp, int) > INT_MAX) {
      return 1;
    }
  }
  return 0;
}

int printList(size_t count, ...) {
  va_list ap;
  va_start(ap, count);

  if (containsOutliers(count, &ap)) {
    va_end(ap);
    return 1;
  }

  for (size_t i = 0; i < count; ++i) {
    printf("%d", va_arg(ap, int));
  }

  va_end(ap);
  return 0;
}
```

Do not violate constraints

## Description

### Rule Definition

*Do not violate constraints.*

### Polyspace Implementation

The rule checker checks for **Inline constraint not respected**.

## Examples

### Inline constraint not respected

#### Issue

**Inline constraint not respected** occurs when you refer to a file scope modifiable static variable or define a local modifiable static variable in a nonstatic inlined function. The checker considers a variable as modifiable if it is not `const`-qualified.

For instance, `var` is a modifiable `static` variable defined in an `inline` function `func`. `g_step` is a file scope modifiable static variable referred to in the same inlined function.

```
static int g_step;
inline void func (void) {
   static int var = 0;
   var += g_step;
}
```

#### Risk

When you modify a static variable in multiple function calls, you expect to modify the same variable in each call. For instance, each time you call `func`, the same instance of `var1` is incremented but a separate instance of `var2` is incremented.

```
void func(void) {
   static var1 = 0;
   int var2 = 0;
   var1++;
   var2++;
}
```

If a function has an inlined and non-inlined definition (in separate files), when you call the function, the C standard allows compilers to use either the inlined or the non-inlined form (see ISO/IEC 9899:2011, sec. 6.7.4). If your compiler uses an inlined definition in one call and the non-inlined definition in another, you are no longer modifying the same variable in both calls. This behavior defies the expectations from a static variable.

#### Fix

Use one of these fixes:

- If you do not intend to modify the variable, declare it as `const`.

  If you do not modify the variable, there is no question of unexpected modification.
- Make the variable non-`static`. Remove the `static` qualifier from the declaration.

  If the variable is defined in the function, it becomes a regular local variable. If defined at file scope, it becomes an extern variable. Make sure that this change in behavior is what you intend.
- Make the function `static`. Add a `static` qualifier to the function definition.

  If you make the function `static`, the file with the inlined definition always uses the inlined definition when the function is called. Other files use another definition of the function. The question of which function definition gets used is not left to the compiler.

#### Example - Static Variable Use in Inlined and External Definition

```
/* file1. c  : contains inline definition of get_random()*/

inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;  //Noncompliant
    static unsigned int m_w = 0xbaddecaf;  //Noncompliant

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}
```

```
/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

In this example, `get_random()` has an inline definition in `file1.c` and an external definition in `file2.c`. When `get_random` is called in `file1.c`, compilers are free to choose whether to use the inline or the external definition.

Depending on the definition used, you might or might not modify the version of `m_z` and `m_w` in the inlined version of `get_random()`. This behavior contradicts the usual expectations from a static variable. When you call `get_random()`, you expect to always modify the same `m_z` and `m_w`.

**Correction — Make Inlined Function Static**

One possible correction is to make the inlined `get_random()` static. Irrespective of your compiler, calls to `get_random()` in `file1.c` then use the inlined definition. Calls to `get_random()` in other files use the external definition. This fix removes the ambiguity about which definition is used and whether the static variables in that definition are modified.

```
/* file1. c  : contains inline definition of get_random()*/

static inline unsigned int get_random(void)
{

    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}

int call_get_random(void)
{
    unsigned int rand_no;
    int ii;
    for (ii = 0; ii < 100; ii++) {
         rand_no = get_random();
    }
    rand_no = get_random();
    return 0;
}

/* file2. c  : contains external definition of get_random()*/

extern unsigned int get_random(void)
{
    /* Initialize seeds */
    static unsigned int m_z = 0xdeadbeef;
    static unsigned int m_w = 0xbaddecaf;

    /* Compute next pseudorandom value and update seeds */
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
    m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w;
}
```

## Description

### Rule Definition

*Never hard code sensitive information.*

### Polyspace Implementation

The rule checker checks for **Hard coded sensitive data**.

## Examples

### Hard coded sensitive data

**Hard coded sensitive data** occurs when data that is potentially sensitive is directly exposed in the code, for instance, as string literals. The checker identifies data as sensitive from their use in certain functions such as password encryption functions.

Following data can be potentially sensitive.

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Host name | • `sethostname`, `setdomainname`, `gethostbyname`, `gethostbyname2`, `getaddrinfo`, `gethostbyname_r`, `gethostbyname2_r` (string argument)<br>• `inet_aton`, `inet_pton`, `inet_net_pton`, `inet_addr`, `inet_network` (string argument)<br>• `mysql_real_connect`, `mysql_real_connect_nonblocking`, `mysql_connect` (2nd argument) |
| Password | • `CreateProcessWithLogonW`, `LogonUser` (1st argument)<br>• `mysql_real_connect`, `mysql_real_connect_nonblocking`, `mysql_connect` (3rd argument) |

| Type of Data | Functions That Indicate Sensitive Nature of Information |
|---|---|
| Database | • MySQL: `mysql_real_connect`, `mysql_real_connect_nonblocking`, `mysql_connect` (4th argument)<br>• SQLite: `sqlite3_open`, `sqlite3_open16`, `sqlite3_open_v2` (1st argument)<br>• PostgreSQL: `PQconnectdb`<br>• Microsoft SQL: `SQLDriverConnect` (3rd argument) |
| User name | • `getpw`, `getpwnam`, `getpwnam_r`, `getpwuid`, `getpwuid_r` |
| Salt | `crypt`, `crypt_r` (2nd argument) |
| Cryptography keys and initialization vectors | OpenSSL:<br>• `EVP_CipherInit`, `EVP_EncryptInit`, `EVP_DecryptInit` (3rd argument)<br>• `EVP_CipherInit_ex`, `EVP_EncryptInit_ex`, `EVP_DecryptInit_ex` (4th argument) |
| Seed | • `srand`, `srandom`, `initstate` (1st argument)<br>• OpenSSL: `RAND_seed`, `RAND_add` |

#### Risk

Information that is hardcoded can be queried from binaries generated from the code.

#### Fix

Avoid hard coding sensitive information.

Do not use std::rand() for generating pseudorandom numbers

## Description

### Rule Definition

*Do not use std::rand() for generating pseudorandom numbers.*

### Polyspace Implementation

The rule checker checks for **Vulnerable pseudo-random number generator**.

## Examples

### Vulnerable pseudo-random number generator

#### Issue

The **Vulnerable pseudo-random number generator** identifies uses of cryptographically weak pseudo-random number generator (PRNG) routines.

The list of cryptographically weak routines flagged by this checker include:

- `rand`, `random`
- `drand48`, `lrand48`, `mrand48`, `erand48`, `nrand48`, `jrand48`, and their `_r` equivalents such as `drand48_r`
- `RAND_pseudo_bytes`

#### Risk

These cryptographically weak routines are predictable and must not be used for security purposes. When a predictable random value controls the execution flow, your program is vulnerable to malicious attacks.

#### Fix

Use more cryptographically sound random number generators, such as `CryptGenRandom` (Windows), `OpenSSL/RAND_bytes`(Linux/UNIX).

#### Example - Random Loop Numbers

```
#include <stdio.h>
#include <stdlib.h>

volatile int rd = 1;
int main(int argc, char *argv[])
{
    int j, r, nloops;
    struct random_data buf;
    int i = 0;
    nloops = rand(); //Noncompliant

    for (j = 0; j < nloops; j++) {
        if (random_r(&buf, &i)) //Noncompliant
            exit(1);
        printf("random_r: %ld\n", (long)i);
    }
    return 0;
}
```

This example uses `rand` and `random_r` to generate random numbers. If you use these functions for security purposes, these PRNGs can be the source of malicious attacks.

**Correction — Use Stronger PRNG**

One possible correction is to replace the vulnerable PRNG with a stronger random number generator.

```
#include <stdio.h>
#include <stdlib.h>
#include <openssl/rand.h>

volatile int rd = 1;
int main(int argc, char* argv[])
{
    int j, r, nloops;
    unsigned char buf;
    unsigned int seed;
    int i = 0;

    if (argc != 3)
    {
        fprintf(stderr, "Usage: %s <seed> <nloops>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    seed = atoi(argv[1]);
    nloops = atoi(argv[2]);

    for (j = 0; j < nloops; j++) {
        if (RAND_bytes(&buf, i) != 1)
            exit(1);
        printf("RAND_bytes: %u\n", (unsigned)buf);
    }
    return 0;
}
```

Ensure your random number generator is properly seeded

## Description

### Rule Definition

*Ensure your random number generator is properly seeded.*

### Polyspace Implementation

The rule checker checks for these issues:

- **Deterministic random output from constant seed**.
- **Predictable random output from predictable seed**.

## Examples

### Deterministic random output from constant seed

#### Issue

**Deterministic random output from constant seed** detects random standard functions that when given a constant seed, have deterministic output.

#### Risk

When some random functions, such as `srand`, `srandom`, and `initstate`, have constant seeds, the results produce the same output every time that your program is run. A hacker can disrupt your program if they know how your program behaves.

#### Fix

Use a different random standard function or use a nonconstant seed.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Random Number Generator Initialization

```
#include <stdlib.h>

void random_num(void)
{
    srand(12345U); //Noncompliant
    /* ... */
}
```

This example initializes a random number generator using `srand` with a constant seed. The random number generation is deterministic, making this function cryptographically weak.

#### Correction — Use Different Random Number Generator

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S
#include <stdlib.h>
#include <stdio.h>

unsigned int random_num_time(void)
{

    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

### Predictable random output from predictable seed

#### Issue

**Predictable random output from predictable seed** looks for random standard functions that use a nonconstant but predictable seed. Examples of predictable seed generators are `time`, `gettimeofday`, and `getpid`.

#### Risk

When you use predictable seed values for random number generation, your random numbers are also predictable. A hacker can disrupt your program if they know how your program behaves.

#### Fix

You can use a different function to generate less predictable seeds.

You can also use a different random number generator that does not require a seed. For example, the Windows API function `rand_s` seeds itself by default. It uses information from the entire system, for example, system time, thread ids, system counter, and memory clusters. This information is more random and a user cannot access this information.

Some standard random routines are inherently cryptographically weak on page 13-97, and should not be used for security purposes.

#### Example - Seed as an Argument

```
#include <stdlib.h>
#include <time.h>

void seed_rng(int seed)
```

```
{
    srand(seed); //Noncompliant
}

int generate_num(void)
{
    seed_rng(time(NULL) + 3);
    /* ... */
}
```

This example uses `srand` to start the random number generator with `seed` as the seed. However, `seed` is predictable because the function `time` generates it. So, an attacker can predict the random numbers generated by `srand`.

**Correction — Use Different Random Number Generator**

One possible correction is to use a random number generator that does not require a seed. This example uses `rand_s`.

```
#define _CRT_RAND_S

#include <stdlib.h>
#include <stdio.h>
#include <errno.h>

int generate_num(void)
{
    unsigned int number;
    errno_t err;
    err = rand_s(&number);

    if(err != 0)
    {
        return number;
    }
    else
    {
        return err;
    }
}
```

Value-returning functions must return a value from all exit paths

## Description

### Rule Definition

*Value-returning functions must return a value from all exit paths.*

### Polyspace Implementation

The rule checker checks for **Missing return statement**.

## Examples

### Missing return statement

#### Issue

**Missing return statement** occurs when a function does not return a value along at least one execution path. If the return type of the function is `void`, this error does not occur.

#### Risk

If a function has a non-`void` return value in its signature, it is expected to return a value. The return value of this function can be used in later computations. If the execution of the function body goes through a path where a `return` statement is missing, the function return value is indeterminate. Computations with this return value can lead to unpredictable results.

#### Fix

In most cases, you can fix this defect by placing the `return` statement at the end of the function body.

Alternatively, you can identify which execution paths through the function body do not have a `return` statement and add a `return` statement on those paths. Often the result details show a sequence of events that indicate this execution path. You can add a `return` statement at an appropriate point in the path. If the result details do not show the event history, you can trace back using right-click options in the source code and see previous related events. See also "Interpret Bug Finder Results in Polyspace Desktop User Interface".

See examples of fixes below.

If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

**Example - Missing or invalid return statement error**

```
int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }
 }  //Noncompliant
/* Defect: No return value if n is not 0*/
```

If `n` is equal to 0, the code does not enter the `if` statement. Therefore, the function `AddSquares` does not return a value if `n` is 0.

**Correction — Place Return Statement on Every Execution Path**

One possible correction is to return a value in every branch of the `if...else` statement.

```
 int AddSquares(int n)
 {
   int i=0;
   int sum=0;

   if(n!=0)
    {
     for(i=1;i<=n;i++)
        {
         sum+=i^2;
        }
     return(sum);
    }

   /*Fix: Place a return statement on branches of if-else */
   else
     return 0;
  }
```

Do not return from a function declared [[noreturn]]

## Description

### Rule Definition

*Do not return from a function declared [[noreturn]]*

### Polyspace Implementation

The rule checker checks for **`[[noreturn]]` functions returning to Caller**.

## Examples

### `[[noreturn]]` functions returning to caller

#### Issue

This defect occurs when a `[[noreturn]]` function eventually returns the flow of execution to the caller function. The compiler expects that a function declared by using the `[[noreturn]]` attribute does not return the flow of execution. That is, if a `[[noreturn]]` function `f()` is called from `main()`, then the compiler expects that the flow of execution is not returned to `main()`. If such a function eventually returns the flow of execution, it leads to undefined behavior.

#### Risk

If a `[[noreturn]]` function eventually returns the flow of execution, it leads to undefined behavior, which can be exploited to cause data integrity violations.

#### Fix

If a function has no `return` statement, then the final closing brace of a function implies an implicit `return`. Omitting a `return` statement in the function does not prevent the flow of execution from returning. A `[[noreturn]]` function can prohibit returning the flow of execution to the calling function by:

- Entering an infinite loop
- Raising an exception
- Calling another `[[noreturn]]` function

#### Example

Consider the following code containing the function `noncompliant()`, which is declared as `[[noreturn]]`.

```
#include <cstdlib>
[[noreturn]] void bad_f(int i)
{
    if (i > 0)
    throw "Received positive input";
    else if (i < 0)
    std::exit(0);
} //Noncompliant
```

When the input `i` is zero, the flow of execution skips the `if-else-if` block of code and returns to the caller implicitly. Because the `[[noreturn]]` function returns the flow of execution in a code path, this function is noncompliant with this rule.

**Correction**

A `[[noreturn]]` function must not return the flow of execution in a code path. You can prevent returning in several ways. Consider the following code where the `[[noreturn]]` function does not return the flow of execution in a code path.

```
#include <cstdlib>
[[noreturn]] void compliant(int i)
{
    if (i > 0)
    throw "Received positive input";
    else if (i < 0)
    std::exit(0);
    else if(i==0)
    while(true){
        //...
    }
}//Compliant
```

This function is compliant with this rule because:

- When `i > 0`, the function raises an exception.
- When `i < 0`, the function calls the `[[noreturn]]` function `std::exit()`.
- When `i==0`, the function enters an infinite loop.

Because the `[[noreturn]]` function does not return the flow of execution in a call path, it is compliant with this rule.

Do not create a universal character name through concatenation

## Description

### Rule Definition

*Do not create a universal character name through concatenation.*

### Polyspace Implementation

The rule checker checks for **Universal character name from token concatenation**.

## Examples

### Universal character name from token concatenation

#### Issue

**Universal character name from token concatenation** occurs when two preprocessing tokens joined with a ## operator create a universal character name. A universal character name begins with `\u` or `\U` followed by hexadecimal digits. It represents a character not found in the basic character set.

For instance, you form the character `\u0401` by joining two tokens:

```
#define assign(uc1, uc2, val) uc1##uc2 = val
...
assign(\u04, 01, 4);
```

#### Risk

The C11 Standard (Sec. 5.1.1.2) states that if a universal character name is formed by token concatenation, the behavior is undefined.

#### Fix

Use the universal character name directly instead of producing it through token concatenation.

#### Example - Universal Character Name from Token Concatenation

```
#define assign(uc1, uc2, val) uc1##uc2 = val

int func(void) {
    int \u0401 = 0;
    assign(\u04, 01, 4);
    return \u0401;
}
```

In this example, the `assign` macro, when expanded, joins the two tokens `\u04` and `01` to form the universal character name `\u0401`.

#### Correction — Use Universal Character Name Directly

One possible correction is to use the universal character name `\u0401` directly. The correction redefines the `assign` macro so that it does not join tokens.

```
#define assign(ucn, val) ucn = val

int func(void) {
    int \u0401 = 0;
    assign(\u0401, 4);
    return \u0401;
}
```

Avoid side effects in arguments to unsafe macros

## Description

### Rule Definition

*Avoid side effects in arguments to unsafe macros.*

### Polyspace Implementation

The rule checker checks for **Side effect in arguments to unsafe macro**.

## Examples

### Side effect in arguments to unsafe macro

#### Issue

**Side effect in arguments to unsafe macro** occurs when you call an unsafe macro with an expression that has a side effect.

- *Unsafe macro*: When expanded, an unsafe macro evaluates its arguments multiple times or does not evaluate its argument at all.

  For instance, the ABS macro evaluates its argument x twice.

  ```
  #define ABS(x) (((x) < 0) ? -(x) : (x))
  ```
- *Side effect*: When evaluated, an expression with a side effect modifies at least one of the variables in the expression.

  For instance, ++n modifies n, but n+1 does not modify n.

  The checker does not consider side effects in nested macros. The checker also does not consider function calls or volatile variable access as side effects.

#### Risk

If you call an unsafe macro with an expression that has a side effect, the expression is evaluated multiple times or not evaluated at all. The side effect can occur multiple times or not occur at all, causing unexpected behavior.

For instance, in the call MACRO(++n), you expect only one increment of the variable n. If MACRO is an unsafe macro, the increment happens more than once or does not happen at all.

The checker flags expressions with side effects in the assert macro because the assert macro is disabled in non-debug mode. To compile in non-debug mode, you define the NDEBUG macro during compilation. For instance, in GCC, you use the flag -DNDEBUG.

#### Fix

Evaluate the expression with a side effect in a separate statement, and then use the result as a macro argument.

For instance, instead of:

```
MACRO(++n);
```

perform the operation in two steps:

```
++n;
MACRO(n);
```

Alternatively, use an inline function instead of a macro. Pass the expression with side effect as argument to the inline function.

The checker considers modifications of a local variable defined only in the block scope of a macro body as a side effect. This defect cannot happen since the variable is visible only in the macro body. If you see a defect of this kind, ignore the defect.

#### Example - Macro Argument with Side Effects

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  int m = ABS(++n); //Noncompliant

  /* ... */
}
```

In this example, the ABS macro evaluates its argument twice. The second evaluation can result in an unintended increment.

#### Correction — Separate Evaluation of Expression from Macro Usage

One possible correction is to first perform the increment, and then pass the result to the macro.

```
#define ABS(x) (((x) < 0) ? -(x) : (x))

void func(int n) {
  /* Validate that n is within the desired range */
  ++n;
  int m = ABS(n);

  /* ... */
}
```

#### Correction — Evaluate Expression in Inline Function

Another possible correction is to evaluate the expression in an inline function.

```
static inline int iabs(int x) {
  return (((x) < 0) ? -(x) : (x));
}

void func(int n) {
  /* Validate that n is within the desired range */

int m = iabs(++n);

  /* ... */
}
```

Do not use preprocessor directives in invocations of function-like macros

## Description

### Rule Definition

*Do not use preprocessor directives in invocations of function-like macros.*

### Polyspace Implementation

The rule checker checks for **Preprocessor directive in macro argument**.

## Examples

### Preprocessor directive in macro argument

#### Issue

**Preprocessor directive in macro argument** occurs when you use a preprocessor directive in the argument to a function-like macro or a function that might be implemented as a function-like macro.

For instance, a `#ifdef` statement occurs in the argument to a `memcpy` function. The `memcpy` function might be implemented as a macro.

```
memcpy(dest, src,
    #ifdef PLATFORM1
      12
    #else
      24
    #endif
  );
```

The checker flags similar usage in `printf` and `assert`, which can also be implemented as macros.

#### Risk

During preprocessing, a function-like macro call is replaced by the macro body and the parameters are replaced by the arguments to the macro call (argument substitution). Suppose a macro `min()` is defined as follows.

```
#define min(X, Y)  ((X) < (Y) ? (X) : (Y))
```

When you call `min(1,2)`, it is replaced by the body `((X) < (Y) ? (X) : (Y))`. `X` and `Y` are replaced by 1 and 2.

According to the C11 Standard (Sec. 6.10.3), if the list of arguments to a function-like macro itself has preprocessing directives, the argument substitution during preprocessing is undefined.

#### Fix

To ensure that the argument substitution happens in an unambiguous manner, use the preprocessor directives outside the function-like macro.

For instance, to execute memcpy with different arguments based on a #ifdef directive, call memcpy multiple times within the #ifdef directive branches.

```
#ifdef PLATFORM1
    memcpy(dest, src, 12);
#else
    memcpy(dest, src, 24);
#endif
```

**Example - Directives in Function-Like Macros**

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
    print(
#ifdef SW //Noncompliant
          "Message 1"
#else
          "Message 2"
#endif //Noncompliant
         );
}
```

In this example, the preprocessor directives #ifdef and #endif occur in the argument to the function-like macro print().

**Correction — Use Directives Outside Macro**

One possible correction is to use the function-like macro multiple times in the branches of the #ifdef directive.

```
#include <stdio.h>

#define print(A) printf(#A)

void func(void) {
#ifdef SW
        print("Message 1");
#else
        print("Message 2");
#endif
}
```

Do not access shared objects in signal handlers

## Description

### Rule Definition

*Do not access shared objects in signal handlers.*

### Polyspace Implementation

The rule checker checks for **Shared data access within signal handler**.

## Examples

### Shared data access within signal handler

#### Issue

**Shared data access within signal handler** occurs when you access or modify a shared object inside a signal handler.

#### Risk

When you define a signal handler function to access or modify a shared object, the handler accesses or modifies the shared object when it receives a signal. If another function is already accessing the shared object, that function causes a race condition and can leave the data in an inconsistent state.

#### Fix

To access or modify shared objects inside a signal handler, check that the objects are lock-free atomic, or, if they are integers, declare them as `volatile sig_atomic_t`.

#### Example - `int` Variable Access in Signal Handler

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* declare global variable. */
int e_flag;

void sig_handler(int signum)
{
    /* Signal handler accesses variable that is not
    of type volatile sig_atomic_t. */
    e_flag = signum;  //Noncompliant
}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

In this example, `sig_handler` accesses `e_flag`, a variable of type `int`. A concurrent access by another function can leave `e_flag` in an inconsistent state.

**Correction — Declare Variable of Type `volatile sig_atomic_t`**

Before you access a shared variable from a signal handler, declare the variable with type `volatile sig_atomic_t` instead of `int`. You can safely access variables of this type asynchronously.

```
#include <signal.h>
#include <stdlib.h>
#include <string.h>

/* Declare variable of type volatile sig_atomic_t. */
volatile sig_atomic_t e_flag;
void sig_handler(int signum)
{
    /* Use variable of proper type inside signal handler. */
    e_flag = signum;

}

int func(void)
{
    if (signal(SIGINT, sig_handler) == SIG_ERR)
    {
        /* Handle error */
        abort();
    }
    /* Program code */
    if (raise(SIGINT) != 0)
    {
        /* Handle error */
        abort();
    }
    /* More code */
    return 0;
}
```

Do not call signal() from within interruptible signal handlers

## Description

### Rule Definition

*Do not call signal() from within interruptible signal handlers.*

### Polyspace Implementation

The rule checker checks for **Signal call from within signal handler**.

## Examples

### Signal call from within signal handler

#### Issue

**Signal call from within signal handler** occurs when you call `signal()` from a signal handler on Windows platforms.

The issue is detected only if you specify a Visual Studio compiler. See `Compiler (-compiler)`.

#### Risk

The function `signal()` associates a signal with a signal handler function. On platforms such as Windows, which removes this association after receiving the signal, you might call the function `signal()` again *within the signal handler* to re-establish the association.

However, this attempt to make a signal handler persistent is prone to race conditions. On Windows platforms, from the time the signal handler begins execution to when the `signal` function is called again, it is the default signal handling, `SIG_DFL`, that is active. If a second signal is received within this time window, you see the default signal handling and not the custom signal handler, but you might expect otherwise.

#### Fix

Do not call `signal()` from a signal handler on Windows platforms.

#### Example - `signal()` Called from Signal Handler

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;

    /* Call signal() to reestablish sig_handler
    upon receiving SIG_ERR. */

    if (signal(s0, sig_handler) == SIG_ERR)  //Noncompliant
    {
        /* Handle error */
    }
}

void func(void)
{
        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */

        }
  /* more code */
}
```

In this example, the definition of `sig_handler()` includes a call to `signal()` when the handler catches `SIG_ERR`. On Windows platforms, signal handlers are nonpersistent. This code can result in a race condition.

The issue is detected only if you specify a compiler such as `visual15.x` for the analysis.

**Correction — Do Not Call `signal()` from Signal Handler**

Avoid attempting to make a signal handler persistent on Windows. If your code requires the use of a persistent signal handler on a Windows platform, use a persistent signal handler after performing a thorough risk analysis.

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <unistd.h>

volatile sig_atomic_t e_flag = 0;

void sig_handler(int signum)
{
    int s0 = signum;
    e_flag = 1;
    /* No call to signal() */
}

int main(void)
{

        if (signal(SIGINT, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }
}
```

Do not return from a computational exception signal handler

## Description

### Rule Definition

*Do not return from a computational exception signal handler.*

### Polyspace Implementation

The rule checker checks for **Return from computational exception signal handler**.

## Examples

### Return from computational exception signal handler

#### Issue

**Return from computational exception signal handler** occurs when a signal handler returns after catching a computational exception signal `SIGFPE`, `SIGILL`, or `SIGSEGV`.

#### Risk

A signal handler that returns normally from a computational exception is undefined behavior. Even if the handler attempts to fix the error that triggered the signal, the program can behave unexpectedly.

#### Fix

Check the validity of the values of your variables before the computation to avoid using a signal handler to catch exceptions. If you cannot avoid a handler to catch computation exception signals, call `abort()`, `quick_exit()`, or `_Exit()` in the handler to stop the program.

#### Example - Signal Handler Return from Division by Zero

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */
void sig_handler(int s)
{
    int s0 = s;
    if (denom == 0)
    {
        denom = 1;
    }
    /* Normal return from computation exception
    signal */
    return;  //Noncompliant
}
```

```
long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

In this example, `sig_handler` is declared to handle a division by zero computation error. The handler changes the value of `denom` if it is zero and returns, which is undefined behavior.

**Correction — Call `abort()` to Terminate Program**

After catching a computational exception, call `abort()` from `sig_handler` to exit the program without further error.

```
#include <errno.h>
#include <limits.h>
#include <signal.h>
#include <stdlib.h>

static volatile sig_atomic_t denom;
/* Declare signal handler to catch division by zero
computation error. */

void sig_handler(int s)
{
    int s0 = s;
    /* call to abort() to exit the program */
    abort();
}

long func(int v)
{
    denom = (sig_atomic_t)v;

        if (signal(SIGFPE, sig_handler) == SIG_ERR)
        {
            /* Handle error */
        }

    long result = 100 / (long)denom;
    return result;
}
```

# AUTOSAR C++14 Rules

# AUTOSAR C++14 Rule A0-1-1

A project shall not contain instances of non-volatile variables being given values that are not subsequently used

## Description

### Rule Definition

*A project shall not contain instances of non-volatile variables being given values that are not subsequently used.*

### Rationale

If you assign a value to a variable but do not use the variable value subsequently, the assignment might indicate a programming error. Perhaps you forgot to use the variable later or incorrectly used other variables at the intended points of use.

### Polyspace Implementation

The checker flags value assignments to local and static variables with file scope if the assigned values are not subsequently used. The checker considers `const`-qualified global variables without the `extern` specifier as static variables with file scope.

The checker flags:

- Initializations if the initialized variable is not used.
- Non-initialization assignments if the assigned values are not used.

The checker does not flag the situation where an initialization value is immediately overwritten and therefore ends up unused.

The checker does not flag redundant assignments:

- To variables with class type.
- In the last iteration of a loop, if the assignments in the previous iterations are not redundant.

  For instance, the assignment `prevIter = i` in the last iteration of the loop is redundant but the assignments in the previous iterations are not.

  ```
  void doSomething(int);

  void func() {
    int prevIter=-1, uBound=100;
    for(int i=0; i < uBound; i++) {
          doSomething(prevIter);
          prevIter = i;
    }
  }
  ```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Initialization Value Not Used

```
class largeInteger {
       largeInteger(int d1, int d2, int d3):
            lastFiveDigits(d1), nextFiveDigits(d2), firstFiveDigits(d3){}
       largeInteger& operator=(const largeInteger& other) {
            if(&other !=this) {
              firstFiveDigits = other.firstFiveDigits;
              nextFiveDigits = other.nextFiveDigits;
              lastFiveDigits = other.lastFiveDigits;
            }
            return *this;
       }
       void printIntegerValue();
    private:
        int firstFiveDigits;
        int nextFiveDigits;
        int lastFiveDigits;
};

bool compareValues(largeInteger, largeInteger);

void func() {
    largeInteger largeUnit{10000,0,0}; //Compliant
    largeInteger smallUnit{1,0,0}; //Compliant
    largeInteger tinyUnit{0,1,0}; //Noncompliant
    if(compareValues (largeUnit, smallUnit)) {
        //Perform some action
    }
}
```

In this example, the variable `tinyUnit` is initialized but never used.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A0-1-2

The value returned by a function having a non-void return type that is not an overloaded operator shall be used

## Description

### Rule Definition

*The value returned by a function having a non-void return type that is not an overloaded operator shall be used.*

### Rationale

The unused return value can indicate a coding error or oversight.

Overloaded operators are excluded from this rule because their usage must emulate built-in operators that might not use their return value.

### Polyspace Implementation

The rule checker reports a violation on functions with a non-`void` return type if the return value is not used or not explicitly cast to a `void` type.

The checker does not flag the functions `memcpy`, `memset`, `memmove`, `strcpy`, `strncpy`, `strcat`, `strncat` because these functions simply return a pointer to their first arguments.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Return Value

```
#include <iostream>
#include <new>
#include <algorithm>
#include <cstdint>
#include <vector>

int assignMemory(int * ptr){
     int res = 1;
     ptr = new (std::nothrow) int;
     if(ptr==NULL) {
         res = 0;
     }
     return res;
}
void foo()
{
}

void main() {
    int val;
    int status;
    std::vector<std::int8_t> numVec{10,10,20,20,30,40,50,50,60};

    assignMemory(&val);   //Noncompliant
    status = assignMemory(&val); //Compliant
    (void)assignMemory(&val); //Compliant

    numVec.erase(std::unique(numVec.begin(), numVec.end()), numVec.end());// Noncompliant
}
```

In this example, Polyspace flags calls to functions with unused return value:

- Because `main` does not use the return value of the first call to the function `assignMemory`, Polyspace reports a violation.
- Because the return value of the second call to `assignMemory` is assigned to a local variable, it is compliant with this rule.
- Because the third call to `assignMemory` is cast to `void`, it is compliant with this rule
- Because `main` does not use the object returned by the function `std::vector::erase()`, Polyspace reports a violation.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A0-1-3

Every function defined in an anonymous namespace, or static function with internal linkage, or private member function shall be used

## Description

### Rule Definition

*Every function defined in an anonymous namespace, or static function with internal linkage, or private member function shall be used.*

### Rationale

Functions defined in an anonymous namespace and static functions with internal linkage are callable only inside the compilation unit in which they are defined. Similarly, private member functions are callable only inside the class implementation that they belong to. In both these cases, such functions are intended to be used exclusively in the current source code and not in external code that is integrated later on into the project. Not using such functions indicates poor software design or missing logic in the current code base.

**Note** An explicit function call in the source code is sufficient to satisfy this rule, even if the call is not reachable at run time. A separate rule, M0-1-1, checks for all unreachable code occurrences.

### Polyspace Implementation

If a function defined in your source code is not called explicitly and belongs to one of these categories, the checker flags the function definition:

- Functions defined in anonymous namespace
- Static functions with internal linkage
- Private member functions that are defined outside the class definition

The checker does not flag an uncalled private member function that is defined inside the class definition.

*The checker does not flag private member functions that are defined outside the class definition in a default Polyspace* as You Code *analysis. See “Checkers Deactivated in Polyspace as You Code Analysis”*.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Function in Anonymous Namespace Not Used

```
#include <cstdint>
```

```
namespace
{
  void F1()   // Compliant, function in anonymous namespace used
  {
  }

  void F2()   // Noncompliant, function in anonymous namespace not used
  {
  }
}

int main()
{
  F1();
  return 0;
}
```

The static function F2 is defined in an anonymous namespace but is not called from the main function, thus violating this coding rule.

### Static Function Not Used

```
#include <cstdint>
static void F1() // Compliant, static function called from main
{
}

static void F2() // Noncompliant, static function not called from main
{
}

int main()
{
  F1();
  return 0;
}
```

The static function F2 has internal linkage but is not called from the main function, thus violating this coding rule.

### Private Member Function Not Used

```
#include <cstdint>

class C
{
  public:
    C() : x(0) {}
    void M1(std::int32_t);
    void M2(std::int32_t, std::int32_t);
  private:
    std::int32_t x;
    void M1PrivateImpl(std::int32_t j);
};

// Compliant, member function is used
void C::M1(std::int32_t i)
{
  x = i;
}

// Compliant, never used but declared as public
void C::M2(std::int32_t i, std::int32_t j)
{
  x = (i > j) ? i : j;
}

void C::M1PrivateImpl(std::int32_t j) // Noncompliant, private member function never used
{
  x = j;
}

int main()
{
  C c;
  c.M1(1);
  return 0;
}
```

The private member function `M1PrivateImpl` is not called from any member of the class `C`, thus violating this coding rule.

# AUTOSAR C++14 Rule A0-1-4

There shall be no unused named parameters in non-virtual functions

## Description

### Rule Definition

*There shall be no unused named parameters in non-virtual functions.*

### Rationale

Unused parameters can indicate that the code is possibly incomplete. The parameter is possibly intended for an operation that you forgot to code or leftover from a design change.

If the parameters are obtained by copy and the copied objects are large, the redundant copies can slow down performance.

### Polyspace Implementation

The checker flags a function that has unused named parameters unless the function body is empty.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** Language Independent Issues
**Category:** Required, Automated

# Version History

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A0-1-5

There shall be no unused named parameters in the set of parameters for a virtual function and all the functions that override it

## Description

### Rule Definition

*There shall be no unused named parameters in the set of parameters for a virtual function and all the functions that override it.*

### Rationale

Unused parameters can indicate that the code is possibly incomplete. The parameter is possibly intended for an operation that you forgot to code.

The rule focuses on virtual functions because all functions that override a virtual function must have the same signature as the virtual function, including number and type of parameters. If a parameter is indeed not required, the issue can cascade from the original function to all overriding functions.

However, in an overriding function, you might not have need for a certain parameter. You can leave that parameter unnamed. This rule enforces the convention that unused parameters stay unnamed.

### Polyspace Implementation

For each virtual function, the checker looks at all overrides of the function. If an override has a named parameter that is not used, the checker shows a violation on the original virtual function and lists the override as a supporting event.

Note that Polyspace checks for unused parameters in virtual functions within single translation units. For instance, if a base class contains a virtual method with an unused parameter but the derived class implementation of the method uses that parameter, the rule is not violated. However, if the base class and derived class are defined in different files, the checker, which operates file by file, flags a violation of this rule on the base class.

The checker does not flag unused parameters in functions with empty bodies.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

**Group:** Language independent issues
**Category:** Required, Automated

**Topics**

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A0-1-6

There should be no unused type declarations

## Description

### Rule Definition

*There should be no unused type declarations.*

### Rationale

If you declare a type but do not use it, determining if the type is redundant or left unused by mistake is difficult when you review your code.

For example, if you declare an enumerated data type to store some specialized data, but then use an integer type to store the data, the unused type can indicate a coding error.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains unused local types.

As an exception, Polyspace does not report a violation if you define the unused type with `public` access in a template class.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused `enum` Declaration

In this example, you do not use the enumerated type `switchValue`.Because you declare the type but do not use it, Polyspace reports a violation.

```
enum switchValue {low, medium, high}; //Noncompliant

void operate(int userInput) {
    switch(userInput) {
        case 0: // Turn on low setting
                 break;
        case 1: // Turn on medium setting
                 break;
        case 2: // Turn on high setting
                 break;
        default: // Return error
    }
}
```

Perhaps the intention was to use the type as `switch` input like this.

```
enum switchValue {low, medium, high}; //Compliant

void operate(switchValue userInput) {
    switch(userInput) {
        case low: // Turn on low setting
                   break;
        case medium: // Turn on medium setting
                     break;
        case high: // Turn on high setting
                   break;
        default: // Return error
    }
}
```

#### Public Unused Types in Templates

When developing template classes, you might declare a public `typedef` that is used by the clients of the template, even if the template itself does not use the `typedef`. In such a case, Polyspace does not report a violation if a public `typedef` remains unused in a template. For instance, in this code, Polyspace does not report a violation for the unused type `T*`.

```
template<typename T>
  class myContainerIterator {
    public:
      using pointer = T*;              // Compliant
      typedef T* Pointer;              // Compliant

    //...
  };
```

# AUTOSAR C++14 Rule A0-4-2

Type long double shall not be used

## Description

### Rule Definition

*Type long double shall not be used.*

### Rationale

The size of `long double` is implementation-dependent and reduces the portability of your code across compilers. Compilers can implement `long double` as a synonym for `double` or an 80-bit extended precision type or 128-bit quadruple precision type that are more precise than `double`.

Instead, for multiple precision arithmetic that requires types more precise than `double`, use libraries that support multiple precision arithmetic with well-defined data types.

### Polyspace Implementation

The rule checker flags all uses of the `long double` keyword.

If you do not want to fix the issue, add a comment justifying the result. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of `long double` Keyword

```
void func() {
  float f{0.1F};  //Compliant
  double D(0.1);  //Compliant
  long double LD(0.1L);  //Noncompliant
}
```

The use of `long double` violates this rule.

# AUTOSAR C++14 Rule A0-4-4

Range, domain and pole errors shall be checked when using math functions

## Description

### Rule Definition

*Range, domain and pole errors shall be checked when using math functions.*

### Rationale

Before using a math function, check input arguments for potential domain, range, and pole errors.

This checker searches for domain errors when a function argument falls outside the allowed domain, pole errors when finite arguments result in infinite results, and range errors when results of a function cannot be represented by the return value limitations.

Domain, pole and range errors result in unexpected or undefined behavior.

### Polyspace Implementation

Polyspace raises this defect when you call a math function that results in a domain, pole, or range error.

By default, a Bug Finder analysis does not recognize infinities and `NaNs`. Operations that results in infinities and `NaNs` might be flagged as defects. To handle infinities and `NaN` values in your code, use the option `Consider non finite floats (-allow-non-finite-floats)`.

### Extend Checker

Extend this checker to check for defects caused by specific values and invalid use of functions from a custom library. For instance:

- You might be using a custom library of mathematical functions. If a custom library function have the same domain and range as another function from the standard library, you can extend this checker to check the custom library function. See “Extend Bug Finder Checkers for Standard Library Functions to Custom Libraries”.
- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Check for Range, Domain, and Pole Errors Before Using Math Functions

```
#include <cmath>

double getSqrt(double val)
{
    return sqrt(val);                       //Noncompliant
}

double getRefinedSqrt(double val)
{
    if (val >= 0)
        return sqrt(val);                   //Compliant
    else
        return 0;
}

void main()
{
    double root, refinedRoot;

    root = getSqrt(4);
    root = getSqrt(-1);

    refinedRoot = getRefinedSqrt(4);
    refinedRoot = getRefinedSqrt(-1);
}
```

Because the math function `sqrt` within the function `getSqrt` results in a domain error, Polyspace flags it as noncompliant. Performing a check on the variable `val`, as seen with the function `getRefinedSqrt`, helps ensure the value passed to the math function `sqrt` is compliant and expected.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A2-3-1

Only those characters specified in the C++ Language Standard basic source character set shall be used in the source code

## Description

### Rule Definition

*Only those characters specified in the C++ Language Standard basic source character set shall be used in the source code.*

### Rationale

In the C++ standard, the basic source character set consists of 96 characters. They are:

- The space character.
- The control characters such as horizontal tab, vertical tab, form feed, and new line.
- Upper and lower case letters, and numbers.
- Special characters, such as _ { } [ ] # ( ) < > % : ; . ? * + - / ^ & | ~ ! = , \ " '.

Using characters outside this set can cause confusion and unexpected bugs. For example, the Greek letter "Τ" is visually similar to the English letter "T", but they are separate characters with different unicode code-point values. To avoid unexpected behavior, use only the above specified characters in your source code, including comments and string literals. You can use characters outside this set in only two cases. You can use:

- Other characters inside the text of a wide string or a UTF-8 encoded string.
- The character @ inside comments, the text of a wide string, or a UTF-8 encoded string.

### Polyspace Implementation

Polyspace flags the characters in your source code that are not in the set of 96 characters specified in C++ standard, with two exceptions that come from the AUTOSAR C++14 Standard. Polyspace does not flag:

- Other characters inside the text of a wide string or a UTF-8 encoded string.
- The character @ inside comments, the text of a wide string, or a UTF-8 encoded string.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Use Characters Outside the Specified Set

The following example demonstrates the Polyspace implementation of AUTOSAR rule A2-3-1.

```
#include <cstdint>

// @ brief foo function    //Compliant by exception
/* @ brief foo function */ //Compliant by exception

#if 0
@ This one is not in a comment  //Noncompliant
#endif
/*Define £ and € as currency */   // Noncompliant
#define CUR1 "£"   //Noncompliant
#define CUR2 "€"   //Noncompliant
void myfunction(char *str );
int  Total = 0;    //Complaint
int  Total = 0;    //Noncompliant
void foo()
{
    char *s1 = "Greek T  - normal string"; //Noncompliant
    wchar_t *s2 { L"Greek T @ wide string"};  //Compliant
    char *s3 = u8"Greek T @ UTF-8";          // Compliant
    char16_t *s4 = u"Greek T UTF-16";  //Noncompliant
    char32_t *s5 = U"Greek T UTF-32";  //Noncompliant
    char *s6 = "mail@company.com"; //Noncompliant
    myfunction("Greek T");//Noncompliant
    myfunction(s3);//Complaint
}

main(){
    // ..
}
```

If your code has characters that are not in the specified character set, Polyspace flags them. Note the global variables `Total` and `Total`. Even though it looks as if they are the same variable, they are two different variables because the latter starts with the Greek letter "T". Confusion between these two characters can lead to unexpected behavior. Because the Greek letter "T" is outside the standard set of characters, Polyspace flags every use of the character, even those in comments and string literals.

Polyspace flags every use of characters outside the specified set, with the following exceptions. You can use:

- Other characters inside a wide string such as `s2` or UTF-8 encoded string such as `s3`.
- The character `@` inside a wide string such as `s2`, a UTF-8 encoded string such as `s3`, or a comment.

# AUTOSAR C++14 Rule A2-5-1

Trigraphs shall not be used

## Description

### Rule Definition

*Trigraphs shall not be used.*

### Rationale

You denote trigraphs with two question marks followed by a specific third character (for instance,`'??-'` represents a `'~'` (tilde) character and `'??)'` represents a `']'`). These trigraphs can cause accidental confusion with other uses of two question marks.

For instance, the string

```
"(Date should be in the form ??-??-??)"
```

is transformed to

```
"(Date should be in the form ~~]"
```

but this transformation might not be intended.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A2-5-2

Digraphs shall not be used

## Description

### Rule Definition

*Digraphs shall not be used.*

### Rationale

Digraphs are a sequence of two characters that are supposed to be treated as a single character. The checker flags use of these digraphs:

- `<%`, indicating {
- `%>`, indicating }
- `<:`, indicating [
- `:>`, indicating ]
- `%:`, indicating #
- `%:%:`, indicating ##

When developing or reviewing code with digraphs, the developer or reviewer can incorrectly consider the digraph as a sequence of separate characters.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-7-1

The character \ shall not occur as a last character of a C++ comment

## Description

### Rule Definition

*The character \ shall not occur as a last character of a C++ comment.*

### Rationale

If your code has the character \ at the end of a single-line comment, the next line of code becomes a continuation of the comment. Ending single line comments by using the character \ can inadvertently comment-out sections of code.

### Polyspace Implementation

Polyspace checks if the character \ is the last character of a C++ comment .

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using the character \ as Last Character of C++ Comments

```
#include <cstdint>

void foo()
{
  int32_t idx = 0;
  int32_t limit = 20;
  int32_t count = 20;
  ++idx; // Incrementing index before the loop starts// Requirement X\\
  for(;idx<limit;++idx)
  {
     --count;
  }
}
```

The `for` loop definition is commented-out because the single-line comment ends with the character \. As a result, `count` is decremented only once, perhaps inadvertently. The checker flags this issue by highlighting the character \ in the single-line comment.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A2-7-2

Sections of code shall not be "commented out"

## Description

### Rule Definition

*Sections of code shall not be "commented out".*

### Rationale

Commenting out code is not a good practice. The commented out code can remain out of sync with the surrounding code without causing compilation errors. Later, if you uncomment the code, you can encounter unexpected issues.

In addition, C-style comments enclosed in `/* */` do not support nesting. A comment beginning with `/*` ends at the first `*/` even when the `*/` is intended as the end of a later nested comment. If a section of code that is commented out already contains comments, you can encounter compilation errors (or at least comment out less code than you intend).

Use comments only to explain aspects of the code that are not apparent from the code itself.

### Polyspace Implementation

The checker uses internal heuristics to detect commented out code. For instance, characters such as `#`, `;`, `{` or `}` indicate comments that might potentially contain code. These comments are then evaluated against other metrics to determine the likelihood of code masquerading as comment. For instance, several successive words without a symbol in between reduces this likelihood.

The checker does not flag the following comments even if they contain code:

- Doxygen comments beginning with `/**`, `/*!`, `///` or `//!`.
- Comments that repeat the same symbol several times, for instance, the symbol = here:

  ```
  // =====================================
  // A comment
  // =====================================*/
  ```
- Comments on the first line of a file.
- Comments that mix the C style (`/* */`) and C++ style (`//`).

The checker considers that these comments are meant for documentation purposes or entered deliberately with some forethought.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Code Commented Out With C-Style Comments

```
#include <iostream>
/* class randInt {
    public:
      int getRandInt();
};
*/

int getRandInt();

/* Function to print random integers*/
void printInteger() {
    /* int val = getRandInt();
     * val++;
     * std::cout << val;*/
    std::cout << getRandInt();
}
```

This example contains two blocks of commented out code, that constitutes two rule violations.

### Code Commented Out With C++-Style Comments

```
#include <iostream>
int getRandInt();

// Function to print random integers
void printInteger() {
    // int val = getRandInt();
    // val++;
    // std::cout << val;
    std::cout << getRandInt();
}
```

This example contains a block of commented out code that violates the rule.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-7-3

All declarations of "user-defined" types, static and non-static data members, functions and methods shall be preceded by documentation

## Description

### Rule Definition

*All declarations of "user-defined" types, static and non-static data members, functions and methods shall be preceded by documentation.*

### Rationale

This rule requires developers to document externally visible declarations so that users of the declared types and functions can form expectations based on this documentation.

In comments preceding the declarations, developers can document information such as function and method usage, parameter descriptions, exceptions thrown, and other specifications such as side effects, memory management and ownership.

### Polyspace Implementation

In cases where a declaration comes before a definition, the checker flags the declaration if there are no preceding comments. Otherwise, the checker flags the definition.

There can be at most one blank line between a declaration or definition and the preceding comment.

In some cases, you might want to disable the rule or justify some violations. For instance:

- Legacy projects might contain many insufficiently documented types or functions. Unless you want to clean up these projects, you might consider disabling this rule.
- In code documentation tools such as Doxygen, you can add documentation comments *after* a data member or member function. In Doxygen, if you begin the comment with <, the tool considers the comment as documentation for the data member or member function. For instance:

  ```
  int var; /*!< Data member description*/
  ```

  However, Polyspace considers such declarations or definitions as rule violations. If you want to continue using this style of documentation comments, you might consider justifying the violations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant and compliant class definitions

```
#include <cstdint>
```

```
class aClass { //Noncompliant class definition
public:
    aClass(std::int32_t aParameter): aVar(aParameter) {} //Noncompliant
private:
    std::int32_t aVar; //Noncompliant variable definition
};

/// @desc Class responsibilities

class anotherClass { //Compliant class definition
public:
    /// @desc Constructor description
    ///
    /// @param aParameter Parameter description
    anotherClass(std::int32_t aParameter): anotherVar(aParameter) {} //Compliant
private:
    /// @desc Data member description
    std::int32_t anotherVar; //Compliant variable definition
};
```

In this example, the definition of class `aClass` has three rule violations. The class definition itself, the constructor definition, and the definition of data member `aVar` are all missing preceding comments explaining the definitions.

The class `anotherClass` is a compliant version of the same class that satisfies the requirements of this rule.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-8-1

A header file name should reflect the logical entity for which it provides declarations.

## Description

### Rule Definition

*A header file name should reflect the logical entity for which it provides declarations.*

### Rationale

A header file name that matches the name of the entity that is declared in that file makes your `#include` directives clearer and your code more readable.

### Polyspace Implementation

Polyspace checks the header file name against the name of relevant declared types such as `class` or `struct`, or `namespace` names. If the names do not match, Polyspace flags the first character on the first line of the header file.

- The name comparison is case insensitive. For instance, `myheader` matches `myHeader`.
- The name comparison ignores:
  - The underscore character '`_`'. For instance, `myheader` matches `my_Header`.
  - Prefix characters '`C`', '`M`', '`T`', or suffix character '`T`'. The comparison ignores either the prefix or suffix characters, but not both. For instance, `myheader` matches `CmyHeader` and `myHeader_T`, but not `CmyHeader_T`.
  - The hyphen character '`-`' in file names. For instance, a file named `my-header.h` matches a `struct` named `_myHeader`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Header File Name Does Not Match `class` Name

**myheader.h**

```
#include <memory> //Noncompliant - header name does not match the class name
#include <string>

class myClass
{
    virtual ~myClass()=default;
};

class Player : public myClass
{
    std::string Name;
    int Rank;
};
```

**file.cpp**

```
#include "myheader.h"

int main(){
  return 0;
}
```

In this example, the name of header file `myheader.h` is not compliant because it does not match the name of the base class (`myClass`) declared in that header file .

# AUTOSAR C++14 Rule A2-8-2

An implementation file name should reflect the logical entity for which it provides definitions.

## Description

### Rule Definition

*An implementation file name should reflect the logical entity for which it provides definitions.*

### Rationale

An implementation file name that matches the name of the entity that is defined in that file makes your project structure clearer and your code more readable.

### Polyspace Implementation

Polyspace checks the implementation file name against the name of relevant defined types such as `class` or `struct`, or `namespace` names. If the names do not match, Polyspace flags the first character on the first line of the implementation file.

- The name comparison is case insensitive. For instance, `myclass` matches `myClass`.
- The name comparison ignores:
  - The underscore character '`_`'. For instance, `myclass` matches `my_Class`.
  - Prefix characters '`C`', '`M`', '`T`', or suffix character '`T`'. The comparison ignores either the prefix or suffix characters, but not both. For instance, `myclass` matches `CmyClass` and `myClass_T`, but not `CmyClass_T`.
  - The hyphen character '`-`' in file names. For instance, a file named `my-class.cpp` matches a `class` named `myClass_`.

Polyspace does not check the file where you implement `main()`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Implementation File Name Does Not Match `class` Name

**username.h**

```
#include <string>

class User
{
public:
    User();
    User(std::string s);
    std::string getUser();
private:
    std::string user;
};
```

**username.cpp**

```
#include "username.h" // Non-compliant

User::User() : user("") { }
User::User(std::string s): user(s) {}
std::string User::getUser()
{
    return user;
}
```

In the is example, the name of implementation file `username.cpp` is not compliant because it does not match the name of the class (`User`) defined in that file.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-10-1

An identifier declared in an inner scope shall not hide an identifier declared in an outer scope

## Description

### Rule Definition

*An identifier declared in an inner scope shall not hide an identifier declared in an outer scope.*

### Rationale

The rule flags situations where the same identifier name is used in two variable declarations, one in an outer scope and the other in an inner scope.

```
int var;
...
{
...
  int var;
...
}
```

All uses of the name in the inner scope refers to the variable declared in the inner scope. However, a developer or code reviewer can incorrectly assume that the usage refers to the variable declared in the outer scope. In all cases flagged by this rule, you cannot clarify the usage further using the scope resolution operator.

### Polyspace Implementation

The rule checker flags all cases of variable shadowing except when:

- The same identifier name is used in an outer and inner named namespace.
- The same name is used for a class data member and a variable outside the class.
- The same name is used for a method in a base and derived class.

The checker flags even those cases where the variable declaration in the outer scope occurs *after* the variable declaration in the inner scope. In those cases, though the variable hiding does not occur, reusing the variable name can cause developer confusion.

The rule does not flag these situations because you can clarify whether an usage of the variable refers to the variable in the inner or outer scope. For instance, in this example:

```
int var;

namespace n1 {
   int var;
}
```

within the namespace `n1`, you can refer to the variable in the inner scope as `n1::var` and the global variable as `::var`.

The rule checker also does not detect these issues:

- A variable in an unnamed namespace hides another variable in an outer scope.
- A variable local to a lambda expression hides a captured variable.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Local Variable Hiding Global Variable

```
int varInit = 1;

void doSomething(void);

void step(void) {
    int varInit = 0; //Noncompliant
    if(varInit)
       doSomething();
}
```

In this example, `varInit` defined in `func` hides the global variable `varInit`. The `if` condition refers to the local `varInit` and the block is unreachable, but you might expect otherwise.

### Loop Index Hiding Variable Outside Loop

```
void runSomeCheck(int);

void checkMatrix(int dim1, int dim2) {
  for(int index = 0; index < dim1; index++) {
      for(int index = 0; index < dim2; index++) { // Noncompliant
          runSomeCheck(index);
      }
  }
}
```

In this example, the variable `index` defined in the inner `for` loop hides the variable with the same name in the outer loop.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A2-10-4

The identifier name of a non-member object with static storage duration or static function shall not be reused within a namespace

## Description

### Rule Definition

*The identifier name of a non-member object with static storage duration or static function shall not be reused within a namespace.*

### Rationale

You use namespaces to narrow the scope of the identifiers that you declare within these namespaces. This prevents these identifiers from being mistaken with identical identifiers in other scopes. If you reuse an identifier with static storage duration within the same namespace across source files, you might mistake one identifier for the other.

### Polyspace Implementation

- When you reuse identifiers, Polyspace flags the last use of the identifier if they are in the same translation unit. If the identifiers are in separate files, the identifier in the last file path by alphabetical order is flagged.

  However, if you reuse an identifier but declare only one instance of the identifier with the keyword `static`, that identifier is flagged regardless of the order in which the identifiers are declared.
- Polyspace raises no violation if you declare an identifier in a namespace and you reuse that identifier in the same namespace, but within a nested or inlined namespace. For instance, no violation is raised on `reusedVar` in this code snippet.

  ```
  //file1.cpp
  namespace foo {
    static int reusedVar; //resuedVar has static storage duration
  }

  //file2.cpp
   namespace foo {
    void func();
    namespace nested_foo {
      float reusedVar;
    }
    inline namespace inlined_foo {
      char reusedVar;
    }
  }
  ```

The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions

- Uncalled and undefined local functions
- Unused types and variables

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Reuse of identifier within a namespace

**file1.cpp**

```
#include <cstdint>

namespace first_namespace
{
    static std::int32_t global_var; //Compliant- Reused in global namespace
    static std::int32_t reusedVar1;  //Noncompliant
    void reusedVar2();
    static std::int32_t reusedVar3; //Noncompliant
    void use(){
        ++reusedVar1;
        reusedVar2();
        ++reusedVar3;
    }
}
static std::int32_t file_var = 10; //Compliant - identifier not reused
```

**file2.cpp**

```
#include <cstdint>

static std::int32_t global_var; //Compliant - Reused in global namespace

namespace first_namespace
{
    std::int32_t reusedVar1;
    static std::int32_t reusedVar2;  //Noncompliant
    void f()
    {
        float reusedVar3;
        ++reusedVar3;
    }
    void otherUse() {
        ++reusedVar2;
    }
}

namespace second_namespace
{
    std::int32_t reusedVar1; //Compliant - Reused in different namespace
}
```

In this example, Polyspace flags the reuse of `resusedVar1`, `reusedVar2`, and `reusedVar3` in the same namespace in both files. Polyspace does not flag the reuse of `reusedVar1` in a different namespace in `file2.cpp`. Note that when only one instance of the reused identifier is declared with the keyword `static`, Polyspace flags that instance. The identifier `global_var` is not flagged because it is declared in different namespaces, the global namespace, and `first_namespace`.

# AUTOSAR C++14 Rule A2-10-5

An identifier name of a function with static storage duration or a non-member object with external or internal linkage should not be reused

## Description

### Rule Definition

*An identifier name of a function with static storage duration or a non-member object with external or internal linkage should not be reused.*

### Rationale

Objects with static storage duration remain available during the entire execution of the program. These include:

- Non-member objects with external linkage that can be referred to from any of the translation units of your project.
- Objects declared with the `static` class specifier. These objects have internal linkage and can be referred to from any scope within their translation unit.

If you reuse the name of an identifier, you might mistake one identifier for the other.

The rule does not apply to objects with no linkage, for instance function local static objects, since the identifiers of those objects cannot be referred to from outside of their scope.

### Polyspace Implementation

- When you reuse identifiers, Polyspace flags the last use of the identifier if they are in the same translation unit. If the identifiers are in separate files, the identifier in the last file path by alphabetical order is flagged.
- If you declare a function in a namespace with the `static` class specifier and reuse the function identifier to declare a non-static function in another namespace, Polyspace flags the identifier of the static function. For instance, in this code snippet, the identifier `func` is reused in namespace `NS_2` but it is flagged in namespace `NS_1`.

```
namespace NS_1 {
    static void func(void); // Polyspace flags this use of "func".
};

namespace NS_2 {
    void func(void); //"func" identifier reused but this is not a static function.
}
```

- Polyspace flags the identifier of a global variable if you reuse the identifier for a local variable.
- Polyspace does not flag the reuse of an identifier for global functions and their arguments that are declared without the `static` class specifier.

The checker is not raised on unused code such as

- Noninstantiated templates
- Uncalled `static` or `extern` functions

- Uncalled and undefined local functions
- Unused types and variables

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Reuse of identifier with static storage duration

### file1.cpp

```
#include <cstdint>

namespace first_namespace
{
    static std::int32_t global_var = 0;

}
static std::int32_t file_var = 10; //Compliant - identifier not reused
```

### file2.cpp

```
;

#include <cstdint>

namespace first_namespace
{
    static std::int32_t global_var = 0;  // Noncompliant - identifier reused
    static std::int16_t module_var = 20; // Compliant - identifier not reused
}

namespace second_namespace
{

    void globalfunc(int argument) // non-static global function and arguments do not raise violation
    {
        int local_var; // local variable
        static std::int16_t local_static; // Object with no linkage
    }
    std::int16_t globalvar_reusedinlocal;
    std::int16_t globalvar_notreused; // Compliant, identifier not reused
    void foo(){
        ++globalvar_reusedinlocal;
        ++globalvar_notreused;
    }
};

namespace third_namespace
{

    void globalfunc(int argument) // non-static global function and arguments do not raise violation
    {
        static std::int16_t local_static; // Object with no linkage
        int local_var; // local variable
        int globalvar_reusedinlocal; // Non-compliant, identifier reused in local variable
        ++globalvar_reusedinlocal;
    }

};
```

In this example, `global_var` is declared with the `static` class specifier in source file file1.cpp. This identifier is reused in source file file2.cpp. In the same file, `globalvar_reusedinlocal` is declared in `second_namespace` and has external linkage. This declaration is non-compliant because the identifier is reused for the local variable in `globalfunc`.

# AUTOSAR C++14 Rule A2-10-6

A class or enumeration name shall not be hidden by a variable, function or enumerator declaration in the same scope

## Description

### Rule Definition

*A class or enumeration name shall not be hidden by a variable, function or enumerator declaration in the same scope.*

### Rationale

When a variable, data member, function, or enumerator shares its name with a class or enumeration in the same scope, the latter is hidden. That is, all uses of the name refers to the variable, data member, function, or enumerator instead of the class or enumeration, regardless of declaration order. Hidden classes or enumerations can be misleading and can lead to compilation errors. Do not re-use names to declare classes and enumerations.

### Polyspace Implementation

Polyspace flags the declaration of a variable, data member, function, or enumerator that shares the name of a class or enumeration in the same block.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Hide Class Declarations

The following example demonstrate the Polyspace implementation of AUTOSAR rule A2-10-6.

```
#include <cstdint>
namespace NS1
{
    class G {};
    void G() {}             //Noncompliant
}
namespace NS2
{
    enum class H { VALUE=0, };
    std::uint8_t H = 17;    //Noncompliant
}
namespace NS3
{
    class J {};
    enum H {
        J=0,                 // Noncompliant
    };
}
main()
{
    //...
}
```

Polyspace flags the declaration of the:

- Function `G()` because it hides the class `G` declared in the same block.
- Variable `H` because it hides the enumeration `H` declared in the same block.
- Enumerator `J` because it hides the class `J` is declared in the same block.

# AUTOSAR C++14 Rule A2-13-1

Only those escape sequences that are defined in ISO/IEC 14882:2014 shall be used

## Description

### Rule Definition

*Only those escape sequences that are defined in ISO/IEC 14882:2014 shall be used.*

### Rationale

Escape sequences are certain special characters represented in string and character literals. They are written with a backslash (\) followed by a character.

The C++ Standard (ISO/IEC 14882:2003, Sec. 2.13.2) defines a list of escape sequences. See Escape Sequences. Use of escape sequences (backslash followed by character) outside that list leads to undefined behavior.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unrecognized Escape Sequences

```
#include <string>
void func () {
  const std::string a = "\k"; //Noncompliant
  const std::string b = "\U0001f34c"; //Compliant
}
```

In this example, Polyspace reports a violation on the unrecognized escape sequence `\k`.

# AUTOSAR C++14 Rule A2-13-2

String literals with different encoding prefixes shall not be concatenated

## Description

### Rule Definition

*String literals with different encoding prefixes shall not be concatenated.*

### Rationale

Narrow string literals are enclosed in double quotes without a prefix. Wide string literals are enclosed in double quotes with a prefix L outside the quotes. See string literals.

Concatenation of narrow and wide string literals can lead to undefined behavior.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Concatenation of Narrow and Wide String Literals

```
char array[] = "Hello" "World";
wchar_t w_array[] = L"Hello" L"World";
wchar_t mixed[] = "Hello" L"World"; //Noncompliant
```

In this example, in the initialization of the array `mixed`, the narrow string literal `"Hello"` is concatenated with the wide string literal `L"World"`.

## Check Information

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A2-13-3

Type wchar_t shall not be used

## Description

### Rule Definition

*Type wchar_t shall not be used.*

### Rationale

The size of `wchar_t` is implementation-dependent. If you use `wchar_t` for Unicode values, your code is bound to a specific compiler.

To improve the portability of your code, use `char16_t` and `char32_t` instead. These are standard types introduced in C++11 for text strings with UTF-16 and UTF-32 encodings.

### Polyspace Implementation

The rule checker flags all uses of the `wchar_t` keyword.

If you do not want to fix the issue, add a comment justifying the result. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of `wchar_t` Keyword

```
char16_t str1[] = u"A UTF-16 string";  //Compliant
char32_t str2[] = U"A UTF-32 string";  //Compliant
wchar_t str3[] = L"A Unicode string";  //Noncompliant
```

The use of `wchar_t` violates this rule. Instead the types `char16_t` and `char32_t` can be used.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-13-4

String literals shall not be assigned to non-constant pointers

## Description

### Rule Definition

*String literals shall not be assigned to non-constant pointers.*

### Rationale

This rule prevents assignments of string literals to pointers that point to non `const` objects. Such assignments allow later modification of the string literal.

An attempt to modify a string literal can result in undefined behavior. For example, some implementations can store string literals in read-only memory. An attempt to modify the string literal can result in an exception or crash.

Later C++ standards require a compiler warning for such modifications. The rule is in place for situations when you suppress compiler warnings (and AUTOSAR C++14 rules associated with those warnings).

### Polyspace Implementation

The rule checker flags assignment of string literals to pointers other than pointers to `const` objects.

The checker does not flag assignment of string literals to non-`const` arrays. The checker for `AUTOSAR C++ 14 Rule A18-1-1` forbids direct use of C-style arrays and prevents these assignments.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Incorrect Assignment of String Literal

```
char *str1 = "xxxxxx";            // Non-Compliant
const char *str2 = "xxxxxx";      // Compliant

void checkSystem1(char*);
void checkSystem2(const char*);

void main() {
 checkSystem1("xxxxxx");    // Non-Compliant
 checkSystem2("xxxxxx");    // Compliant
}
```

In this example, the rule is not violated when string literals are assigned to `const char*` pointers, either directly or through copy of function arguments. The rule is violated only when the `const` qualifier is not used.

#### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-13-5

Hexadecimal constants should be uppercase

## Description

### Rule Definition

*Hexadecimal constants should be uppercase.*

### Rationale

Hexadecimal notation uses digits 0–9 and letters A to F. Using only uppercase alphabetic letters in a hexadecimal constant definition helps keep the source code consistent, readable, and easy to maintain.

A mix of uppercase and lowercase hexadecimal constants might lead to confusion in the development process, which in turn might lead to bugs. Consistently enforcing the exclusive use of uppercase hexadecimal constants reduces this potential issue.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Lowercase Alphabetic Letters in Hexadecimal Constant Definitions

This example shows the Polyspace implementation of AUTOSAR rule A2-13-5.

```
#include <cstdint>

int main(void)
{
  std::int16_t a = 0x0f0f; //Noncompliant
  std::int16_t b = 0x0f0F; //Noncompliant
  std::int16_t c = 0x0F0F; //Compliant
  return 0;
}
```

In this example, three hexadecimal constants are defined. All three constants have the same value, but two of these definitions use lowercase letters. Because the definitions of the hexadecimal constants a and b do not use uppercase letters exclusively, Polyspace flags their definitions as noncompliant with this rule. Because the definition of the hexadecimal constant c uses uppercase letters exclusively, Polyspace does not flag its definition as noncompliant with this rule.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A2-13-6

Universal character names shall be used only inside character or string literals

## Description

### Rule Definition

*Universal character names shall be used only inside character or string literals.*

### Rationale

Universal character names are a way to represent unicode characters by using code points. For example, `\U0000231A` represents the unicode character '⌚'. When you use universal character names to define an identifier, it is difficult to read the source code. Using universal character names as identifier is confusing and troublesome. Avoid using universal character names outside a character or string literal.

### Polyspace Implementation

Polyspace flags the use of universal character names outside a character or string literal.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Use Universal Character Names Outside Character or String Literal

The following example demonstrate the Polyspace implementation of AUTOSAR rule A2-13-6.

```
#include <cstdint>
#define \U0000231AMACRO(x) (x)     // Noncompliant
void €uro(){            // Compliant
    std::int32_t €uro;    // Compliant
    std::int32_t \U0000231Ahello; // Noncompliant
    wchar_t wc = '\U0000231A';    // Compliant
    std::int32_t Hello\U0000231AWorld;  // Noncompliant
}
typedef struct \U0000231Astruct {    // Noncompliant
    std::int32_t regular;
    std::int32_t €uro;                // Compliant
    std::int32_t \U0000231Ahello;     // Noncompliant
} \U0001f615type;                // Noncompliant

main(){
    //...
}
```

The variable `\U0000231Ahello` is declared using universal character name. Such a variable name is difficult to use, and makes the code confusing. Polyspace flags the use of universal character names outside a character or string literal.

# AUTOSAR C++14 Rule A3-1-1

It shall be possible to include any header file in multiple translation units without violating the One Definition Rule

## Description

### Rule Definition

*It shall be possible to include any header file in multiple translation units without violating the One Definition Rule.*

### Rationale

If a header file with variable or function definitions appears in multiple inclusion paths, the header file violates the One Definition Rule possibly leading to unpredictable behavior. For instance, a source file includes the header file `include.h` and another header file, which also includes `include.h`.

### Polyspace Implementation

The rule checker flags variable and function definitions in header files.

Polyspace reports violation of this rule in header files. In a nonheader source file, violation of this rule is not reported.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Variable and Function Definitions in Header Files

In this example, Polyspace reports violations of this rule when variables and function definitions are placed in the header file `header.hpp`.

```
// header.hpp
#include <cstdint>
void F1();         // Compliant
extern void F2(); // Compliant
void F3()         // Noncompliant
{
}
static inline void F4()
{
} // Compliant
template <typename T>
void F5(T) // Compliant
{
}
std::int32_t a;                        // Noncompliant
extern std::int32_t b;                 // Compliant
constexpr static std::int32_t c = 10; // Compliant
namespace ns
{
    constexpr static std::int32_t d = 100; // Compliant
    const static std::int32_t e = 50;      // Compliant
    static std::int32_t f;                 // Noncompliant
    static void F6() noexcept;             // Noncompliant
}
```

```
//source.cpp
#include "header.hpp"
void foo()
{
    //...
}
```

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A3-1-2

Header files, that are defined locally in the project, shall have a file name extension of one of: `.h`, `.hpp` or `.hxx`

## Description

### Rule Definition

*Header files, that are defined locally in the project, shall have a file name extension of one of: `.h`, `.hpp` or `.hxx`.*

### Rationale

Developers and code reviewers expect a header file to have one of the standard file name extensions.

### Polyspace Implementation

The rule checker flags files included with the `#include` directive with names that have an extension other than `.h`, `.hpp` or `.hxx`. For instance:

```
#include <header.c>
#include <header2.cpp>
```

Instead of `<...>`, if you use `"..."` around the file, the checker also flags the case where the file does not have an extension at all.

The checker does not flag the following inclusions:

- Files included with the `Include (-include)` option.
- Included files that do not exist.

The checker is case-insensitive.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

When an array with external linkage is declared, its size shall be stated explicitly

## Description

### Rule Definition

*When an array with external linkage is declared, its size shall be stated explicitly.*

### Rationale

Though you can declare an incomplete array type and later complete the type, specifying the array size during the first declaration makes the subsequent array access less error-prone.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Array Size Unspecified During Declaration

```
int array[10];
extern int array2[]; //Noncompliant
int array3[]= {0,1,2};
extern int array4[10];
```

In the declaration of `array2`, the array size is unspecified.

# AUTOSAR C++14 Rule A3-1-5

A function definition shall only be placed in a class definition if (1) the function is intended to be inlined (2) it is a member function template (3) it is a member function of a class template

## Description

### Rule Definition

*A function definition shall only be placed in a class definition if (1) the function is intended to be inlined (2) it is a member function template (3) it is a member function of a class template.*

### Rationale

Placing a function definition in a class definition is allowed only if:

- The function is intended to be inlined. Placing the definition of a member function in the class definition instructs the compiler to inline the member function. Inlining small functions avoids the run-time overhead of function calls and improves the performance of the compiled executable. But if you place the definition of a large member function inside the class definition unaware of this implicit inlining, the compiled executable might be too large.
- The function is a member function template or a member of a class template. These coding practices reduce repetitions of template syntax elements (for example, the parameter list). This reduction improves the readability and maintainability of the code.

### Polyspace Implementation

The checker uses the heuristic that, unless you explicitly use the `inline` keyword, you intend to inline only small functions that consist of no more than one statement. The checker interprets AUTOSAR C++14 Rule A3-1-5 in the following way.

For nontemplate member functions and member functions of nontemplate classes, the checker flags one-line member functions defined outside a class and larger member functions defined inside a class.

For template member functions and member functions of template classes, the checker flags any member function that is defined outside a class.

Polyspace does not report a violation of this rule for `constexpr` and `consteval` functions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Defining a Small Member Function Outside Class Definition

```
#include <cstdint>
#include <iostream>
```

```
class A
{
    private:
    std::uint32_t val = 5;

    public:
    std::uint32_t Foo()  // Compliant with (1)
    {
        return val;
    }

    std::uint32_t Bar();
};

std::uint32_t A::Bar() // Noncompliant with (1)
{
    return (val + 5);
}

std::uint32_t main()
{
    A a;
    std::cout << a.Foo() << std::endl;
    std::cout << a.Bar() << std::endl;
    return 0;
}
```

The placement of the definition of `Bar` outside the definition of class `A` violates the rule, because `Bar` consists of a single statement.

### Defining a Member Function Template Outside Class Definition

```
#include <cstdint>
#include <iostream>

class A
{
  public:
    template <typename T>     // Compliant with (2)
    void Foo(T t)
    {
      std::cout << "This function is defined inside with param: "
      << t << std::endl;
    }

    template <typename T>     // Non-compliant with (2)
    void Bar(T t);
};

template <typename T>
void A::Bar(T t)
{
  std::cout << "This function is defined outside with param: "
  << t << std::endl;
}

std::uint32_t main(void)
```

```
{
  A a;
  a.Foo<float>(3.14f);
  a.Bar<std::uint32_t>(5);
  return 0;
}
```

The placement of the definition of the member function template `Bar` outside the definition of class `A` violates the rule.

### Defining a Member Function Outside Class Template Definition

```
#include <cstdint>
#include <iostream>

template <typename T>
class B
{
  public:
    B(const T x) : t(x) {}

    void display()   //Compliant with (3)
    {
      std::cout << t << std::endl;
    }

    void display2();   //Non-compliant with (3)

  private:
    T t;
};

template <typename T>
void B<T>::display2()
{
  std::cout << t << std::endl;
}

int main(void)
{
  B<std::int32_t> b(7);
  b.display();
  b.display2();
  return 0;
}
```

The placement of the definition of the member function `display2` outside the definition of the class template `B` violates the rule.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A3-1-6

Trivial accessor and mutator functions should be inlined

## Description

### Rule Definition

*Trivial accessor and mutator functions should be inlined.*

### Rationale

Inlined functions avoid the run-time overhead of function calls but can result in code bloat. If an accessor (getter) or mutator (setter) method is trivial, code bloat is not an issue. You can inline these methods to avoid the unnecessary overhead of function calls. You can also avoid repeating several syntax elements inside and outside the class definition.

Methods defined inside classes are implicitly considered as inlined methods. You can inline methods defined outside classes explicitly by using the `inline` keyword.

### Polyspace Implementation

To determine if a method is trivial, the checker uses this criteria:

- An accessor method is trivial if it has no parameters and contains one `return` statement that returns a non-static data member or a reference to a non-static data member.

  The return type of the method must exactly match or be a reference to the type of the data member.
- A mutator method is trivial if it has a `void` return type, one parameter, and contains one assignment statement that assigns the parameter to a non-static data member.

  The parameter type must exactly match or be a reference to the type of the data member.

The checker flags trivial accessor and mutator methods defined outside their classes without the `inline` keyword.

The checker does not flag template methods or virtual methods.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Trivial Accessor and Mutator Methods Defined Outside Classes

```
class PhysicalConstants {
    public:
       double getSpeedOfLight() const;
       void setSpeedOfLightInMedium(double newSpeed);
```

```
        double getRefractiveIndexGlass() { //Compliant
            return refractiveIndexGlass;
        }
    private:
        double speedOfLight;
        double refractiveIndexGlass;
};

double PhysicalConstants::getSpeedOfLight() const{ //Noncompliant
    return speedOfLight;
}

void PhysicalConstants::setSpeedOfLightInMedium(double newSpeed) {//Noncompliant
    speedOfLight = newSpeed;
}
```

In this example, the accessor methods `getSpeedOfLight` and `getRefractiveIndexGlass` are trivial. The `getSpeedOfLight` method is defined outside its class and is noncompliant. The `getRefractiveIndexGlass` method is defined inside the class definition and complies with the rule.

The trivial mutator method `setSpeedOfLightInMedium` is also defined outside the class definition and violates the rule.

# AUTOSAR C++14 Rule A3-3-1

Objects or functions with external linkage (including members of named namespaces) shall be declared in a header file

## Description

### Rule Definition

*Objects or functions with external linkage (including members of named namespaces) shall be declared in a header file.*

### Rationale

If you declare a function or object in a header file, it is clear that the function or object is meant to be accessed in multiple translation units. If you intend to access the function or object from a single translation unit, declare it `static` or in an unnamed namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declaration in Header File Missing

This example uses two files:

- `decls.h`:

  ```
  extern int x;
  ```
- `file.cpp`:

  ```
  #include "decls.h"

  int x = 0;
  int y = 0; //Noncompliant
  static int z = 0;
  ```

In this example, the variable `x` is declared in a header file but the variable `y` is not. The variable `z` is also not declared in a header file but it is declared with the `static` specifier and does not have external linkage.

# AUTOSAR C++14 Rule A3-3-2

Static and thread-local objects shall be constant-initialized

## Description

### Rule Definition

*Static and thread-local objects shall be constant-initialized.*

### Rationale

Static and thread-local objects are initialized at the start of code execution. The C++ language standard only partially defines the initialization order of multiple static or thread-local objects and the order can change from build to build. If you initialize a static or thread-local object from another such object, the compiler might access the latter object before it is initialized. To avoid access before initialization, initialize static and thread-local objects by using objects that evaluate to a constant at compile time. Initialization with constants occurs before initialization with variables and often happens at compile time.

This rule applies to global variables, static variables, static class member variables, and static function-scope variables.

### Polyspace Implementation

Polyspace flags initializations of static or thread-local objects using initializers and constructors that do not evaluate to constants at compile time. To constant-initialize static or thread-local objects, use:

- A `constexpr` constructor with only constant arguments
- A constant expression
- A value

Because string objects use dynamic memory allocation of unknown size, the compiler cannot evaluate them at compile time. Polyspace flags initialization of string objects irrespective of whether you specify an initializer.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Initializing Static and Thread-Local Objects

```
#include <cstdint>
#include <limits>
#include <string>
class A{
    //..
public:
    constexpr A(){
        //...
    }
};
class B{
    //..
public:
    B(){
        //...
    }
};
const int global_const_a = 10;              // Compliant
const int global_const_b = global_const_a;  // Compliant
int global_a = 10;                          // Compliant
int global_b = global_a;                    // Noncompliant
static std::string global_name = "Name";    // Noncompliant
static std::string global_id;               // Noncompliant
char *ptr = "hello world";                  // Compliant
char arr_up[3] = {'U','p','\0'};            // Compliant
char container[10];                         // Compliant
extern const int global_extern_c;
const int global_const_c = global_extern_c; // Noncompliant
static A obj1{};                            //Compliant
static B obj2{};                             //Noncompliant
main()
{

    //
}
```

Polyspace flags the initialization of:

- `global_b` by `global_a` because whether `global_b` evaluates to a constant at compile time depends on the order in which these variables are initialized.
- `global_name` and `global_id` because the compiler cannot evaluate constructor for string objects at compile time.
- `global_const_c` by the `extern` variable `global extern_c` because the compiler cannot evaluate `extern` variables at compile time.
- `obj2`, which calls the constructor `B::B()`, because the constructor is not specified as `constexpr`.

Polyspace does not flag the initialization of:

- `global_const_b` by `global_const_a` because the compiler can evaluate these objects at compile time regardless of their initialization order.
- `global_const_a` and `global_a` by literals because the compiler can evaluate literals at compile time.
- Global character pointers and arrays by literal initializers because the compiler can allocate static memory at compile time.
- `obj1`, which calls the constructor `A::A()`, because the constructor is specified as `constexpr`.

# AUTOSAR C++14 Rule A3-8-1

An object shall not be accessed outside of its lifetime

## Description

### Rule Definition

*An object shall not be accessed outside of its lifetime.*

### Rationale

The lifetime of an object begins when it is created by its constructor. The lifetime ends when the object is deleted. Accessing a variable before its construction or after its destruction can lead to undefined behavior. Depending on the context, many operations might inadvertently access an object outside its lifetime. Examples of such operations include:

- Noninitialized pointer: You might inadvertently access a pointer before assigning an address to it. This operation accesses an object before its lifetime and results in accessing an unpredictable memory location. The best practice is to initiate a pointer by using `nullptr` during its declaration.
- Noninitialized variable: You might inadvertently read a variable before it is initialized. This operation accesses an object before its lifetime and results in reading a garbage value that is unpredictable and useless. The best practice is to initiate a variable during its declaration.
- Use of previously deallocated pointer: You might access the dynamically allocated memory of a pointer after deallocating the memory. Trying to access this block of memory accesses an object after its lifetime and results in unpredictable behavior or even a segmentation fault. To address this issue, set the deallocated pointer to `nullptr`, and then to check if a pointer is `nullptr` before accessing it. Alternatively, use a `std::unique_ptr` instead of a raw pointer. Because you do not need to deallocate the allocated memory for a `std::unique_ptr` explicitly, you can avoid inadvertently accessing the deallocated memory.
- Pointer or reference to stack variable leaving scope: You might assign a nonlocal pointer to a local object. For instance:

  - A nonlocal or global pointer is assigned to a variable that is local to a function.
  - A passed-by-reference function parameter, such as a pointer, is assigned to a variable that is local to a function.
  - A pointer data member of a class is assigned to a variable that is local to a function.

  Once the local variable goes out of scope, their corresponding memory blocks might hold garbage or unpredictable values. Accessing pointers to these memory locations accesses an object after its lifetime and might result in undefined or unpredictable behavior. The best practice is to not assign nonlocal pointers to local objects.
- Modifying object with temporary lifetime: You might attempt to modify a temporary object returned by a function call. Modifying temporary objects is an undefined behavior that might lead to abnormal program termination depending on the hardware and software that you use. The best practice is to assign the temporary objects in local variables, and then modifying the local variables.

Avoid operations that might access an object outside of its lifetime.

#### Polyspace Implementation

Polyspace checks for these scenarios where an object might be accessed outside of its lifetime:

- Noninitialized pointer: Polyspace flags a pointer if it is not assigned an address before it is accessed.
- Noninitialized variable: Polyspace flags a variable if it is not initialized before its value is read.
- Use of previously deallocated pointer: Polyspace flags an operation where you access a block of memory after deallocating the block, for instance, by using the `free()` function or the `delete` operator.
- Pointer or reference to stack variable leaving scope: Polyspace flags a local variable when a pointer or reference to it leaves its scope. For example, a local variable is flagged when:

  - A function returns a pointer to the local variable
  - A global pointer is pointed to the local variable
  - A pass-by-reference function parameter, such as a pointer, is pointed to the local variable
  - A pointer data member of a class is pointed to the local variable

  Polyspace assumes that the local objects within a function definition are in the same scope.
- Accessing object with temporary lifetime: Polyspace flags an operation where you access a temporary object that is returned by a function call.

#### Extend Checker

You can extend the checker in the following ways:

- Polyspace does not flag passing pointers to noninitialized variables to functions. To detect noninitialized variables that are passed to functions by pointers, extend the checker by using the option `-code-behavior-specification`. See “Extend Checkers for Initialization to Check Function Arguments Passed by Pointers”.
- If a variable in your code is non-initialized only for certain system input values, you can see one possible combination of input values causing the defect. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Avoid Accessing Noninitialized Pointer

This example shows how Polyspace flags accessing pointers that are not assigned to an address.

```
#include <cstdlib>

int* Noncompliant(int* prev)
{
    int j = 42;
    int* pi;
    if (prev == nullptr){
        pi = new int;
        if (pi == nullptr)
        return nullptr;
    }
    *pi = j; //Noncompliant
    return pi;
}
int* Compliant(int* prev)
{
    int j = 42;
    int* pi;
    if (prev == nullptr){
        pi = new int;
        if (pi == nullptr)
        return nullptr;
    }
    else
    pi = prev;
    *pi = j;//Compliant
    return pi;
}
int* AltCompliant(int* prev)
{
    int j = 42;
    int* pi=nullptr;
    if (prev == nullptr){
        pi = new int;
        if (pi == nullptr)
        return nullptr;
    }
    else
    if(pi!= nullptr)
    *pi = j;//Compliant
    return pi;
}
```

Polyspace flags the pointer pi in Noncompliant() because pi is accessed before an address is assigned to it when prev is not NULL. You can address this issue in various ways. For instance:

- Initiate pi before the statement *pi = j. Assignment to pi in Compliant() is not flagged because pi is initiated by prev before it is accessed.
- Initiate pi by using nullptr during its declaration. Assignment to pi in AltCompliant() is not flagged because pi is initiated by nullptr during its declaration.

### Avoid Accessing Noninitialized Variable

This example shows how Polyspace flags accessing noninitialized variables.

```
int Noncompliant(void)
{
    extern int getsensor(void);
    int command;
    int val;
    command = getsensor();
    if (command == 2){
        val = getsensor();
    }
    return val;//Noncompliant

}
int Compliant(void)
{
    extern int getsensor(void);
    int command;
    int val=0;//Initialization
    command = getsensor();
    if (command == 2){
        val = getsensor();
    }
    return val;//Compliant
}
```

Polyspace flags the statement `return val` in `Noncompliant()` because this statement accesses `val` before the variable is initialized when `command` is not equal to `2`. You can address this issue in several ways. For instance, initialize the variable `val` to zero during its declaration, as shown in `Compliant()`. By initializing the variable during declaration, it is initialized in all execution paths, making the statement `return val` compliant with this rule.

### Avoid Using Previously Deallocated Pointer

This example shows how Polyspace flags accessing pointers that might point to already released memory blocks.

```
#include <memory>
int Noncompliant(double base_val, double shift){
    double j;
    double* pi = new double;
    if (pi == nullptr)
    return 0;
    *pi = base_val;
    //...
    delete pi;
    //...
    j = *pi + shift;//Noncompliant
    return j;
}
int Compliant(double base_val, double shift){
    double j;
    std::unique_ptr<double>   pi(new double(3.1416));
    if (pi == nullptr)
    return 0;
    *pi = base_val;
    j = *pi + shift;
    return j;
}
```

In the function `Noncompliant()`, a pointer `pi` is declared and initialized by using the operator `new`. Later, the dynamically allocated memory is deallocated by using the operator `delete`. The deallocated pointer is then inadvertently accessed in the statement `j = *pi + shift;`. Polyspace flags this statement. You can address this issue in various ways. For instance, you might want to deallocate the allocated resource after performing all relevant operations. Alternatively, you can use smart pointers instead of raw pointers. In `Compliant()`, the pointer `pi` is declared as a `std::unique_ptr`. The acquired resources for `pi` are automatically deallocated at the end of

Compliant() by calling its destructor. Because the memory allocated for pi is not accessed after it is deallocated, Compliant() is compliant with this rule.

### Avoid Emitting Pointers or References to Local Variables to Outer Scopes

This example shows how Polyspace flags operations where pointers to local variables might escape to outer scopes.

```
int* Noncompliant1(void) {
    int ret = 0; //Noncompliant
    return &ret ;
}
auto Noncompliant2(int var) {
    int rhs = var; //Noncompliant
    auto adder = [&] (int lhs) {
        return (rhs + lhs);
    };
    return adder;
}
int Compliant1(void) {
    int ret = 0; //Compliant
    return ret ;
}
auto Compliant2(int var) {
    int rhs = var; //Compliant
    auto adder = [=] (int lhs) {
        return (rhs + lhs);
    };
    return adder;
}
```

- The function Noncompliant1() returns a pointer to the local variable ret. The local variable ret is deleted as soon as Noncompliant() finishes execution. The returned pointer points to an unpredictable value. Such operations are noncompliant with the rule. You can fix this issue by returning local variables by value, as shown in Compliant().
- The function Noncompliant2() returns a lambda expression, which captures the local variable rhs by reference. This reference dereferences to an unpredictable value because rhs is deleted when the function Noncompliant2() finishes execution. You can fix this issue by capturing local variables by copy in the lambda expression, as shown in Compliant2().

### Avoid Accessing Temporary Objects

This example shows how Polyspace flags operations that might access temporary objects that are created by a function call.

```
#include<vector>
struct S_Array{
    int t;
    int a[5];
};
struct S_Array Factory(void);
std::vector<int> VectorFactory(int aNumber);
int Noncompliant(void) {

    return ++(Factory().a[0]); //Noncompliant
}
int Compliant(void) {
    auto tmp = Factory();
    return ++(tmp.a[0]); //Compliant
}
int Compliant2(void) {
    return ++(VectorFactory(5)[1]); //Compliant
}
```

In `Noncompliant()`, the call to `Factory()` creates a temporary object. Modifying this object is noncompliant with this rule. Polyspace flags the statement `return ++(Factory().a[0])`. You can address this issue in various ways. For instance, you can assign the temporary object to a local variable before modifying it, as shown in `Compliant()`. Alternatively, use smart containers such as `std::vector` as shown in `Compliant2()`. Containers such as `std::vector` manage their own lifetime and have move semantics. Polyspace does not flag the statement `return ++(VectorFactory(5)[1]);`.

# AUTOSAR C++14 Rule A4-5-1

Expressions with type enum or enum class shall not be used as operands to built-in and overloaded operators other than the subscript operator [], the assignment operator =, the equality operators == and !=, the unary & operator, and the relational operators <, <=, >, >=

## Description

### Rule Definition

*Expressions with type enum or enum class shall not be used as operands to built-in and overloaded operators other than the subscript operator [], the assignment operator =, the equality operators == and !=, the unary & operator, and the relational operators <, <=, >, >=.*

### Rationale

In C++, enumerations such as `enum` or `enum class` have implementations defined behavior. For instance, their underlying type can be any integral type, including `short` or `char`. If you use enumerations as operands to arithmetic operators such as + or `-`, they are converted to their underlying type. Because the underlying type of an enumeration is implementation dependent, outcome of arithmetic operations using enumerations as operands is unpredictable. To avoid unpredictable and non-portable code, use enumerations as operands to only these operators:

- Subscript operator `[]`
- Assignment operator =
- Equality operators == and `!=`
- The Unary & operator
- The relational operators `<, <=,>,>=`

You can use enumerations as operands to the built in or overloaded instances of only the above operators. Note that Bitmask type enumerations are an exception to this rule. That is, you can use Bitmask type enumerations as operands to any operators.

### Polyspace Implementation

Enumerations are valid operands to only the operators listed above. Polyspace flags enumerations when they are used as operands to any other operators. Note that Polyspace makes no exception for BitmaskType enumerations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Do Not Use Enumerations as Operands to Arithmetic Operators

```
#include <cstdint>
enum Color : std::uint8_t {  Red,  Green,  Blue,  ColorsCount};
enum class Car : std::uint8_t { Model1, Model2, Model3, ModelsCount};
enum BMT {Exec = 0x1,Write  = 0x2,Read = 0x4};
Car operator+(Car lhs, Car rhs)
{
    return Car::Model3;
}
Color operator|=(Color lhs, Color rhs)
{
    return rhs;
};
void F1()
{
    Car car = Car::Model1;
    Color color = Red;
    if (color == Green) {                  // Compliant
    }

    if (color == (Red + Blue)) {           // Noncompliant
    }

    if (color < ColorsCount) {             //Compliant
    }
    if (car == (Car::Model1 + Car::Model2)) // Noncompliant
    {
    }
    Color value;
    value = (Color)(Red | 3);              // Noncompliant
    value |= Blue;                         // Noncompliant
    value = (Color)0;                      // Compliant
    if (value & Blue) {};                  // Noncompliant
    value = (Color)(Blue * value       );  // Noncompliant
    value = (Color)(Red << 3);             // Noncompliant
    value = (Color)(Red >> 12);            // Noncompliant
    BMT bitmask1 = (BMT)(Exec + Write);    // Noncompliant
    BMT bitmask2 = (BMT)(Exec | Write);    // Noncompliant
}
```

The line `BMT bitmask1 = (BMT)(Exec + Write);` adds two enumerators and assigns the result to the `enum` object `bitmask1`. The addition operation implicitly converts the enumerators into their underlying type. Because the underlying type of enumerators are implementation dependent, the outcome of this code can be unpredictable. Polyspace flags the enumerators that are operands to the built in + operator.

Polyspace treats both built in and overloaded operators similarly. For example, Polyspace flags the operands in the operation `Car::Model1 + Car::Model2`, even though the + operator is overloaded for the `enum class Car`.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A4-7-1

An integer expression shall not lead to data loss

## Description

### Rule Definition

*An integer expression shall not lead to data loss.*

### Rationale

A data loss might occur if you perform an explicit cast or if your integer expression results in an implicit conversion, an overflow, an underflow, or a wraparound. For instance:

- An implicit conversion from `uint16_t` to `uint8_t` discards the high byte of the larger data type.
- An arithmetic expression with signed integers that results in an overflow is undefined behavior.

To make sure that no unexpected data loss occurs:

- Avoid integral type conversions by performing all operations in a uniform type.
- Use appropriate guards (such as asserts and if statements) to handle other possible causes of data loss.

### Polyspace Implementation

- Polyspace flags these integral expressions that might result in data loss:
  - Operation on a signed or an unsigned integer variables that results in an overflow.
  - Assignment of a compile-time constant to signed or unsigned integer variables whose data type cannot accommodate the value of that constant.
  - Conversion of a signed (unsigned) integer to a narrower signed (unsigned) integer type.
  - Conversion of an unsigned integer to a signed integer.
  - Shift operation that results in a value that cannot be represented by the result data type.
- Polyspace does not flag the use of `static_cast` to cast to a narrower type. The software assumes that these conversion are intentional even if they might result in data loss.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Integer Expressions that Lead to Data Loss

```
#include <iostream>
#include <cstdint>
#include <stdexcept>
#include <climits>

uint8_t sum(uint8_t a, uint8_t b) noexcept
{
    return (a + b); //Non-compliant
}

uint8_t sum_check(uint8_t a, uint8_t b)
{
    if (b > UCHAR_MAX - a) {
        throw std::range_error("Operation overflows");
    }
    return (a + b); // Compliant
}

int16_t increment(int16_t var)
{
    return ++var; //Non-compliant
}

void func()
{

    uint8_t small_sum = sum(50, 50);
    uint8_t large_sum = sum(150, 150);
    try {
        uint8_t large_sum_check = sum_check(150, 150);
    } catch (std::range_error&) {
        //Handle error
    }

    int16_t max_var = increment(SHRT_MAX);

}
```

In this example, Polyspace flags:

- The return statement of `sum()` because the second call to `sum()` to initialize `large_sum` results in an overflow. The sum of the input parameters exceeds the size of the return type (`uint8_t`).
- The integer expression of `increment()` because the call when initializing `max_var` attempts to increment `SHRT_MAX`.

Polyspace does not flag the return statement of `sum_check` because the function checks the range of its inputs and throws an error when `large_sum_check` is initialized.

## Check Information

**Group:** Standard conversions

**Category:** Required, Automated

## Tips

Polyspace Bug Finder makes certain assumptions about the values of inputs. See “Bug Finder Analysis Assumptions”.

At the cost of a possibly longer runtime, you can perform a more exhaustive analysis where all values of function inputs are considered when showing defects, including inputs of uncalled functions. See `Run stricter checks considering all values of system inputs (-checks-using-system-input-values)`.

# Version History

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A4-10-1

Only nullptr literal shall be used as the null-pointer-constraint

## Description

### Rule Definition

*Only nullptr literal shall be used as the null-pointer-constraint.*

### Rationale

`nullptr` was introduced in C++11 to support the concept of a pointer that does not point to a valid object. Before C++11, the macro `NULL` and the constant 0 were the only ways to define the null pointer constant. Using `nullptr` to indicate null-pointers has several advantages over using `NULL` or `0`. For instance:

- `nullptr` can be used with any type of null-pointer without requiring an implicit cast.
- `nullptr` literals allow parameter forwarding by using a template function.

`NULL` is a macro that expands to an integer `0` which is cast into `void*` type. Using `NULL` or `0` to indicate null-pointers is contrary to developer expectation. If code expecting `nullptr` encounters `NULL` or `0` instead, it might lead to confusion or unexpected behavior.

### Polyspace Implementation

Polyspace flags the use of `NULL` or `0` instead of `nullptr` to indicate a null-pointer. This rule does not check for conversion between `NULL` and `0`. See `AUTOSAR C++14 Rule M4-10-1`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `NULL` or `0` as Alternatives to `nullptr`

```
#include <cstdint>
#include <cstddef>

void foo(int*);
void foo2(int*);

void bar() {
    foo(NULL);    //Noncompliant
    foo2(0);      //Noncompliant
    foo(nullptr); //Compliant
}
```

In this example, the rule is violated when the macro NULL or the constant 0 is used as a null-pointer instead of nullptr.

# AUTOSAR C++14 Rule A5-0-1

The value of an expression shall be the same under any order of evaluation that the standard permits

## Description

### Rule Definition

*The value of an expression shall be the same under any order of evaluation that the standard permits.*

### Rationale

If an expression results in different values depending on the order of evaluation, its value becomes implementation-defined.

### Polyspace Implementation

Polyspace raises a violation if an expression satisfies any of these conditions:

- The same variable is modified more than once in the expression or it is both read and written.
- The expression allows more than one order of evaluation.
- The expression contains a single `volatile` object that occurs multiple times.
- The expression contains more than one `volatile` object.

Because `volatile` objects can change their value at anytime, an expression containing multiple `volatile` variables or multiple instances of the same `volatile` variable might have different results depending on the order of evaluation.

When checking an expression containing function calls, Polyspace checks the body of the functions. If the function body contains calls to other functions, their bodies are not checked. For instance:

```
int f1(){return 1;}
int f2(){return g();}
int g(){return 2;}

void foo(void){
    int z = f1()+f2();
}
```

Here, when checking the expression `z = f1()+f2()`, Polyspace checks the body of `f1()` and `f2()`. The body of `g()` is not checked.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Modified More Than Once in Expression

```
int a[10], b[10];
#define COPY_ELEMENT(index) (a[(index)]=b[(index)])
```

```
void main () {
    int i=0, k=0;

    COPY_ELEMENT (k);         // Compliant
    COPY_ELEMENT (i++);    // // Non-compliant
}
```

In this example, the rule is violated by the statement `COPY_ELEMENT(i++)` because `i++` occurs twice and the order of evaluation of the two expressions is unspecified.

### Variable Modified and Used in Multiple Function Arguments

```
void f (unsigned int param1, unsigned int param2) {}

void main () {
    unsigned int i=0;
    f ( i++, i );                 // Noncompliant
}
```

In this example, the rule is violated because it is unspecified whether the operation `i++` occurs before or after the second argument is passed to `f`. The call `f(i++,i)` can translate to either `f(0,0)` or `f(0,1)`.

### Multiple `volatile` Objects in an Expression

```
volatile int a, b;
int mathOp(int x, int y);

int foo(void){
    int temp = mathOp(5,a) + mathOp(6,b);//Noncompliant
    return temp * mathOp(a,a);//Noncompliant
}
```

In this example, this rule is violated twice.

- The declaration of `temp` uses two `volatile` objects in the expression. Because the value of `volatile` objects might change at any time, the expression might evaluate to different values depending on the order of evaluation. Polyspace flags the second `volatile` object in the expression.
- The `return` statement uses the same `volatile` object twice. Because the expression might have different results depending on the order of evaluation, Polyspace raises this defect.

# AUTOSAR C++14 Rule A5-0-3

The declaration of objects shall contain no more than two levels of pointer indirection

## Description

### Rule Definition

*The declaration of objects shall contain no more than two levels of pointer indirection.*

### Rationale

If you use pointers with more than two levels of indirection, a developer reading the code might find it difficult to understand the behavior of the code.

### Polyspace Implementation

Polyspace flags all declarations of objects that contain more than two levels of pointer indirection.

- If you use type aliases, the checker includes pointer indirections from the alias in the evaluation of the level of indirection. For instance, in this code snippet, the declaration of `var` is non-compliant. The type of `var` is `const` pointer to a `const` pointer to a pointer to `char`, which is three levels of pointer indirection. The declaration of `var2` has two levels of pointer indirection and is compliant.

  ```
  using ptrToChar = char*;

  void func()
  {
      ptrToChar* const* const var = nullptr; //Non-compliant, 3 levels of indirection
      char* const* const var2 = nullptr; //Compliant, 2 levels of indirection
      //...
  }
  ```
- If you pass an array to a function, the conversion of the array to a pointer to the first element of the array is included in the evaluation of the level of indirection. For instance, in this code snippet, parameter `arrParam` is non-compliant. The type of `arrParam` is a pointer to a pointer to a pointer to `char` (three levels of pointer indirection). The declaration of `arrVar` is compliant because `arrVar` has type array of pointer to pointer to char (two levels of pointer indirection).

  ```
  void func(char** arrParam[])  //Non-compliant
  {
      //...
      char** arrVar[5]; //Compliant
  }
  ```

This checker does not flag the use of objects with more than two levels of indirection. For instance, in this code snippet, the declaration of `var` is non-compliant, but the evaluation of the size of `var` is compliant.

```
#include<iostream>

using charToPtr = char*;

void func()
{
    charToPtr* const* const var = nullptr; //Non-compliant
```

```
    std::cout << sizeof(var) << std::endl; //Compliant

}
```

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A5-1-1

Literal values shall not be used apart from type initialization, otherwise symbolic names shall be used instead

## Description

### Rule Definition

*Literal values shall not be used apart from type initialization, otherwise symbolic names shall be used instead.*

### Rationale

Improve the readability and maintainability of code by using symbolic names. Literal constants do not clearly indicate what the constant represents

### Polyspace Implementation

Polyspace flags use of literal values other than those with the data type `char` in expressions and `case` clauses of a `switch` statement.

Polyspace does not flag the use of literal values in logging mechanisms.

Polyspace does not flag the use of literal values '`0`' and '`1`' in expressions, as they are often part of the logic of the code. For instance, '`0`' represents a `NULL` pointer.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using Literal Values

```
double foo(void){
    constexpr int speedLimit = 65;
    constexpr double coeff = 0.2;
    int flag{0};
    int negOne{-1};
    //...
    return (flag)?speedLimit*coeff*negOne + 35 //Noncompliant
            : speedLimit*coeff*negOne - 35; //Noncompliant
}

double bar(void){
    constexpr int speedLimit = 65;
    constexpr double coeff = 0.2;
    int flag{0};
    int negOne{-1};
    int addedValue = 65;
    return (flag)?speedLimit*coeff*negOne + addedValue //Compliant
```

```
            : speedLimit*coeff*negOne - addedValue; //Compliant
}
```

In this example, Polyspace flags the use of literal values in the `return` expression of `foo`. In `bar`, the return expression uses symbolic names, which makes code more readable. The use of literals to initiate objects does not violate this rule.

# AUTOSAR C++14 Rule A5-1-2

Variables shall not be implicitly captured in a lambda expression

## Description

### Rule Definition

*Variables shall not be implicitly captured in a lambda expression.*

### Rationale

In a lambda expression, you have the option to capture variables implicitly. For instance, this lambda expression

```
[&](std::int32_t var) {
   sum+ = var;
}
```

indicates that all local variables in the calling context are captured by reference. However, it is not immediately clear from this lambda expression:

- If a variable in the body of the expression comes from the calling context.

  For instance, in the preceding lambda expression, it is not clear if `sum` is captured from the calling context or is a global variable.
- If all variables captured from the calling context are used and whether the variables are modified or just read (If the variables are read, a by-copy capture is preferred).

If you capture variables explicitly in a lambda expression, you have more control on whether to capture by reference or copy. In addition, you or a reviewer can read the lambda expression and determine whether a variable was captured from the calling context.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Lambda Expressions with Implicit and Explicit Capture

```
#include <iostream>
#include <algorithm>
#include <vector>
#include <cstdint>

void addEvenNumbers(std::vector<std::int32_t> numbers)
{
    std::int64_t sum = 0;
    std::int32_t divisor = 2;
    for_each(numbers.begin(), numbers.end(), [&] (std::int32_t y) //Noncompliant
    {
        if (y % divisor == 0)
        {
            std::cout << y << std::endl;
            sum += y;
        }
    });

    std::cout << sum << std::endl;
}

void addOddNumbers(std::vector<std::int32_t> numbers)
{
    std::int64_t sum = 0;
    std::int32_t divisor = 2;
    for_each(numbers.begin(), numbers.end(), [&sum, divisor] (std::int32_t y) //Compliant
    {
        if (y % divisor != 0)
        {
            std::cout << y << std::endl;
            sum += y;
        }
    });

    std::cout << sum << std::endl;
}
```

The lambda expression in the `addEvenNumbers` function captures all local variables in the calling context implicitly by reference and violates this rule. Some of the issues are:

- Unless you go through the body of the expression, it is not clear which variables are used.
- Though the variable `divisor` is only read and not modified, it is captured by reference. A by-copy capture is preferred.

The lambda expression in the `addOddNumbers` function captures each variable explicitly and does not violate this rule. Without looking at the body of the lambda expression, you can determine which variables are intended to be modified in the expression.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A5-1-3

Parameter list (possibly empty) shall be included in every lambda expression

## Description

### Rule Definition

*Parameter list (possibly empty) shall be included in every lambda expression.*

### Rationale

You do not have to include a parameter list in a lambda expression. For instance, this expression is syntactically valid and indicates a closure that can be called without parameters:

```
[&counter] {
   ++counter;
}
```

However, without the `()`, you or a reviewer might not recognize this as a function object. It is visually clearer to use the parameter list `(...)` even when the list is empty. For instance:

```
[&counter]() {
   ++counter;
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Lambda Expressions Without Parameter List

```
#include <cstdint>

void func() {
    std::int32_t count = 0;

    auto lambda1 = [&count] {++count;}; //Noncompliant
    auto lambda2 = [&count] () { //Compliant
        ++count;
    };
}
```

The lambda expression assigned to `lambda1` does not have a parameter list and violates the rule. The issue is fixed when the same lambda expression is assigned to `lambda2`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A5-1-4

A lambda expression object shall not outlive any of its reference-captured objects

## Description

### Rule Definition

*A lambda expression object shall not outlive any of its reference-captured objects.*

### Rationale

The rule flags cases where a lambda expression captures an object *by reference* and you can potentially access the captured object outside its scope. This situation happens if the lambda expression object outlives the object captured by reference.

For instance, consider this function `createFunction`:

```
std::function<std::int32_t()> createFunction() {
   std::int32_t localVar = 0;
   return ([&localVar]() -> std::int32_t {
       localVar = 1;
       return localVar;
   });
}
```

`createFunction` returns a lambda expression object that captures the local variable `localVar` *by reference*. The scope of `localVar` is limited to `createFunction` but the lambda expression object returned has a much larger scope.

This situation can result in an attempt to access the local object `localVar` outside its scope. For instance, when you call `createFunction` and assign the returned lambda expression object to another object `aFunction`:

```
auto aFunction = createFunction();
```

and then invoke the new object `aFunction`:

```
std::int32_t someValue = aFunction();
```

the captured variable `localVar` is no longer in scope. Therefore, the value returned from `aFunction` is undefined.

If a function returns a lambda expression, to avoid accessing a captured object outside its scope, make sure that the lambda expression captures all objects by copy. For instance, you can rewrite `createFunction` as:

```
std::function<std::int32_t()> createFunction() {
   std::int32_t localVar = 0;
   return ([localVar]() mutable -> std::int32_t {
       localVar = 1;
       return localVar;
   });
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Lambda Expressions that Accesses variables Out-of-Scope

```
auto createAdder(int amountToAdd) {
  int addThis = amountToAdd; //Noncompliant
  auto adder = [&] (int initialAmount) {
      return (initialAmount + addThis);
  };
  return adder;
}

void foo() {
  auto AddByTwo = createAdder(2);
  int res = AddByTwo(10);
}

auto createMultiplier(int amountToMultiply) {
  int multiplyThis = amountToMultiply; //Compliant
  auto adder = [=] (int initialAmount) {
      return (initialAmount + multiplyThis);
  };
  return adder;
}

void bar() {
  auto MultiplyByTwo = createMultiplier(2);
  int res = MultiplyByTwo(10);
}
```

In this example, the `createAdder` function defines a lambda expression `adder` that captures the local variable `addThis` by reference. The scope of `addThis` is limited to the `createAdder` function. When the object `AddByTwo`, which is returned by `createAdder`, is called, a reference to the variable `addThis` is accessed outside its scope. When accessed in this way, the value of `addThis` is undefined.

The issue does not occur with the `createMultiplier` function, which returns a lambda expression that captures local variables by copy.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A5-1-6

Return type of a non-void return type lambda expression should be explicitly specified

## Description

### Rule Definition

*Return type of a non-void return type lambda expression should be explicitly specified.*

### Rationale

A compiler can deduce the return type of a lambda expression based on the type of the return expression. For instance, if a lambda expression does not return anything, the compiler deduces that the return type is `void`.

Specifying a return type when you declare a lambda expression is optional. For non-void return type lambda expressions, if you do not specify a return type explicitly, a developer reading your code might be confused about which type the lambda expression returns.

An explicit return type also reinforces type checking when the compiler generates an implicit conversion from the type of the returned expression to the expected return type.

### Polyspace Implementation

Polyspace flags lambda expressions with non-void-return types if the return type is not specified explicitly.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Return Type not Specified for Lambda Expression with Non-Void Return Type

```
#include<iostream>
#include <cstdint>
#include <cstdio>

void  func()
{
    std::uint8_t TARGET = 10;
    auto lambda_incr = [&](std::uint8_t x) -> std::uint8_t {//Compliant
        while (x < TARGET)
            x++;
        return x;

    };
    auto lambda_decr = [&](std::uint8_t y) { //Non-compliant, returned type is not specified
        while (y > TARGET)
            y--;
        return y;

    };
    char exp[] = "hello.";
    auto lambda3 = [exp]() { //Compliant, void return type.
        std::cout << exp << std::endl;
    };
    auto x = lambda_incr(5);
    auto y = lambda_decr(11);
    lambda3();

}
```

In this example, Polyspace flags lambda expression `lambda_decr` because no return type is specified. Polyspace does not flag `lambda3` even though no return type is specified because the expression does not return anything (void return type).

# AUTOSAR C++14 Rule A5-1-7

A lambda shall not be an operand to decltype or typeid

## Description

### Rule Definition

*A lambda shall not be an operand to decltype or typeid.*

### Rationale

According to the C++ Standard, the type of a lambda expression is a unique, unnamed class type. Because the type is unique, another variable or expression cannot have the same type. Use of `decltype` or `typeid` on a lambda expression indicates that you expect a second variable or expression to have the same type as the operand lambda expression.

Both `decltype` and `typeid` return the data type of their operands. Typically the operators are used to:

- Assign a type to another variable. For instance:

  ```
  decltype(var1) var2;
  ```

  creates a variable `var2` with the same type as `var1`.
- Compare the types of two variables. For instance:

  ```
  (typeid(var1) == typeid(var2))
  ```

  compares the types of `var1` and `var2`.

These uses do not apply to a lambda expression, which has a unique type.

### Polyspace Implementation

The rule checker flags uses of `decltype` and `typeid` with lambda expressions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `typeid` on Lambda Expressions

```
#include <cstdint>
#include <typeinfo>

 void func()
 {
 auto lambdaFirst = []() -> std::int8_t { return 1; };
```

```
 auto lambdaSecond = []() -> std::int8_t { return 1; };

 if (typeid(lambdaFirst) == typeid(lambdaSecond))
     {
     // ...
     }
 }
```

The use of `typeid` on lambda expressions can lead to unexpected results. The comparison above is false even though `lambdaFirst` and `lambdaSecond` appear to have the same body.

#### Correction – Assign Lambda Expression to Function Object Before Using typeid

One possible correction is to assign the lambda expression to a function object and then use the `typeid` operator on the function objects for comparison.

```
#include <cstdint>
#include <functional>
#include <typeinfo>

 void func()
 {
 std::function<std::int8_t()> functionFirst = []() { return 1; };
 std::function<std::int8_t()> functionSecond = []() { return 1; };

 if (typeid(functionFirst) == typeid(functionSecond))
     {
     // ...
     }
 }
```

# AUTOSAR C++14 Rule A5-1-8

Lambda expressions should not be defined inside another lambda expression

## Description

### Rule Definition

*Lambda expressions should not be defined inside another lambda expression.*

### Rationale

Developers can use lambda expressions to write anonymous function objects that contain a few lines of code. Nesting lambda expression reduces the readability of the code because the body of a lambda expression is typically in the line where it is used. For instance, the `find_if` algorithm takes a unary predicate as one of its arguments. A developer can use a lambda expression to define a predicate condition in the declaration of `find_if`. In this code snippet, the `find_if` algorithm returns the first member of a vector of integers that is greater than 2 and that is even.

```
std::vector<int> v = { 1, 2, 3, 4 };
std::find(v.begin(), v.end(),
    [](int val) { return val>2 && val%2==0;});
```

### Polyspace Implementation

Polyspace flags lambda expressions that are defined inside another lambda expression. Polyspace also highlights the closest nesting lambda expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Nested Lambda Expressions

```
#include<iostream>
#include<vector>
#include<algorithm>

int main()
{

    using namespace std;

    vector<int> v {1, 2, 3, 4};

    vector<int>::iterator it = v.begin();
    while (it != v.end()) {
        auto evenGreater2 = [](int val) {

            return [](int val2) { //Noncompliant
                return val2 % 2 == 0;
            }(val)&& (val) > 2;

        }(*it);
        if (evenGreater2) {
            cout << *it << endl;
            break;
        }
        ++it;
    }

}
```

In this example, Polyspace flags the lambda expression that checks whether a value is even (`[](int val2) { return val2 % 2 ==0; }`) because it is nested inside another lambda expression that also checks whether a value is greater than 2.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A5-1-9

Identical unnamed lambda expressions shall be replaced with a named function or a named lambda expression

## Description

### Rule Definition

*Identical unnamed lambda expressions shall be replaced with a named function or a named lambda expression.*

### Rationale

When you reuse an unnamed lambda expression, you insert the body of that lambda expression wherever you invoke it in your code. This code duplication might result in maintainability issues when you make changes, as you might misidentify which lambda expressions are identical when applying those changes. The code duplication also decreases the readability of your code.

### Polyspace Implementation

After the first use of an unnamed lambda expression, Polyspace flags each subsequent uses of an identical lambda expression. For instance, if you reuse the same lambda expression three times, Polyspace flags the second and third uses of the lambda expression as separate violations. Polyspace also highlights the first use of the unnamed lambda expression in your source code.

Polyspace does not flag the reuse of global scope lambda expressions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Reuse of Unnamed Lambda Expression

```
#include<vector>
#include<algorithm>

void func1(std::vector<int>& v)
{
    if (none_of(v.begin(), v.end(),
    [](int i) {return i % 2 == 1;})) {
        //Handle error
    }

    int odds = std::count_if(v.begin(), v.end(),
    [](int i) {return i % 2 == 1;}); //Noncompliant

    std::vector<int>::iterator first_odd = find_if(v.begin(), v.end(),
    [](int i) {return i % 2 == 1;}); //Noncompliant
}

void func2(std::vector<int>& v)
{
    auto is_odd = [](int i) { return i % 2 == 1;};

    if (none_of(v.begin(), v.end(), is_odd)) {
        //Handle error
    }

    int odds = std::count_if(v.begin(), v.end(), is_odd); //Compliant,
                                                          //reusing named lambda expression

    std::vector<int>::iterator first_odd = find_if(v.begin(),
            v.end(), is_odd); //Compliant, reusing named lambda expression
}
```

In this example, unnamed lambda expression `[](int i) {return i % 2 == 1;}` is reused twice inside `func1`. Polyspace flags the second and third uses of this lambda expression.

The reuse of the lambda expression in `func2` is not flagged because the lambda expression is named (`is_odd`).

# AUTOSAR C++14 Rule A5-2-1

dynamic_cast should not be used

## Description

### Rule Definition

*dynamic_cast should not be used.*

### Rationale

You use `dynamic_cast` to convert the type of a pointer or reference to a class along the inheritance hierarchy, for instance to convert a pointer to base class into a pointer to a derived class. The conversion incurs an overhead due to the type checking that is performed at run-time. This overhead is unsuitable for the low memory, speed, and predictable performance requirements of real-time systems.

If you cannot avoid dynamic casting in your application, consider using a custom implementation to perform the cast. You might also consider using virtual functions if you are casting to the most derived class, or static polymorphism with overloaded functions and templates. In the latter case, the types are resolved at compile-time which avoids the overhead.

### Polyspace Implementation

Polyspace flags all uses of `dynamic_cast` in your code.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `dynamic_cast`

```
#include<iostream>

using namespace std;

class Base
{
public:
    virtual void f()
    {
        cout << "Using Base class\n";
    }
};

class Derived1 : public Base
{
public:
    virtual void f()
    {
        cout << "Using Derived class\n";
    }
};

class Derived2 : public Derived1
{
public:
    virtual void f()
    {
        cout << "Using Derived2 class\n";
    }
};

int main()
{
    Derived2* ptrd2 = new Derived2;

    Derived1* ptrd1 = dynamic_cast<Derived1*>(ptrd2); // Noncompliant
    ptrd1 -> f();

    Base* ptrb = dynamic_cast<Base*>(ptrd2); // Noncompliant
    ptrb -> f();
}
```

In this example, `Base` and `Derived1` are indirect and direct base classes of `Derived2` respectively. The use of `dynamic_cast` to upcast `ptrd2` from type `Derived2` to `Derived1` then to `Base` is noncompliant. Note that in this case, the use of `dynamic_cast` is not necessary since an upcast can be performed through implicit conversion (`Derived1 * ptr = ptrd2;`).

# AUTOSAR C++14 Rule A5-2-2

Traditional C-style casts shall not be used

## Description

### Rule Definition

*Traditional C-style casts shall not be used.*

### Rationale

C-style casts are difficult to distinguish in source code. Such casts cannot communicate the goal and necessity of the conversion. Code containing C-style casts is difficult to understand and debug.

Avoid C-style casts. C++ introduces explicit casting operations that are easily identified and clearly communicate the goal and necessity of each cast. Use these casting operations instead.

### Polyspace Implementation

Polyspace flags C-style casts and functional notation casts in your code. Compliant C++ style casting operations include:

- `std::static_cast`
- `std::reinterpret_cast`
- `std::const_cast`
- `std::dynamic_cast`
- `{}` notation casts

The `reference_cast` operation from the Boost library and the `safe_cast` operation from the Microsoft library are also allowed.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid C-Style Casts and Functional Casts

In this example, the function `Foo()` shows several C++ casting operations. These operations are easily identified. They communicate the goal of necessity of the casting operations. For instance, in `Base* obj4 = const_cast<Base*>(&obj3)`, it is clear that the cast operation removes the `const` qualifier from `obj3`. These casting operations are compliant and Polyspace does not flag them.

The function `Bar()` shows several C-style casts and functional casts. These operations are difficult to locate, and their purpose is not communicated. Polyspace flags these casts.

```
#include <cstdint>
class Base
```

```
{
public:
    explicit Base(std::int32_t) {}
    virtual void Fn() noexcept {}
};
class Derived : public Base
{
public:
    void Fn() noexcept override {}
};
class myClass
{
};
std::int32_t G() noexcept
{
    return 7;
}

void Foo() noexcept(false)
{
    Base obj = Base{10};        // Compliant
    const Base obj3(5);
    Base* obj4 = const_cast<Base*>(&obj3);        //Compliant
    Base* obj2;
    myClass* d1 = reinterpret_cast<myClass*>(obj4); // Compliant
    Derived* d2 = dynamic_cast<Derived*>(obj2);       // Compliant
    std::int16_t var1 = 20;
    std::int32_t var2 = static_cast<std::int32_t>(var1);      // Compliant
    std::int32_t var4 = 10;
    float f1 = static_cast<float>(var4);                    // Compliant

    std::int32_t var5 = static_cast<std::int32_t>(f1);      //Compliant

    std::uint32_t var7 = std::uint32_t{0};//Compliant
    static_cast<void>(G());                               //Compliant
}
void Bar(){
    Base obj = Base{1};
    Base* obj2 = (Base*)(&obj); //Noncompliant
    std::int16_t var1 = 20;
    std::int32_t var3 = (std::int32_t)var1;                   // Noncompliant
    float f = float(var3);                                 // Noncompliant
    std::int32_t var6 = (std::int32_t)f;                   // Noncompliant
    std::int32_t var7 = std::int32_t(f);                   // Noncompliant
}
```

# AUTOSAR C++14 Rule A5-2-3

A cast shall not remove any const or volatile qualification from the type of a pointer or reference

## Description

### Rule Definition

*A cast shall not remove any const or volatile qualification from the type of a pointer or reference.*

### Rationale

Removing the `const` or `volatile` qualification from a pointer or reference might be unexpected. Consider this code:

```
void foo(const char* p){
  *const_cast< char * >( p ) = '\0';
}
```

The function `foo()` accepts a `const` pointer to a `char`. The caller of this functions expects that the parameter `p` remains unchanged. Modifying `p` in `foo()` by converting it to a non-`const` pointer is unexpected. If `*p` dereferences to a `const` character, this modification might lead to unexpected behavior. Avoid casting the `const` or `volatile` away from a pointer or reference.

### Polyspace Implementation

Polyspace raises a violation of this rule if you remove the `const` or `volatile` qualification from the type of a pointer or a reference by using a casting operation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Casting Away `Const` from Pointers

```
void foo(const char* p){
  *const_cast< char * >( p ) = '\0';//Noncompliant
}

void foo1(volatile char* p){
  (char*) p ;//Noncompliant
}
```

In this example, Polyspace flags the casting operations that cast away the `const` and `volatile` qualifiers from pointers.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A5-2-4

reinterpret_cast shall not be used

## Description

### Rule Definition

*reinterpret_cast shall not be used.*

### Rationale

`reinterpret_cast` is typically used to explicitly convert between two unrelated data types. For instance, in this example, `reinterpret_cast` converts the type `struct S*` to `int*`:

```
struct S { int x; } s;
int* ptr = reinterpret_cast<int*> (&s);
```

However, it is difficult to use `reinterpret_cast` and not violate type safety. If the result of `reinterpret_cast` is a pointer, it is safe to dereference the pointer only after you cast the pointer back to its original type.

### Polyspace Implementation

The rule checker flags all uses of the `reinterpret_cast` keyword.

If the rule checker flags an use of `reinterpret_cast` that you consider safe, add a comment justifying the result. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `reinterpret_cast` Keyword

```
class A {
    int x;
    int y;
    public:
      void getxy();
};

class B {
    int z;
    public:
      void getz();
};

void func (B* Bptr) {
    A* Aptr = reinterpret_cast<A*>(Bptr); // Noncompliant
}
```

The use of `reinterpret_cast` violates this rule. The result of `reinterpret_cast` is not safe to dereference since `A` and `B` are unrelated classes. Dereferencing `Aptr` as if it were an `A*` pointer can result in illegal memory access.

# AUTOSAR C++14 Rule A5-2-5

An array or container shall not be accessed beyond its range

## Description

### Rule Definition

*An array or container shall not be accessed beyond its range.*

### Rationale

An array or container accessed beyond its range results in undefined behavior. This rule applies to C-style arrays and all other containers where you access the array or container elements by using an iterator (including pointers) or an index.

To avoid undefined behavior, use appropriate safeguards in your code to make sure that you access the array or container within its range. For example:

- Perform a range check explicitly.
- Use a built-in standard template library (STL) function that performs a range check, such as `array::at()`.
- Use a range-based for loop when appropriate to iterate through the elements of an array or container.

Pointing to one-past the last element of the array or container is well defined, but dereferencing that element is not.

### Polyspace Implementation

Polyspace flags these issues when you enable this rule checker:

- You access a C-style array beyond its range. For instance:

  ```
  #include <iostream>

  void func() {
      int idx, arr[10];

      for (idx = 0; idx < 10; ++idx) {
          arr[idx] = 2 * idx;
      }
      // idx = 10 after for loop
      std::cout << arr[idx]; //Noncompliant
  }
  ```
- You use an unsanitized tainted value as an index to access an element of a C-style array. For instance, in this code snippet, variable `idx` is obtained from the environment list and is used to access an element of array `arr2`. The value of `idx` is not checked and might be outside the range of the array:

  ```
  #include <iostream>

  extern int arr2[50];
  ```

```
void printElem() {
    int idx = strtol(getenv("INDEX"), NULL, 10);
    std::cout << arr2[idx]; //Noncompliant
}
```

Polyspace considers that data from all external sources are tainted. For information about tainted data sources, see “Sources of Tainting in a Polyspace Analysis”.

### Extend Checker

Extend this checker to check for defects caused by specific values and external inputs. For instance:

- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Array Accessed Outside its Range

```
#include <cstdint>

constexpr std::int32_t MAXSIZE = 64;
void foo() {

    int  arr[MAXSIZE]{0};
    int iter;
    for(iter = 0;iter<MAXSIZE;iter++){/**/}
    int val = arr[iter]; //Noncompliant
}

void externalSource(uint8_t externalVar) {

    int8_t idx, arr[10];
    for (idx = 0; idx < 10; ++idx) {
        arr[idx] = idx;
    }
    for (idx = 0; idx < 10; ++idx) {
        if (arr[idx] == arr[externalVar]) { /* Noncompliant, with option
        -consider-analysis-perimeter-as-trust-boundary enabled*/
            // print idx
        }
    }
}
```

In this example:

- In the function `foo()`, after the `for` loop, the value of `iter` is `64`. The array access in `arr[iter]` is out of bound. Polyspace reports a violation on the out of bound array access.
- In the function `externalSource`, the iterator `externalVar` is not checked for validity before it is used to access an element of `arr`. The iterator `externalVar` originated outside of the current module might have a value beyond the bound of `arr`. Polyspace reports a violation when you enable the option `-consider-analysis-perimeter-as-trust-boundary`.

# AUTOSAR C++14 Rule A5-2-6

The operands of a logical && or || shall be parenthesized if the operands contain binary operators

## Description

### Rule Definition

*The operands of a logical && or || shall be parenthesized if the operands contain binary operators.*

### Rationale

In a logical expression containing binary operators, relying on C++ operator precedence rules results in code that is confusing and difficult to understand. This code might lead to unexpected behavior and bugs that are difficult to resolve. Parenthesizing operands that include binary operators enhances the readability of code, makes code easier to review, and ensures that the operator precedence behavior is as expected.

### Polyspace Implementation

During preprocessing, violations of this rule are detected on the expressions in `#if` directives.

The checker allows exceptions on associativity `(a && b && c)`, `(a || b || c)`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Operands Containing Binary Operators That Are Not Parenthesized

```
#include <cstdint>

void Fn(std::int32_t value) noexcept
{
  if (value > 1 && value < 2) { //Noncompliant
    // do some work
  } else if ((value > 0) && (value < 3)) { //Compliant
    // do some work
  } else if ((value == 0) || value == 3) { //Noncompliant
    // do some work
  } else if ((value < 0) || (value == 4)) { //Compliant
    // do some work
  } else {
    // do some work
  }

  return;
}
```

There are multiple uses of the logicals && and ||. In the first and third logical expressions, there are operands containing binary operators that are not parenthesized. Polyspace flags them as noncompliant with this rule. In the second and fourth logical expressions, all operands containing binary operators are parenthesized. Polyspace does not flag them as noncompliant with this rule.

# AUTOSAR C++14 Rule A5-3-1

Evaluation of the operand to the typeid operator shall not contain side effects

## Description

### Rule Definition

*Evaluation of the operand to the typeid operator shall not contain side effects.*

### Rationale

The `typeid` operator evaluates its operand only if it is a call to a function that returns a reference to a polymorphic type (a polymorphic type is a class type that contains virtual functions). In all other cases, expressions provided to the `typeid` operator are not evaluated.

For code that is easier to maintain, avoid expressions with side effects altogether when using the `typeid` operator. You or another developer will be saved from tracking down the ingredients of the expression to their definitions and determining if the side effects actually occur.

### Polyspace Implementation

The checker flags `typeid` operators with expressions that have side effects. Function calls are assumed to have side effects.

The checker message states whether the expression is evaluated or ignored. If the expression is evaluated and you want to retain the expression in the `typeid` operation instead of performing the evaluation in a separate statement, add comments to your result or code to avoid another review. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Expressions with Side Effects as `typeid` Operand

```
#include <iostream>
#include <typeinfo>

class Base
{
public:
    virtual ~Base();
};

class Derived: public Base
{
```

```
public:
    ~Derived();
};

Base& getObj();

void main()
{

    Base& b = getObj();

    std::cout << "Dynamic type:" << typeid(getObj()).name(); //Noncompliant
    std::cout << "Dynamic type:" << typeid(b).name(); //Compliant
}
```

The rule is violated when the `typeid` operand involves a function call.

# AUTOSAR C++14 Rule A5-3-2

Null pointers shall not be dereferenced

## Description

### Rule Definition

*Null pointers shall not be dereferenced.*

### Rationale

Dereferencing a null pointer is undefined behavior. In most implementations, the dereference can cause your program to crash.

### Polyspace Implementation

The checker flags pointer dereferences where the pointer might be NULL-valued.

If the issue occurs despite an earlier check for `NULL`, look for intermediate events between the check and the subsequent dereference. Often the result details (or source code tooltips in Polyspace as You Code) show a sequence of events that led to the defect. You can implement the fix on any event in the sequence. If the result details do not show this event history, you can search for previous references of variables relevant to the defect using right-click options in the source code and find related events. See also “Interpret Bug Finder Results in Polyspace Desktop User Interface” or “Interpret Bug Finder Results in Polyspace Access Web Interface”.

### Extend Checker

A default Bug Finder analysis might not raise a violation of this rule when the input values are unknown and only a subset of inputs can cause an issue. To check for violations caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Possible Null Pointer Dereference

```
#include <iostream>
#include <cstdint>
#include <cstddef>

class A
{
  public:
    A(std::uint32_t a) : a(a) {}
    std::uint32_t GetA() const noexcept
    {
      return a;
    }
  private:
    std::uint32_t a;
};

std::uint32_t Sum(const A* lhs, const A* rhs)
{
  return lhs->GetA() + rhs->GetA(); //Noncompliant
}

A* getAPtr(void);

int main(void)
{
  A* leftVal = new A(3);
  A* rightVal = getAPtr();

  std::uint32_t sum;

  if(!rightVal)  {
      sum = Sum(leftVal, rightVal);
  }
  else
      sum = 0;

  std::cout << sum << std::endl;
  return 0;
}
```

In this example, the order of the `if` and `else` clause have been switched leading to an accidental null pointer dereference. The variable `rightVal` is checked for NULL and the NULL-valued of `rightVal` is used for the subsequent dereference in the function `Sum`.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A5-3-3

Pointers to incomplete class types shall not be deleted

## Description

### Rule Definition

*Pointers to incomplete class types shall not be deleted.*

### Rationale

When you delete a pointer to an incomplete class, it is not possible to call any nontrivial destructor that the class might have. If the destructor performs cleanup activities such as memory deallocation, these activities do not happen.

A similar problem happens, for instance, when you downcast to a pointer to an incomplete class (downcasting is casting from a pointer to a base class to a pointer to a derived class). At the point of downcasting, the relationship between the base and derived class is not known. In particular, if the derived class inherits from multiple classes, at the point of downcasting, this information is not available. The downcasting cannot make the necessary adjustments for multiple inheritance and the resulting pointer cannot be dereferenced.

### Polyspace Implementation

The check raises a defect when you delete or cast to a pointer to an incomplete class. An incomplete class is one whose definition is not visible at the point where the class is used.

For instance, the definition of class `Body` is not visible when the `delete` operator is called on a pointer to `Body`:

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; }
  // ...
};
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Deletion of Pointer to Incomplete Class

```
class Handle {
  class Body *impl;
public:
  ~Handle() { delete impl; }
  // ...
};
```

In this example, the definition of class Body is not visible when the pointer to Body is deleted.

#### Correction — Define Class Before Deletion

One possible correction is to make sure that the class definition is visible when a pointer to the class is deleted.

```
class Handle {
  class Body *impl;
public:
  ~Handle();
  // ...
};

// Elsewhere
class Body { /* ... */ };

Handle::~Handle() {
  delete impl;
}
```

#### Correction — Use std::shared_ptr

Another possible correction is to use the std::shared_ptr type instead of a regular pointer.

```
#include <memory>

class Handle {
  std::shared_ptr<class Body> impl;
  public:
    Handle();
    ~Handle() {}
    // ...
};
```

### Downcasting to Pointer to Incomplete Class

File1.h:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

File2.h:

```
void funcprint(class Derived *);
class Base *get_derived();
```

File1.cpp:

```
#include "File1.h"
#include "File2.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(reinterpret_cast<class Derived *>(v));
}
```

`File2.cpp`:

```
#include "File2.h"
#include "File1.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;
public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
 };

void funcprint(Derived *d) {
  d->do_something();
}

Base *get_derived() {
  return new Derived;
}
```

In this example, the definition of class `Derived` is not visible in `File1.cpp` when a `Base*` pointer to downcast to a `Derived*` pointer.

In `File2.cpp`, class `Derived` derives from two classes, `Base` and `Base2`. This information about multiple inheritance is not available at the point of downcasting in `File1.cpp`. The result of downcasting is passed to the function `funcprint` and dereferenced in the body of `funcprint`. Because the downcasting was done with incomplete information, the dereference can be invalid.

#### Correction — Define Class Before Downcasting

One possible correction is to define the class `Derived` before downcasting a `Base*` pointer to a `Derived*` pointer.

In this corrected example, the downcasting is done in `File2.cpp` in the body of `funcprint` at a point where the definition of class `Derived` is visible. The downcasting is not done in `File1.cpp` where the definition of `Derived` is not visible. The changes from the previous incorrect example are highlighted.

`File1_corr.h`:

```
class Base {
protected:
  double var;
public:
  Base() : var(1.0) {}
  virtual void do_something();
  virtual ~Base();
};
```

File2_corr.h:

```
void funcprint(class Base *);
class Base *get_derived();
```

File1.cpp:

```
#include "File1_corr.h"
#include "File2_corr.h"

void getandprint() {
  Base *v = get_derived();
  funcprint(v);
}
```

File2.cpp:

```
#include "File2_corr.h"
#include "File1_corr.h"
#include <iostream>

class Base2 {
protected:
  short var2;
public:
  Base2() : var2(12) {}
};

class Derived : public Base2, public Base {
  float var_derived;

public:
    Derived() : Base2(), Base(), var_derived(1.2f) {}
    void do_something()
    {
        std::cout << "var_derived: "
                  << var_derived << ", var : " << var
                  << ", var2: " << var2 << std::endl;
    }
};

void funcprint(Base *d) {
  Derived *temp = dynamic_cast<Derived*>(d);
  if(temp)  {
     d->do_something();
  }
  else {
      //Handle error
  }
}
```

```
Base *get_derived() {
  return new Derived;
}
```

# AUTOSAR C++14 Rule A5-5-1

A pointer to member shall not access non-existent class members

## Description

### Rule Definition

*A pointer to member shall not access non-existent class members.*

### Rationale

You use pointer-to-member operators `.*` and `->*` to refer to a non-static class member of the first operand object. For instance, in this code snippet, the call `(obj.*ptrToMember)();` is equivalent to `obj.f();`. Both calls refer to member function `f()` of class `myObj`:

```
class myObj {
  public:
    void f();
};

void func() {
    myObj obj;
    void (myObj::*ptrToMember)() = &myObj::f;

    (obj.*ptrToMember)(); // Equivalent to obj.f();
}
```

The use of pointer-to-member operators results in undefined behavior in these cases:

- The dynamic type of the first operand does not contain the member referred to by the second operand.
- The second operand pointer is null.

### Polyspace Implementation

Polyspace flags the use of pointer-to-member operators in these instances:

- You cast a pointer-to-member type to another pointer-to-member type which does not contain the class member pointed to. For instance, in this code snippet, pointer-to-member `ptrToMember` is obtained from `myObj::f` but is then upcast to `baseObj::*` which does not contain a method `f`.

  ```
  class baseObj {
    public:
      virtual ~baseObj() = default;
  };

  class myObj : public baseObj {
    public:
      void f();
  };
  ```

```
void func() {
    baseObj* foo = new baseObj();
    void (baseObj::*ptrToMember)() =
        static_cast<void (baseObj::*)()>(&myObj::f); //Noncompliant
    (foo->*ptrToMember)();
}
```

Polyspace does not flag the casting operation if the type being cast to inherits from the other type. For example, in the preceding code, if `baseObj` inherits from `myObj`.

- The second operand of the pointer-to-member operator is a null pointer. For instance, in this code snippet, `ptrToMember` is declared but not initialized and defaults to a null pointer.

```
class baseObj {
  public:
    virtual ~baseObj() = default;
};
static void (baseObj::*ptrToMember)(); //Not initialized

void func() {
    baseObj* foo = new baseObj();

    (foo->*ptrToMember)(); //Noncompliant
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pointer-to-Member Accesses Non-Existent Class Member

```
class Base {
  public:
    void f() {
    }
};

class Derived : public Base {
  public:
    int myVar;
};

void func() {
    Base myObj;
    auto ptrToMethod =
        static_cast<void (Base::*)()>(&Derived::f); // Compliant
    auto ptrToMember =
        static_cast<int(Base::*)>(&Derived::myVar); // Noncompliant

    (myObj.*ptrToMethod)(); // OK, equivalent to myObj.f()
    myObj.*ptrToMember;     // Undefined behavior
}
```

In this example, Polyspace flags the casting of `ptrToMember`, which is obtained from `Derived::myVar`, to `Base::*` because this class does not contain a member `myVar`. If you execute the code, the call `myObj.*ptrToMember;` results in undefined behavior.

Polyspace does not flag the casting of `ptrToMethod` to `Base::*` because class `Derived` inherits method `f` from `Base`.

# AUTOSAR C++14 Rule A5-6-1

The right hand operand of the integer division or remainder operators shall not be equal to zero

## Description

### Rule Definition

*The right hand operand of the integer division or remainder operators shall not be equal to zero.*

### Rationale

- If the numerator is the minimum possible value and the denominator is `-1`, your division operation overflows because the result cannot be represented by the current variable size.
- If the denominator is zero, your division operation fails possibly causing your program to crash.

These risks can be used to execute arbitrary code. This code is usually outside the scope of a program's implicit security policy.

- If the second remainder operand is zero, your remainder operation fails, causing your program to crash.
- If the second remainder operand is `-1`, your remainder operation can overflow if the remainder operation is implemented based on the division operation that can overflow.
- If one of the operands is negative, the operation result is uncertain. For C89, the modulo operation is not standardized, so the result from negative operands is implementation-defined.

These risks can be exploited by attackers to gain access to your program or the target in general.

### Polyspace Implementation

The checker raises a defect when:

- The denominator of a division or modulo operation can be a zero-valued integer.
- There are division operations where one or both of the integer operands is from an unsecure source.
- There are modulo operations with one or more tainted operands.

### Extend Checker

Extend this checker to check for defects caused by specific values and external inputs. For instance:

- A default Bug Finder analysis might not raise a defect when the input values are unknown and only a subset of inputs can cause an issue. To check for defects caused by specific system input values, run a stricter Bug Finder analysis. See “Extend Bug Finder Checkers to Find Defects from Specific System Input Values”.
- By default, Polyspace assumes that data from external sources are tainted. See “Sources of Tainting in a Polyspace Analysis”. To consider any data that does not originate in the current scope of Polyspace analysis as tainted, use the command line option `-consider-analysis-perimeter-as-trust-boundary`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Dividing an Integer by Zero

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    result = num/denom;

    return result;
}
```

A division by zero error occurs at `num/denom` because `denom` is zero.

#### Correction — Check Before Division

```
int fraction(int num)
{
    int denom = 0;
    int result = 0;

    if (denom != 0)
        result = num/denom;

    return result;
}
```

Before dividing, add a test to see if the denominator is zero, checking before division occurs. If `denom` is always zero, this correction can produce a dead code defect in your Polyspace results.

#### Correction — Change Denominator

One possible correction is to change the denominator value so that `denom` is not zero.

```
int fraction(int num)
{
    int denom = 2;
    int result = 0;

    result = num/denom;

    return result;
}
```

### Modulo Operation with Zero

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        arr[i] = input % i;
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

In this example, Polyspace flags the modulo operation as a division by zero. Because modulo is inherently a division operation, the divisor (right hand argument) cannot be zero. The modulo operation uses the `for` loop index as the divisor. However, the `for` loop starts at zero, which cannot be an iterator.

#### Correction — Check Divisor Before Operation

One possible correction is checking the divisor before the modulo operation. In this example, see if the index `i` is zero before the modulo operation.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
        if(i != 0)
        {
             arr[i] = input % i;
        }
        else
        {
             arr[i] = input;
        }
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

#### Correction — Change Divisor

Another possible correction is changing the divisor to a nonzero integer. In this example, add one to the index before the `%` operation to avoid dividing by zero.

```
int mod_arr(int input)
{
    int arr[5];
    for(int i = 0; i < 5; i++)
    {
         arr[i] = input % (i+1);
    }

    return arr[0]+arr[1]+arr[2]+arr[3]+arr[4];
}
```

### Division of Function Arguments

```
#include <limits.h>
#include <stdio.h>

extern void print_int(int);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    int r =  num/denum; //Noncompliant
    print_int(r);
    return r;
}
```

This example function divides two argument variables, then prints and returns the result. The argument values are unknown and can cause division by zero or integer overflow.

#### Correction — Check Values

One possible correction is to check the values of the numerator and denominator before performing the division.

```
#include <limits.h>
#include <stdio.h>

extern void print_long(long);

int taintedintdivision(void) {
    long num, denum;
    scanf("%lf %lf", &num, &denum);
    long res= 0;
    if (denum!=0 && !(num==INT_MIN && denum==-1)) {
        res = num/denum;
    }
    print_long(res);
    return res;
}
```

### Modulo with User Input

```
#include <stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem =  128%userden; //Noncompliant
    print_int(rem);
    return rem;
}
```

In this example, the function performs a modulo operation by using a user input. The input is not checked before calculating the remainder for values that can crash the program, such as 0 and -1.

#### Correction — Check Operand Values

One possible correction is to check the values of the operands before performing the modulo operation. In this corrected example, the modulo operation continues only if the second operand is greater than zero.

```
#include<stdio.h>
extern void print_int(int);

int taintedintmod(void) {
    int userden;
    scanf("%d", &userden);
    int rem = 0;
    if (userden > 0 ) {
        rem = 128 % userden;
    }
    print_int(rem);
    return rem;
}
```

# AUTOSAR C++14 Rule A5-10-1

A pointer to member virtual function shall only be tested for equality with null-pointer-constant

## Description

### Rule Definition

*A pointer to member virtual function shall only be tested for equality with null-pointer-constant.*

### Rationale

A call to a member virtual function is resolved by the compiler at run-time to the most derived version of the function. If you use the equality operators (==) or (`!=`) to compare anything other than the null-pointer constant `nullptr` with a pointer to a member virtual function, the result is unspecified.

### Polyspace Implementation

Polyspace flags any (==) or (`!=`) comparison where one operand is a pointer to a member virtual function and the other operand is not `nullptr`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Equality Comparison Between Pointer to Virtual Member Function and Non-`nullptr` Operand

```
class Base
{
public:
    virtual void f();
    void g();
};

template<typename T>
class Derived : public Base
{
public:
    void f();
};

void f()
{

    bool b = (&Derived<int>::f == &Derived<int>::f); // Noncompliant

    void (Derived<float>::* p)() = &Derived<float>::f;
    bool b1 = (&Derived<float>::f == p); // Noncompliant
    bool b2 = (p == p); // Noncompliant
    bool b3 = (p == nullptr); // Compliant

    void (Base::* q)() = &Base::g;
    bool b4 = (q == q); // Compliant

    void (Base::* r)() = &Base::f;
    bool b5 = (q == r); // Noncompliant

}
```

In this example, the result of the comparison in boolean `b` is non-compliant because the operands point to a member virtual function. Similarly, pointers `p` and `r` are pointers to member declarators that point to a member virtual function and Polyspace flags their use in equality comparison operations, except for the comparison of `p` to `nullptr`.

# AUTOSAR C++14 Rule A5-16-1

The ternary conditional operator shall not be used as a sub-expression

## Description

### Rule Definition

*The ternary conditional operator shall not be used as a sub-expression.*

### Rationale

A ternary conditional operator used as a subexpression makes the full expression less readable and difficult to maintain. It is often visually clearer if you assign the result of a ternary operator to a variable and then use the variable in subsequent operations.

### Polyspace Implementation

The checker flags uses of the ternary conditional operator in subexpressions with some exceptions. Exceptions include uses of the operator when:

- The result is assigned to a variable.
- The result is used as a function argument or returned from a function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Ternary Operators as Sub-expressions

```
#include <cstdint>
const int ULIM = 100000;

std::int32_t foo(int32_t x) {
    int ret;
    ret = (x <= 0? 0: (x >= ULIM? 0 : x)); //Noncompliant
    return ret;
}

std::int32_t bar(int32_t x) {
    int ret, retInterim;
    retInterim = x >= ULIM? 0 : x; //Compliant
    ret = retInterim <= 0? 0 : retInterim; //Compliant
    return ret;
}
```

In this example, in `foo`, a ternary conditional operation is chained with a second operation to return the value 0 if `x` is in the range `[0, ULIM]` and return `x` otherwise. The ternary operation comparing `x` with `ULIM` is a sub-expression in the full chain and violates the rule.

In `bar`, each ternary conditional operation is written in a separate step and does not violate the rule. Alternatively, the same algorithm can be implemented by combining the conditions with the boolean AND operator and using a single ternary conditional operation.

# AUTOSAR C++14 Rule A6-2-1

Move and copy assignment operators shall either move or respectively copy base classes and data members of a class, without any side effects

## Description

### Rule Definition

*Move and copy assignment operators shall either move or respectively copy base classes and data members of a class, without any side effects.*

### Rationale

When you use move and copy assignment operators, you expect that the operation moves or copies a source object to a target object without producing any side effects. If move or copy assignment operators of a class produce side effects, the invariant of an object can change during move or copy assignments. Consider this code where multiple objects of class `C` are copy-assigned to each other.

```
class C{
    //...
    C& operator=(const C& oth) {
        value = oth.value / 2;
        return *this;
    }
public:
    int value;
};

int main(){
    C a, b, c;
    a.value = 48;
    // …
    b = a; // b.m = 24
    c = b; // c.m = 12
    a = c; // a.m = 6
}
```

During each copy assignment, the `value` in the target object becomes half of the `value` in the source object. After three successive copy assignment operations, `a.value` becomes `6`, which is unexpected. Algorithms expect move and copy assignment operators that do not change the object invariant. If move or copy assignment operators of a class have side effects that change the object invariant, using algorithm libraries such as the standard template library (STL) can produce unexpected results.

Because you use move and copy assignments many times in a code, any side effect producing code can make the code slower and resource intensive. In a move assignment operator, code that produce side effects can also cause the compiler to use copy operation with every assignment, which is inefficient.

To maintain optimum and reliable performance during move and copy assignment, perform only these operations in move and copy assignment operators:

- Copy or move data members and base classes.

- Return the pointer *this.
- If possible, set the moved-from object to a valid state.

Avoid superfluous code that add unrelated side effects or performance overhead.

### Polyspace Implementation

In the body of a copy or move assignment operator, Polyspace does not flag these operations:

- Copy or move assignments.
- Relational or comparison operations.
- Modification of the source object in a move operation.
- Calls to the function std::swap or equivalent user-defined noexcept swap functions. Polyspace identifies functions that these signatures as swap functions: void T::swap(T&) or void [N::]swap(T&, T&). The first signature represents a member function of class T that takes one argument. The second signature represents a nonmember or static function in the namespace N that takes two arguments. The name swap can be case-insensitive and prefixed or postfixed by underscores.
- Assignment and modification of static variables.

Polyspace flags any other operations in a copy or move assignment operator as unwanted side effect. For instance, a call to a user-defined swap function is considered an unwanted side effect if the swap function is not noexcept. For a similar rule on copy and move constructor, see AUTOSAR C++14 Rule A12-8-1.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Move and Copy Assignment Operators with Side Effects

This code shows how Polyspace flags move and copy assignment operators that have side effects.

```
#include<cstdint>
#include<iostream>
class B
{
public:
    B() : ptr(0) {}
    B& operator=(B&& oth) //Noncompliant
    {

        if(&oth == this) {
            return *this;
        }
        ptr = std::move(oth.ptr);
        std::cout<<"Moved";
        return *this;
    }

private:
    std::int32_t* ptr;
};
class C
{
public:
    C(int t=0) : x(t) {}
    C& operator=(const C& oth)  // Noncompliant
    {
        if(&oth == this) {
            return *this;
        }
        x = oth.x % 2;         // This operation produces side-effect
        count++; //Not a side effect
        return *this;
    }

private:
    std::int32_t x;
    static std::int32_t count;

};
class D
{
public:
    D(const D&) = default;
    D(D&&) = default;

    D& operator=(const D& oth) & {     // Noncompliant
        D tmp(oth);
        swap(tmp);
        return *this;
    }

    // Member function swap
    void swap(D& rhs)  {
        //...
    }

private:
    std::int32_t x;
};
```

- As a side effect, the move assignment operator of class B prints a string into the output stream. This side effect adds performance overhead to the move operation. If this statement `std::cout<<"Moved"` causes an exception, code execution can unexpectedly stop. Polyspace flags the move assignment operator and highlights the statement.
- The copy assignment operator of C modifies the data member `x` of the source object. This side effect adds performance overhead. Unexpected change to data members during move and copy operations can make the code incompatible with the standard template library and introduce errors during development. Polyspace flags the copy assignment operator and highlights the statement `x = oth.x % 2`. Incrementing the static variable `count` is not a side effect.
- The copy assignment operator of the class `D` calls a user-defined swap function called `_swap_`. This swap function is not `noexcept`. If an exception is raised from `_swap_`, the exception is an unexpected side effect of the copy assignment operator. Polyspace flags the copy constructor as noncompliant with this rule. Use user-defined swap function that are `noexcept`.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A6-2-2

Expression statements shall not be explicit calls to constructors of temporary objects only

## Description

### Rule Definition

*Expression statements shall not be explicit calls to constructors of temporary objects only.*

### Rationale

Objects that the compiler creates for a short duration, and then deletes, are temporary objects. The compiler might create temporary objects for specific purposes, such as:

- Initializing references
- Storing values returned by functions
- Type casting
- Exception handling

Temporary objects are destroyed once the expression that requires their construction is completely evaluated. For instance, in evaluating the expression `sum = a*b+c`, the compiler creates two temporary objects to store the results of the multiplication and addition operations. After the expression is evaluated, both temporary objects are destroyed. Their scope is limited to the expression statement.

If an expression is an explicit call to a constructor omitting the object name, the compiler creates a temporary object which is immediately destroyed. Such an explicit call to a constructor might indicate that:

- You inadvertently omitted the object name.
- You expected the unnamed variable to remain in scope up to the end of the declaration block.

Consider this code snippet where a `lock_guard` object is created.

```
void foo(){
std::mutex mymutex;
std::mutex mymutex2;
std::lock_guard<std::mutex> lock{mymutex};
std::lock_guard<std::mutex> {mymutex2};
//...
}
```

The first declaration creates a `lock_guard` object named `lock`. The object `lock` protects `mymutex` from concurrent access by multiple thread until the end of the current block. The second declaration attempts a similar protection for `mymutex2`. Because the `lock_guard` object in this case is not named, it is destroyed immediately after the declaration statement. Perhaps inadvertently, `mymutex2` remains unprotected from concurrency issues.

Avoid expression statements that are only an explicit call to a constructor. To implement the Resource Acquisition Is Initialization (RAII) pattern, use named objects.

### Polyspace Implementation

Polyspace flags any expression statement that constructs an unnamed object and does not use it. You can construct unnamed temporary objects when you use the objects within the declaration expression statement. For example, a temporary object that is used as a function return or on the right-hand side of an assignment is compliant with this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Statements That Are Only Explicit Calls To Constructors

This code shows how Polyspace flags statements that are only explicit calls to a constructor.

```
#include <cstdint>
#include <fstream>
#include <string>
class MyException {
    MyException(const std::string &);
};
void with_exception() {
    MyException("Exception");              //Noncompliant
    throw MyException("Exception");        //Compliant

};
```

Polyspace flags an expression statement that constructs an unnamed temporary object and does not use it. If you use the temporary object in the statement, then the statement is compliant with the rule. For example, the statement `MyException("Exception");` is flagged because the unnamed object created by the explicit call to the constructor `MyException()` is not used in the statement. The statement `throw MyException("Exception");` is not flagged because the unnamed object is used as an argument to `throw`.

### Avoid Unnamed `lock_guard` Objects

Compilers destroy an unnamed `lock_guard` object immediately after its declaration statement. Unnamed `lock_guard` objects cannot protect `mutex` objects from concurrency issues. Polyspace flags a statement when it declares an unnamed `lock_guard` object. Consider this code:

```
#include <cstdint>
#include <mutex>
class A {
public:
    void SetValue1(std::int32_t value) {
        std::lock_guard<std::mutex> {mutex1}; //Noncompliant
        private_value = value;
    }

    void SetValue2(std::int32_t value) {
        std::lock_guard<std::mutex> lock{mutex2}; //Compliant
        private_value = value;
    }
private:
    mutable std::mutex mutex1;
    mutable std::mutex mutex2;
    std::int32_t private_value;
};
```

- The statement `std::lock_guard<std::mutex> {mutex1};` declares an unnamed `lock_guard` object. Polyspace flags the statement.
- The statement `std::lock_guard<std::mutex> lock{mutex2};` is not flagged because the `lock_guard` object is named.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A6-4-1

A `switch` statement shall have at least two case-clauses, distinct from the default label

## Description

### Rule Definition

*A `switch` statement shall have at least two case-clauses, distinct from the default label.*

### Rationale

A `switch` statement with no case-clauses is redundant. Use an `if` statement to better express a `switch` statement with a single case-clause.

### Polyspace Implementation

This rule checker reports a violation for `switch` statements that contain less than two case-clauses in addition to the default-clause. This includes situations where no case-clause exists.

```
    switch (x) {    //Noncompliant
        default:
                   //...
            break;
    }
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Example

### Use at Least Two Case-Clauses in `switch` Statements

Because this `switch` statement contains a single case-clause alongside the default-clause, Polyspace flags the `switch` statement as noncompliant.

```
void example(int x)
{
    switch (x) {    //Noncompliant
        case 0:
            break;
        default:
            break;
    }
}
```

You can express the same code in an `if` statement form to avoid a rule violation.

```
void example(int x)
{
    if (x == 0)
    {
        //...
    }
    else
    {
        //...
    }
}
```

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A6-5-1

A for-loop that loops through all elements of the container and does not use its loop-counter shall not be used

## Description

### Rule Definition

*A for-loop that loops through all elements of the container and does not use its loop-counter shall not be used.*

### Rationale

If you loop through all the elements of a container and you use the loop counter variable to access only the value of the elements, a `for` loop is slower, less readable, and more difficult to maintain than an equivalent range-based `for` loop.

### Polyspace Implementation

Polyspace flags the use of `for` loops that loop through all elements of a container or a C-style array when both of these conditions are true:

- The `for` loop has only one loop counter variable. For instance, Polyspace does not flag this `for` loop:

  ```
  for(int i=0, j=0; i < 10; ++i, ++j){ //Compliant
  //...
  }
  ```
- The `for` loop uses the loop counter variable only to access the elements of the container or the C-style array. For instance, in this code snippet, Polyspace flags the first `for` loop because the array counter "`i`" is used only the access elements of `myArray` which are then assigned a value. Use a range-based `for` loop instead to perform an equivalent operation.

  Polyspace does not flag the second `for` loop because the array counter is used to access the array elements and is assigned to the element.

  ```
  #include <iostream>

  int myArray[10];

  void cArray()
  {
      //First for loop: Loop counter 'i' used only to access elements
      //of myArray which are then assigned a value
      for (int i = 0; i < 10; ++i)
      { //Non-compliant
          myArray[i] = 0;
      }
      //Range-based for loop - equivalent to first for loop
      for (int idx : myArray)
      {
          myArray[idx] = 0; // compliant
      }
  ```

```
    //Second for loop: Loop counter assigned to elements of myArray
    for (int i = 0; i < 10; ++i)
    { //Compliant
        myArray[i] = i;
    }
}
```

Polyspace does not flag violations of this rule in these scenarios:

- You iterate through a user-defined container. For instance, this `for` loop is compliant.

  ```
  template<typename T>
  class customContainer {
    typedef T* iterator;
    public:
      iterator begin();
      iterator end();
  };

  void func() {
    customContainer<int> myContainer;

    for(auto it = myContainer.begin(); it != myContainer.end(); it++) { //Compliant
      std::cout << *it;
    }
  }
  ```

  Polyspace flags violations of the rule only for C-style arrays and Standard Template Library containers.

- You use reverse iterators to loop through the elements of the C-style array or container. For instance, in this code snippet, there is no violation of the rule because you cannot use a range-based `for` loop to perform an equivalent operation.

  ```
  #include <iostream>
  #include <vector>
  #include <cstdint>

  std::vector<std::uint32_t> myVector(10);

  void myContainer()
  {
      //loop uses reverse iteration
      for (auto it = myVector.rbegin(); it != myVector.rend(); ++it) { //Compliant

          std::cout << *it;
      }
  }
  ```

- If you loop through arrays:

  - You loop through the elements of multiple arrays or you loop through the elements of a multidimensional array.
  - The array size is unknown.

  For instance, Polyspace considers these `for` loops compliant:

  ```
  int myArray[10];
  int myOtherArray[10];
  int multiArray[10][10];

  void cArray()
  {
      //loop through multiple array
      for (int i = 0; i < 10; ++i) { //Compliant
          myArray[i] = 0;
  ```

```
            myOtherArray[i] = 0;
        }
        //loop through 2-dimensional array
        for (int i = 0; i < 10; ++i) { //Compliant
            multiArray[i][i] = 0;
        }

    }

    void unknownSize(int someArray[])
    {
        //loop through array of unknown size
        for (int i = 0; i < 10; ++i) { //Compliant
            someArray[i] = 0;
        }
    }
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Inefficient Use of a for Loop

```
#include <iostream>
#include <vector>
#include <cstdint>

std::vector<std::uint32_t> myVector(10);

void myContainer()
{
    for (auto it = myVector.begin(); it != myVector.end(); ++it) { //Non-compliant
        std::cout << *it;
    }

    for (auto it : myVector) { //Compliant
        std::cout << it;
    }
}
```

In this example, Polyspace flags the `for` loop, which iterates through all the elements of vector `myVector` and uses the loop counter `it` to only print the value of each element. The range-based for loop `for (auto it: myVector)` performs an equivalent operation, uses less code and makes your code run more efficiently, more readable, and easier to maintain.

# AUTOSAR C++14 Rule A6-5-2

A `for` loop shall contain a single loop-counter which shall not have floating-point type

## Description

### Rule Definition

*A `for` loop shall contain a single loop-counter which shall not have floating-point type.*

### Rationale

In situations where your code has a `for` loop without a loop counter, replace the `for` loop with a `while` loop.

In floating-point arithmetic operations, floating-point types are rounded to fit into a finite representation. This introduces rounding errors which can cause unexpected results when loop-counter comparisons occur.

### Polyspace Implementation

This rule checker reports a rule violation in these situations:

- The `for` loop index has a floating-point type.
- You increment more than one loop counter in the `for` loop increment statement.

  For instance:

  ```
  for(i=0, j=0; i<10 && j < 10;i++, j++) {}
  ```
- You do not increment a loop counter in the `for` loop increment statement.

  For instance:

  ```
  for(i=0; i<10;) {}
  ```

  Even if you increment the loop counter in the loop body, Polyspace still reports a violation. The rule is based on MISRA C++ rule 6-5-1. According to the MISRA C++ specifications, a loop counter is one that is initialized in or prior to the loop expression, acts as an operand to a relational operator in the loop expression, and is modified in the loop expression. If the increment statement in the loop expression is missing, the rule checker cannot find the loop counter modification and considers the loop counter not present.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Example

### Use Single Loop Counter Only

Because the code increments both loop counters, `x` and `i`, this example is noncompliant.

```
#include <iostream>

int main()
{
    int x = 0;
    for (int i = 0; i >= x; i = x++)   // Non-compliant
    {
        //...
    }
}
```

#### Avoid Using Floating-Point Numbers as Loop Counters

In this noncompliant example, because floating-point calculations contain rounding errors, the `for` loop executes only nine times. This is due to the value of `x` being larger than `1.0f` on the tenth loop.

```
#include <iostream>

int main()
{
    for (float x = 0.1f; x <= 1.0f; x += 0.1f) {   //Noncompliant
        std::cout << x << std::endl;
    }
}
```

# AUTOSAR C++14 Rule A6-5-3

Do statements should not be used

## Description

### Rule Definition

*Do statements should not be used.*

### Rationale

A do statement can introduce bugs in your code because its termination condition is checked after executing the code block. Consider this code where an array is accessed by using a pointer in a do-while loop.

```
int* array;
//...
do {
cout<<*array;
--array;
} while (array != nullptr);
```

Because the termination condition is checked after executing the block of code, this code might dereference an invalid or null pointer, which can unexpectedly terminate code execution during run time. The code is also hard to read because the condition for executing the block is at the end of the block where it can be easily missed.

Avoid do statements in your code. You can use do statements to write function-like macros.

### Polyspace Implementation

Polyspace flags all do statements, except those located in macros.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid do Statements

This example shows how Polyspace flags do statements outside of a macro. This code uses a pointer within a do-while loop. The terminating condition is that the pointer is not a null pointer.

```
#include<cstdint>
struct P
{
    int val;
    struct P* next;
};
```

```
void psKO(P*p)
{
    do              // Noncompliant
    {
        p = p->next;
    } while(p!=nullptr);
}
```

This code can dereference a null pointer because the terminating condition is checked after executing the do block. The code is also difficult to read because the terminating condition is placed at the end of the block. Polyspace flags the do statement.

### do Statements in Macros

This example shows how Polyspace treats do statements in a macro. Consider this code where two macros, SWAP and SWAP2 are implemented. SWAP uses a do statement while SWAP2 does not.

```
#include <cstdint>
//Compliant by exception
#define SWAP(a, b) \
        do                          \
        {                           \
            decltype(a) tmp = (a); \
           (a) = (b);              \
           (b) = tmp;              \
       } while (0)

#define SWAP2(a, b)        \
       decltype(a) tmp = (a); \
       (a) = (b);             \
       (b) = tmp;

int main(void)
{
  uint8_t a = 24;
  uint8_t b = 12;

  if (a > 12)
//  SWAP2(a, b);  // Compilation Error
  SWAP(a, b);
return 0;
}
```

The two macros are intended to be invoked like functions. You cannot use SWAP2 as a function-like macro in the if block because after expansion, only the first expression statement of SWAP2 remains within the if block. This breakup of the macro changes its meaning, and in this case, causes a compilation error. A solution to this issue is to enclose the macro in a do-while block and put the terminating condition as false. Such enclosed macros cannot be broken up and can be invoked as functions. Polyspace does not flag do statements in macros.

# AUTOSAR C++14 Rule A6-5-4

For-init-statement and expression should not perform actions other than loop-counter initialization and modification

## Description

### Rule Definition

*For-init-statement and expression should not perform actions other than loop-counter initialization and modification.*

### Rationale

For-init-statements and expressions are easier to read, understand, and maintain when they contain only the loop-counter initialization and modification.

### Polyspace Implementation

This checker flags the following situations

- Reports if `loop` parameter cannot be determined. Assumes JSF C++ Rule 200 is not violated. The `loop variable` parameter is assumed to be a variable.
- Assumes 1 loop parameter (see JSF C++ Rule 198), with non class type. JSF C++ Rule 200 must not be violated for this rule to be reported.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Noncompliant Actions in For-Init-Statement

Because the `for` loop contains multiple loop parameters, Polyspace flags the `for` loop as noncompliant.

```
#include <cstdint>

void example()
{
    for (std::int32_t x, y = 0; x < y; x++)  //Noncompliant
    {
        //...
    }
}
```

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A6-6-1

The `goto` statement shall not be used

## Description

### Rule Definition

*The `goto` statement shall not be used.*

### Rationale

Unrestricted use of `goto` statements increases the complexity of the logic of a program and makes the code difficult to understand. Additionally, `goto` statements can introduce memory leaks or incorrectly release resources.

### Polyspace Implementation

Polyspace reports a rule violation when you use a `goto` statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `goto` Statements

Polyspace reports a rule violation every time this code uses a `goto` statement.

```
void foo(void)
{
    int i = 0, result = 0;

label1:
    for (i; i < 5; i++) {
        if (i > 2) goto label2;     // Non-compliant
    }

label2: {
        result++;
        goto label1;                // Non-compliant
    }
}
```

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-1-1

Constexpr or const specifiers shall be used for immutable data declaration

## Description

### Rule Definition

*Constexpr or const specifiers shall be used for immutable data declaration.*

### Rationale

Declaring a variable `const` or `constexpr` reduces the chances that you modify the variable by accident. In addition, compilers can perform various optimizations on `const` and `constexpr` variables to improve run-time performance.

### Polyspace Implementation

The checker flags:

- Function parameters or local variables that are not const-qualified but never modified in the function body.
- Pointers that are not const-qualified but point to the same location during its lifetime.

Function parameters of integer, float, enum, and Boolean types are not flagged.

If a variable is passed to another function by reference or pointers, the checker assumes that the variable can be modified. These variables are not flagged.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unmodified Local Variable

```
#include <cstddef>
bool Status;
extern int setStatus(); //sets Status; returns -1 if fails

char getNthChar(const char* str, int N){ //noncompliant
    int index=0;
    int status = setStatus(); //noncompliant
    while(*(str+index)!='\0'){
        if(index==N)
            return *(str+N);
        ++index;
    }

    return '\0';
}
```

```
char getNthChar_const_safe(const char* const str, int N){
    int index=0;
    const int status = setStatus();
    while(*(str+index)!='\0'){
        if(index==N)
            return *(str+N);
        ++index;
    }

    return '\0';
}
```

In the function `getNthChar()`, the C-string `str` is passed as a `const char*` parameter, meaning that the string `*str` is `const`. Because the pointer `str` does not change value, the pointer itself must be `const` qualified, as shown in the function `getNthChar_const_safe`. Polyspace flags the parameter `str`.

Because the local integer `status` is not modified in `getNthChar()`, it must be declared `const`, as shown in `getNthChar_const_safe`. Polyspace flags the declaration.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-1-2

The constexpr specifier shall be used for values that can be determined at compile time

## Description

### Rule Definition

*The constexpr specifier shall be used for values that can be determined at compile time.*

### Rationale

If a variable value is computed from an expression that involves compile-time constants only, using `constexpr` before the variable definition, like this:

```
constexpr double eValSquared = 2.718*2.718;
```

ensures that the expression is evaluated at compile time. The compile-time evaluation saves on run-time overheads. Sometimes, the performance gains at run time can be significant.

If the expression cannot be evaluated at compile time, the `constexpr` keyword ensures that you get a compilation error. You can then fix the underlying issue if possible.

Note that the `const` keyword does not guarantee compile-time evaluation. The `const` keyword simply forbids direct modification of the variable value after initialization. Depending on how the variable is initialized, the initialization can happen at compile time or run time.

### Polyspace Implementation

The checker flags a local variable definition without the `constexpr` specifier if the variable is initialized with one of the following and not modified subsequently in the code:

- A compile-time constant, for instance, a literal value.
- An expression involving compile-time constants only.
- Calls to a function with compile-time constants as parameters, provided the function is itself `constexpr` or the function contains only a return statement involving its parameters.
- A constructor call with a compile-time constant, provided all member functions of the class including the constructor are themselves `constexpr`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Potential `constexpr` Variables

```
double squareIfPositive(double val) {
    return val > 0? (val * val): 0;
}
```

```
constexpr double square(double val) {
    return val > 0? (val * val): 0;
}

void initialize(void) {
    double eVal = 2.718; //Noncompliant
    double eValSquare = squareIfPositive(2.718); //Noncompliant
    const double eValCubed = 2.718 * 2.718 * 2.718; //Noncompliant

    constexpr double eValSquareAnother = square(2.718); //Compliant
}
```

In this example, the first three variable definitions in the `initialize` function are noncompliant because the variables are initialized with expressions involving literal values and the `constexpr` keyword is omitted.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-1-3

CV-qualifiers shall be placed on the right hand side of the type that is a typedef or a using name

## Description

### Rule Definition

*CV-qualifiers shall be placed on the right hand side of the type that is a typedef or a using name.*

### Rationale

Suppose a `typedef` or `using` statement defines a pointer type. For instance:

```
using IntPtr = std::int32_t*;
```

A `const`-qualification of the type written as:

```
const IntPtr ptr = &someValue;
```

Results in this expansion:

```
const (std::int32_t*) ptr = &someValue;
```

In this expression, `ptr` is a constant pointer, which cannot be reassigned to another memory location. However, a developer or reviewer might expect this expansion:

```
(const std::intr32_t) *ptr = &someValue;
```

In this expression, `ptr` is a pointer to a constant, which means that the contents of the location that `ptr` points to, or `*ptr`, cannot be changed.

To avoid this confusion, place a `const` or `volatile` qualifier to the right of a data type defined through `typedef` or `using`. For instance:

```
IntPtr const ptr = &someValue;
```

The only possible expansion of this expression is:

```
std::intr32_t const *ptr = &someValue;
```

which makes `ptr` a constant pointer.

### Polyspace Implementation

The checker reports a violation if `const` or `volatile` qualifiers are placed on the left side of data types defined through `typedef` or `using` statements.

The checker reports violations on both pointer and nonpointer data types. The checker does not report a violation on `typedefs` defined in the `std` namespace.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### CV Qualifiers in Right Side of using Name

In this example, Polyspace reports violations of this rule when the `const` qualifier is placed on the right hand side of type that uses a `using` name. This violation is not reported for `typedef`-s that are part of the standard (`std`) namespace.

```
#include <cstdint>
#include <string>
using int_p = std::int32_t*;
using int_const_p = int32_t* const;
using const_int_p = const int32_t*;
void Fn(const std::uint8_t& input) // Compliant
{
    std::int32_t value1 = 10;
    std::int32_t value2 = 20;

    const int_p ptr1 =   // Noncompliant deduced type is std::int32_t* const, not const std::int3
    &value1;

    int_p const ptr2 = // Compliant
    &value1;

    int_const_p ptr3 = &value1;    // Compliant

    const_int_p ptr4 = &value1;    //Compliant
    const const_int_p ptr5 = &value1;    // Noncompliant, type is const std::int32_t* const,
                                        //   not const const std::int32_t*
    const_int_p const ptr6 =
    &value1; // Compliant
    const std::string str = "Foo"; //Compliant
}
```

# AUTOSAR C++14 Rule A7-1-4

The register keyword shall not be used

## Description

### Rule Definition

*The register keyword shall not be used.*

### Rationale

The `register` keyword will be removed from the C++ language in a future release, resulting in code that either no longer compiles or that exhibits undefined behavior. Most compilers ignore the `register` specifier and assign registers themselves. By relying on the presence of specific objects in the processor register, the code might behave in unexpected ways.

To resolve this issue, remove the `register` keyword.

### Polyspace Implementation

Polyspace flags the declaration of an object if its storage type is `register`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Remove `register` Keyword in C++ Source Code

```
#include <cstdint>

int main() {
  register std::int32_t x = 7; //Noncompliant
  std::int32_t y = 7; //Compliant
  return 0;
}
```

In this example, Polyspace flags the use of the keyword `register`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-1-5

The auto specifier shall not be used apart from following cases: (1) to declare that a variable has the same type as return type of a function call, (2) to declare that a variable has the same type as initializer of non-fundamental type, (3) to declare parameters of a generic lambda expression, (4) to declare a function template using trailing return type syntax

## Description

### Rule Definition

*The auto specifier shall not be used apart from following cases: (1) to declare that a variable has the same type as return type of a function call, (2) to declare that a variable has the same type as initializer of non-fundamental type, (3) to declare parameters of a generic lambda expression, (4) to declare a function template using trailing return type syntax.*

### Rationale

When you use the `auto` type specifier with a variable declaration, the type of the variable is deduced by the compiler. A developer reading the code might be confused if the type deduction is not what he or she would expect. The information needed to deduce the type might be in a separate part of the code.

This rule permits the use of the `auto` specifier in these cases:

- You declare a variable that is initialized with a function call. This avoids a repetition of the type and ensures that there are no unexpected conversions if you change the return type of the function. For example, in this code snippet, variable `var` has the same type as the return type of `myfunc()`:

  ```
  #include<cstdint>

  int32_t myfunc();

  int foo(){
    auto var=myfunc();
    return var;
  }
  ```
- You declare a variable that you initialize with a non-fundamental type initializer. A type `T` is non-fundamental if `std::is_fundatmental<T>::value` is false. For a list of fundamental types, see Fundamental types. For example, the type of `var` in this code snippet is `std::vector<int>::iterator`.

  ```
  std::vector<int> v = { 1, 2, 3};
  auto var = v.begin();
  ```

  By using the `auto` keyword, you make the code more readable and avoid having to write a difficult to remember non-fundamental type.

  Note that a pointer is a non-fundamental type.
- You declare the parameters of a generic lambda function. The function can then accept more than one kind of parameter types, similar to a function template. For instance, the custom

implementation of `std::sort` in this code snippet can be used to sort vectors of ints, or floats, or other arithmetic types.

```
//sort in ascending order
std::sort(v.begin(), v.end(),
              [](auto lhs, auto rhs){
                  return lhs < rhs});
```

- You use a trailing return type syntax to declare a function template. In this case, there is no type deduction. The `auto` keyword is used as part of an alternative syntax for the declaration of function templates. This code snippet shows an example of trailing return type syntax.

```
template<typename T, typename U>
auto subtract(T lhs, U rhs) -> decltype(lhs - rhs);
```

### Polyspace Implementation

- Polyspace flags the use of the `auto` specifier except when it is used in one of the cases listed in the previous section.
- Polyspace flags the use `auto` to declare a variable that is initialized with a `std::initializer_list` of a fundamental type.
- Polyspace does not flag the use of `decltype(auto)`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of the `auto` Specifier

```
#include <string>
#include<vector>

auto func(int a)   // Non-compliant
{
    return a;
}

void func2()
{
    auto int_type = new int[5];           //  Non-compliant

    auto vector_type = std::vector<int> { 1, 2, 3 }; // Compliant

    const char* c = "hello";
    auto str2 =  std::string(c); // Compliant

    auto lambda = [](auto x, auto y) { // Compliant
        return x > y;
    };

}
```

In this example, the use of the `auto` specifier for the return type of `func` is non-compliant. The deduced return type of the function might not be obvious. Similarly, the use of `auto` in the declaration of `int_type` is non-compliant because the initializer of this variable is an array of type int, which is a fundamental type.

Other uses of `auto` in this example are compliant with the use cases specified by this rule:

- The initializers of `vector_type` and `str2` are non-fundamental types `std::vector<int>` and `stdd::string` respectively (use case (2)).
- The initializer of variable `lambda` is a non-fundametal type lambda expression (use case (2))
- Variables `x` and `y` are parameters of a lambda expression (use case (3)).

# AUTOSAR C++14 Rule A7-1-6

The typedef specifier shall not be used

## Description

### Rule Definition

*The typedef specifier shall not be used.*

### Rationale

The `using` syntax is a better alternative to `typedef`-s for defining aliases.

Since C++11, the `using` syntax allows you to define template aliases where the template arguments are not bound to a data type. For instance, the following statements define an alias `vectorType` for `vector`, where the argument `T` is not bound to a data type and can be substituted later:

```
template<class T, class Allocator = allocator<T>> class vector;
template<class T> using vectorType = vector<T, My_allocator<T>>;
vectorType<int> primes = {2,3,5,7,11,13,17,19,23,29};
```

The `typedef` keyword does not allow defining such template aliases.

### Polyspace Implementation

The rule checker flags all uses of the `typedef` keyword.

If you do not want to remove certain instances of the `typedef` keyword, add a comment justifying those results. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use of `typedef` Keyword

```
#include <cstdint>
#include <type_traits>

typedef std::int32_t (*fptr1) (std::int32_t); //Noncompliant
using fptr2 = std::int32_t (*) (std::int32_t); //Compliant

template <class T> using fptr3 = std::int32_t (*) (T); //Compliant
```

The alias definitions for `fptr1` and `fptr2` are exactly equivalent. There is no `typedef` equivalent for the alias definition for `fptr3`.

The use of `typedef`-s violates this rule. The rule requires that you stick to the `using` syntax for consistency even when a `typedef` equivalent exists.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-1-8

A non-type specifier shall be placed before a type specifier in a declaration

## Description

### Rule Definition

*A non-type specifier shall be placed before a type specifier in a declaration.*

### Rationale

Non-type specifiers include:

- `typedef`.
- `friend`.
- `constexpr`.
- `register`.
- `static`.
- `extern`.
- `thread-local`.
- `mutable`.
- `inline`.
- `virtual`.
- `explicit`.

To make the code more readable, place non-type specifiers before type specifiers in a declaration.

### Polyspace Implementation

Polyspace flags declarations that place non-type specifiers after a type specifier. If more than one non-type specifiers follow a type specifier, Polyspace flags the rightmost non-type specifier.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Place Non-Type Specifiers Before Type Specifiers

The following example demonstrate the Polyspace implementation of AUTOSAR rule A7-1-8.

```
#include <cstdint>

typedef std::int32_t int1;  // Compliant
std::int32_t typedef int2;  // Noncompliant
```

```
class to_be_friend
{
    explicit to_be_friend(int); // Compliant
    static void* foo(void);     // Compliant
    void static* bar(void);     // Noncompliant
    virtual inline void i1(void) {}; // Compliant
    inline void virtual i2(void) {}; // Noncompliant
    constexpr static long long l1 = 0; // Compliant
    long long constexpr static l3 = 0; //Noncompliant
};
main()
{
    //...
}
```

Polyspace flags declarations where you place non-type specifiers after type-specifiers. The declaration of the static object `l3` is flagged because the non-type specifiers `static` and `constexpr` are placed after the type-specifier `long long`. The violation is highlighted on the rightmost non-type specifier, which is `static`.

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A7-2-1

An expression with enum underlying type shall only have values corresponding to the enumerators of the enumeration

## Description

### Rule Definition

*An expression with enum underlying type shall only have values corresponding to the enumerators of the enumeration.*

### Rationale

If your program evaluates an expression with `enum` underlying type and returns a value that is not part of the enumerator list of the enumeration, the behavior is unspecified.

Compliance with this rule validates the assumption made by other rules in this standard that objects of type `enum` contain only values corresponding to the enumerators.

To avoid unspecified behavior when evaluating expressions of type `enum`, use a `switch` statement. For example:

```
#include <cstdio>
enum class E : size_t { Pass, Warning, Error };

E Evaluate(size_t input) noexcept {
    E output = E::Pass;
    switch (input) {
      case 0: {
          output = E::Pass;
          break;
      }
      case 1: {
          output = E::Warning;
          break;
      }
      case 2: {
          output = E::Error;
          break;
      }
      default: {
          output = static_cast<E>(0);
      }
    }
    return output;
}
```

### Polyspace Implementation

Polyspace flags the use of a value that is not part of the enumerators of an enumeration.

Polyspace does not flag the use of unknown values, even if you do not check the range of the value before you use it in the `enum` expression.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Value Does Not Correspond to Enumerators of Enumeration

```
#include <cstdint>

enum class Suit : uint8_t { None = 1, Diamonds, Clubs, Hearts, Spades };

Suit resetRedSuit(uint8_t card) noexcept {
    Suit hand = Suit::None;
    if(card < 6){ //check range of card is inside Suit enum
        hand = static_cast<Suit>(card);
    }

    if (hand == Suit::Diamonds ||
        hand == Suit::Hearts) {
            hand = static_cast<Suit>(0); // Noncompliant
    }
    return hand;
}
```

In this example, Polyspace flags the second `static_cast` in function `resetRedSuit` because the expression uses a value (0) that is not part of the enumerator list of enumerator `Suit`.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A7-2-2

Enumeration underlying type shall be explicitly defined

## Description

### Rule Definition

*Enumeration underlying type shall be explicitly defined.*

### Rationale

In an unscoped enumeration declaration such as:

```
enum someEnum : type { ... }
```

if `: type` is omitted, the underlying type is implementation-defined (with the only requirement that the type must accommodate all the enumeration values). Not declaring an underlying type explicitly results in implementation-defined behavior.

In a scoped enumeration declaration such as:

```
enum class someEnum : type { ... }
```

if `: type` is omitted, the underlying type is `int`. If an enumeration value exceeds the values allowed for `int`, you see compilation errors.

For both unscoped and scoped enumerations, declare the underlying type explicitly to avoid implementation-defined behavior or compilation errors.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Enums with Underlying Type Omitted

```
#include <cstdint>

enum E1 { //Noncompliant unscoped enum
    E10,
    E11,
    E12
};

enum E2 : std::uint8_t { //Compliant unscoped enum
    E20,
    E21,
    E22
};

enum class E3 { //Noncompliant scoped enum
```

```
    E30,
    E31,
    E32
};

enum class E4 : std::uint8_t { //Compliant scoped enum
    E40,
    E41,
    E42
};
```

In this example, the code is noncompliant when the underlying types of the enumerations are omitted.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-2-3

Enumerations shall be declared as scoped enum classes

## Description

### Rule Definition

*Enumerations shall be declared as scoped enum classes.*

### Rationale

Enumeration values in an unscoped enum can conflict with other identifiers in the same scope as the enum and cause compilation errors. For instance:

```
enum E: std::int32_t { E0, E1};
std::int32_t E0;
```

If you scope the enum, such conflicts can be avoided. For instance:

```
enum class E: std::int32_t { E0, E1};
std::int32_t E0;
```

Scoping the enum also disallows implicit conversions of the enumeration values to other types.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unscoped Enums

```
#include<cstdint>

enum E1: std::int32_t { E10, E11}; //Noncompliant
// std::int32_t E10; causes compilation errors

enum class E2: std::int32_t { E20, E21}; //Compliant
std::int32_t E20;
```

In this example, the declaration of unscoped enum `E1` is noncompliant. Redeclaring an enumeration value of the unscoped enum causes compilation errors (as shown in the commented line that redeclares the enumeration value `E10`).

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A7-4-1

The asm declaration shall not be used

## Description

### Rule Definition

*The asm declaration shall not be used.*

### Rationale

The asm declaration is a method to include assembly instructions directly within C++ source code. Support and implementation of the asm declaration is inconsistent across environments. The asm declaration interacts differently with C++ source code in different environments. To avoid restricting the portability of your code, do not use the asm declaration and do not include assembly instructions in your C++ source code.

### Polyspace Implementation

Polyspace flags the use of the asm declaration anywhere in C++ source code.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Assembly Instructions in C++ Source Code

```
#include <cstdint>
using namespace std;
const char* p = "hello world";

void Fn1(void)
{
    asm("movq p, %rdi\n" // Noncompliant
        "call puts");
}

#define _debug() asm volatile("debug":::"memory")  // Noncompliant

void Fn2(void)
{
    _debug();
}

main()
{
    //
}
```

Polyspace flags the use of asm declaration in Fn(1) because the assembly instructions following the declaration are environment-specific. For example, if you use a gcc compiler in a x64 Linux environment, Fn1() produces the string hello world when called. In other environments, the output of the call to Fn1() is unpredictable. Polyspace also flags the use of the asm declaration in creating the _debug() macro.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A7-5-2

Functions shall not call themselves, either directly or indirectly

## Description

### Rule Definition

*Functions shall not call themselves, either directly or indirectly.*

### Rationale

Variables local to a function are stored in the call stack. If a function calls itself directly or indirectly several times, the available stack space can be exceeded, causing serious failure. Unless the recursion is tightly controlled, it is difficult to determine the maximum stack space required.

### Polyspace Implementation

The checker reports each function that calls itself, directly or indirectly. Even if several functions are involved in one recursion cycle, each function is individually reported.

You can calculate the total number of recursion cycles using the code complexity metric `Number of Recursions`. Note that unlike the checker, the metric also considers implicit calls, for instance, to compiler-generated constructors during object creation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Direct and Indirect Recursion

```
void foo1(int);
void foo2(int);

void foo1( int n ) {    // Non-compliant - Indirect recursion foo1->foo2->foo1...
    if(n > 0) {
        foo2(n);
        foo1(n);    // Non-compliant - Direct recursion
        n--;
    }
}

void foo2( int n ) { // Non-compliant - Indirect recursion foo2->foo1->foo2...
    foo1(n);
}
```

In this example, the rule is violated because of:

- Direct recursion `foo1` → `foo1`.

- Indirect recursion `foo1` → `foo2` → `foo1`.
- Indirect recursion `foo2` → `foo1` → `foo2`.

Note that the location of the rule violation is different for direct and indirect recursions:

- When a function calls itself directly, the rule violation is shown on the function call.
- When several functions are involved in an indirect recursion chain, for every function in the chain, a rule violation is shown on the function signature in the function body.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A7-6-1

Functions declared with the [[noreturn]] attribute shall not return

## Description

### Rule Definition

*Functions declared with the [[noreturn]] attribute shall not return.*

### Rationale

If you declare a function by using the `[[noreturn]]` attribute, the compiler expects that the function does not return the flow of execution. That is, if a `[[noreturn]]` function `f()` is called from `main()`, then the compiler expects that the flow of execution is not returned to `main()`. If such a function eventually returns the flow of execution, it leads to undefined behavior, which can be exploited to cause data integrity violations.

If a function has no `return` statement, then the final closing brace of a function implies an implicit `return`. Omitting a `return` statement in the function does not prevent the flow of execution from returning. A `[[noreturn]]` function can prohibit returning the flow of execution to the calling function by:

- Entering an infinite loop
- Raising an exception
- Calling another `[[noreturn]]` function

### Polyspace Implementation

If a function specified as `[[noreturn]]` returns the control flow to its caller, Polyspace flags the `[[noreturn]]` function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Returning The Flow of Execution From `[[noreturn]]` Function

Consider this code containing two `[[noreturn]]` functions.

```
#include <iostream>

[[noreturn]] void noncompliant(int i)
{
    if (i > 0)
    throw "Received positive input";
    else if (i < 0)
    std::exit(0);
} //Noncompliant
```

```
[[noreturn]] void compliant(int i)
{
    if (i > 0)
    throw "Received positive input";
    else if (i < 0)
    std::exit(0);
    else if(i==0)
    while(true){
        //...
    }
}//Compliant
```

- In the `noncompliant()` function, the flow of execution skips the `if-else-if` block of code and returns to the caller implicitly if `i == 0`. Because the `[[noreturn]]` function returns the flow of execution in a code path, this function is noncompliant with this rule.
- In the `compliant()` function:

  - The function raises an exception if `i > 0`.
  - The function calls the `[[noreturn]]` function `std::exit()` if `i < 0`.
  - The function enters an infinite loop if `i==0`.

  Because the `[[noreturn]]` function does not return the flow of execution in any code path, it is compliant with this rule

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A8-2-1

When declaring function templates, the trailing return type syntax shall be used if the return type depends on the type of parameters

## Description

### Rule Definition

*When declaring function templates, the trailing return type syntax shall be used if the return type depends on the type of parameters.*

### Rationale

When the return type of a template depends on the types of parameters, using the trailing return type syntax improves readability of the code significantly.

For instance, for out-of-class definitions of methods, using the trailing return type syntax means that you do not have to use the fully qualified return type of a function along with the `typename` keyword. Instead of explicitly specifying the fully qualified return type for `aMethod` in this example:

```
template <typename T>
class aClass {
    public:
      using vectorType = std::vector<T>;
      vectorType aMethod(T const&);
};

//Difficult-to-read method definition
//Part in bold indicates fully qualified return type of method
template <typename T>
typename aClass<T>::vectorType aClass<T>::aMethod(T const &) {
};
```

You can use the trailing return type syntax:

```
template <typename T>
class aClass {
    public:
      using vectorType = std::vector<T>;
      vectorType aMethod(T const&);
};
template <typename T>
auto aClass<T>::aMethod(T const &) -> vectorType {
};
```

### Polyspace Implementation

The checker flags function template declarations where the explicitly specified return type of a template function has the same scope as the template function itself.

For instance, in the preceding example, the function `aMethod` has a return type `vectorType`, which has the same scope as `aMethod`, namely the class `aClass<T>`. Instead of explicitly specifying the fully qualified return type, you can use the trailing return type syntax.

Because C++14 has enabled return-type deduction, you can use the `auto` keyword to declare generic templates while omitting the trailing return type. In such cases, Polyspace does not raise a violation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Explicitly Specifying Return-Types of Generic Templates

```
#include <vector>
#include<cstdint>

template<class T, class U>
decltype(std::declval<T>() * std::declval<U>())
bar(T const& lhs, U const& rhs) {// Noncompliant
  return lhs * rhs;
}

template<class T, class U>
auto foo(T a, U b) -> decltype(a*b){        //Compliant
  return a*b;
}
template<class T, class U>
auto foo2(T a, U b) {        //Compliant
  return a*b;
}
```

In this example, three generic function templates are declared:

- The template `bar` explicitly defines the return-type. Such declarations are difficult to read and understand. Polyspace flags the declaration.
- The template `foo` uses the keyword `auto`, and then specifies a trailing return-type. Such declarations are easy to read and understand. Polyspace does not flag the declaration.
- The template `foo2` uses the keyword `auto` but omits the trailing return-type. From C++14 onward, the compiler can deduce the return type of such templates. Polyspace does not flag the declaration.

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A8-4-3

Common ways of passing parameters should be used.

## Description

### Rule Definition

*Common ways of passing parameters should be used.*

### Rationale

If you follow well-established conventions for passing parameters, a developer or reviewer can determine from your function signature whether a parameter is an input parameter, an output parameter, or a different type of parameter.

These conventions are commonly used to pass parameters to a function `f(X)`:

- **In**: If the input parameter data type `X` is cheap to copy or cannot be copied (for instance, the `std::unique_ptr` type), pass the parameter by value as `f(X)`. Otherwise, pass the parameter by `const` reference as `f(const X &)`.
- **Out**: If the output parameter data type `X` is expensive to move, pass the parameter by reference as `f(X &)`. Otherwise, do not pass a parameter, but instead return the value as `X f()`.
- **In/Out**: Pass the parameter by lvalue reference as `f(X &)`.
- **Consume**: Pass the parameter by rvalue reference as `f(X &&)`.
- **Forward**: Pass the parameter by template rvalue reference as `template<typename T> f(T &&)`.

### Polyspace Implementation

The checker flags these incorrect ways of passing parameters:

- **In** parameters:

  - You pass by value an input parameter that is expensive to copy:

    ```
    f(X); //X is expensive to copy
    ```
  - You pass by reference an input parameter that is cheap to copy:

    ```
    f(X &); //X is cheap to copy
    f(const X &); //X is cheap to copy
    ```

  The checker considers a data type that has a size less than twice `sizeof(void *)` as cheap to copy.
- **Out** parameters:

  - You return by value an output parameter that is expensive to move:

    ```
    X f(); //X is expensive to move
    ```
  - You pass by reference an output parameter that is cheap to move:

    ```
    f (X &); //X is cheap to move
    ```

The checker considers a fundamental data type that has a size less than eight times `sizeof(void *)` as cheap to move.

The checker does not include pass by pointers under the umbrella of pass by reference.

Resolving a violation of this rule can sometimes involve invasive changes. For instance, if the checker suggests that an output parameter can be returned by value, but the function already returns a value, you have to rewrite your code significantly. You have to combine the output parameter and already returned value into a structure or n-tuple and then return this structure or n-tuple. If the output parameter and already returned value are not semantically related, combining them into a structure might not be appropriate. In this case, add a comment to the result or code to avoid another review. See "Address Results in Polyspace User Interface Through Bug Fixes or Justifications".

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Input Parameters

```
#include <iostream>
#include <array>
#include <numeric>

typedef struct smallStruct {
    char x;
    char y;
}smallStruct;

void sum(smallStruct& aStruct) { //Noncompliant
    std::cout<<aStruct.x+aStruct.y;
}

typedef struct largeStruct {
    std::array<int,20> arrayOfIntegers;
    int init;
}largeStruct;

void add(largeStruct aStruct) { //Noncompliant
    std::cout<<std::accumulate(aStruct.arrayOfIntegers.begin(),
                     aStruct.arrayOfIntegers.end(), aStruct.init);
}
```

In this example, functions `sum` and `add` only read the contents of their parameters. Therefore, these parameters are input parameters.

- The function `sum()` with signature:

  ```
  void sum(smallStruct& aStruct);
  ```

  takes as argument an object of type `smallStruct` that is cheap to copy. The argument can be passed by value instead of reference.

- The function `add()` with signature:

  ```
  void add(largeStruct aStruct);
  ```

  takes as argument an object of type `largeStruct` that is expensive to copy. The argument can be passed by reference instead of value.

### Output Parameters

```
#include <array>
#include <algorithm>

void init(int& val) { //Noncompliant
    val = 0;
}

typedef struct largeStruct {
    std::array<int,100> arrayOfIntegers;
    int init;
}largeStruct;

largeStruct reset(void) { //Noncompliant
    largeStruct aStruct;
    std::fill(aStruct.arrayOfIntegers.begin(), aStruct.arrayOfIntegers.end(), 0);
    aStruct.init = 0;
    return aStruct;
}
```

In this example, functions `init` and `reset` only write to the contents of their parameters. Therefore, these parameters are output parameters.

- The function `init()` with signature:

  ```
  void init(int& val);
  ```

  takes as an argument an object of type `int` that is cheap to move. The object can be returned by value instead of being passed by reference.
- The function `reset()` with signature:

  ```
  largeStruct reset(void);
  ```

  takes as an argument an object of type `largeStruct` that is expensive to move. The object can be passed by reference instead of being returned by value.

# AUTOSAR C++14 Rule A8-4-4

Multiple output values from a function should be returned as a struct or tuple

## Description

### Rule Definition

*Multiple output values from a function should be returned as a struct or tuple.*

### Rationale

In a C++ function, the `return` statement can return only the value stored in a single variable. But the values stored in any number of additional variables in the caller's scope can be modified by the callee if you pass these values by reference, and then modify them in the body of the callee. For example, consider the function `foo`:

```
int foo(int x, int& y)
{
  int z;
  y = x*x;
  z = x*x*x;
  return z;
}
```

The function `foo` effectively returns two integer values: the square of the input parameter x (returned by reference) and the cube of the input parameter x (returned by copy by using the `return` statement). Simultaneously using both strategies to return multiple values results in a complicated function interface and can make your code less readable and maintainable. Instead, storing all return values in a single struct or tuple and returning it by using the `return` statement results in a simpler, more unified interface.

A `return` statement that has a struct or a tuple might require expensive copying from one memory location to another. Most compilers support return value optimization and can eliminate this expensive copy, resulting in executable code with little to no overhead associated with such returns.

To help you decide whether to use a struct or a tuple to return multiple values, consider:

- If your return type represents an abstraction, it is preferable to use a struct because you can provide a custom name for each component of the abstract data type.
- Tuples are easier to work with because a returned tuple can be conveniently processed by using `std::tie` at the call site. The `std::tie` method puts the tuple elements directly into existing local variables in the caller.

**Note** This rule also applies to `std::pair`, which is a special kind of tuple that has exactly two elements.

### Polyspace Implementation

The checker flags a function declaration that satisfies one of these two conditions:

- The function has a nonvoid return type and at least one nonconstant reference parameter
- The function has more than one nonconstant reference parameters

Usage notes and limitations:

- The checker flags pure virtual functions that violate this rule. These functions are flagged because, for any implementation of a pure virtual function to be compliant with this rule, the interface of the pure virtual function itself must obey this rule.
- The checker does not flag operators that violate this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Combine Multiple Return Values into a Tuple

```
#include <tuple>

int Divide1(int dividend, // Noncompliant, remainder returned as reference parameter
            int divisor, int& remainder)
{
  remainder = dividend % divisor;
  return dividend / divisor;
}

// Compliant, quotient and remainder combined into a tuple
std::tuple<int, int> Divide2(int dividend, int divisor)
{
  return std::make_tuple(dividend / divisor, dividend % divisor);
}

int main()
{
  int quotient, remainder;
  // store in local variables
  std::tie(quotient, remainder) = Divide2(26, 5);
  return 0;
}
```

The function `Divide1` has the quotient as the return value and the remainder as a nonconstant reference parameter. Having a nonvoid return value and a nonconstant reference parameter violates this coding rule.

The function `Divide2` combines the quotient and the remainder into a tuple and returns the tuple. This code pattern complies with the rule.

### Combine Multiple Return Values into a Structure

```
struct fraction {
  int quotient;
  int remainder;
} ;

int Divide1(int dividend, // Noncompliant, quotient and remainder returned as reference parameters
            int divisor, int& quotient, int& remainder)
{
  quotient = dividend / divisor;
  remainder = dividend % divisor;
}

// Compliant, quotient and remainder combined into a struct
```

```
fraction Divide2(int dividend, int divisor)
{
  fraction answer;
  answer.quotient = dividend / divisor;
  answer.remainder = dividend % divisor;
  return answer;
}

int main()
{
  fraction answer;
  answer = Divide2(26,5);
  return 0;
}
```

The function `Divide1` has both the quotient and the remainder as nonconstant reference parameters. Having multiple nonconstant reference parameters violates this coding rule

The function `Divide2` combines the quotient and the remainder into a struct and returns the struct. This code pattern complies with the rule.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-4-5

"consume" parameters declared as X && shall always be moved from

## Description

### Rule Definition

*"consume" parameters declared as X && shall always be moved from.*

### Rationale

When declaring a function, you might indicate your intention of moving the content of a function parameter by declaring it as a nonconst and nontemplate rvalue reference or a "consume" (X&&) parameter. For instance, the parameter of this function is declared as a "consume" parameter: `void foo(std::vector<std::string>&& V)`. This declaration implies that the content of the vector `V` is intended to be moved instead of copied within the body of the function.

When you declare a function parameter as a "consume" parameter, use move semantics when using the parameter. Within the body of the function, use the `std::move` function explicitly if you use an lvalue reference to invoke the function.

### Polyspace Implementation

Polyspace flags the definition of a function if both of these conditions are true:

- At least one function parameter is declared as a nonconst and nontemplate rvalue reference, that is, a "consume" or X&& parameter.
- The content of the X&& parameter is not completely moved to another object by using the `std::move` function within the body of the function.

Polyspace does not raise this defect in move constructors and move assignment operators.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use `std::move` on Nonconst and Nontemplate rvalue Reference Function Parameters

```
#include <utility>
class C
{
    C(C&& c): a{std::move(c.a)}     // Compliant by exception.
    {
    }

    C& operator=(C&& c)             // Compliant by exception.
    {
        a = std::move(c.a);
        return *this;
    }

    void move(C&& c)                // Noncompliant
    {
        a = std::move(c.a);//Partial move
    }

    void cond(C&& c, bool b)        // Compliant
    {
        if (b) {
            move(std::move(c));
        } else {
            a++;
        }
    }
public:
    int a;
    void set(int&& num)     // Compliant
    {
        a = std::move(num);
    }
    void set1(int&&)     // Noncompliant
    {
        //Unnamed temporary variable cannot be moved from.
    }
    void set2(int&& i12);  // Violation raised on definition.
    void set3(int&& i11a,  // Noncompliant
    int&& i11b)  // Noncompliant
    {
        if(i11a != i11b)
        {
        }
    }

};
void C::set2(int&& i12)   // Noncompliant
{
    a = i12;
}

template<typename T>
void tf1(T&& t1)      // Compliant - not a "consume" parameter
{
}
```

In this example, the data member `a` of the class `C` is set to an integer by using move semantics.

- Polyspace does not flag the move constructor and the move assignment operator even though these functions do not completely move the "consume" or X&& parameter. These functions are compliant by exception.
- Polyspace flags the function `C::move` because the body of the function partially moves the "consume" or X&& parameter.
- Polyspace flags the function `C::set1` because this function uses an unnamed "consume" parameter. Because the parameter is unnamed, you cannot use the function `std::move` on this X&& parameter.

- Polyspace flags the function `C:: set2` because the body of the function copies the "consume" parameter instead of using the function `std::move`. Polyspace raises the violation on the definition of the variable. Similarly, the function `C::set2` is also noncompliant with this rule because its body does not use `std::move` on X&& variables.
- The function `C::cond` and `C::set` are compliant with this rule because the bodies of these functions use `std::move` on the "consume" parameters.
- Polyspace does not flag the function template because this rule does not apply to templates.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-4-6

"forward" parameters declared as T && shall always be forwarded

## Description

### Rule Definition

*"forward" parameters declared as T && shall always be forwarded.*

### Rationale

Because rvalue references cannot bind to lvalues, functions that enable the use of move semantics by using rvalue references in their signature do not accept lvalues. This issue is resolved by using an rvalue reference to a nonconst template type object, which is called a "forward" parameter. These parameters can bind to both rvalues and lvalues while preserving their cv qualifications and value categories. "Forward" parameters are useful when you want to forward a value to a destination object or function by using the function `std::forward`.

When you declare a function template by using a "Forward" parameter, do not use the parameter in any operations. Because "Forward" parameters can bind to both lvalues and rvalues, using them in an operation might corrupt their cv qualifications and value categories. Forward these parameters directly to the destination by using `std::forward` without using them in an operation.

### Polyspace Implementation

Polyspace flags a "Forward" parameter in the definition of a function template or a Lambda expression if any of these conditions are true:

- A "Forward" parameter is not forwarded to a destination by using `std::forward`.
- An operation other than forwarding is performed on the "Forward" parameter or on a member object of it.

Polyspace ignores the templates and Lambda expressions that remain unused in your code.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Compliant Use of "Forward" Parameters

```
#include<string>
#include<vector>
#include <iostream>

struct intWrapper {
    intWrapper(int&& n) { std::cout << "rvalue overload, n=" << n << "\n"; }
    intWrapper(int& n)  { std::cout << "lvalue overload, n=" << n << "\n"; }
};
```

```
struct floatWrapper {
    floatWrapper(double&& n) { std::cout << "rvalue overload, n=" << n << "\n"; }
    floatWrapper(double& n)  { std::cout << "lvalue overload, n=" << n << "\n"; }
};

class mixedNumerical {
public:
    template<class T1, class T2, class T3>
    mixedNumerical(T1&& t1, T2&& t2, T3&& t3) :   //violation on T3
    a1_{std::forward<T1>(t1)},
    a2_{std::forward<T2>(t2)},
    a3_{std::forward<T3>(t3)}
    {
    }

private:
    intWrapper a1_, a2_;
    floatWrapper    a3_;
};

template<class T, class... U>
std::unique_ptr<T> unique_ptr_factory(U&&... u)
{
    return std::unique_ptr<T>(new T(std::forward<U>(u)...));
}

int main()
{
    auto p1 = unique_ptr_factory<intWrapper>(2); // rvalue
    int i = 1;
    auto p2 = unique_ptr_factory<intWrapper>(i); // lvalue

    std::cout << "mixedNumerical\n";
    double lvalue = 2.2;
    auto t = unique_ptr_factory<mixedNumerical>(2, i, 2.2);// rvalue
    auto t2 = unique_ptr_factory<mixedNumerical>(2, i, lvalue);// lvalue
}
```

This example shows the implementation of a flexible interface to the function `unique_ptr_factory` by using a "forward" parameter pack. This function accepts the "forward" parameter pack, and then forwards the parameters to their respective constructors by using `std::forward`. The constructors are overloaded to accept both rvalues and lvalues. As a result, the function `unique_ptr_factory` produces `unique_ptr` to `intWrapper` type objects and `mixedNumerical` type objects while requiring minimal overloading. This use of "forward" is compliant with this rule because the "forward" parameters are forwarded to their destination by using `std::forward`. Because no other operation is performed on them, their cv qualification and value categories are preserved.

### Noncompliant Use of "Forward" Parameters

```
#include<string>
#include<vector>
void task(int i);
template<typename T>
T NoncompliantTemplate(T&& arg)    // Noncompliant
```

```
{
    return arg;       // Noncompliant
}

auto NoncompliantLambda = [](auto&& truc) {    // Noncompliant
    return truc;                           // Noncompliant
};
template<typename T>
T ReturnStaticCast(int&& i) //Compliant: not a template parameter.
{
    return static_cast<T>(i);
}
template<typename T>
void ConstArg(const T&& t)      // Compliant: const
{}

template<typename T>
void UnusedArg(T&& t)              // Noncompliant
{}

template<typename T>
void UnnamedArg(T&& )              // Noncompliant
{}
template<typename T>
void usage(T&& t1, T&& t2)
{
    if (t1==t2)                       // Noncompliant
    {
        task(std::forward<T>(t1));
    }
    else
    {
        task(std::forward<T>(t1));
        task(std::forward<T>(t2));
    }
}
class intWrapper
{
public:
    int m;
};

template<typename T>
void CheckForward(T&& t)
{
    if (t.m != 0)                          // Noncompliant
    {
        UnusedArg(std::forward<T>(t));
    }
}
auto CompliantLambda = [](auto&& truc) {    // Compliant
    return NoncompliantLambda(std::forward<decltype(truc)>(truc));
};
template<typename T>
T NoninstantiatedTemplate(T&& arg)    // Not checked
{
    return arg;       // Not checked
}
```

```
void foo(){
    int i;
    intWrapper C;
    C.m = i;
    NoncompliantTemplate(i);
    CheckForward(std::move(C));
    usage(i,C.m);
    UnnamedArg(i);
    CompliantLambda(i);
}
```

This example shows use of "forward" parameters that are not compliant with this rule.

- Polyspace flags the nonconst `T&&` parameter `arg` of the template `NoncompliantTemplate` because this "forward" parameter is not forwarded to a destination by using `std::forward`. The parameter is flagged in the declaration and the return statement.
- Polyspace flags the nonconst `auto&&` parameter `truc` of the Lambda expression `NoncompliantLambda` because this "forward" parameter is not forwarded to a destination by using `std::forward`. The parameter is flagged in the declaration and the return statement.
- Polyspace does not flag `int&&` argument `i` of the template `ReturnStaticCast` because this argument is not a nonconst template type rvalue reference. For the same reason, Polyspace does not flag the argument of `ConstArg`.
- Polyspace flags the nonconst template type rvalue reference argument `t` of the template `UnusedArg` because this "forward" parameter is not forwarded to a destination by using `std::forward`.
- Polyspace flags the argument of the template `UnnamedArg` because the "forward" parameter is unnamed and it cannot be forwarded by using `std::forward`.
- Polyspace flags the parameters `t1` and `t2` in the statement `if (t1==t2)` in the template `usage` because these "forward" parameters are used in an operation before they are forwarded by using `std::forward`. This checker is also raised on `t` in the statement `if (t.m != 0)` in the template `CheckForward` because a member of the "forward" parameter `t` is accessed.
- Polyspace does not check the template `NoninstantiatedTemplate` because this template is unused in the code.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A8-4-7

"in" parameters for "cheap to copy" types shall be passed by value

## Description

### Rule Definition

*"in" parameters for "cheap to copy" types shall be passed by value.*

### Rationale

You use an "in" parameter when you intend to only read that parameter within a function. If the parameter is cheap to copy, pass the parameter by value to:

- Make it clear that you do not plan on modifying the parameter.
- Avoid the additional indirection that is required to access the parameter from the function when you pass the parameter by reference.

A parameter is cheap to copy when both these conditions are true:

- The parameter has a size less than or equal to two words. For instance, for a parameter `foo`, `sizeof(foo) <= 2 * sizeof(int)`.
- The parameter is trivially copyable type. See *is_trivially_copyable*.

### Polyspace Implementation

- Polyspace flags:
  - `const` parameters that are passed by reference if the parameters are cheap to copy (`sizeof <= 2 * sizeof(int)` and trivially copyable).
  - `const` parameters that are passed by value if the parameters are not cheap to copy. For instance, in this code snippet, both parameters `str` (expensive to copy) and `b` (non-trivially copyable) are noncompliant.

    ```
    void func1(const std::string str);
    struct B {
        B(B const&) {}
    };
    void func2(const B b);
    ```

    .
- Polyspace does not flag :
  - Non-`const` parameters that are passed by reference if those parameters are not cheap to copy and are not modified inside the function. Polyspace considers these parameters as "in" parameters.
  - "in" parameters that are passed by reference if those parameters are move-only types. For instance, `int f(const std::unique_ptr<int>& p);`.
  - `const` parameters that are passed by reference in copy constructors. For instance, no defect is raised on `point` in this code snippet.

```
class coord
{
public:
    coord(int x, int y) {p_x = x; p_y = y;}
    coord(const coord& point) { p_x = obj.p_x; p_y = obj.p_y;}
    //...
private:
    int p_x, p_y;

};
coord point{1, 1};
void func(const coord& point);
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### "in" Parameters Passed by Reference

```
#include <memory>
#include <string>
#include <cstdint>

int func(const std::unique_ptr<int>& ptr) // Compliant
{
    *ptr = *ptr + 1;
    return *ptr;
}
union Small {
    uint8_t var1 ;
    uint8_t var2;
} ;

struct Large {
    std::uint32_t v1;
    std::uint32_t v2;
    std::uint32_t v3;
    std::uint32_t v4;
};

void func2(Small& arg) // Noncompliant
{
//...
}

void func3(Large val,   // Noncompliant
           std::string& str) // Compliant
{
//...
}
```

In this example, Polyspace flags "in" parameters:

- `arg`, because it is passed by reference and its type is trivially copyable. This parameter can be passed by value instead.
- `val`, because it is passed by value and it is expensive to copy. Passing this parameter by reference avoids making expensive copies for each call to `func3()`.

These passed by reference "in" parameters are compliant:

- Parameter `ptr` because it is a move-only type.
- Parameter `str` because it is expensive to copy. This parameter is non-`const` but it is not modified inside `func3()`.

## Check Information

**Group:** Declarators
**Category:** Required, Automated

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A8-4-8

Output parameters shall not be used

## Description

### Rule Definition

*Output parameters shall not be used.*

### Rationale

You can store the output value of a function in a variable that you pass to that function as a non-const reference or pointer parameter, for example:

```
void func(const T* input_var, T* output_var); //declaration
void func(const T* input_var, T* output_var)
{
    *output_var = *input_var % 2;
}
```

However, it is unclear from the function declaration whether the output parameter `output_var` passes a value to `func` and then stores the output (in-out parameter), or whether `output_var` only stores the output (out parameter). This might cause a developer to misuse the parameter, for instance by passing a null parameter when the function expects a non-null parameter.

Instead, use a return value to store the function output. The return value makes your intent clear and prevents possible misuse of the passed parameters, for example:

```
T* func(const T* input_var)
{
    return *input_var % 2;
}
```

### Polyspace Implementation

Polyspace flags all uses of non-const references or pointers in the parameter list of:

- Functions, except for `main()`.
- Class constructors and operators.

If your code contains a function declaration and its definition, Polyspace flags the violation in the function definition.

**Note** Polyspace flags a non-const reference or pointer in parameter lists even if that parameter is not used as an output parameter.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of Possible Output Parameters

```
#include<iostream>

std::int32_t func(const std::vector<int32_t>& inParam,
                  std::vector<int32_t>& outParam)  //  Non-Compliant
{
    //...
    return 1;
}

class C
{
public:

    C(C* ptr) {}         //  Non-Compliant
    C(C& ref) {}         //  Non-Compliant
    C(C&& rvalue_ref) {} //  Compliant
    C(const C& c) {}     //  Compliant
    C(const C&& c) {}    //  Compliant

    C& operator=(C& ref) { return *this; }    //    Non-Compliant

};
```

In this example, `func` has a return value of type `std::int32_t` but its parameter list is still non-compliant because it contains non-const lvalue reference `outParam`. Similarly, non-const parameters `ptr` and `ref` in the class constructors and in `operator=` are non-compliant.

Note that non-const parameter `rvalue_ref` is compliant because rvalue reference parameters bind only to temporary objects and these objects cannot be referenced after the function goes out of scope.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-4-9

"in-out" parameters declared as T & shall be modified

## Description

### Rule Definition

*"in-out" parameters declared as T & shall be modified.*

### Rationale

A function parameter meant to be both read and modified within a function is called an "in-out" parameter.

If you do not both read and modify a parameter, avoid passing by non-`const` reference so that the function prototype reflects the true nature of the parameter.

- If you only read a parameter within a function, the parameter is actually an "in" parameter.

  Pass the parameter by `const` reference.
- If you replace the entire contents of a parameter within a function, the parameter is actually an "out" parameter.

  If possible, avoid "out" parameters completely and store any output of the function in the function return value. See also `AUTOSAR C++14 Rule A8-4-8`.

### Polyspace Implementation

The checker checks each function parameter passed by non-`const` reference and raises a violation if the parameter is only read within the function or its value completely replaced within the function.

The checker does not raise a violation if:

- The parameter is an object and you access one or more of its data members, or invoke a non-`const` member function.
- You pass a pointer or reference to the parameter on to another function.
- The function is virtual. The reason is that even if the current function might not modify its parameter, an override of the function might modify its corresponding parameter.
- The function is an unused class method.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### "In-out" Parameter Not Modified in Function Body

```
#include <cstdint>
#include <vector>
```

```
#include <numeric>
#include <string>

int32_t addAllElements (std::vector<int32_t>& aVec) { //Noncompliant
     return std::accumulate(aVec.cbegin(), aVec.cend(), 0);
}

int32_t addEveryElement (const std::vector<int32_t>& anotherVec) { //Compliant
     return std::accumulate(anotherVec.cbegin(), anotherVec.cend(), 0);
}
```

In this example, the vector `aVec` is passed as a non-`const` reference to the function `addAllElements`. However, the vector is only read within the function and is only an "in" parameter, not an "in-out" parameter.

The function `addEveryElement` is a compliant version of the same function. The "in" parameter `anotherVec` is passed as a `const` reference.

**"In-out" Parameter Fully Replaced in Function Body**

```
#include <string>

void replaceString(std::string &Source, const std::string Replacement) { //Noncompliant
    if(Replacement.at(0)=='_')
         Source = Replacement;
    else
         Source = "_null";
}

std::string replacementString(const std::string str) { //Compliant
    if(str.at(0)=='_')
         return str;
    else
         return "_null";
}
```

In this example, the string `Source` is passed as a non-`const` reference to the function `replaceString`. However, the string is fully replaced within the function and is only an "out" parameter, not an "in-out" parameter.

The function `replacementString` is a compliant version of the same function, which also does not violate `AUTOSAR C++14 Rule A8-4-8`. The function has the same output as `replaceString` but stores the output in its return value.

# AUTOSAR C++14 Rule A8-4-10

A parameter shall be passed by reference if it can't be NULL

## Description

### Rule Definition

*A parameter shall be passed by reference if it can't be NULL*

### Rationale

A reference cannot be NULL. If a parameter is required (it cannot be NULL), pass that parameter by reference to make your intent clearer. Passing by reference also yields cleaner code because you do not need to check whether the parameter is NULL before you use it.

### Polyspace Implementation

Polyspace flags passed-by-pointer parameters except if:

- The pointer is a smart pointer such as `std::shared_ptr`.
- The pointer is not dereferenced in the function.
- The pointer is checked against NULL, even if the check happens after the dereference.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Pass-by-Pointer Parameters

```
#include <iostream>
#include <vector>

void other_func(std::vector<int32_t>*);

void func(std::vector<int32_t>* v_ptr1, //  Non-Compliant
             std::vector<int32_t>* v_ptr2, //  Compliant
             std::vector<int32_t>* v_ptr3) //  Compliant
{

    auto v = v_ptr1;
    auto ptr_size = 0;
    if (v_ptr2 != NULL) {
        ptr_size = v_ptr2->size();
    }
    v->resize(ptr_size);

    other_func(v_ptr3);
    //....
}
```

In this example pass-by-pointer parameter `v_ptr1` is non-compliant because it is dereferenced inside `func` without checking if the pointer is NULL. If `v_ptr1` cannot be NULL, pass this parameter by reference. If the `v_ptr1` can be NULL, check whether the pointer is NULL before you dereference it to avoid a segmentation fault.

Parameter `v_ptr2` is compliant because it is checked against NULL, which indicates it could be NULL.

`v_ptr3` is compliant because it is not dereferenced inside `func`.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-4-11

A smart pointer shall only be used as a parameter type if it expresses lifetime semantics

## Description

### Rule Definition

*A smart pointer shall only be used as a parameter type if it expresses lifetime semantics.*

### Rationale

A smart pointer manages the lifetime of a dynamically allocated object and destroys that object when the smart pointer goes out of scope. When you use a smart pointer as a parameter type for a function, you restrict that function to callers that use smart pointers, which is unnecessary if the function does not affect the lifetime of the managed object. In the case of shared smart pointers such as `std::shared_ptr`, your program incurs additional run-time overhead.

Examples of functions that affect the lifetime of a managed object include:

- A function that transfers ownership of the managed object from the `std::unique_ptr` smart pointer parameter to a different `std::unique_ptr` smart pointer through a move operation.
- A function that copies the `std::shared_ptr` smart pointer parameter inside the function body, sharing the ownership of the managed object with another `std::shared_ptr` smart pointer.

If the function does not affect the lifetime of the managed object, pass the object by reference or as a raw pointer instead.

If that object is managed by a non-local smart pointer, check that both these conditions are true:

- The object is not reset or reassigned inside a function that is down the call tree of the called function.
- The managed object is not destroyed before it is dereferenced.

For instance, if the object is managed by a non-local shared pointer, make a local copy inside the called function.

The use of a non-owning smart pointer as a parameter type, such as `std::observer_ptr`, is compliant with this rule. See `std::experimental::observer_ptr`.

### Polyspace Implementation

Polyspace reports a violation of this rule when you use smart pointers `std::shared_ptr` or `std::unique_ptr` as parameter types in a user-defined function that does not affect the lifetime of those smart pointers in the function body.

Polyspace considers the lifetime of an `std::shared_ptr` smart pointer parameter affected if, along at least one execution path:

- The pointer is copied through a copy constructor or a copy assignment.
- The pointer is moved-from through a move constructor or move assignment. This operation involves a call to `std::move`.

- The pointer is passed as an argument to a function with one of these parameter types:
  - An `std::shared_ptr<T>` type. In this case the copy constructor is invoked.
  - A `const std::shared<T>&` type. This `const` lvalue reference indicates that the function retains a reference count and might make a copy of the pointer.
  - An `std::shared<T>&` type. This lvalue reference indicates that the passed parameter will be modified.
- A modifier member function such as `std:shared_ptr::reset` or a modifier non-member function such as `std::shared_ptr::swap` is called on the pointer. For a list of modifier functions, see std::shared_ptr.
- The pointer is the destination of a copy or move assignment.

`const`-qualified `std::shared_ptr` smart pointer parameters cannot be modified.

Polyspace considers the lifetime of an `std::unique_ptr` smart pointer parameter affected if, along at least one execution path:

- The pointer is moved-from with a call to `std::move`.
- The pointer is moved-from through a move constructor or a move assignment.
- The pointer is passed as an argument to a function with one of these parameter types:
  - An `std::unique_ptr<T>` type. In this case, the move constructor is invoked.
  - An `std::unique<T>&` type. This lvalue reference indicates that the function modifies the passed parameter.
- A modifier member function such as `std::unique_ptr::reset` or a modifier non-member function such as `std::unique_ptr::swap` is called on the pointer. For a list of modifier functions, see std::unique_ptr.
- The pointer is the destination of a move assignment.

`const`-qualified `std::unique_ptr` smart pointer parameters cannot be moved-from or modified and their lifetimes are not affected. The lifetime of the passed argument is also not affected in the case of the `const` lvalue reference parameter `const std::unique_ptr<T>&`.

Polyspace does not report a violation of this rule when you use smart pointers as parameter types in these cases:

- The pointer is used as a parameter of a template function. The parameter types of a template function depend on the instantiation of the function and a fix is not always possible at the template design level. For instance, the use of the shared pointer `ptr` is not reported as a violation in this code.

  ```
  #include <iostream>
  #include <memory>
  #include <cassert>

  template <typename T>
  double XtimesY(T ptr) // Use of ptr not flagged
  {
    return (ptr->x) * (ptr->y);
    // ...
  }
  struct S
  ```

```
{
  double x;
  double y;
  S(double x0, double y0) : x{x0}, y{y0} {}
};
void func()
{
  auto a = new S{100.0, 200.0};
  auto a_cpy = std::shared_ptr<S>(a);
  assert(XtimesY(a) == XtimesY(a_cpy));
}
```

- The smart pointer parameter is captured by a `lambda` function inside the function body. For instance, Polyspace does not report a violation when you use the shared pointer `ptr` as a parameter of `func()` in this code. The parameter is captured by a `lambda` function inside the body of `func()`. Polyspace reports the use of `lambda` function parameters `sp1` and `up1` as violations because their lifetime is not modified inside the `lambda` function.

```
#include <memory>

struct S
{
  double x;
  double y;
  S(double x0, double y0) : x{x0}, y{y0} {}
};

void func(std::unique_ptr<S> ptr)
{ // no defect is detected on 'ptr'
  auto lambdaF =
      [&ptr0 = ptr]            // 'ptr' is captured (by reference)
      (std::shared_ptr<S> sp1, // Non-compliant
       std::unique_ptr<S> up1) // Non-compliant
  {                            // lifetime of 'sp1' and 'up1' not affected
    // ...
  };
  auto a = std::make_shared<S>(1.0, 2.0);
  auto b = std::make_unique<S>(100.0, 200.0);
  lambdaF(a, std::move(b));
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### shared_ptr Used as Function Parameter Type

```
#include <memory>
#include <cassert>
#include <iostream>
#include <string>

class A
{
};

//

void ptr_is_moved_from(
    std::shared_ptr<A> ptr,       // Compliant
    const std::shared_ptr<A> ptr1 // Compliant
)
{

  std::shared_ptr<A> destinationPtr = std::move(ptr);
  destinationPtr = std::move(ptr1); // copy takes place
}
```

```
//

void ptr_param_is_lvalue_ref(std::shared_ptr<A> &ptr)
{
  ptr.reset(new A()); // ptr is modified by member function
}
void pass_to_function_with_lvalue_ref_param(
    std::shared_ptr<A> ptr,       // Compliant
    const std::shared_ptr<A> ptr1 // Non-compliant
)
{

  ptr_param_is_lvalue_ref(ptr);
#if 0
        // compilation error
        use_lvalue_reference_shared_ptr(ptr1); //ptr1 is const-qualified and cannot be modified
#endif
}

//

void member_function_modifies_ptr(
    std::shared_ptr<A> ptr,       // Comliant
    const std::shared_ptr<A> ptr1 // Non-compliant
)
{
  ptr.reset();
#if 0
        // compilation error
        ptr1.reset(); //ptr1 is const-qualified and cannot be modified

#endif
}

//

void ptr_is_destination_of_copy_move(
    std::shared_ptr<A> ptr,       // Comliant
    const std::shared_ptr<A> ptr1 // Non-compliant
)
{

  std::shared_ptr<A> gPtr0 = std::make_shared<A>();
  ptr = gPtr0; // ptr destination of copy assignment
#if 0
        // compilation error
        ptr1 = gPtr0; // ptr1 is const-qualified and cannot be modified
#endif
}
```

In this example, Polyspace reports the use of the shared pointer parameter `const std::shared_ptr<A> ptr1` as a violation because the parameter is `const`-qualified and cannot be modified. The lifetime of the parameter is not affected inside these functions and running the program results in a compilation error.

- Function `pass_to_function_with_lvalue_ref_param()`
- Function `member_function_modifies_ptr()`
- Function `ptr_is_destination_of_copy_move()`

Polyspace does not report the use of `const std::shared_ptr<A> ptr1` in the function `ptr_is_moved_from()` because the call to `std::move` creates a copy, which modifies the lifetime of `ptr1` by incrementing the reference count.

Polyspace does not report the use of the shared pointer parameter `std::shared_ptr<A> ptr` in these functions because, in each case, the lifetime of the smart pointer is affected:

- In the function `ptr_is_moved_from()`, the managed object is moved-from.

- In the function `pass_to_function_with_lvalue_ref_param()`, the pointer is passed to the function `ptr_param_is_lvalue_ref()` as an lvalue reference and is then modified inside that function by member function `reset()`.
- In the function `member_function_modifies_ptr()`, the pointer is modified by member function `reset()`.
- In the function `ptr_is_destination_of_copy_move()`, the pointer is the destination of a copy assignment.

### unique_ptr Used as Function Parameter Type

```
#include <memory>
#include <cassert>
#include <iostream>
#include <string>

static int level = 0;
class A
{
};
void ptr_is_moved_from(
    std::unique_ptr<A> ptr,       // compliant
    const std::unique_ptr<A> ptr1 // non-compliant
)
{

  std::unique_ptr<A> destinationPtr = std::move(ptr);
#if 0
        // compilation error
        destinationPtr = std::move(ptr1); //Cannot be copied
#endif
}

//

void ptr_param_is_lvalue_ref(std::unique_ptr<A> &ptr)
{
  ptr.reset(new A());
}

void ptr_param_is_const_lvalue_ref(const std::unique_ptr<A> &ptr) // compliant
{
  ++level;
  std::cout << std::string(level, '\t') << __FUNCTION__ << "\n";
  std::cout << std::string(level, '\t') << "ptr " << ptr.get() << "\n";
  std::cout << std::string(level, '\t') << __FUNCTION__ << "\n";
  --level;
}

void pass_input_unique_ptr_as_lvalue_reference(
    std::unique_ptr<A> ptr,        // compliant
    const std::unique_ptr<A> ptr1, // non-compliant
    std::unique_ptr<A> ptr2,       // non-compliant
    const std::unique_ptr<A> ptr3  // non-compliant
)
{
  ptr_param_is_lvalue_ref(ptr);

#if 0
        // compilation error
        ptr_param_is_lvalue_ref(ptr1);
#endif

  ptr_param_is_const_lvalue_ref(ptr2); // ptr2 passed as const lvalue reference, lifetime not affected

  ptr_param_is_const_lvalue_ref(ptr3); // ptr3 passed as const lvalue reference, lifetime not affected
}

//

void ptr_modified_by_member_function(
    std::unique_ptr<A> ptr,       // compliant
    const std::unique_ptr<A> ptr1 // non-compliant
)
{
  ptr.release();
#if 0
```

```
        // compilation error
        ptr1.release();
#endif
}

//

void ptr_is_destination_of_copy_move(
    std::unique_ptr<A> ptr,       // compliant
    const std::unique_ptr<A> ptr1 // non-compliant
)
{
  std::unique_ptr<A> gPtr0 = std::make_unique<A>();

  ptr = std::move(gPtr0);
#if 0
        // compilation error
        ptr1 = std::move(gPtr0);

#endif
}
```

In this example, Polyspace reports the use of the unique pointer parameter `const std::unique_ptr<A> ptr1` because the parameter is `const`-qualified and cannot be modified. The lifetime of the parameter is not affected inside these functions and attempts to modify the parameter results in compilation errors.

- Function `ptr_is_moved_from()`.
- Function `pass_input_unique_ptr_as_lvalue_reference()`.
- Function `ptr_modified_by_member_function()`.

Similarly, Polyspace reports the use of the parameters `std::unique_ptr<A> ptr2` and `const std::unique_ptr<A> ptr3` because they are passed to the function `ptr_param_is_const_lvalue_ref()`, which does not affect the lifetime of these parameters.

Polyspace does not report the use of the unique pointer parameter `std::unique_ptr<A> ptr` in these functions because, in each case, the lifetime of the smart pointer is affected:

- In the function `ptr_is_moved_from()`, the unique pointer is moved-from.
- In the function `pass_input_unique_ptr_as_lvalue_reference()`, the pointer is passed to the function `ptr_param_is_lvalue_ref()` as an lvalue reference and is then modified inside that function by member function `reset()`.
- In the function `ptr_modified_by_member_function()`, the pointer is modified by member function `release()`.
- in the function `ptr_is_destination_of_copy_move()`, the pointer is the destination of a move assignment.

# AUTOSAR C++14 Rule A8-4-12

A std::unique_ptr shall be passed to a function as: (1) a copy to express the function assumes ownership (2) an lvalue reference to express that the function replaces the managed object.

## Description

### Rule Definition

*A std::unique_ptr shall be passed to a function as: (1) a copy to express the function assumes ownership (2) an lvalue reference to express that the function replaces the managed object.*

### Rationale

You use an `std::unique_ptr` smart pointer to indicate that only one smart pointer owns the managed object. A smart pointer manages the lifetime of a dynamically allocated object and destroys that object when the smart pointer goes out of scope. Pass an `std::unique_ptr` smart pointer to a function in one of these ways:

- If you expect the function to take ownership of the managed object, pass the smart pointer by value . For instance, the `std::unique_ptr` argument of the caller in this code is moved-from and ownership of the `int` object is transferred to an implicitly constructed `std::unique_ptr` smart pointer, which is then passed to the function `func()`.

  ```
  void func(std::unique_ptr<int>) {}
  void otherFunc()
  {
      auto smartPtr = make_unique<int>(1);
      func(std::move(smartPtr)); //caller
  }
  ```
- If you expect the function to replace the object that the smart pointer manages, pass the smart pointer as an lvalue reference. For instance, you might replace the managed object by calling the assignment operator or the `reset()` smart pointer member function. For example, `uniquePtr` is reset inside `func()` and no longer manages the `int` object in this code.

  ```
  void func(std::unique_ptr<int>& smartPtr)
  {
      smartPtr.reset();
  }
  void otherFunc
  {
      auto uniquePtr = make_unique<int>(1);
      func(std::move(uniquePtr); //caller
  }
  ```

  If you do not intend to replace the managed object, pass an lvalue reference to the managed object itself.

You cannot move or reset a `const`-qualified lvalue reference to an `std::unique_ptr` smart pointer. If you do not intend to modify the managed object, pass a `const`-qualified lvalue reference to the managed object instead.

There is no violation of this rule if you pass an rvalue reference to an `std::unique_ptr` smart pointer and the reference is moved into a different `std::unique_ptr` smart pointer inside the function. For instance, `rvalueRefPtr` is passed by rvalue reference to an `std::unique_ptr` smart pointer and then moved into a different smart pointer `std::unique_ptr newPtr`.

```
void func(std::unique_ptr<int>&& rvalueRefPtr)
{
    std::unique_ptr<int> newPtr(std::move(rvalueRefPtr));
}
```

### Polyspace Implementation

Polyspace the use of a parameter passed as an lvalue reference to `std::unique_ptr` if that parameter is not reset.

Polyspace considers the parameter reset in these cases:

- The parameter is used as the destination of a move assignment.
- The parameter is moved-from through a call to `std::move`.
- The parameter is used as the argument of `std::unique_ptr` member functions `reset()`, `swap()`, or `release()`.
- The parameter is used as the argument of any function that takes a non-`const` qualified lvalue reference to an `std::unique_ptr` smart pointer, regardless of the implementation of the callee.

Polyspace also reports the use of `const`-qualified lvalue references to an `std::unique_ptr` smart pointer because you cannot modify the pointer and transfer ownership of the managed object.

Polyspace does not report the use of smart pointers as parameter types in these cases:

- The pointer is used as a parameter of a template function. The parameter type of template functions depends on the instantiation of the function and a fix is not always possible at the template design level. For instance, Polyspace does not report the use of unique pointer `ptr` as parameter in this code.

  ```
  #include <iostream>
  #include <memory>
  #include <cassert>

  template <typename T>
  double XtimesY(T& ptr) // Use of ptr not flagged
  {
    return (ptr->x) * (ptr->y);
    // ...
  }
  struct S
  {
    double x;
    double y;
    S(double x0, double y0) : x{x0}, y{y0} {}
  };
  void func()
  {
    auto a = std::make_unique<S>{100.0, 200.0};
    auto b = new S(100.0, 200.0);
    assert(XtimesY(a) == XtimesY(b));
  }
  ```
- The smart pointer parameter is captured by a lambda function inside the function body. For instance, Polyspace does not report a violation when you use an lvalue reference to unique pointer

`ptr` as a parameter of `func()` because it is captured by a lambda function inside the body of `func()`. Polyspace reports the use of lambda function parameter `up1` because its lifetime is not modified inside the lambda function.

```
#include <memory>

struct S
{
  double x;
  double y;
  S(double x0, double y0) : x{x0}, y{y0} {}
};

void func(std::unique_ptr<S>& ptr)
{ // no defect is detected on 'ptr'
  auto lambdaF =
      [&ptr0 = ptr]            // 'ptr' is captured (by reference)
      (std::unique_ptr<S> up1) // Non-compliant
  {                            // lifetime of 'up1' not affected
    // ...
  };
  auto b = std::make_unique<S>(100.0, 200.0);
  lambdaF(std::move(b));
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `std::unique_ptr` Passed to Function

```
#include <memory>
#include <cassert>
#include <iostream>

void func1(std::unique_ptr<int>& uniquePtrParam) // Non-compliant
{
  // uniquePtrParam not reset or modified
}

void func2(const std::unique_ptr<int>& uniquePtrParam) // Non-compliant
{
  // const lvalue reference cannot be modified
}

void func_param_lvalue_ref(std::unique_ptr<int>& uniquePtrParam) // Compliant
{
  std::unique_ptr<int> newPtr = std::make_unique<int>(-8);
  std::swap(newPtr, uniquePtrParam);
}

void func_param_const_lvalue_ref(const std::unique_ptr<int>& uniquePtrParam);

void func3(std::unique_ptr<int>& uniquePtrParam) // Compliant
{
  // uniquePtrParam passed to function with lvalue reference
  // to std::unique_ptr parameter

  func_param_lvalue_ref(uniquePtrParam);
}

void func4(std::unique_ptr<int>& uniquePtrParam) // Non-compliant
{
  // uniquePtrParam passed to function with const lvalue reference
  // to std::unique_ptr parameter. Function cannot modify managed object

  func_param_const_lvalue_ref(uniquePtrParam);
}
```

In this example, Polyspace reports the use of `uniquePtrParam` as a parameter to these functions: v

- `func1()` — The lvalue reference is not modified or reset inside the function.
- `func2()` — The lvalue reference is `const`-qualified and cannot be modified.
- `func4()` — The lvalue reference parameter is passed as an argument to function `func_param_const_lvalue_ref()`, which has a `const`-qualified parameter. This indicates the passed parameter will not be modified inside that function.

If you do not intend to transfer the ownership of the managed object or to reset the `std::unique_ptr` smart pointer, pass an lvalue reference to the managed object itself instead.

Polyspace does not report the use of the `std::unique_ptr` lvalue reference as a parameter of `func_param_lvalue_ref()` because the parameter is used as an argument of `swap()` and the ownership of the managed object is transferred.

Similarly, Polyspace does not report the use of the parameter of `func3()` because it is used as an argument of the function `func_param_lvalue_ref()`. The function `func_param_lvalue_ref()` takes an non-`const` lvalue reference to an `std::unique_ptr` smart pointer as a parameter which indicates it might modify that parameter.

Polyspace does not report the use of the parameter of `func3()` regardless of the implementation of `func_param_lvalue_ref()`.

# AUTOSAR C++14 Rule A8-4-13

A std::shared_ptr shall be passed to a function as: (1) a copy to express the function shares ownership (2) an lvalue reference to express that the function replaces the managed object (3) a `const` lvalue reference to express that the function retains a reference count.

## Description

### Rule Definition

*A std::shared_ptr shall be passed to a function as: (1) a copy to express the function shares ownership (2) an lvalue reference to express that the function replaces the managed object (3) a* `const` *lvalue reference to express that the function retains a reference count.*

### Rationale

You use an `std::shared_ptr` smart pointer to indicate that more than one smart pointer manages and shares ownership of the same object. A smart pointer manages the lifetime of a dynamically allocated object and destroys that object when the smart pointer goes out of scope. Pass an `std::shared_ptr` smart pointer to a function in one of these ways:

- If you expect the function to share ownership of the managed object, pass the smart pointer by value. The `std::shared_ptr` reference count is incremented at the start of the function and decremented at the end of the function. For instance, `smartPtr` is passed to `func()` in this code and that `func()` shares ownership of the managed `int` object until the function ends.

  ```
  void func(std::shared_ptr<int> smartPtr) {
    //Shared ownership of managed object
    //smartPtr until end of func
  }
  ```
- If you expect the function to replace the object that the smart pointer manages on at least one code path, pass the smart pointer by lvalue reference. For instance, you replace the managed object by calling `operator=` or `std::shared_ptr` member function `reset()`.

  For example, the lvalue reference parameter of `func()` is reset inside the function and manages a new `int` object in this code. The function does not share ownership of the original managed object.

  ```
  void func(std::shared_ptr<int>& smartPtr) {
    smartPtr.reset(new int(1));
  }
  ```

  If you do not intend to replace the managed object on at least one code path, pass an lvalue reference to the managed object itself (`void func(int& obj);`).
- If you expect that the function might share ownership of the managed object and copy the parameter to another `std::shared_ptr` smart pointer on at least one execution path, pass the smart pointer by `const` lvalue reference. Passing by `const` lvalue reference avoids unnecessary copies on the other execution paths.

  For instance, the parameter `smartPtr` is not compliant because it is not copied to another `std::shared_ptr` on any execution path in this code. If you do not intend to copy the parameter to another `std::shared_ptr` smart pointer, pass the parameter by `const` lvalue reference to the managed object itself.

```
#include <iostream>
#include <memory>

void func(const std::shared_ptr<int>& smartPtr) { //Non-compliant
  std::cout << *smartPtr << std::endl;
}
```

### Polyspace Implementation

Polyspace reports the use of an `std::shared_ptr` smart pointer parameter passed as an lvalue reference if that parameter is not reset.

Polyspace considers that a parameter is reset in these cases:

- The parameter is used as the destination of a copy or move assignment.
- The parameter is moved-from through a call to `std::move`.
- The parameter is used as an argument to `std::shared_ptr` member functions `reset()` or `swap()`.
- The parameter is used as the argument of any function that takes a non-`const` qualified lvalue reference to an `std::shared_ptr` smart pointer, regardless of the implementation of the callee.

Polyspace also reports the use of an `std::shared_ptr` pointer parameter passed as a `const` lvalue reference if that parameter is not copied to another `std::shared_ptr` pointer along at least one execution path.

The parameter is copied to another `std::shared_ptr` smart pointer if it is used as the argument of one of these functions that take a `const` lvalue reference to `std::shared_ptr` as a parameter:

- `std::static_pointer_cast`
- `std::dynamic_pointer_cast`
- `std::const_pointer_cast`
- `std::reinterpret_pointer_cast`

If you do not intend to copy the parameter to another `shared_ptr` smart pointer, pass a `const` lvalue reference to the managed object instead.

Polyspace does not report the use of smart pointers as parameter types in these cases:

- The pointer is passed as an rvalue reference parameter to a function and the pointer is effectively moved-from inside that function.
- The pointer is used as a parameter of a template function. The parameter type of a template function depends on the instantiation of that function and a fix is not always possible at the template design level. For instance, Polyspace does not report the use of shared pointer `ptr` in this code.

  ```
  #include <iostream>
  #include <memory>
  #include <cassert>

  template <typename T>
  double XtimesY(T& ptr) // Use of ptr not flagged
  {
    return (ptr->x) * (ptr->y);
    // ...
  ```

```
}
struct S
{
  double x;
  double y;
  S(double x0, double y0) : x{x0}, y{y0} {}
};
void func()
{
  auto a = std::make_shared<S>{100.0, 200.0};
  auto b = new S(100.0, 200.0);
  assert(XtimesY(a) == XtimesY(b));
}
```

- The smart pointer parameter is captured by a lambda function inside the function body. For example, Polyspace does not report the use of the lvalue reference to a shared pointer `ptr` as a parameter of `func()` because a lambda function captures the parameter inside the body of `func()`. Polyspace reports the use of the lambda function parameter `up1` because its lifetime is not modified inside the lambda function.

```
#include <memory>

struct S
{
  double x;
  double y;
  S(double x0, double y0) : x{x0}, y{y0} {}
};

void func(std::shared_ptr<S>& ptr)
{ // no defect is detected on 'ptr'
  auto lambdaF =
      [&ptr0 = ptr]            // 'ptr' is captured (by reference)
      (std::shared<S> up1) // Non-compliant
  {                            // lifetime of 'up1' not affected
    // ...
  };
  auto b = std::make_shared<S>(100.0, 200.0);
  lambdaF(std::move(b));
}
```

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `std::shared_ptr` Passed to Function

```
#include <iostream>
#include <memory>

void func1(
    std::shared_ptr<int>& smartPtr,      //Non-compliant
    const std::shared_ptr<int>& constSmartPtr//Non-compliant
)
{
  std::cout << smartPtr;
  auto deleter = std::get_deleter<void (*)(int *)>(constSmartPtr);
}
```

```
void func2(std::shared_ptr<int>& smartPtr){ //Non-compliant
  ++(*smartPtr); // Managed object not replaced
}

struct Base
{
  int a;
  virtual ~Base() {}
};
struct Derived : Base
{
  ~Derived() {}
};
void func3(
    std::shared_ptr<Base>& basePtr,            //Compliant
    const std::shared_ptr<Derived>& derivedPtr //Compliant
)
{
  //derivedPtr is copied to another shared_ptr
  //basePtr is the destination of a copy assigment
  basePtr = std::static_pointer_cast<Base>(derivedPtr);
}
```

In this example, Polyspace reports the use of the `std::shared_ptr` parameters that are passed to these functions:

- `func1()` — The lvalue reference parameter `smartPtr` is not reset and the object managed by `smartPtr` is not replaced. Parameter `constSmartPtr` is noncompliant because the parameter is not copied to another shared pointer. The function `get_deleter` returns the deleter of the smart pointer, but does not create a new shared pointer.
- `func2()` — The `int` object managed by the smart pointer is not replaced.

If you do not intend to modify the managed object of the lvalue reference parameters, pass an lvalue reference to the managed object instead. If you do not intend to copy the `const` lvalue reference parameter to another shared pointer, pass a `const` lvalue reference to the managed object instead.

Polyspace does not report the parameters of `func3()` because:

- The lvalue reference parameter `basePtr` is the destination of a copy assignment.
- The `const` lvalue reference parameter `derivedPtr` is copied to another shared pointer through the call to `std::static_pointer_cast`.

# AUTOSAR C++14 Rule A8-4-14

Interfaces shall be precisely and strongly typed

## Description

### Rule Definition

*Interfaces shall be precisely and strongly typed.*

### Rationale

Interfaces describe the behavior or capabilities of an object. Precisely and strongly typed interfaces specify the purpose and properties of their parameters by using parameters that are custom objects and templates instead of fundamental types. Compare the interfaces in this code snippet:

```
void draw_circle(float R, float x, float y);
void draw_circle(Length R, Position O);
```

Both interfaces represent a function that draws a circle. The first interface uses three floating numbers as input parameters. The second interface uses an object of class `Length` and another object of class `Position` as input parameters.

- The second interface makes it explicit that the first parameter is a length and the second parameter is a position. This interface is easy to understand and use because it highlights the required input parameters and their order for a specific circle. By contrast, you cannot discern the input parameters or their order in the first interface because it is not clear how the three floating numbers relate to the circle.
- The compiler checks the arguments against the input parameter types at compile time. If you put the input parameters of the second interface in the wrong order accidentally, the compiler flags the mismatched parameters at compile time. If all three input parameters of the first interface are floating-point numbers, the compiler cannot check if the input order is correct.
- The definition of the classes `Length` and `Position` can specify the units of these parameters, such as cm or mm. The class definitions can also specify whether these parameters are immutable. When you use fundamental types as input parameters, such specification is difficult.

The first interface is ambiguous because it uses fundamental type input parameters, which can lead to mistakes. Avoid using interfaces that have many fundamental type parameters. Use precisely and strongly typed interfaces instead. Compilers can often optimize such interfaces better than weakly typed interfaces.

When several parameters are related, combine them into a user-defined type. When implementing polymorphic interfaces, use pointers to a common base class instead of pointers to void (`void*`). For generic interfaces, use templates as parameters.

### Polyspace Implementation

In Polyspace, these types are *fundamental types*:

- Integer types, such as `int`, `short`, and `long`
- Floating point types, such as `float` or `double`

- Boolean (bool) types
- Pointers to void (void*)
- Pointers or references to the preceding types
- typedef of the preceding types
- Arrays of the preceding types

In Polyspace, enumerations or enums are not fundamental types. Polyspace flags an interface if its input parameters include any of the following:

- One or more void related types
- Two or more bool related types
- Three or more identical fundamental types

You can use alternatives such as comments or parameter names to clarify an interface definition. In such cases, you can justify the Polyspace result by using comments in your result or code. See "Address Results in Polyspace User Interface Through Bug Fixes or Justifications"

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using Interfaces with Many Fundamental Type Parameters

Polyspace flags interfaces when their input parameters include:

- Two or more bool related types
- Three or more identical fundamental types

Consider the interfaces in this code:

```
#include <cstdint>
#include <chrono>

void Sleep(std::uint32_t duration);//Compliant

void SetProperty(bool Status);//Compliant

void SetAlarm(std::uint32_t year, std::uint32_t month, //Noncompliant
              std::uint32_t day, std::uint32_t hour,
              std::uint32_t minute, std::uint32_t second);

//Compliant
void StartClock(std::chrono::system_clock::time_point const& when);
typedef struct {
    int a, b, c, d;
} Point;
void Triangle(float a, float b, float c);//Noncompliant
void Rectangle(Point a, Point b, Point c, Point d); //Compliant

main()
```

```
{
    //...
}
```

- Polyspace flags the interfaces that use three or more fundamental type variables as input parameters, such as `SetAlarm()` and `Triangle()`.
- The interfaces `StartClock()` and `Rectangle()` use precise and strongly typed input parameters. Polyspace does not flag these interfaces.
- Polyspace does not flag an interface that has less than three fundamental type input parameters or less than two `bool` type input parameters.

### Avoid Using Pointer to Void (void*)

Polyspace flags interfaces when their input parameters include one or more pointers to void (`void*`). Consider the interfaces in this code:

```
#include <cstdint>

class A{
    //...
};
class B:public A{
    //...
};
class C:public A{
    //...
};

void polymorphic_function(void*);//Noncompliant
void polymorphic_function(A*);//Compliant

void printArray(void* Array);//Noncompliant
template <typename T>
void printArray (T* Array);//Compliant

main(){
    //...
}
```

All pointer types implicitly convert to `void*`, which is a weak and under-qualified type. Avoid using `void*` pointers.

- To implement polymorphic interfaces, use pointers to base classes such as `A*` instead of `void*`.
- To implement generic interfaces, use templates such as `T*` instead of `void*`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-5-0

All memory shall be initialized before it is read

## Description

### Rule Definition

*All memory shall be initialized before it is read.*

### Rationale

The C++ standard does not specify what the value of an uninitialized memory can be. This value is unpredictable and can be different every time the program runs. Reading and using the value of an uninitialized memory results in unexpected behavior.

### Polyspace Implementation

Polyspace reports a violation of this rule if your code contains these issues:

- `Non-initialized variable`
- `Member not initialized in constructor`
- `Non-initialized pointer`

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Variable Read Before Initialization

If `command` is not 2, the variable `val` is unassigned. In this case, the return value of function `get_sensor_value` is undetermined.

```
int get_sensor_value(void)
{
    extern int getsensor(void);
    int command;
    int val;

    command = getsensor();
    if (command == 2)
      {
        val = getsensor();
      }

    return val; //Noncompliant

}
```

### Member Not Initialized in Constructor

In this example, if flag is not 0, the member _c is not initialized.

The defect appears on the closing brace of the constructor. Following are some tips for navigating in the source code:

- On the **Result Details** pane, see which members are not initialized.
- To navigate to the class definition, right-click a member that is initialized in the constructor. Select **Go To Definition**. In the class definition, you can see all the members, including those members that are not initialized in the constructor.

```
class MyClass {
public:
    explicit MyClass(int);
private:
    int _i;
    char _c;
};

MyClass::MyClass(int flag) {
    if(flag == 0) {
        _i = 0;
        _c = 'a';
    }
    else {
        _i = 1;
    }
}//Noncompliant
```

### Pointer Dereferenced Before Initialization

If prev is not NULL, the pointer pi is not assigned an address. However, pi is dereferenced on every execution paths, irrespective of whether prev is NULL or not.

```
#include <stdlib.h>

int* assign_pointer(int* prev)
{
    int j = 42;
    int* pi;

    if (prev == NULL)
      {
        pi = (int*)malloc(sizeof(int));
        if (pi == NULL) return NULL;
      }

    *pi = j; //Noncompliant

    return pi;
}
```

# AUTOSAR C++14 Rule A8-5-2

Braced-initialization {}, without equals sign, shall be used for variable initialization

## Description

### Rule Definition

*Braced-initialization {}, without equals sign, shall be used for variable initialization.*

### Rationale

Braced initialization:

```
classType Object{arg1, arg2, ...};
```

is less ambiguous than other forms of initialization. Braced initialization has the following advantages:

- Prevents implicit narrowing conversions such as from `double` to `float`.
- Avoids the ambiguous syntax that leads to the problem of most vexing parse.

  For instance, from the declaration:

  ```
  ResourceType aResource();
  ```

  It is not immediately clear if `aResource` is a function returning a variable of type `ResourceType` or an object of type `ResourceType`.

  For more information, see `Ambiguous declaration syntax`.

The rule also forbids the use of = sign for initialization because the = sign can give the impression that an assignment or copy constructor is invoked even in situations when it is not.

### Polyspace Implementation

In general, the checker flags initializations of an object `obj1` of data type `Type` using these formats:

- `*Type* obj1 = obj2;`
- `*Type* obj1(obj2);`

The checker allows an exception for these cases:

- Initialization of variables with type `auto` using a simple assignment to a constant, a variable, a lambda expression, a standard initializer list or a function call.
- Initialization of reference types using a simple assignment
- Declarations with global scope using the format *`Type`* `a()` where *`Type`* is a class type with default constructor. The analysis interprets `a` as a function returning the type *`Type`*.
- Loop variable initialization in OpenMP parallel `for` loops, that is, in `for` loop statements that immediately follow `#pragma omp parallel for`

The checker is enabled only if you specify a C++ version of C++11 or later. See `C++ standard version (-cpp-version)`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Braced and Nonbraced Initialization

```
class ResourceType {
      int memberOne;
      int memberTwo;
    public:
      ResourceType() {memberOne = 0; memberTwo = 0;}
      ResourceType(int m, int n) {memberOne = m; memberTwo = n;}
      ResourceType(ResourceType &anotherResource) {
          memberOne = anotherResource.memberTwo;
          memberTwo = anotherResource.memberOne;
      }
};

void func() {
    ResourceType aResourceOne(); //Noncompliant
    ResourceType aResourceTwo(1, 2); //Noncompliant
    ResourceType aResourceThree = {1,2};   //Noncompliant

    ResourceType aResourceFour{1,2}; //Compliant

}
```

In this example, the function `func` declares four objects of type `ResourceType`. Only the declaration of `aResourceFour` does not violate this rule.

The declarations of `aResourceOne`, `aResourceTwo` and `aResourceThree` violate the rule. In particular:

- The declaration of `aResourceOne` suffers from the problem of most vexing parse. It is not clear whether `aResourceOne` is an object of type `ResourceType` or a function returning an object of type `ResourceType`.
- The declaration of `aResourceThree` seems to suggest that the copy constructor `ResourceType(ResourceType &)` is invoked for initialization. The copy constructor initializes the data member `memberOne` to 2 and `memberTwo` to 1. However, the constructor `ResourceType(int, int)` is invoked. This constructor initializes the data member `memberOne` to 1 and `memberTwo` to 2.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-5-3

A variable of type auto shall not be initialized using {} or ={} braced-initialization

## Description

### Rule Definition

*A variable of type auto shall not be initialized using {} or ={} braced-initialization.*

### Rationale

Type deduction for `auto` has a counter-intuitive result when the initialization uses braces. The deduced type is `std::initializer_list<>` instead of the type that you might guess from the initializer.

For instance, the definition:

```
auto x{1};
```

results in the type of `x` being `std::initializer_list<int>` instead of `int`. Some compilers deduce an `int` type from this definition, but the behavior is not uniform across compilers.

### Polyspace Implementation

The checker flags variable definitions that use the type `auto` if the variable is initialized using the `{}` or `={}` braced initialization.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `auto` in Braced Initialization

```
#include<initializer_list>

void func() {
    auto aVar{1}; //Noncompliant
    auto anotherVar(1); //Compliant
    int aThirdVar{1}; //Compliant

    auto aVarList{1,2,3}; //Noncompliant
    std::initializer_list<int> anotherVarList{1,2,3}; //Compliant
}
```

In this example, the rule is violated when the `auto` type is used with braced initialization. Instead of `auto`, an explicit type specification is preferred. Alternatively, the initialization can use parenthesis `()`, which ensures the expected type deduction.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A8-5-4

If a class has a user-declared constructor that takes a parameter of type std::initializer_list, then it shall be the only constructor apart from special member function constructors

## Description

### Rule Definition

*If a class has a user-declared constructor that takes a parameter of type std::initializer_list, then it shall be the only constructor apart from special member function constructors.*

### Rationale

If a class contains a constructor that takes a parameter of type `std::initializer_list` and another constructor with parameters, braced initializations such as:

```
classType obj {0,1}
```

Can lead to confusion about which of the two constructors is invoked. Compilers prefer the constructor with the `std::initializer_list` parameter, but developers might expect otherwise.

### Polyspace Implementation

The checker flags class definitions that contain a constructor whose first parameter is of type `std::initializer_list` and also contains another constructor (excluding the special member function constructors). The rule violation is followed by events that point to the location of the other constructors that might lead to confusion with the `std::initializer_list` constructor.

A class definition with an `std::initializer_list`-parameter constructor that does not violate this rule has only the default, copy and move constructors (and copy and move assignment operators). If you cannot avoid a second constructor with parameters, you can justify this rule violation. In that case, for initializing with a list, use a syntax such as:

```
classType obj ({0,1})
```

so that it is clear that the `std::initializer_list`-parameter constructor is invoked. For initializing with the other constructors, use a syntax such as:

```
classType obj (0,1)
```

Both invocations are exceptions to Rule A8-5-2, which generally flags initializations with `()`, but allows such initializations for classes with a mix of `std::initializer_list`-parameter constructor and other constructors.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant and Compliant Definitions of Classes with `std::initializer_list`-Parameter Constructors

```
#include <cstdint>
#include <initializer_list>
#include <vector>

class entrySizes {                  //Noncompliant
    public:
       entrySizes()=default;
       entrySizes(std::size_t aCurrentSize, std::size_t aLastSize):
              currentSize{aCurrentSize}, lastSize{aLastSize} {}
       entrySizes(std::initializer_list<std::size_t> sampleEntry):
              currentSize{sampleEntry.size()}, lastSize{sampleEntry.size()} {}
    private:
       std::size_t currentSize;
       std::size_t lastSize;
};

class recordSizes {                 //Compliant
    public:
       recordSizes()=default;
       recordSizes(std::initializer_list<std::size_t> sampleRecord):
              currentSize{sampleRecord.size()}, lastSize{sampleRecord.size()} {}
    private:
       std::size_t currentSize;
       std::size_t lastSize;
};

void createEntry() {
    entrySizes defaultEntrySize{};
    entrySizes stdEntrySize{0,1};
       //Calls entrySizes(std::initializer_list<std::size_t> ),
       //but developer might expect otherwise
    entrySizes expectedEntrySize({0,1});
       //Calls entrySizes(std::initializer_list<std::size_t> ),
       //but developer might expect otherwise
    entrySizes typicalEntrySize(1,1);
        //Calls entrySizes(std::size_t, std::size_t)
}

void createRecord() {
    recordSizes defaultRecordSize{};
    recordSizes stdRecordSize{0,1};
       //Calls recordSizes(std::initializer_list<std::size_t> )
}
```

In this example, the class `entrySizes` contains two user-defined constructors, one with an `std::initialize_list` parameter and a second one with two `size_t` parameters. The presence of two constructors can lead to developer confusion as shown in the `createEntry` function. In case you want to retain the current class definition and justify the rule violation, the `createEntry` function also shows a cleaner way to invoke the `std::initialize_list`-parameter constructor.

The class `recordSizes` does not violate the rule since it does not contain another constructor other than the default constructor and the constructor with the `std::initialize_list` parameter.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A9-3-1

Member functions shall not return non-constant "raw" pointers or references to private or protected data owned by the class

## Description

### Rule Definition

*Member functions shall not return non-constant "raw" pointers or references to private or protected data owned by the class.*

### Rationale

Returning a nonconstant pointer or reference to private or protected class-owned data enables clients to externally access and modify the state of the object without an interface. Such access without an explicit interface might bypass the private/protected data access hierarchy of the class, which might result in unexpected behavior and lead to bugs.

This rule applies to data that is owned by the class. Nonconstant handles to objects that are shared between different classes might be returned. Classes that mimic smart pointers and containers do not violate this rule.

### Polyspace Implementation

The checker flags a rule violation only if a member function returns a non-`const` pointer or reference to a nonstatic data member. The rule does not apply to static data members.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Returning Non-Constant Raw Pointers to Private Data

```
#include <cstdint>
#include <memory>
#include <utility>

class A
{
  public:
    explicit A(std::int32_t number) : x(number) {}
    std::int32_t&
    GetX() noexcept // Noncompliant
    {
      return x;
    }

  private:
    std::int32_t x;
};

void Fn1() noexcept
{
  A a{10};
  std::int32_t& number = a.GetX();
  number = 15; // External modification of private class data
}
```

In this example, the `class A` member function `GetX()` returns a non-constant raw pointer to `x`, which is private data owned by `class A`. Polyspace flags this implementation as noncompliant. `Fn1()` demonstrates the issues of `a.GetX()` returning a non-constant raw pointer to private class data, which is then stored and modified by number. The class has no control over changes to its own private data member, which might lead to unexpected behavior.

#### Compliant: Return Shared Smart Pointer Variables

```
#include <cstdint>
#include <memory>
#include <utility>
class B
{
  public:
    explicit B(std::shared_ptr<std::int32_t> ptr) : sharedptr(std::move(ptr)) {}
    std::shared_ptr<std::int32_t> GetSharedPtr() const noexcept // Compliant
    {
      return sharedptr;
    }

  private:
    std::shared_ptr<std::int32_t> sharedptr;
};

void Fn2() noexcept
{
  std::shared_ptr<std::int32_t> ptr = std::make_shared<std::int32_t>(10);
  B b1{ptr};
  B b2{ptr};
  *ptr = 50; // External modification of ptr which shared between b1 and b2
  // instances
  auto shared = b1.GetSharedPtr();

  *shared = 100;   // External modification of ptr which shared between b1 and
  // b2 instances
}
```

In this example, the `class B` function `GetSharedPtr()` returns a smart pointer variable that is shared between the instances `b1` and `b2`. Polyspace does not flag this implementation as noncompliant.

#### Compliant: Return Constant References

```
#include <cstdint>
#include <memory>
#include <utility>
class C
{
  public:
    explicit C(std::int32_t number)
      : ownedptr{std::make_unique<std::int32_t>(number)}
    {
    }
    const std::int32_t& GetData() const noexcept // Compliant
    {
      return *ownedptr;
    }

  private:
    std::unique_ptr<std::int32_t> ownedptr;
};
void Fn3() noexcept
{
  C c{10};
  const std::int32_t& data = c.GetData();
  // data = 20; // Cannot modify data, it is a const reference
}
```

In this example, `GetData()` returns a constant reference. You cannot modify private class-data by using this member function. Polyspace does not flag this implementation as noncompliant.

# AUTOSAR C++14 Rule A9-5-1

Unions shall not be used

## Description

### Rule Definition

*Unions shall not be used.*

### Rationale

Using unions to store a value might result in misinterpretation of the value and lead to undefined behavior. For instance:

```
union Data{
    int i;
    double d;
};
void bar_int(int);
void bar_double(double);
void foo(void){
    Data var;
    var.d = 3.1416;
    bar_int(var.d);//Undefined Behavior
}
```

In the call to `bar_int`, the `double` data in the union is misinterpreted as an `int`, which is undefined behavior. Compilers might react to this misinterpretation differently depending on their implementation. To avoid undefined behaviors, do not use a `union`.

In some cases, use of unions might be necessary to increase efficiency. In such cases, use unions after documenting the relevant implementation-defined compiler behaviors. In the preceding case, before using a `union`, consult the manual of the compiler that you use and document how the compiler reacts to interpreting a `double` as an `int`.

As an exception, use of tagged union is allowed until `std::variant` becomes available in the C++ standard library (C++17).

### Polyspace Implementation

Polyspace flags the declaration of a `union`. You might consider the use of `union` necessary or acceptable in your code. In such cases, justify the violation by annotating the result or by using code comments. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using union

```
#include <iostream>

union Pi{ //Noncompliant
    int i;
    double d;
};

void foo(void){

    std::cout << std::endl;

    Pi pi;
    pi.d = 3.1416;// pi holds a double
    std::cout << "pi.d: " << pi.d << std::endl;
    std::cout << "pi.i: " << pi.i << std::endl;      // Undefined Behavior

    std::cout << std::endl;

    pi.i = 4;     // pi holds an int
    std::cout << "pi.i: " << pi.i << std::endl;
    std::cout << "pi.d: " << pi.d << std::endl;      // Undefined Behavior

    std::cout << std::endl;

}
```

In this example, the union Pi contains a double and an int. In the code, a double is misinterpreted as an int and vice versa by using the union. These misinterpretations are undefined behaviors and might lead to bugs and implementation dependent code behavior. Polyspace flags the union declaration.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A9-6-1

Data types used for interfacing with hardware or conforming to communication protocols shall be trivial, standard-layout and only contain members of types with defined sizes

## Description

### Rule Definition

*Data types used for interfacing with hardware or conforming to communication protocols shall be trivial, standard-layout and only contain members of types with defined sizes.*

### Rationale

When interfacing with hardware or when conforming to communication protocols, the layout of the data type you use must be consistent and standardized. For these tasks, use data types with layout and size that are not dependent on your hardware or software.

Types with well defined sizes are listed in the header `<cstdint>`. Examples of such data type includes types such as `int16_8` and `int32_t`. This list excludes types such as `bool`, `wchar_t`, and pointers. Avoid using excluded types when interfacing with hardware or when conforming to communication protocols.

Using enumerations are allowed only when the underlying data types of the `enum` has a well defined size. Using bitfields for these tasks are allowed only when the underlying type has a well defined size,

### Polyspace Implementation

Polyspace raises a violation of this rule if you use a data type other then these two in a bit field:

- Enumeration
- Unsigned integral type

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use `enum` and Unsigned Integral Types in Bitfields

```
#include <cstdint>
enum class E1: std::uint8_t {
    E11,
    E12,
    E13
};
enum class E2{
    E21,
    E22,
    E23
};
class hwInterface{
public:
    std::int32_t A:2; //Noncompliant- signed integer
    std::uint8_t B:2U; //Compliant
    E1 field1:2; //Compliant

    char D:2;//Noncompliant
    E2 field2:2; //Compliant
};
```

In this example, Polyspace flags the use of any types other than `enums` and unsigned integers in bitfields. For instance, the use of `std::int32_t` and `char` is flagged. Polyspace does not flag the use of `std::uint8_t` or enums such as `E1` or `E2`.

# AUTOSAR C++14 Rule A10-1-1

Class shall not be derived from more than one base class which is not an interface class

## Description

### Rule Definition

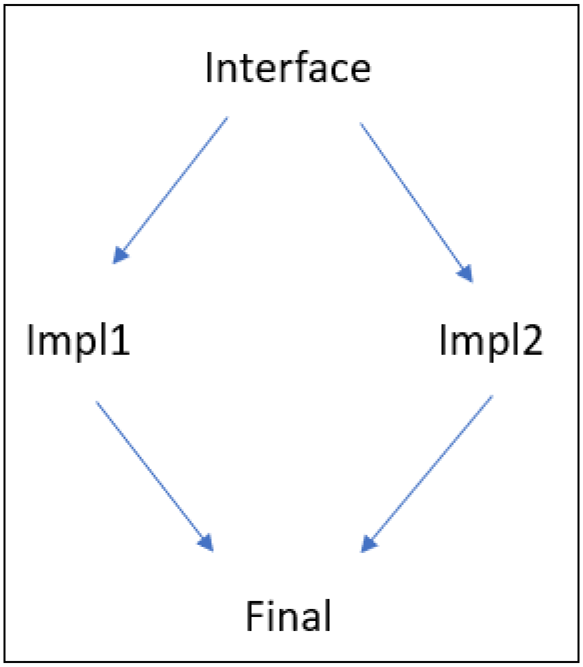
*Class shall not be derived from more than one base class which is not an interface class.*

### Rationale

If a class inherits from multiple non-interface classes, the class essentially has access to multiple implementations. Maintaining the code can be difficult.

When a class inherits from multiple non-interface classes, there is a likelihood that the same member function exists in those base classes and must be overridden in the derived class. The likelihood increases when those base classes themselves inherit from a common base class (diamond structure).

Suppose, an interface class `Interface` has two concrete implementations, `Impl1` and `Impl2`, and a class `Final` derives from both implementations. The class hierarchy has this diamond structure.



The following issues can occur:

- *Overrides required in final derived class for disambiguation*:

  Both implementations `Impl1` and `Impl2` have a copy of all methods of the class `Interface`. To disambiguate which copy can be called through a `Final` object, you typically create yet another override of all methods in the `Final` class where you call both copies explicitly using the scope resolution operator `::` (or one copy, if you choose). See example below.

Each time you add a new pure virtual function to the class `Interface`, you have to not only create implementations in the immediate derived classes but also keep track of the entire class hierarchy and create overrides of those implementations in the class `Final`.

If the original class `Interface` is not an interface class, the problem is even more acute. Unless the inheritances are virtual, two copies of the methods of `Interface` are *implicitly* made in `Impl1` and `Impl2` (the diamond problem).

- *Final derived class responsible for initializing all classes in hierarchy*:

  To avoid double initializations in multiple inheritance, the C++ standard requires that you call the constructors of all previous classes in the most derived class.

  In the preceding example, the `Final` class constructor not only has to call the constructors of `Impl1` and `Impl2` but also the constructor of their parent class `Interface`. You have to trace beyond the immediate parents to determine which constructors to call in the final derived class.

These problems disappear if multiple inheritances are restricted to situations where a class can derive from multiple classes but only one of them can be a non-interface class. An interface class is a class that has only pure virtual functions and data members that are compile-time constants (static, `contexpr`-s). The class has no state and its sole purpose is to be implemented by derived classes.

Multiple inheritance was designed for situations where a class extends one concrete implementation but also implements other ideas represented by interface classes. Other uses of multiple inheritance can lead to maintenance hazards.

### Polyspace Implementation

The checker flags multiple inheritances where more than one base class is a non-interface class.

An interface class is one that has only pure virtual functions and data members that are compile-time constants (static, `contexpr`-s). Any constructor or destructor is set to `=default` or `=delete`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Multiple Inheritance from Non-interface Classes

```
class Interface {
    public:
    virtual void setVal()=0;
};

class Impl1: public Interface{
    int val1;
public:
    void setVal() {
        val1 = 0;
    }
};

class Impl2: public Interface{
    int val2;
public:
    void setVal() {
        val2 = 0;
    }
};

class Final: public Impl1, public Impl2 { //Noncompliant
public:
    void setVal() {
        Impl1::setVal();
        Impl2::setVal();
    }

};

void main() {
    Final finalObj;
    finalObj.setVal();
}
```

In this example, the class final derives from classes `Impl1` and `Impl2`. Both classes `Impl1` and `Impl2` have data members that are not compile-time constants and member functions that are not pure virtual functions. Therefore, the classes are non-interface classes. Inheriting from two non-interface classes causes a coding rule violation.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A10-2-1

Non-virtual public or protected member functions shall not be redefined in derived classes

## Description

### Rule Definition

*Non-virtual public or protected member functions shall not be redefined in derived classes.*

### Rationale

When a nonvirtual public or protected member function is redefined in a derived class, the new definition in the derived class hides the definition in the base class instead of overriding it. When functions are hidden in the derived class, you cannot implement a common interface to handle different classes of the same hierarchy, resulting in unnecessary complexity and error. Such behavior might be unexpected and lead to bugs that are difficult to resolve.

Redefinitions of functions from private inheritance or functions that are private in the base class are not affected by this rule.

### Polyspace Implementation

Polyspace flags redefinitions of non-virtual member functions in a derived class. Polyspace does not raise this defect on destructors.

To justify a redefinition that you deem as acceptable, use annotations. See “Annotate Code and Hide Known or Acceptable Results”

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Redefining Public or Protected Member Functions in Derived Classes

```
class A
{
  public:
    virtual ~A() = default;
    void F() noexcept {}
    virtual void G() noexcept {}
  private:
    void H() noexcept;
};

class B : public A
{
  public:
    void F() noexcept {} //Noncompliant
    void G() noexcept override {} //Compliant
};
```

In this example, the `A::F()` function is a non-virtual public member function that is hidden by the B class. Hiding `A::F()` prevents the use of polymorphic interfaces, so Polyspace flags the redefinition in `B::F()` as noncompliant. The `A::G()` function is virtual and is overridden (rather than hidden) in `B::G()`, so Polyspace does not flag this implementation as noncompliant.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A10-3-1

Virtual function declaration shall contain exactly one of the three specifiers: (1) virtual, (2) override, (3) final

## Description

### Rule Definition

*Virtual function declaration shall contain exactly one of the three specifiers: (1) virtual, (2) override, (3) final.*

### Rationale

Virtual functions implement polymorphic behavior in a class hierarchy. Once you declare a function as `virtual` in a base class, all instances of the function with an identical parameter list in the derived classes override the base function implicitly. If you rely on this implicit action by the compiler for implementing polymorphic functions, it can lead to errors. For instance:

- A function can become inadvertently `virtual` because its signature matches a virtual function in the base class.
- A function can become inadvertently non-virtual because there are differences in the parameter list.

Implicitly declaring virtual functions can also make the code hard to read.

To avoid inadvertent errors and to enhance readability, use the specifiers `virtual`, `override`, or `final` to explicitly define virtual or overriding functions. Because using more than one of these specifiers in a declaration is either redundant or a source of error, use exactly one of these specifiers:

- Only `virtual` to declare a new virtual function.
- Only `override` to declare a non-final overriding function of a virtual function.
- Only `final` to declare a final overriding function of a virtual function.

### Polyspace Implementation

Polyspace flags declaration of virtual functions if:

- The declaration uses none of the specifiers.
- The declaration uses more than one of the specifiers.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use Exactly One Specifier to Declare Virtual Functions

```
#include<cstdint>
class Base
```

```
{
public:
    virtual void F() noexcept = 0;                  // Compliant
    virtual void G() noexcept final = 0;            // Noncompliant
    virtual void H() noexcept final {}              // Noncompliant
    virtual void J() noexcept {}                    // Compliant
    virtual void K() noexcept {}                    // Compliant
    virtual ~Base() {}                              // Compliant
    virtual void M() noexcept {}                    // Compliant
    virtual void Z() noexcept {}                    // Compliant
    virtual void X() throw() {}                     // Compliant
    virtual void Y() noexcept {}                    // Compliant
};

class Derived : public Base
{
public:
    ~Derived() {}                                   // Noncompliant
    virtual void F() noexcept override {}           // Noncompliant
    void K() noexcept override final {}             // Noncompliant
    virtual void M() noexcept {}                    // Compliant
    void Z() noexcept override {}                   // Compliant
    void J() noexcept {}                            // Noncompliant
    void J(int) noexcept {}                         // Compliant
    virtual void X() throw() final {}               // Noncompliant
    virtual void Y() noexcept override final {}     // Noncompliant
};
class DD: public Derived{
//    void J(int) noexcept override{}       //Compilation error
};
main(){
    //...
}
```

- The destructor of the derived class `~Derived()` is a virtual function. Its declaration violates this rule because the declaration contains none of the three specifiers for virtual functions.
- The declaration of the pure virtual function `Base::G()` also violates this rule because the declaration contains both `virtual` and `final` as specifiers. A pure virtual function that is also specified as `final` is redundant.
- The declaration of the virtual function `Derived::J()` violates this rule because `Derived::J()` implicitly overrides the virtual function `Base::J()` without using the specifier `override`.
- The declarations of the virtual functions `Derived::X()` and `Derived::Y()` violate this rule because their declarations use more than one specifier.

The declaration of the function `DD::J(int)` produces a compilation error because `DD::J(int)` is trying to override `Derived::J(int)`. Because `Derived::J(int)` has a different signature than `Base::J()`, perhaps by error, `Derived::J(int)` is no longer a virtual function. Attempting to override `Derived::J(int)` by `DD::J(int)` results in a compilation error. Using exactly one specifier in the declaration of virtual functions can help detect errors.

## Check Information

**Group:** Derived classes
**Category:** Required, Automated

## Version History

**Introduced in R2020a**

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A10-3-2

Each overriding virtual function shall be declared with the override or final specifier

## Description

### Rule Definition

*Each overriding virtual function shall be declared with the override or final specifier.*

### Rationale

Virtual functions implement polymorphic behavior in a class hierarchy. Once you declare a function as `virtual` in a base class, all instances of the function with an identical parameter list in the derived classes override the base function implicitly. If you rely on this implicit action by the compiler for implementing polymorphic functions, it can lead to errors. For instance:

- A function can become inadvertently `virtual` because its signature matches a virtual function in the base class.
- A function can become inadvertently non-virtual because there are differences in the parameter list.

Implicitly declaring overriding virtual functions can also make the code hard to read.

To avoid inadvertent errors and to enhance readability, use the specifiers `override` and `final` explicitly in every declaration of overriding functions.

### Polyspace Implementation

Polyspace flags the declarations of `virtual` functions if all of these statements are true:

- The function is in a derived class.
- The signature of the function matches the signature of a virtual function in the base class.
- The declaration of the function lacks the specifier `override` or `final`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declare Overriding Virtual Functions by Using `override` or `final` Specifier

```
#include <cstdint>
class Base
{
public:
    virtual ~Base() {}
    virtual void F() noexcept = 0;
    virtual void G() noexcept {}
    virtual void Z() noexcept {}
    virtual Base& operator+=(Base const& oth) = 0;
};
class Derived1 : public Base
{
public:
    ~Derived1() override {}                           //Compliant
    void F() noexcept{}                               //Noncompliant
    virtual void G() noexcept {}                      //Noncompliant
    void Z() noexcept override {}                     // Compliant
    Derived1& operator+=(Base const& oth) override  // Compliant
    {
        return *this;
    }
};
class Derived2 : public Base
{
public:
    ~Derived2() {}                                    //  Noncompliant
    void F() noexcept override {}                     //  Compliant
    void G() noexcept override {}                     //  Compliant
    void Z() noexcept override {}                     //  Compliant
    Derived2& operator+=(Base const& oth)             //  Noncompliant
    {
        return *this;
    }
};
class Derived3 : public Base
{
    void F() noexcept override;                       // Compliant
};

main(){

}
```

- The declaration of the function `Derived::F()` is flagged because its signature matches the signature of `Base::F()` and its declaration does not contain `override` or `final`.
- The declaration of the function `Derived::G()` is flagged because its signature matches the signature of `Base::G()` and its declaration does not contain `override` or `final`, even though the declaration uses the specifier `virtual`.
- The declaration of the function `Derived3::F()` in class `Derived3` is not flagged because the declaration uses the specifier `override`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A10-3-3

Virtual functions shall not be introduced in a final class

## Description

### Rule Definition

*Virtual functions shall not be introduced in a final class.*

### Rationale

Declaring a function as `virtual` indicates that you intend to override the function in a derived class with a different implementation. The same function can then interact differently with different classes of a hierarchy. When you explicitly specify a class as `final`, you cannot derive a class from it. Because you cannot derive classes from a `final` class, do not introduce virtual functions in a `final` class. Specify all virtual functions in a `final` class by using the specifier `final`.

### Polyspace Implementation

Polyspace flags the declaration of virtual functions in a `final` class. Polyspace does not flag virtual functions in a final class that uses the specifiers `override final` or `virtual final`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Specify Virtual Function in `final` Classes by Using `final`

```
#include <cstdint>
class Base
{
public:
    virtual ~Base() = default;
    virtual void F() noexcept = 0;
    virtual void G() noexcept {/*...*/}
    virtual void Y() noexcept {/*...*/}
};
class Derived final : public Base
{
public:

    void G() noexcept override{/*...*/} //Noncompliant
    virtual void Z() noexcept{/*...*/}  //Noncompliant
    virtual void H() noexcept = 0;    //Noncompliant
    void F() noexcept final{/*...*/}    //Compliant
    void Y() noexcept override final{/*...*/}    //Compliant
};
```

The functions `Derived::G()`, `Derived::Z()`, and `Derived::H()` are `virtual` functions that are not specified as `final`. Their declarations indicate that some functions in a derived class might override these functions. The class `Derived` is specified as `final`. That is, there are no derived classes from this class. The declarations of `Derived::G()`, `Derived::Z()`, and `Derived::H()` are inconsistent with the declaration of their class `Derived`. Polyspace flags the declarations of the functions. The functions `Derived::F()` and `Derived::Y()` are declared as `final`. These declaration comply with this rule.

#### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A10-3-5

A user-defined assignment operator shall not be virtual

## Description

### Rule Definition

*A user-defined assignment operator shall not be virtual.*

### Rationale

Defining an assignment operator as `virtual` in a base class indicates that you want to override it in the derived classes. Overriding the assignment operator in derived classes can lead to undefined behavior and run-time errors. Consider this code snippet where a virtual assignment operator is overridden in two derived classes.

```
class Base {public:
    virtual Base& operator=(Base const& oth) = 0;
    //...
};
class Derived public: Base{ public:
    Derived& operator=(Base const& oth) override{/*...*/}
    //...
};
class Derived2 public: Base{public:
    Derived2& operator=(Base const& oth) override{/*...*/}
    //...
};
main(){
    Derived d1;
       Derived2 d2;
    d1 = d2;
}
```

Because `Derived::operator=` and `Derived2::operator=` overrides `Base::operator=`, their parameter lists must be identical.

- `Derived::operator=` takes reference to a `Base` object as input and returns a reference to `Derived`.
- `Derived2::operator=` takes reference to a `Base` object as input and returns a reference to `Derived2`.

The `Derived::operator=` accepts references to both `Base` and `Derived` class objects because references to derived classes are type-compatible with their base classes. Similarly, the `Derived2::operator=` also accepts references to both `Base` and `Derived2` class objects. Assigning a `Derived` object to a `Derived2` object in `d1=d2` produces no compilation error. The objects `d1` and `d2` are unrelated. Assigning, copying, or moving operations between such unrelated objects are undefined and can lead to run-time errors.

To avoid undefined behavior and run-time errors, keep user-defined assignment operators as non-virtual. This rule applies to these operators:

- Assignment
- Copy and move assignment
- All compound assignment

**Polyspace Implementation**

Polyspace flags the declaration of any virtual assignment operators in a base class.

**Troubleshooting**

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Defining Assignment Operators as `virtual`

This example shows how Polyspace flags `virtual` assignment operators.

```
#include <cstdint>
class Base
{
  public:
    virtual Base& operator=(Base const& oth) = 0;   // Noncompliant
    virtual Base& operator+=(Base const& rhs) = 0; // Noncompliant
};
class Derived : public Base
{
  public:
    Derived& operator=(Base const& oth) override
    {
      return *this;
    }
    Derived& operator+=(Base const& oth) override
    {
      return *this;
    }
    Derived& operator-=(Derived const& oth) // Compliant
    {
      return *this;
    }
};
class Derived2 : public Base
{
  public:

    Derived2& operator=(Base const& oth) override
    {
      return *this;
    }
    Derived2& operator+=(Base const& oth) override
    {
      return *this;
    }
    Derived2& operator-=(Derived2 const& oth)   // Compliant
    {
      return *this;
    }
};
/*
*/
void Fn() noexcept
{
  Derived b;
  Derived2 c;
  b = c;
  b += c;
  c = b;
  c += b;
  // b -= c; // Compilation error
  // c -= b; // Compilation error

}
```

The classes `Derived` and `Derived2` are derived from `Base`. In the `Base` class, the assignment operators `Base::operator=` and `Base::operator+=` are declared as virtual. None of the following cause compilation errors:

- You can assign the `Derived` object `b` to `Derived2` object `c` and vice versa.
- You can add the `Derived` object `b` to `Derived2` object `c`. You can assign the result to either `b` or `c`.

Because `b` and `c` are unrelated objects, all of the preceding behaviors are undefined and can cause run-time errors. Declaring the `Base::operator=` and `Base::operator+=` as `virtual` eventually lead to the undefined behaviors. Polyspace flags these virtual assignment operators.

The declaration of `Base::operator-=` is non-virtual. Operations such as `b-=c` and `c-=b` cause compilation errors.

# AUTOSAR C++14 Rule A10-4-1

Hierarchies should be based on interface classes

## Description

### Rule Definition

*Hierarchies should be based on interface classes.*

### Rationale

An interface class has these properties:

- If the class has member functions, they are public and pure `virtual`.
- If the class has data members, they are public and `static constexpr`.

Using an interface class as a base class in a hierarchy:

- Separates the interface and implementation. The code of the base class is more stable and easier to maintain.
- Avoids unnecessary computations of nonstatic data members in the derived classes and other compilation dependencies.
- Makes your software easier to extend and enables the use of alternative implementations through the same interface.

### Polyspace Implementation

Polyspace flags the base of a class hierarchy if that base class is not an interface.

When class definitions are nested in other classes, the checker follows these conventions:

- Non-interface base classes are flagged even if the hierarchy is nested inside another class. For example, in this code snippet, class `NestedBase` is flagged :

  ```
  class ClassWithNestedHierarchy
  {
      class NestedBase //Non-compliant, not an interface
      {
      public:
          int i;
      };

      class NestedDerived : public NestedBase
      {
      public:
          int j;
      };
  };
  ```
- Base classes with nested non-interface classes are not flagged. For example, in this code snippet, `NestedClass` is not an interface class but the outer class `InterfaceWithInnerClass` is not flagged when used as a base class:

```
   class InterfaceWithInnerClass
   {
   public:
       class NestedClass   //not an interface class
       {
       private:
           int i;
       };

       static constexpr NestedClass i{};
   };

   class DerivedBaseWithInnerClass : public InterfaceWithInnerClass
   {
   private:
       int i;
   };
```

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Interfaces as Base Classes in Hierarchies

```
class Interface
{
public:
    virtual ~Interface() = 0;
    virtual void SomeFunc() = 0;
};

class NotAnInterface //Non-compliant
{
public:
    void Implementation() {}

};

class IsDerived1 : public Interface
{

public:
    ~IsDerived1() {}

    void SomeFunc() final {}

};

class IsDerived2 : public NotAnInterface
{
public:
    IsDerived2() = default;
};

template <typename T>
class TmplInterface
{
public:
    virtual T func() noexcept = 0;

};
template<typename T>
class TmplNotInterface //Non-compliant
{
public:
    T func2();
};

template <typename T>
class TmplDerived: public TmplInterface<T>, TmplNotInterface<T>
{
public:
    T func() noexcept override { return t;}

    T t;
};

class TmplDerived<int> var;
```

In this example, the checker flags:

- The non-interface class `NotAnInterface`, which acts as a base for the class `IsDerived2`. The class `NotAnInterface` is not an interface class because it contains a nonvirtual member function.
- The template non-interface class `TmplNotInterface`, which acts as a base for the class `TmplDerived`. Note that `TmplDerived` also derives from the interface class `TmplInterface`, which is compliant with the rule.

# AUTOSAR C++14 Rule A11-0-1

A non-POD type should be defined as class

## Description

### Rule Definition

*A non-POD type should be defined as class.*

### Rationale

A POD (Plain Old Data) type can be exchanged with C code in its binary form, and can be safely copied by using the `std::memcpy` function. Scalar types, C-style structures and unions, and arrays of these types are all examples of POD types. However, the C++ language also allows you to create structures and unions that are non-POD types. Such structures and unions can provide custom-defined constructors, have nonstatic data members with private or protected access control, have an interface, and implement an invariant.

A software developer typically expects object-oriented concepts such as encapsulation to be implemented by using classes. In addition, a class specifier forces the type to provide private access control for all its members by default and is naturally suited for implementing encapsulated types. So, to create easily readable and maintainable code, define a non-POD type as a class instead of a structure or a union.

### Polyspace Implementation

The checker flags a structure or a union in your code is not a POD type. This includes structures and unions that are instantiated by using templates.

For a simplified explanation of a POD type in C++ language, see the previous section. For a full specification of a POD type, see the C++ reference manual.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Define a Non-POD Type as a Class

```
#include <cstdint>
#include <limits>

class A // Compliant, non-POD type defined as class
{
    std::int32_t x; // Data member is private by default

  public:
    static constexpr std::int32_t maxValue = std::numeric_limits<std::int32_t>::max();
    A() : x(maxValue) {}
    explicit A(std::int32_t number) : x(number) {}
    std::int32_t GetX() const noexcept
    {
      return x;
    }

    void SetX(std::int32_t number) noexcept
    {
      x = number;
    }
};

struct B // Noncompliant, non-POD type defined as struct
{
  private:
    std::int32_t x;  // Must provide private access specifier for x member

  public:
    static constexpr std::int32_t maxValue = std::numeric_limits<std::int32_t>::max();
    B() : x(maxValue) {}
    explicit B(std::int32_t number) : x(number) {}

    std::int32_t GetX() const noexcept
    {
      return x;
    }

    void SetX(std::int32_t number) noexcept
    {
      x = number;
    }
};
```

Both `class A` and `struct B` implement the same non-POD type. This type has:

- A nonstatic data member `x` that has private access control.
- Two user-defined constructors. The default constructor initializes `x` to the maximum value that an `int32` type can store. The constructor that has one parameter disallows implicit conversion.
- An interface provided by the `GetX` and the `SetX` methods to access and modify the state of an object.

It is preferable that you implement this type, that encapsulates its contents, as a class.

The definition of `class A` complies with this coding rule. The definition of `struct B` violates this coding rule.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A11-0-2

A type defined as struct shall: (1) provide only public data members, (2) not provide any special member functions or methods, (3) not be a base of another struct or class, (4) not inherit from another struct or class

## Description

### Rule Definition

*A type defined as struct shall: (1) provide only public data members, (2) not provide any special member functions or methods, (3) not be a base of another struct or class, (4) not inherit from another struct or class.*

### Rationale

The items prohibited by this rule are not supported for `struct` types in C code. In C++, a `struct` type can have private data members, member functions, be inherited and inherit from other `struct`-s or `class`-es. However, a developer typically associates these features with a `class` type. Adhering to this rule makes sure that you use only classes to implement object oriented concepts such as data encapsulation and inheritance.

Adhering to this rule also makes sure that your `struct` types conform to the rules of Plain Old Data (POD) types and can be exchanged with C code.

### Polyspace Implementation

The checker flags `struct` types with one or more of these features:

- Contains private or protected data members.

  `struct` members are public by default.
- Contains member functions.
- Acts as base class for another `struct` or `class`, or inherits from another `struct` or `class`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Struct Types with Class-Like Features

```
#include <cstdint>
#include <iostream>

struct loginCredentials1 { //Noncompliant: Private members
    int32_t username;
private:
    int32_t pwd;
};
```

```
struct loginCredentials2 {   //Noncompliant: Member functions
    int32_t username;
    int32_t pwd;
    void readFromFile(std::string fileName) {
        //Read members data from file
    }
};

struct loginCredentials3 {  //Noncompliant: Acts as base for another struct
    int32_t username;
    int32_t pwd;
};

struct adminLoginCredentials: loginCredentials3 { //Noncompliant: Inherits from another struct
    std::string permissions;
};
```

In this example, all `struct` types are noncompliant.

- `loginCredentials1` contains a private data member `pwd`.
- `loginCredentials2` contains a member function `readFromFile()`.
- `loginCredentials3` acts as a base for the struct `adminLoginCredentials`.
- `adminLoginCredentials` inherits from the struct `loginCredentials3`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A11-3-1

Friend declarations shall not be used

## Description

### Rule Definition

*Friend declarations shall not be used.*

### Rationale

You declare a function as friend of a class to access private members of the class outside the class scope.

```
class A
{
  int data;
  public:
    // operator+ can access private members of class A such as data
    friend A const operator+(A const& lhs, A const& rhs);
};
```

Friend functions and friend classes reduce data encapsulation. Private members of a class are no longer accessible only through the class methods.

Code with friend functions can be difficult to maintain. For instance, if class `myClass` has a friend class `anotherClass`, when you change a data member of `myClass`, you have to find all instances of its usage in member functions of `anotherClass`.

### Polyspace Implementation

The rule checker flags all uses of the `friend` keyword.

The checker follows specifications of AUTOSAR C++ 14 release 18-03 (March 2018). However, release 18-10 and later releases of AUTOSAR C++14 allows an exception for comparison operators such as `operator==`. If the rule checker flags the use of comparison operators, add a comment justifying the result. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `friend` Keyword

```
class myClass
{
    int data;
public:
    myClass& operator+=(myClass const& oth);
    friend myClass const operator+(myClass const& lhs, // Noncompliant: Use of friend keyword
                                   myClass const& rhs);

};
```

`operator+` is a friend function of class `myClass` and can access its private member, `data`. The presence of this friend function violates the rule.

# AUTOSAR C++14 Rule A12-0-1

If a class declares a copy or move operation, or a destructor, either via "=default", "=delete", or via a user-provided declaration, then all others of these five special member functions shall be declared as well

## Description

### Rule Definition

*If a class declares a copy or move operation, or a destructor, either via "=default", "=delete", or via a user-provided declaration, then all others of these five special member functions shall be declared as well.*

### Rationale

These special member functions are called for copy or move operations:

- Copy constructor
- Copy assignment operator
- Move constructor
- Move assignment operator
- Destructor

If you do not explicitly declare any of these functions, the compiler defines them implicitly. This implicit definition implements shallow copying of objects and can cause errors. If you need to explicitly declare any of the special member functions, you must declare all of them. For instance, suppose you want to copy an object that contains a raw pointer to a dynamically allocated memory. The implicit copy constructor shallow-copies the object, after which the original pointer and the copied pointer point to the same memory. If one of the objects is destroyed, the allocated memory is deallocated, leaving a dangling pointer in the other object. Accessing the dangling pointer can cause segmentation errors. Because all the special member functions are closely related, the implicit implementation of the other functions can lead to similar errors. To manage the life cycle of the dynamically allocated resource, explicitly declare all five of the special member functions (Rule of Five). Alternatively, you can use objects where memory management is correctly implemented in the implicit definition of the special member functions and explicitly declare none of them (Rule of Zero).

When you explicitly declare some but not all of the special member functions, the compiler can prevent the use of the undeclared special member functions. For example, if you explicitly declare only the copy constructor or destructor functions of a class, the compiler no longer defines the move constructor and move assignment operator implicitly. The class becomes a copy-only class, perhaps inadvertently. Conversely, if you explicitly declare only the move constructor and move assignment operator, the compiler disables the copy constructor and copy assignment operator by defining them as deleted. The class becomes a move-only class, which might not have been your intention. To avoid such unwanted effects, either follow the Rule of Five or follow the Rule of Zero.

The constructor of a class is not part of this rule.

### Polyspace Implementation

Polyspace flags classes that explicitly declare some but not all of the five special member functions. Note that the move constructor and move assignment operators were introduced in C++11. Polyspace does not make any exception for older codes.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Follow Either The Rule of Five or The Rule of Zero

This example demonstrates the Polyspace implementation of AUTOSAR rule A12-0-1.

```
// Class rendered copy-only, perhaps inadvertently
class A               // Noncompliant.
{
    public:
      ~A()
      {
        // ...
      }

    private:
      // Member data ...
};

//Class rendered move-only, perhaps inadvertently
class B          // Noncompliant
{
   public:
        B(B&&) = default;
        B& operator=(B&&) = default;
    private:
      // Member data ...

};
template<typename T>
class BaseT              // Compliant - rule of five.
{
  public:
    BaseT(BaseT const&) = delete;
    BaseT(BaseT&&) = delete;
    virtual ~BaseT() = default;
    BaseT& operator=(BaseT const&) = delete;
    BaseT& operator=(BaseT&&) = delete;
    protected:
    BaseT() = default;
};

template<typename T>
class SimpleT           // Compliant - rule of zero.
{
  public:
    SimpleT(T t): t_(t)
    {

    }

  private:
    T t_;
};

main()
{
    //..
}
```

The class `A` declares only its destructor, which makes this class copy-only because the compiler no longer defines the move constructor and move assignment operator. The class `B` declares the move constructor and the move assignment operator, which makes this class move-only because the compiler disables the copy constructors and copy assignment operators. It is not clear whether these effects are deliberate. Polyspace flags these declarations and indicates which special member functions are missing. The class `BaseT` is compliant with this rule because all five of the special member functions are declared. Similarly, `SimpleT` is compliant because it declares none of the special member functions and relies on their implicit definition.

# AUTOSAR C++14 Rule A12-0-2

Bitwise operations and operations that assume data representation in memory shall not be performed on objects

## Description

### Rule Definition

*Bitwise operations and operations that assume data representation in memory shall not be performed on objects.*

### Rationale

In C++, object representation in memory might include:

- Data members declared with different access privileges
- Bit-field data members
- Padding bytes between data members
- Padding bytes at the end of data members
- Pointers to the vtable to support virtual functions

The arrangement of these different parts of an object in memory is environment dependent. In addition, static data members or function members of an object are stored in a separate physical location in memory. When you perform bitwise operation on an object by assuming certain arrangement of data in memory, you might inadvertently assume incorrectly, and access bits are not part of the value representation of the object. Accessing these bits can lead to undefined behavior.

Consider this class that contains a virtual function:

```
class notPOD{
public:
    virtual void foo();
    int value;
protected:
    double dvalue;

};
//...
int main(){
    notPOD Obj;
    std::memset(&Obj, 57, 2); // attempts to set Obj::value to 57
}
```

When `Obj` is stored in a memory block, the block contains a pointer to the virtual table in addition to the variables `Obj::value` and `Obj::dvalue`. The size of this pointer or its location in memory can depend on the environment. In `main()`, `std::memset()` attempts to set the value of `Obj::value` by assuming that:

- `Obj::value` is the first block in the memory representation of `Obj`.
- `Obj::value` is represented by 2 bytes in the memory.

Because these assumptions are generally not correct, using `std::memset()` can lead to undefined behavior. For instance, if you inadvertently modify the pointer to virtual table, calling `foo()` can invoke an unexpected function.

The representation of class and structures in memory is environment-dependent and can contain additional bytes alongside the value representation. Relying on the data representation of an object to perform bitwise operations can result in modifying bits that are not part of the value representation, leading to undefined behavior. Avoid operations that assume a certain representation of an object in memory to access its bits. To perform operations on a class, use dedicated member functions, overloaded operators, or mutators.

### Polyspace Implementation

The C functions that access accesses memory bits includes `std::memset()`, `std::memcpy()`, `std::memmove()`, `std::strcpy()`, `std::memcmp()`, `std::strcmp()`. Polyspace flags a statement when:

- You use the C functions to initialize or copy initialize nontrivial objects
- You use the C functions to compare nonstandard layout objects
- You use the C functions on any objects that contain padding data

The statements containing the noncompliant operations are flagged and relevant class declarations are highlighted. For definitions of trivial and standard layout classes, see the C++ Standard, [class], paragraphs 6 and 7 respectively.

As an exception, Polyspace does not flag operations that use the C functions to access the memory bits of trivial and standard layout objects with no padding data. Although using bitwise operation on trivial and standard layout classes with no padding data complies with this rule, it is not a good practice. Instead, use dedicated member function, overloaded operators, or mutators.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Bitwise Operations on Objects

Consider this code that contains these classes:

- `TrivialClass` is a trivial class with padding data and an overloaded `operator|=`.
- `NonTrivialClass` is a nontrivial class with a virtual function and an overloaded `operator==`.

These classes are represented in different ways in the memory. This example shows how Polyspace flags bitwise operations that are performed on such objects.

```
#include <cstdint>
#include <cstring>
class TrivialClass
{
public:
    TrivialClass() = default;
    TrivialClass(uint8_t c, uint32_t i, int8_t d) :
```

```
    c(c), i(i), d(d) {}
    TrivialClass& operator |=(const TrivialClass& other)
    {
        uint32_t buf[4] {this->c|other.c,this->i|other.i,this->d|other.d};
        memcpy(this, buf, sizeof(uint32_t) * 3); //Noncompliant
        return *this;
    }

private:
    uint8_t c;
    uint32_t i;
    int8_t d;
};

class NonTrivialClass
{
public:
    NonTrivialClass() = default;
    NonTrivialClass(uint32_t a, uint32_t b, uint32_t c) :
    a(a), b(b), c(c){}
    bool operator==(const NonTrivialClass& rhs) const noexcept
    {
        return a==rhs.a && b==rhs.b && c==rhs.c;
    }
    virtual ~NonTrivialClass() {}
private:
    uint32_t a;
    uint32_t b;
    uint32_t c;
};

int main(void)
{
    TrivialClass A, A1{3,5,7};
    NonTrivialClass B, B1{10,11,12};
    std::memset(&A, 3, 1); //Noncompliant
    A |= A1;
    if (!std::memcmp(&A, &A1, sizeof(TrivialClass))) {} //Noncompliant
    std::memcpy(&B, &B1, sizeof(NonTrivialClass)); //Noncompliant
    if (B == B1){} //Compliant
    return 0;
}
```

- Polyspace flags the statement `std::memset(&A, 3, 1);` because in this statement, `std::memset()` modifies the individual bits in the memory representation of the trivial object `A` including padding data. Accessing padding data bits of an object is a violation of this rule even if the object is a trivial class object. For the same reason, Polyspace flags the statement in the definition of `TrivialClass::operator|=` containing `memcopy()`.
- Polyspace flags the statement `std::memcpy(&B, &B1, sizeof(NonTrivialClass));` because `std::memcpy()` accesses the individual bits in the memory representation of the nontrivial object `B` including the pointer to vtable. This pointer is not part of the value representation and accessing this pointer is a violation of this rule.
- Polyspace does not flag the statement `if(B==B1)` because `NonTrivialClass` has an overloaded `operator==` that can compare `B` and `B1` without accessing their individual bits.

# AUTOSAR C++14 Rule A12-1-1

Constructors shall explicitly initialize all virtual base classes, all direct non-virtual base classes and all non-static data members

## Description

### Rule Definition

*Constructors shall explicitly initialize all virtual base classes, all direct non-virtual base classes and all non-static data members.*

### Rationale

If a derived class does not explicitly initialize the constructors of its base class, then the compiler implicitly initializes the base class. An object of invalid state or an object with unintended initial values might be constructed, which risks unexpected code behavior during run time. Consider this diamond class hierarchy, where the base class `Parent` has multiple constructors.

```
class Parent{
    public:
    Parent(){/*...*/}
    Parent(int i){/*...*/}
};

class Child1: public virtual Parent{
    public:
    Child1(): Parent(2){/*...*/}
};

class Child2: public virtual Parent{
    public:
    Child2(): Parent(1){/*...*/}

};

class GrandChild: public Child1, public child2{
    public:
    GrandChild(){/*...*/}
}
```

When constructing a `GrandChild` object, it is unclear whether `Parent` is constructed by using `1` or `2` as the argument. Having `GrandChild` explicitly specify the constructor used to initialize the `Parent` resolves the ambiguity. To avoid invalid state and unintended initial values, directly call the necessary base class constructors in the derived class constructor initialization list.

### Polyspace Implementation

Polyspace flags the constructor of a derived class if its initialization list:

- Does not explicitly call the constructors of the virtual base classes.
- Does not explicitly call the constructors of the direct nonvirtual base classes.
- Does not explicitly initialize nonstatic data members.

If a nonstatic data member is initialized in at least one branch of a branching, looping, or exception handling statement, Polyspace considers the data member to be initialized.

Polyspace does not report a violation of this rule if you use delegating constructors.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Class Construction When Using Multiple Inheritance

```
#include <cstdint>

class A {
public:
    A() : a{1} {}
    virtual void abstractA() const = 0;
private:
    int a;
};

class B : public  A {
public:
    B() : b{1} {} //Noncompliant
    void abstractA() const override {}
private:
    int b;
};

class C {
public:
    C() : c{3} {}
private:
    int c;
};

class D : public B, public C {
public:
    D() : B(), C(), e{5} {} //Compliant
private:
    int e;
};

int main() {
    D dName;
    return 0;
}
```

In this example, Polyspace flags the class constructors that do not explicitly initialize the base classes and nonstatic data members. For instance:

- The B class constructor is noncompliant because it is missing an explicit initialization of its base class A. To resolve this issue, call the A class constructor in the B constructor initialization list.

- The D class constructor is compliant because it explicitly initializes both of its direct nonvirtual base classes through initialization list constructor calls.

### Class Construction When Using Multiple and Virtual Inheritance

```
#include <cstdint>
class A {
public:
    A() : a{1} {}
    virtual void abstractA() const = 0;
private:
    int a;
};

class B : public virtual A {
public:
    B() : A(), b{1} {} //Compliant
    void abstractA() const override {}
private:
    int b;

};

class C : public virtual A {
public:
    C() : c{3} {} //Noncompliant
    void abstractA() const override {}
private:
    int c;
};

class D : public B, public C {
public:

    D() : B(), C(), e{5} {} //Noncompliant
private:
    int e;
};

int main() {
    D dName;
    return 0;
}
```

In this example, Polyspace flags the class constructors that do not explicitly initialize the base classes and nonstatic data members. For instance:

- The B class constructor is compliant because it explicitly initializes its direct base class within its initialization list.
- The C class constructor is noncompliant because it does not explicitly call its direct base class A. To resolve this issue, call the A class constructor in the C constructor initialization list.

- The D class constructor is noncompliant because it does not explicitly call its virtual base class A. As a result of multiple and virtual inheritance, the most derived class must initialize the virtual base class. To resolve this issue, call the A class constructor in the D constructor initialization list.

### Class Construction by Using Delegating Constructor

In C++11 and later, if a class contains more than one constructors, the class design can be simplified by using delegating constructor. When you use delegating constructors, it is not necessary to initialize all data members and base classes in each constructor. In this example, Polyspace does not report violations of this rule when the constructor `Derived::Derived(int)` delegates its initialization duties to `Derived::Derived(int, int)`.

```
class Base {
public:
    Base() : a{1} {}

    virtual void abstractA() const = 0;

private:
    int a;
};
class Derived: public Base {
public:
    Derived(int a, int b): Base{}, z{a}, y{b} {}  //Compliant
    Derived(int a): Derived(a, 0) {}  //Compliant

private:
    int z;
    int y;
};
```

# AUTOSAR C++14 Rule A12-1-2

Both NSDMI and a non-static member initializer in a constructor shall not be used in the same type

## Description

### Rule Definition

*Both NSDMI and a non-static member initializer in a constructor shall not be used in the same type.*

### Rationale

You can initialize a non-static data member of a class in one of these ways:

- In the declaration of the member in the class body by using the non-static data member initializer (NSDMI)
- By using a non-static member initializer in a constructor

In a class, initializing a subset of the non-static data members by using the NSDMI and initializing the remaining non-static data members by using a constructor reduces code readability. This code pattern might cause confusion for the reader about which initial values for each data member are actually used. Using either the NSDMI or a constructor to initialize all non-static data members of the class avoids this potential confusion.

The move and copy constructors are exempt from this rule because these constructors have the special behavior of initializing the data members by using their existing values from other objects. These constructors are unlikely to cause the confusion for the reader.

### Polyspace Implementation

If you use the NSDMI to initialize a subset of the non-static data members of a class and a constructor to initialize the remaining non-static data members, the checker flags the constructor and the associated NSDMI initializations.

The checker does not flag the move and copy constructors that violate this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Using Both NSDMI and Constructor Initializer

```
#include <cstdint>
#include <utility>

class A
{
  public:
    A() : i1{0}, i2{0} // Compliant, i1 and i2 are initialized by the constructor only
    {
    }

  private:
    std::int32_t i1;
    std::int32_t i2;
};

class B
{
  private:
    std::int32_t i1{0};
    std::int32_t i2{0}; // Compliant, i1 and i2 are initialized by NSDMI only
};

class C
{
  public:
    C() : i2{0}   // Noncompliant, i1 is initialized by NSDMI, i2 is initialized by constructor
    {
    }

  private:
    std::int32_t i1{0};
    std::int32_t i2;
};

class D
{
    D(D const& oth) : i1{oth.i1}, i2{oth.i2} // Compliant by exception, copy constructor
    {
    }

    D(D&& oth): i1{std::move(oth.i1)}, i2{std::move(oth.i2)}
    // Compliant by exception, move constructor
    {
    }

  private:
    std::int32_t i1{0};
    std::int32_t i2{0};
};
```

In this code, only the constructor in class C does not comply with this coding rule because:

- The data member i1 is initialized by using the NSDMI.
- The data member i2 is initialized in the constructor.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A12-1-3

If all user-defined constructors of a class initialize data members with constant values that are the same across all constructors, then data members shall be initialized using NSDMI instead

## Description

### Rule Definition

*If all user-defined constructors of a class initialize data members with constant values that are the same across all constructors, then data members shall be initialized using NSDMI instead.*

### Rationale

You might be using user-defined class constructors to initialize the nonstatic data members of your class. When all user-defined constructors initialize nonstatic data members to the same value, using a user-defined constructor for initialization purposes is unnecessary. The best practice is to initialize the nonstatic data members directly in the class definition. Such in-class nonstatic data member initialization (NSDMI) enables you to use the error-free and efficient implicit constructor to obtain an instance of the class that has the data members initialized to a default values.

### Polyspace Implementation

Polyspace flags a nonstatic data member declaration if either of these conditions is true:

- The nonstatic data member is not initialized in-class and all user-defined constructors initialize the data member to the same value.
- The nonstatic data member is initialized in-class and at the same time, it is also initialized in user-defined constructors.

This checker does not apply to:

- Copy and move constructors
- Union definitions
- Arrays that are initialized in constructors
- Objects that are initialized field by field in constructors

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Initialize Nonstatic Data Members With Default Values

```
#include <cstdint>
#include <string>
class MessageBox1
{
```

```
public:
    MessageBox1() : LowerLeft(0), UpperRight(0.0F), msg()
    {
    }
    // ...

private:

    int LowerLeft;     // Noncompliant
    float UpperRight;  // Noncompliant
    std::string msg;    // Noncompliant
};

class MessageBox2
{
public:
    // ...

private:
    int LowerLeft = 0;     // Compliant
    float UpperRight = 0.0F;         // Compliant
    std::string msg = "";   // Compliant
};
class MessageBox3
{
public:
    MessageBox3() : LowerLeft(0), UpperRight(0.0F), msg()
    {
    }

private:
    int LowerLeft = 0;      // Noncompliant
    float UpperRight = 0.0F;          // Noncompliant
    std::string msg = "";    // Noncompliant
};
class MessageBox4
{
public:
    MessageBox4() : LowerLeft(0), UpperRight(0.0F), msg()
    {
    }
    // ...
    MessageBox4(int int_i): LowerLeft(int_i),UpperRight(0.1F), msg("str"){}
private:

    int LowerLeft;     // Compliant
    float UpperRight;            // Compliant - Initialized differently in two c'tor
    std::string msg = "";//Noncompliant -  Initialized differently in two c'tor
};
```

In this example, Polyspace flags nonstatic data member initializations that violate this rule. For instance:

- In class `MessageBox1`, the declarations of the data members are noncompliant because they are initialized by a user-defined constructor instead of by in-class initialization. The best practice is to declare such data members directly in-class and to use the default implicit constructors.

- In class `MessageBox2`, the declarations of the data members are compliant because they are initialized directly in-class and the class defines no user-defined constructor.
- In class `MessageBox3`, the declarations of the data members are noncompliant because they are initialized in-class while the constructor of the class also initialize the data members. The best practice is to declare the data members in class and omit a user defined constructor.
- In class `MessageBox4`:

  - The declaration of `AA::LowerLeft` and `AA::UpperLeft` are compliant because two different constructors initialize them to different values and they are not initialized in-class.
  - The declaration of `AA::msg` is noncompliant because two different constructors initialize it to different value and it is also initialized in-class.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A12-1-5

Common class initialization for non-constant members shall be done by a delegating constructor

## Description

### Rule Definition

*Common class initialization for non-constant members shall be done by a delegating constructor.*

### Rationale

C++ classes often have several constructors with different syntaxes. These initializers might have some initializations in common. For instance, in this code, both constructors of the class `Circle` initialize the nonconstant members `x`, `y` and `r`.

```
class Circle{
    int x;
    int y;
    int r;
    public:
    Circle(int x_in, int y_in, int r_in): x{x_in}, y{y_in},r{r_in}{
        //...
    }
    Circle( int x_in, int y_in): x{x_in}, y{y_in}, r{0}{
        //...
    }
    //...
};
```

It is expected that all constructors of a class have equivalent behavior. When these common tasks are performed repeatedly in multiple constructors, any inadvertent differences might lead to confusion and unexpected results. Performing the common tasks repeatedly can also be tedious.

To avoid unexpected results, delegate the initialization of nonconstant members to existing constructors whenever possible. Avoid repeating initializations in multiple constructors.

### Polyspace Implementation

Polyspace flags a class, union, or structure if any of their nonconstant members are initialized in multiple constructors. Polyspace does not flag:

- Copy or move constructors that do not use delegate constructors.
- Arrays that are initialized in multiple constructors.
- Objects that are initialized field by field in multiple constructors.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Repeating Initialization in Multiple Constructors

```
#include <cstdint>
#include <string>
#include<initializer_list>

class Circle // Noncompliant
{
public:
    Circle(std::int32_t xx, std::int32_t yy, std::int32_t rr):x{xx}, y{yy}, r{rr}
    {}

    Circle(std::int32_t xx, std::int32_t yy):Circle(xx,yy,0) //Delegated constructor
    {}

    Circle(std::int32_t xx):x(xx),y(1),r(1) // Could be delegated
    {}

    Circle():x(0),y(0),r(0)//Could be delegated
    {}

protected:
    std::int32_t x;
    std::int32_t y;
    std::int32_t r;
};
class Flag // Compliant
{
public:
    Flag(bool a):a(a)
    {}

    Flag():a(0)
    {}

protected:
    const bool a;
};

class Tuple    // Noncompliant
{
public:
    Tuple(std::initializer_list<float> ilist) {
        auto* p = ilist.begin();
        x = *p++;
        y = *p++;
        z = *p++;
    }
    Tuple(float _x, float _y, float _z) : x(_x), y(_y), z(_z) {}

    float x = 0, y = 0, z = 0;
};
```

This example shows compliant and noncompliant classes.

- The class `Circle` has four constructors. It delegates the common initializations in the second constructor, but repeats the initializations in the third and fourth constructors. This repetition might lead to unexpected results. Polyspace flags the class.
- The class `Flag` repeats the initialization of its member `a` in two constructors. Because `a` is a `const`, Polyspace does not flag the class.
- The class `Tuple` initializes its non`const` members repeatedly in two constructors. Polyspace flags the class.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A12-1-6

Derived classes that do not need further explicit initialization and require all the constructors from the base class shall use inheriting constructors

## Description

### Rule Definition

*Derived classes that do not need further explicit initialization and require all the constructors from the base class shall use inheriting constructors.*

### Rationale

If a derived class uses all the base class constructors and does not explicitly initialize any additional data member that is not in the base class, reimplementing these constructors in the derived class adds unnecessary lines of code. The reimplementation might not exactly match the constructors in the base class due to human error and might introduce bugs in your code. Moreover, every time you change the base class constructors, you must also update the derived class constructors. This increases the overhead of code maintenance.

In such situations, using inheriting constructors in the derived class solves these issues.

### Polyspace Implementation

Polyspace flags a class for violation of this rule if the class satisfies all of these conditions:

- The class derives from a single base class.
- The class uses all the base class constructors and reimplements them in the class definition.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Derived Class Reimplements the Constructors

```
#include <cstdint>

class A
{
  public:
    A(std::int32_t x, std::int32_t y) : x(x + 8), y(y) {}
    explicit A(std::int32_t x) : A(x, 0) {}

  private:
    std::int32_t x;
    std::int32_t y;
};

class B : public A    // Non-compliant
```

```
{
  public:
    B(std::int32_t x, std::int32_t y) : A(x, y) {}
    explicit B(std::int32_t x) : A(x) {}
};

class C : public A   // Compliant
{
  public:
    using A::A;
};
```

The reimplementation of `B(std::int32_t x, std::int32_t y)` and `explicit B(std::int32_t x)` violates the rule because they are identical to the base class constructors `A(std::int32_t x, std::int32_t y)` and `explicit A(std::int32_t x)`.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A12-4-1

Destructor of a base class shall be public virtual, public override or protected non-virtual

## Description

### Rule Definition

*Destructor of a base class shall be public virtual, public override or protected non-virtual.*

### Rationale

If a base class destructor is not public virtual or public override, the class cannot behave polymorphically for deletion of derived class objects.

If a pointer to a base class refers to a derived class object and you use the pointer to delete the object:

```
class Base {
  public:
    ~Base() {}
};

class Derived: public Base {
  public:
    ~Derived() {}
};
...
void func(Base* ptr) {
    //ptr might point to a Base or Derived object
    delete ptr;
}
```

only the base class destructor is called. Additional resources allocated in the derived class are not released and can cause a resource leak. See example below.

If you want to prevent calling the derived class destructor through a base class pointer, make your intent explicit by making the destructor protected. Otherwise, it might appear that the possibility of polymorphic deletion of derived class objects was not considered.

### Polyspace Implementation

The checker flags base classes with destructors that are not public virtual, public override or protected non-virtual.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Base Class Destructor Not Virtual

```
#include <new>

class Base {
  public:
    Base() {}
    ~Base() {} //Noncompliant
};

class Derived: public Base {
     int *arr;
  public:
     Derived() {
        arr = new int(5);
     }
    ~Derived() {
        delete arr;
     }
};

void main() {
    Base* basePtr = new Derived();
    delete basePtr;
}
```

In this example, the class `Base` has a non-virtual destructor. As a result, when the pointer `basePtr` is deleted, only the destructor of class `Base` is invoked. However, `basePtr` points to an object of class `Derived`. The deletion is not complete because the destructor of class `Derived` is not invoked. In particular, the data member `arr` in the derived object is not deleted.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A12-4-2

If a public destructor of a class is non-virtual, then the class should be declared final

## Description

### Rule Definition

*If a public destructor of a class is non-virtual, then the class should be declared final.*

### Rationale

In C++, when any object of a derived class is destroyed, first the destructor of its class is invoked, and then the destructors of the base classes are invoked. Class hierarchies can also be polymorphic. You can declare a base class pointer and assign a derived class object to it. To safely destroy objects belonging to a class hierarchy, declare the `public` class destructors as `virtual`. Consider this code where two base class pointers that point to derived objects are destroyed.

```
class Base{
public:
    virtual    ~Base();
    //..
};

class Derived : public Base{
public:
    ~Derived();
    //..
};
class Base2{
public:
    ~Base2();
    //..
};

class Derived2 : public Base2{
public:
    ~Derived2();
    //...
};
int main(){

    Base* ptr = new Derived;
    Base2* ptr2 = new Derived2;
    delete ptr;
    delete ptr2;
}
```

- The object `ptr` is a pointer of class `Base` that points to an object of class `Derived`. When `ptr` is deleted, the destructor of the derived class is called first, and then the destructor of the base class is called. Even though `ptr` is a base class object, the correct destructors are called to release all acquired resources because the `public` destructors in this class hierarchy are declared as `virtual`.

- When the pointer ptr2 is deleted, the destructor of only the base class is called because the public destructors in this class hierarchy are nonvirtual. This kind of incomplete destruction is undefined behavior, which can lead to memory leaks and unexpected termination of code execution.

To prevent undefined behavior, do not use classes with public nonvirtual destructors as base classes. Declare such classes as final to specify that these classes are not base classes and new classes cannot be derived from them.

### Polyspace Implementation

Polyspace flags a class declaration if both these statements are true:

- The public destructor of the class is not declared as virtual.
- The class is not declared final.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Declare a Class as final if Its Public Destructor Is Nonvirtual

This example shows how Polyspace flags base classes that have public nonvirtual destructors.

```
#include<cstdint>
class Base{    //Noncompliant
public:
    ~Base();
    //..
};

class Derived : public Base{  //Noncompliant
public:
    ~Derived();
    //..
};
class Base2 final{  //Compliant
public:
    ~Base2();
    //..
};

//class Derived2 : public Base2{ //Compilation error
//public:
//    ~Derived2();
//    //...
//};
int main(){

    Base* ptr = new Derived;
//    Base2* ptr2 = new Derived2;  //Compilation Error
    delete ptr;
    //    delete ptr2;
}
```

The classes `Base` and `Derived` have public nonvirtual destructors. In `main()`, when `ptr` is destroyed, only `~Base()` is called, resulting in partial destruction of the pointed-to object. This behavior is undefined behavior that can lead to memory leak and unexpected program termination. Polyspace flags the declaration of both `Base` and `Derived`.

The class `Base2` has a public nonvirtual destructor. `Base2` is compliant with this rule because it is declared as `final`. Deriving any class from `Base2` results in compilation failure. Consequently, you cannot declare a pointer of class `Base2` that points to an object of a derived class. Declaring classes with public nonvirtual destructors as `final` prevents undefined behaviors and can protect the code from memory leaks and unexpected program termination.

### Declare Nonvirtual Destructors as `protected`

This example shows that Polyspace allows nonvirtual destructors when they are declared `protected`.

```
#include<cstdint>
class Base{    //Compliant
protected:
    ~Base();
    //..
};

class Derived : public Base{  //Compliant
protected:
    ~Derived();
    //..
};

int main(){

    Base* ptr = new Derived;
    delete ptr;//Compilation error
}
```

Nonvirtual destructors declared as `protected` are compliant with this rule. Because the destructor for `Base` is protected, the statement `delete ptr;` causes a compilation failure. Declaring nonvirtual destructors as `protected` can prevent memory leaks and unexpected program termination. When nonfinal classes have nonvirtual destructors declared as `protected`, the classes comply with this rule and Polyspace does not flag them.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A12-6-1

All class data members that are initialized by the constructor shall be initialized using member initializers

## Description

### Rule Definition

*All class data members that are initialized by the constructor shall be initialized using member initializers.*

### Rationale

It is inefficient to initialize data members of a class by assigning a copy of passed values to them in the body of a constructor. For instance, this code is inefficient:

```
class foo{

private:
    int i;
public:
    foo(int input){
        i = input;
        //...
    }
};
```

It is more efficient to initialize data members of classes by using member initializers. For instance:

- Initialize data members by using a initializer list.
- Initialize data members by using default member initializers.

To increase the efficiency of your code and to protect your code from using an uninitialized data member, use the preceding methods to initialize data members of a class.

### Polyspace Implementation

Polyspace flags the constructor definition of a class if the constructor initializes the nonstatic data members of the class in its body by copying the passed values to the data members. Polyspace does not flag constructors with uninitialized static data members.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Efficient Initialization of Class Data Members

This example shows efficient initialization methods of class data members that are compliant with this rule.

```
#include <cstdint>
#include <string>
using namespace std;
class A
{
public:
    A(int32_t n, string s) : number{n}, str{s}
    { //Compliant
        n += 1; // This does not violate the rule
        str.erase(str.begin(),
        str.begin() + 1); // This does not violate the rule
        // Implementation
    }

private:
    int32_t number;
    string str;
};

class C
{
public:
    C(int32_t n, string s)
    { //Compliant
        n += 1; // This does not violate the rule
        str.erase(str.begin(),
        str.begin() + 1); // This does not violate the rule
    }
    // Implementation

private:

    int32_t number = 0;
    string str = "string";
    static double pi;
};
```

- The constructor of class A initializes the data members by using an initializer list. This constructor is compliant with this rule.
- The constructor of class C initializes the data members by using default initialization. These data members cannot be used before they are initialized. This constructor is compliant with this rule. Polyspace does not flag constructors that do not initialize static data members.

### Inefficient Initialization of Class Data Members

This example shows inefficient initialization of class data members that is not compliant with this rule.

```
#include <cstdint>
#include <string>
using namespace std;
class B
{
public:
    B(int32_t n, string s)
    { //Noncompliant
        number = n;
        str = s;
    }
    // Implementation

private:
    int32_t number;
    string str;
};
class E{
public:
    E():E(1,"string")
    {

    }
    E(int32_t a, string str) : number(a)
    {//Noncompliant

    }
private:
    int32_t number;
    string str;
};
```

- The constructor of class B initializes the data members by copying the passed parameters. This initialization is inefficient. The data members of class B might be used before they are initialized. Polyspace flags this inefficient and risky constructor.
- The default constructor of class E attempts to initialize the nonstatic data members by delegating the initialization to another constructor. The second constructor does not initialize the nonstatic data members by using member initializers. Polyspace flags the second constructor.

# AUTOSAR C++14 Rule A12-7-1

If the behavior of a user-defined special member function is identical to implicitly defined special member function, then it shall be defined "=default" or be left undefined

## Description

### Rule Definition

*If the behavior of a user-defined special member function is identical to implicitly defined special member function, then it shall be defined "=default" or be left undefined.*

### Rationale

Compilers implicitly define special member functions if these functions are declared as `=default` or left undefined. These implicitly defined functions are consistent, error-free, and do not require maintenance. If the implicitly defined special member functions are sufficient, then replacing them with user-defined functions makes the code error-prone and harder to maintain. Unless a class manages resources like a raw pointer or a POSIX file descriptor, the implicit definition of the special member functions might be sufficient. Avoid defining the special member functions when the implicit definitions are sufficient.

Default construction of `const` objects might cause a compilation failure if the nonstatic data members are not initialized during definition. The best practice is to initialize nonstatic data members in the class definition. Alternatively, initialize the `const` instance by using an empty initializer list. These practices enable the default constructor to correctly construct `const` instances of a class.

### Polyspace Implementation

Polyspace raises the checker if the user-defined special member functions of your class are the same as the implicitly defined special member functions. The implicit special member functions typically have these properties:

- The implicit default constructor have an empty body, an empty parameter list, and an empty initializer list.
- The implicit destructors have an empty body.
- The implicit copy/move constructor and assignment operators copy/move the base classes and nonstatic data members by using an initializer list. These functions does not perform any deep copy and does not move the data associated with a raw pointer.

For details about how implicitly defined special member function behave, see:

- Default constructor
- Destructor
- Copy constructor
- Copy Assignment operator
- Move constructor
- Move assignment operator

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Define Special Member Functions Only When Managing Resources

```
#include <cstdint>
#include <utility>
class A
{
public:
    A() : x(0), y(0) {}                                 // Compliant
    A(std::int32_t first, std::int32_t second)          // Compliant
    : x(first), y(second) {}
    A(const A& oth) : x(oth.x),y(oth.y){}               // Noncompliant
    A(A&& oth): x(std::move(oth.x)),y(std::move(oth.y)){} // Noncompliant
    ~A(){}                                              // Noncompliant

private:
    std::int32_t x;
    std::int32_t y;
};
class B
{
public:
    B() {}  // Noncompliant
    B(std::int32_t first, std::int32_t second)// Compliant
    : x(first), y(second)
    {}
    B(const B&) = default; // Compliant
    B(B&&) = default;     // Compliant
    ~B() = default;       // Compliant

private:
    std::int32_t x;
    std::int32_t y;
};
class D
{
public:
    D() : ptr(nullptr) {}  // Compliant - Managing a raw pointer
    D(B* p) : ptr(p) {}    // Compliant - Managing a raw pointer
    D(const D&) = default; // Requires user defined copy constructor
    D(D&&) = default;      // Requires user defined move constructor
    ~D() = default;        // Requires user defined destructor

private:
    B* ptr;
};
class E      // Compliant
{
};
```

In this example, the classes A, B, and D are defined.

- For the class A:
  - The user defined default constructor has a nonempty initializer list. Because this definition is different than an implicit default constructor, Polyspace does not report a violation.
  - Because this rule does not apply to nondefault constructors, Polyspace does not report a violation.
  - Because the user-defined copy and move constructors of A do not manage any resources and they can be defined as =default or left undefined, Polyspace reports violations on these functions.
- For the class B:
  - The default constructor of B is user-defined even though it does not manage any resources. Because this user-defined constructor can be defined as =default or left undefined, Polyspace reports a violation on it.
  - Because the other constructors of B are defined as =default, they are compliant..
- The class D contains a raw pointer to the class B. For the class D:
  - Because the user-defined constructor explicitly initializes the raw pointer ptr to nullptr, it is different than an implicit constructor. Polyspace does not report a violation.
  - Because the other special member functions are declared as =default, these functions do not violate this rule.

  When managing resources such as a raw pointer, the implicitly defined special member functions are typically incorrect. For instance, the implicit copy constructor of D performs a shallow copy of ptr, without duplicating the underlying resources. When managing raw pointers, the best practice is to define all the special member functions appropriately to avoid unexpected behavior.

### Initialize Nonstatic Data Members to Default Construct const Instances

```
class B_NC{
    public:
    //B_NC()=default;// Compile fail
    B_NC(){}         //Noncompliant
    int x;
};
class B_C{
    public:
    B_C() = default;//Compliant
    int x = 0;
};
const B_NC a;
const B_C b;
```

In this example, classes B_NC and B_C are defined and const instances of these classes are constructed. According to the C++ standard, a const object can be constructed by the implicit default constructor only if all the members of the object is const-default-constructible. The variable B_NC::x cannot be const-default-constructed. If you declare the constructor as =default, constructing a const instance of B_NC results in a compilation failure. To resolve the compilation failure, you might want to provide a user-defined constructor that is identical to the implicit constructor, such as the constructor B_NC::B_NC() in the preceding code. Though this code compiles, B_NC::B_NC() is noncompliant with this rule.

To resolve the compilation failure without violating this rule, initialize the nonstatic data members of the class in its definition, as shown in the definition of `B_C`. Because `B_C::x` can be const-default-constructed, a `const` instance of `B_C` can be constructed by the implicit default constructor. After initializing the nonstatic data members, set the constructor to `=default`.

# AUTOSAR C++14 Rule A12-8-1

Move and copy constructors shall move and respectively copy base classes and data members of a class, without any side effects

## Description

### Rule Definition

*Move and copy constructors shall move and respectively copy base classes and data members of a class, without any side effects.*

### Rationale

The expected behavior of move and copy constructors is:

- They move or copy the base classes and data members.
- The move constructor sets the source object into a valid state.

Authoring move or copy constructors that have additional side effects might cause these issues:

- Performance: Move and copy constructors are frequently called by standard template library (STL) algorithms and containers. Performance overhead in these constructors caused by side effects can accumulate and affect the performance of your code.
- Unexpected behavior: Because compilers might omit calls to copy constructors to optimize the code, the number of times a copy constructor might be invoked is indeterminate. As a result, the side effects of a copy constructor might produce unexpected behavior.

### Polyspace Implementation

In the body of a copy or move constructor, Polyspace does not flag these operations:

- Copy or move assignments.
- Relational or comparison operations.
- Modification of the source object in a move operation.
- Calls to the function `std::swap` or equivalent user-defined `noexceot` swap functions. Polyspace identifies functions that these signatures as swap functions: `void T::swap(T&)` or `void [N::]swap(T&, T&)`. The first signature represents a member function of class `T` that takes one argument. The second signature represents a nonmember or static function in the namespace `N` that takes two arguments. The name `swap` can be case-insensitive and prefixed or postfixed by underscores.
- Assignment and modification of `static` variables.

Polyspace flags any other operations in a copy or move constructor as unwanted side effect. For instance, a call to a user-defined swap function is considered an unwanted side effect if the swap function is not `noexcept`. For a similar rule on copy and move assignment operator, see `AUTOSAR C++14 Rule A6-2-1`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Side Effects in Copy and Move Constructors

This code shows how Polyspace flags move and copy constructors that have side effects.

```
#include<cstdint>
#include <utility>
#include<iostream>
class B
{
public:
    // Implementation
    B(B&& oth) : ptr(std::move(oth.ptr)) // Noncompliant
    {
        oth.ptr = nullptr; // Does not have a side effect
        std::cout<<"Moved"; //Has a side effect
    }
    ~B()
    {
        delete ptr;
    }

private:
    std::int32_t* ptr;
};
class C
{
public:
    C(int t=0) : x(t) {}
    C(const C& oth): x(oth.x)  // Noncompliant
    {
        //...
        x = oth.x % 2;  // Has a side effect
        count++; //Not a side effect
    }

private:
    std::int32_t x;
    static std::int32_t count;
};
class D
{
public:

    D(const D& oth): x(oth.x)  // Noncompliant
    {
        D tmp(oth);
        _swap_(tmp);
    }
    void _swap_(D& rhs){ //Might raise exceptions
        //...
    }
private:
    std::int32_t x;
    static std::int32_t count;
};
```

- As a side effect, the move constructor of class B prints a string into the output stream. This side effect adds performance overhead to the move operation. Polyspace flags the move assignment operator and highlights the statement. Setting the moved-from object `oth.ptr` to `nullptr` is not a side effect.
- The copy constructor of the class C modifies the data member `x` of the source object. This side effect adds performance overhead. Unexpected change to data members during move and copy operations can make the code incompatible with the standard template library and introduce errors during development. Polyspace flags the copy assignment operator and highlights the statement `x = oth.x % 2`. Incrementing the static variable `count` is not a side effect.
- The copy constructor of the class `D` calls a user-defined swap function called `_swap_`. This swap function is not `noexcept`. If an exception is raised from `_swap_`, the exception is an unexpected side effect of the copy constructor. Polyspace flags the copy constructor as noncompliant with this rule. Use user-defined swap functions that are `noexcept`.

# AUTOSAR C++14 Rule A12-8-2

User-defined copy and move assignment operators should use user-defined no-throw swap function

## Description

### Rule Definition

*User-defined copy and move assignment operators should use user-defined no-throw swap function.*

### Rationale

A naive copy or move assignment operator that is implemented without using a swap function might follow the pattern in this code:

```
class A{
    //...
    A & operator=(const A & rhs)
    {
        if (this != &rhs) // check for self assignment
        {
            // release resource in lhs

            // Allocate resource for modified lhs

            // Copy or move the resources from rhs to lhs

        }

        return *this;
    }
private:
    //resources
    int* mArray;
};
```

Such naive implementation of the copy or move assignment operator cannot provide strong exception safety because if any of the operations raises an exception, the left operand cannot be reverted back to its original state. The preceding pattern is also inefficient because it requires a check for self-assignment. Code duplication between such a copy or move assignment operator and a copy or move constructor makes the code difficult to maintain.

To resolve these issues, utilize user-defined `swap` functions that do not raise exceptions. Consider this pattern:

```
class A{
    //...
    A & operator=(A rhs)
    {
        Swap(*this,rhs);
    }
    friend void Swap(A& lhs, A& rhs) noexcept{
        //...
    }
private:
    //resources
    int* mArray;

};
```

This implementation of the copy or move assignment operator does not attempt allocation or deallocation of memory. Instead, It swaps the resources between the left and right operands by calling a user-defined `noexcept` function `Swap`. This `Swap` function might be implemented by utilizing the `std::swap` function. The benefits of this pattern are:

- Strong exception safety: This implementation of the copy or move assignment operator takes a temporary copy of the right operand by using the copy or move constructor and swaps the temporary copy with the left operand. Because the move and swap functions must be `noexcept`, only the copy operation might raise an exception. If this operator raises an exception, only the temporary copy of the right operand might be invalidated. The state of the right or the left operand remains untouched.
- Code reuse: In this implementation, the copy or move assignment operator reuses the copy or move constructor. The class-specific `swap` function can also be reused for implementing other algorithms.
- Efficiency: By eliminating the check against self-assignment, the operator is more efficient.

To implement a copy or move assignment operator, use user-defined `noexcet` swap functions.

### Polyspace Implementation

Polyspace flags a copy or move assignment operator if it does not contain at least one call to a user-defined swap function. Polyspace identifies functions that have these signatures as swap functions: `void T::swap(T&)` or `void [N::]swap(T&, T&)`. The first signature represents a member function of class `T` that takes one argument. The second signature represents a nonmember or static function in the namespace `N` that takes two arguments. The name `swap` can be case-insensitive and prefixed or postfixed by underscores.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Naive Implementation of Copy and Move Assignment Operators

```
#include <utility>
#include <string>
class B
{
  public:
    B& operator=(const B& oth) & { // Noncompliant
      if (this != &oth)
      {
        ptr1 = new std::int32_t(*oth.ptr1);
        ptr2 = new std::int32_t(
          *oth.ptr2); // Exception thrown here results in
        // a memory leak of ptr1
      }
      return *this;
    }
    B& operator=(B&& oth) & noexcept { // Noncompliant
      if (this != &oth)
      {
        ptr1 = std::move(oth.ptr1);
        ptr2 = std::move(oth.ptr2);
        oth.ptr1 = nullptr;
        oth.ptr2 = nullptr;
      }

      return *this;
    }
private:
    std::int32_t* ptr1;
    std::int32_t* ptr2;
};
```

In this example, the copy and move assignment operator for class B uses a naive implementation instead of a copy-and-swap implementation. The copy and move operator of B is inefficient and does not provide strong exception safety. Polyspace flags these operators as noncompliant.

#### Avoid Using Generic std::swap

```
#include <utility>
#include <string>
class C
{
  public:
    C(const C&) = default;
    C(C&&) = default;

    C& operator=(const C& oth) & {     //Noncompliant
      C tmp(oth);
      std::swap(ptr1, tmp.ptr1);
      return *this;
    }
    C& operator=(C&& oth) & {          // Noncompliant
      C tmp(std::move(oth));
      std::swap(ptr1, tmp.ptr1);
      return *this;
    }

  private:
    std::int32_t* ptr1;
};
```

In this example, the copy and move assignment operator for class C uses a copy-and-swap implementation, but uses the standard std::swap function instead of a class-specific, user-defined swap function. Because class C requires user-defined copy and move operator, it also require a user-defined swap function. Polyspace flags the operators as noncompliant.

#### Avoid swap Functions That Might Raise Exceptions

```
#include <utility>
#include <string>
```

```
class D
{
  public:
    D(const D&) = default;
    D(D&&) = default;
    D& operator=(const D& oth) & {     // Noncompliant
      D tmp(oth);
      _swap_(*this,tmp);
      return *this;
    }
    D& operator=(D&& oth) & {          // Noncompliant
      D tmp(std::move(oth));
      _swap_(*this,tmp);
      return *this;
    }
    //...
    friend void _swap_(D& lhs, D& rhs){ // swap function not noexcept
    //...
    }
};
```

In this example, the copy and move assignment operator for class `D` uses a `swap` function that is not `noexcept`. These operators do not provide strong exception safety. Polyspace flags them as noncompliant.

#### Avoid swap Functions With Unexpected Signature

```
#include <utility>
#include <string>

class E
{
  public:
    E(const E&) = default;
    E(E&&) = default;

    E& operator=(const E& oth) & {     // Noncompliant
      E tmp(oth);
      swap(*this,tmp);
      return *this;
    }
    E& operator=(E&& oth) & {          // Noncompliant
      E tmp(std::move(oth));
      swap(*this,tmp);
      return *this;
    }

    // Member function swap
    void swap(E& lhs, E& rhs) noexcept {
      std::swap(lhs.ptr1, rhs.ptr1);
      std::swap(lhs.ptr2, rhs.ptr2);
    }

  private:
    std::int32_t* ptr1;
    std::int32_t* ptr2;
};
```

In this example, the copy and move assignment operator for class `E` uses a `swap` function that takes two arguments. Because the swap function is defined as a nonstatic member function of `E`, Polyspace expects the `E::swap` function to have only one argument. Polyspace flags the copy and move operators of `E` because the swap function has an unexpected signature.

# AUTOSAR C++14 Rule A12-8-3

Moved-from object shall not be read-accessed

## Description

### Rule Definition

*Moved-from object shall not be read-accessed.*

### Rationale

Because the content of a source object is generally unspecified after a move operation, it is unsafe to perform operations that access the contents of the source object after a move operation. Accessing the contents of the source object after a move operation might result in a data integrity violation, an unexpected value, or an illegal dereferencing of a pointer.

Operations that make no assumptions about the state of an object do not violate this rule.

The C++ standard specifies that these move operations leave the source object in a well-specified state after the move:

- Move construction, move assignment, converting[22] move construction, and converting move assignment of `std::unique_ptr` type
- Move construction, move assignment, converting move construction, converting move assignment of `std::shared_ptr` type
- Move construction and move assignment from a `std::unique_ptr` of `std::shared_ptr` type
- Move construction, move assignment, converting move construction, and converting move assignment of `std::weak_ptr` type
- `std::move()` of `std::basic_ios` type
- Move constructor and move assignment of `std::basic_filebuf` type
- Move constructor and move assignment of `std::thread` type
- Move constructor and move assignment of `std: unique_lock` type
- Move constructor and move assignment of `std::shared_lock` type
- Move constructor and move assignment of `std::promise` type
- Move constructor and move assignment of `std::future` type
- Move construction, move assignment, converting move construction, and converting move assignment of `std::shared_future` type
- Move constructor and move assignment of `std::packaged_task` type

Because these move operations leave the source object in a well-specified state, accessing the source object after calling these functions is compliant with this rule.

[22] A converting constructor is a constructor that is not declared with the specifier `explicit`. See Converting constructor.

### Polyspace Implementation

Polyspace raises a flag if the source object is read after its contents are moved to a destination object by calling the `std::move` function explicitly. Polyspace does not flag accessing a source object if:

- The source object of an explicit move operation is of these types:
  - `std::unique_ptr`
  - `std::shared_ptr`
  - `std::weak_ptr`
  - `std::basic_ios`
  - `std::basic_filebuf`
  - `std::thread`
  - `std::unique_lock`
  - `std::shared_lock`
  - `std::promise`
  - `std::future`
  - `std::shared_future`
  - `std::packaged_task`
- The move operation is performed implicitly. For instance, the function `std::remove` might access the source object after an implicit move operation. Polyspace does not flag it. A best practice is to avoid such operations and use safer alternatives that prevent accidental access, such as `std::erase`.
- The source object is of a built-in base type, such as: `int`, `enum`, `float`, `double`, pointer, `std::intptr_t`, `std::nullptr_t`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Reading Source Object After Calling `std::move`

This example shows how Polyspace flags reading the source object after an explicit move operation.

```
#include<string>
#include<iostream>
void F1()
{
    std::string s1{"string"};
    std::string s2{std::move(s1)};
    // ...
    std::cout
    <<  // Noncompliant
    s1
    << "\n";
}
```

```
void F2()
{
    std::unique_ptr<std::int32_t> ptr1 = std::make_unique<std::int32_t>(0);
    std::unique_ptr<std::int32_t> ptr2{std::move(ptr1)};
    std::cout << ptr1.get() << std::endl; // Compliant by exception
}
void g(std::string v)
{
    std::cout << v << std::endl;
}

void F3()
{
    std::string s;
    for (unsigned i = 0; i < 10; ++i) {
        s.append(1, static_cast<char>('0' + i));  //Noncompliant
        g(std::move(s));
    }
}
void F4()
{
    for (unsigned i = 0; i < 10; ++i) {
        std::string s(1, static_cast<char>('0' + i)); // Compliant
        g(std::move(s));
    }
}
```

- In the function `F1`, string `s1` is explicitly moved to `s2` by calling `std::move`. After the move operation, the function attempts to read `s1`. Polyspace flags this attempt of reading a source object after an explicit move.
- In the function `F2`, the unique pointer `ptr1` is explicitly moved to `ptr2`. Because the `std::unique_ptr` remains in a specified state after the move, reading a source unique pointer after an explicit move is compliant with this rule.
- In the function `F3`, the string `s` is explicitly moved, and then it is read by the `std::string::append` function. Polyspace flags this attempt of reading a source object after an explicit move.
- In the function `F4`, the string `s` is explicitly moved. In each iteration of the loop, `s` is initiated to specific content before the move operation is triggered. As a result, the state of `s` is specified before the object is accessed. This method of accessing the source object after a move operation is compliant with this rule.

# AUTOSAR C++14 Rule A12-8-4

Move constructor shall not initialize its class members and base classes using copy semantics

## Description

### Rule Definition

*Move constructor shall not initialize its class members and base classes using copy semantics.*

### Rationale

In C++, move operations transfer the ownership of resources rather than duplicating the resources themselves from a source object to a target object. Because move constructors do not duplicate resources, these constructors are faster than copy constructors. Consider this code where the object `CopyTarget` is copy-constructed and the object `MoveTarget` is move-constructed from the object `Source`.

```
class BigData{
    //...
    BigData(BigData&&){  //Move Constructor
        //...
    } copy constructed
    BigData(const BigData&){  //Copy Constructor
        //...
    }
private:
    std::map<int, std::string> BigBook;
};

int main(){
    BigData Source;
    BigData CopyTarget = Source;
    BigData Movetarget = std::move(Source);
    //...
}
```

When copy-constructing `CopyTarget`, the compiler duplicates the resource `Source::BigBook` from `Source` to `CopyTarget`. After the copy-construction, both of these objects have a copy of the resource `BigBook`. When move-constructing `Movetarget`, the compiler transfers the ownership of the resource `Source::BigBook` to `MoveTarget`. Because move-construction does not duplicate the resource physically, it is faster than copy-construction.

Move-construction is an optimization strategy. You expect that move-construction is cheaper and faster than copy-construction. Copy-initializing data members and base classes can make a move constructor slow and inefficient, which reduces program performance. Developers expect that move-construction uses move semantics only. Unexpectedly using copy semantics in move constructors might introduce resource leaks and inconsistency in future development. When authoring move constructors, initialize data members and base classes by using move semantics. You can copy-initialize scalar data members without violating this rule.

You might use `std::move()` to implement move semantics in your code. When you use `std::move()` to move objects, declare the objects or data members without the qualifier `const`. For more information, see `AUTOSAR C++14 Rule A18-9-3`.

### Polyspace Implementation

When a move constructor does not use move semantics to initialize nonscalar data members and base classes, Polyspace flags its declaration. For instance, if a move constructor initializes the base class by using the default constructor instead of the move constructor, Polyspace flags the declaration of the move constructor.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Move-Initialize Nonscalar Data Members and Base Classes in Move Constructors

This example shows how Polyspace flags move constructors that uses copy-initialization and default construction.

```
#include<cstdint>
#include<string>
#include<map>
#include <vector>
class BigData{
public:
    BigData()=default;
    //...
    BigData(BigData&& oth): //Compliant
    BigBook(std::move(oth.BigBook)),
    Length(oth.Length)
    {
        //...
    }

private:
    std::map<int, std::string> BigBook;
    int Length;
};

class slowBigData{
    //...
    slowBigData(slowBigData&& oth): //Noncompliant
    BigBook(oth.BigBook),
    Length(oth.Length)
    {
        //...
    }

private:
    std::map<int, std::string> BigBook;
    int Length;
};

class BigData2: public BigData{
    //...
    BigData2(BigData2&& oth):BigData() //Noncompliant
    {
        BigVector = std::move(oth.BigVector);
        //...
    }

private:
    std::map<int, std::string> BigBook;
    std::vector<int> BigVector;
    int Length;
};

class BigData3: public BigData{
    //...
    BigData3(BigData3&& oth):BigData(std::move(oth)) //Compliant

    {
        str = std::move(oth.str);
        //...
    }

private:
    std::map<int, std::string> BigBook;
    int Length;
    std::string str;
};
```

- The move constructor of the class `BigData` initializes the data member `BigBook` by using move semantics. The move constructor initializes the scalar member `Length` by using copy semantics. This move constructor is compliant because copying scalar data members does not violate this rule.
- The move constructor of the class `slowBigdata` initializes the data members by using copy semantics. This move constructor violates the rule and Polyspace flags the declaration of the move constructor.
- The move constructor of the class `BigData2` invokes the default constructor of the base class, which might make the code slow and inefficient. Polyspace flags the declaration of this move constructor. The move constructor of the class `BigData3` invokes the move constructor of the base class. This move constructor is compliant with this rule.

# AUTOSAR C++14 Rule A12-8-5

A copy assignment and a move assignment operators shall handle self-assignment

## Description

### Rule Definition

*A copy assignment and a move assignment operators shall handle self-assignment.*

### Polyspace Implementation

Reports when copy assignment body does not begin with “`if (this != arg)`”

A violation is not raised if an empty `else` statement follows the `if`, or the body contains only a return statement.

A violation is raised when the `if` statement is followed by a statement other than the return statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A12-8-6

Copy and move constructors and copy assignment and move assignment operators shall be declared protected or defined "=delete" in base class

## Description

### Rule Definition

*Copy and move constructors and copy assignment and move assignment operators shall be declared protected or defined "=delete" in base class.*

### Rationale

Pointers to derived classes are type-compatible with pointers to base classes. A pointer can be an object of the base class while pointing to an object of the derived class. When such an object is copied, the base copy constructor is invoked and the copied object has only the base part of the original object. To avoid inadvertent slicing during copy and move, suppress these operations in the base class by:

- Declaring copy and move constructors and copy assignment and move assignment operators as `protected`.
- Defining copy and move constructors and copy assignment and move assignment operators as "`=delete`".

### Polyspace Implementation

Polyspace flags these special member functions of a base class when they are not declared `protected` or defined as `=delete`:

- Copy constructor
- Move constructor
- Copy assignment operator
- Move assignment operator

Polyspace indicates which special member function violates this rule.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Suppress Copy and Move Operations in Base Classes

```
#include <cstdint>
#include <memory>
#include <utility>
#include <vector>
class A
```

```
{
  public:
    int base_var;
    A() = default;
    A(A const&) = default;                //Noncompliant
    A(A&&) = default;                     //Noncompliant
    virtual ~A() = 0;
    A& operator=(A const&) = default;     //Noncompliant
    A& operator=(A&&) = default;          //Noncompliant
};
class B : public A
{
    int derived_var;
};
class C //
{
  public:
    int base_var;
    C() = default;
    virtual ~C() = 0;

  protected:
    C(C const&) = default;                //Compliant
    C(C&&) = default;                     //Compliant
    C& operator=(C const&) = default;     //Compliant
    C& operator=(C&&) = default;          //Compliant
};
class D : public C
{
    int derived_var;
};
class E
{
  public:
    int base_var;
    E() = default;
    virtual ~E() = default;
    E(E const&) = delete;                   //Compliant
    E(E&&) = delete;                        //Compliant
    E& operator=(E const&) = delete;        //Compliant
    E& operator=(E&&) = delete;             //Compliant
};

class F : public E
{
    int derived_var;
};
void Fn1() noexcept
{
  B obj1;
  B obj2;
  A* ptr1 = &obj1;
  A* ptr2 = &obj2;
  *ptr1 = *ptr2;             // Partial assignment only
  *ptr1 = std::move(*ptr2); // Partial move only
  D obj3;
  D obj4;
  C* ptr3 = &obj3;
  C* ptr4 = &obj4;
  // *ptr3 = *ptr4; // Compilation error
  // *ptr3 = std::move(*ptr4); // Compilation error
  F obj5;
  F obj6;
  E* ptr5 = &obj5;
  E* ptr6 = &obj6;
  // *ptr5 = *ptr6; // Compilation error
  // *ptr5 = std::move(*ptr6); // Compilation error
}
```

The Class A is a base class with default copy and move constructors and default copy and move assignment operators. The class B is derived from A and has a variable derived_var that is absent in A. In Fn1(), two pointers ptr1 and ptr2 are created. They are objects of the base class A, but point to obj1 and obj2 respectively, which are objects of the derived class B. The assignment A *ptr = &obj1; is an example of polymorphic behavior where you can declare a pointer of the base class and assign objects of any derived class to it.

Because ptr1 and ptr2 are objects of the base class A, the copy operation in *ptr1 = *ptr2 invokes the default copy assignment operator of class A. The default semantics copies only the base part of obj2 into obj1. That is, obj2.derived_var is not copied into obj1.derived_var. Similarly, the ownership of obj2.derived_var is not moved to obj1 by the move operation in *ptr1 = std::move(*ptr2). To avoid inadvertent slicing, suppress the copy and move operations in the base class of a class hierarchy. Polyspace flags the copy and move functions in base class A because these functions are neither declared as protected nor defined as =delete.

In class C, the copy and move functions are suppressed by declaring the copy and move constructors and copy assignment and move assignment operators protected. In class E, the copy and move operations are suppressed by declaring these special member functions as =delete. If you invoke the copy or move operations of these base classes, the compiler generated an error. The definitions of the base classes C and E are compliant with this rule.

# AUTOSAR C++14 Rule A12-8-7

Assignment operators should be declared with the ref-qualifier &

## Description

### Rule Definition

*Assignment operators should be declared with the ref-qualifier &.*

### Rationale

You can use ref-qualifiers to specify whether a function or operator applies to lvalues or rvalues. Functions or operators that apply to lvalues have the ref-qualifier &. Functions and operators that apply on rvalues have the ref-qualifier && at the end of their declaration.

Built-in assignment operators in C++ accept only lvalues as input parameters. If user-defined assignment operators take both rvalue and lvalue as input parameters, it can cause confusion and errors. Consider this code where the user-defined assignment operator for the class `obj` accepts both rvalues and lvalues as input parameters.

```
class obj{
    obj& operator=(Obj const&){
        //...
        return *this;
    }
    //...
};

int main(){
    int i,j,k;
    obj a,b,c;

    if((i+j)=k) // compilation error
    //...
    if((a+b)=c) // silent error
    //...
}
```

- In the first `if` statement, the equal-to operator (==) is written as an assignment operator (=) because of a typographical error. Because the built-in assignment operator for `int` does not accept rvalues as input, the statement `(i+j) = k` causes a compilation error.
- The condition for the second `if` statement contains a similar error. Because the user-defined assignment operator for class `obj` accepts both lvalues and rvalues as input, the statement `(a+b) = c` compiles without error. The `if` block executes unexpectedly, resulting in a silent bug.

To avoid errors and confusion, specify that assignment operators take only lvalues as input parameters by adding the ref-qualifier & to their declaration.

### Polyspace Implementation

Polyspace flags user-defined assignment, compound assignment, increment, and decrement operators when:

- They do not have the ref-qualifier & in their declaration.
- They are member functions of a class.
- They are not declared as `= delete`.

Because ref-qualifiers are applicable only to nonstatic member functions, this rule does not apply to nonmember assignment operators.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declare Assignment Operators by Using Ref-Qualifier &

This example shows how Polyspace flags assignment operators and increment or decrement operators when their declarations do not specify the ref-qualifier &.

```
#include<cstdint>
class Obj
{
public:
    Obj() = default;
    Obj& operator=(Obj const&) & = default; //Compliant
    Obj& operator=(Obj&&) & = default;      //Compliant
    Obj& operator++() & noexcept;           //Compliant
    Obj& operator--()  noexcept;            //Noncompliant
    Obj& operator<<=(Obj const&) noexcept;  //Noncompliant
    Obj& operator>>=(Obj const&) & noexcept;//Compliant
    Obj& operator+=(Obj const&)&;           //Compliant
    Obj& operator-=(Obj const&);            //Noncompliant
    Obj& operator*=(Obj const&)= delete;    //Compliant
    Obj& operator+(Obj const&)&;            //Compliant
};

Obj& operator|=(Obj& f,const std::int32_t i) // Rule does not apply
{
    return f;
}

Obj& Obj::operator+=(Obj const&) &  // Polyspace flags the declaration
{
    return *this;
}
Obj F1() noexcept
{
    return Obj{};
}
int main()
{
    Obj c;
    //F1() += c; // Compilation Error
    //F1() = c; // Compilation Error
    F1() -= c; // Silent Bug
}
```

In `main()`, the assignment operators `+=`, `-=`, and `=` are used with an rvlaue input. Because the declarations of the operators `+=` and `=` specify the ref-qualifier `&`, using these operators with an rvalue input results in a compilation failure. The operator `-=` is declared without the reference qualifier `&`. Using this operator with an rvalue input creates a silent bug.

- Polyspace flags nondeleted member assignment operators, increment operators, and decrement operators that do not specify the ref-qualifier `&` in their declarations.
- When a member assignment operator is declared without the reference qualifier `&` in a class and defined elsewhere, Polyspace flags the declaration.
- Polyspace does not flag nonmember operators without the ref-qualifier `&` because this rule applies only to nonstatic member functions.
- Polyspace does not flag deleted operators because using the ref-qualifier `&` on a deleted operator has no impact on the code.

# AUTOSAR C++14 Rule A13-1-2

User defined suffixes of the user defined literal operators shall start with underscore followed by one or more letters

## Description

### Rule Definition

*User defined suffixes of the user defined literal operators shall start with underscore followed by one or more letters.*

### Rationale

Since C++11, you can add suffixes to literals that convert numeric values under the hood. For instance, in code where you perform all calculations in a common unit, you can leave unit conversions to dedicated operators and simply use literal suffixes for the units when defining constant values.

In this example, the literal suffixes `_m` and `_km` resolve to calls to `operator"" _m()` and `operator"" _km()` respectively. The operators ensure that all values are converted to the same unit.

```
constexpr long double operator"" _m(long double metres) {
    return metres;
}

constexpr long double operator"" _km(long double kilometres) {
    return 1000*kilometres;
}
...
long double minSteps = 100.0_m;
long double interCityDist = 100.0_km;
```

User defined literal suffixes must begin with an underscore (_). Literal suffixes not beginning with underscore are reserved for the Standard Library.

### Polyspace Implementation

The rule checker flags definitions of the form:

```
operator "" suffix
```

where *`suffix`* does not begin with an underscore or following the underscore, contains characters other than letters (numbers, special characters, and so on).

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A13-1-3

User defined literals operators shall only perform conversion of passed parameters

## Description

### Rule Definition

*User defined literals operators shall only perform conversion of passed parameters.*

### Rationale

User-defined literal operators are expected to simply convert their parameters to the operator return type. If your operators perform operations other than this conversion, reviewers or other developers who use the operator might find this behavior unexpected.

For instance, the operator `_km` is expected to convert a `long long int` parameter to the type `Distance`:

```
Distance operator"" _km(long long int param) {
  ...
}
```

Any other operation performed by this operator might be unexpected.

### Polyspace Implementation

The checker flags user-defined literal operators that have one of these issues:

- The operator has a return type `void`. Such an operator cannot return the converted parameter.
- The operator does not even use its parameter, let alone convert its parameter to the operator return type.
- The operator performs an operation that has or might have side-effects. Such an operator defies the expectation that a user-defined literal operator *only* converts its parameter. For instance, the operator might update a global or static variable (definite side-effect) or call another function (possible side-effect). In the latter case, look into the callee function body to make sure it does not have side effects.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### User-defined Literal Operator with Side Effects

```
#include <cstdint>

struct Distance {
   unsigned long long int distparam;
   constexpr explicit Distance(unsigned long long int v) : distparam(v) {}
};

constexpr Distance operator"" _m(unsigned long long int distparam) //Compliant
{
   return Distance(distparam);
}

static void updateNumberOfConversions() {
   static std::int32_t numberOfConversions = 0;
   numberOfConversions++;
}

constexpr Distance operator"" _km(unsigned long long int distparam) //Noncompliant
{
   updateNumberOfConversions();
   return Distance(distparam);
}
```

In this example, the operator `_m` simply converts its parameter to the return type `Distance` and does not violate the rule. The operator `_km`, in addition to converting its parameter, also calls the function `updateNumberOfConversions`, which modifies a static variable. Therefore, the operator `_km` has additional side effects and violates the rule.

# AUTOSAR C++14 Rule A13-2-1

An assignment operator shall return a reference to "this"

## Description

### Rule Definition

*An assignment operator shall return a reference to "this".*

### Polyspace Implementation

The following operators should return `*this` on method, and `*first_arg` on plain function:

- `operator=`
- `operator+=`
- `operator-=`
- `operator*=`
- `operator >>=`
- `operator <<=`
- `operator /=`
- `operator %=`
- `operator |=`
- `operator &=`
- `operator ^=`
- Prefix `operator++`
- Prefix `operator--`

Does not report when no return exists.

No special message if type does not match.

Messages in report file:

- An assignment operator shall return a reference to `*this`.
- An assignment operator shall return a reference to its first arg.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A13-2-2

A binary arithmetic operator and a bitwise operator shall return a "prvalue"

## Description

### Rule Definition

*A binary arithmetic operator and a bitwise operator shall return a "prvalue".*

### Rationale

Binary arithmetic operators such as `operator+()` and bitwise operators such as `operator|()` must return an object of type `T` by value without qualifiers (and not references, `T&`, or pointers ,`T*`). This requirement makes the return types consistent with the implementation of the same operators in the C++ Standard Library. A developer familiar with the standard operators can easily work with the overloaded forms of the operators.

A prvalue or pure rvalue is an object that does not have a name, cannot be pointed to or referenced, but can still be moved from. For instance, the result of a call to a function that returns by value is a prvalue.

### Polyspace Implementation

The checker flags implementations of binary and bitwise operators that return:

- A type with a qualifier such as `const` or `volatile`.
- A pointer or reference to another type.

Operators flagged by the checker include:

- Binary operators such as `operator+()`, `operator*()`, `operator/()`, and so on.
- Bitwise operators such as `operator&()`, `operator|()`, `operator<<()`, and so on.

  Note that the checker does not show violations on `operator<<()` and `operator>>()` that return `std::basic_istream`, `std::basic_ostream`, or `std::basic_iostream` types.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant and Compliant Binary Operators

```
#include <cstdint>

class A
{
};
class B
```

```
{
};

A* operator+(A const&, A const&) noexcept //Noncompliant
{
  return new A{};
}
B operator+(B const&, B const&) noexcept //Compliant
{
  return B{};
}

const A operator*(A const&, A const&) noexcept //Noncompliant
{
  return A{};
}
B operator*(B const&, B const&) noexcept //Compliant
{
  return B{};
}

std::int32_t* operator/(A const&, A const&) noexcept //Noncompliant
{
  return 0;
}
std::int32_t operator/(B const&, B const&) noexcept //Compliant
{
  return 0;
}
```

In this example, the operator overloads that take operands of type `A` return objects that are not prvalues. Hence, these operators violate the rule. For instance:

- `operator+` and `operator/` return pointers to objects.
- `operator*` returns a `const`-qualified object.

The equivalent operator overloads for type `B` return objects by value without qualifiers and comply with the rule.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A13-2-3

A relational operator shall return a boolean value

## Description

### Rule Definition

*A relational operator shall return a boolean value.*

### Rationale

The return value from relational operators of the C++ Standard Library can be directly checked to see if a relation is true or false. Overloads of the relational operator must be consistent with this usage. Otherwise, users of the overloaded relational operator might see unexpected results. See example below.

### Polyspace Implementation

The checker flags overloads of relational operators that do not return a value of type `bool`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Relational Operator Not Returning Boolean Value

```
class aClass {
    int val;
public:
    aClass(int initVal) {
        val = initVal;
    }
    bool operator<=(aClass const& comparingObj )  noexcept{ //Compliant
        return(this->val <= comparingObj.val);
    }
    int operator>=(aClass const& comparingObj ) noexcept { //Noncompliant
        return(this->val <= comparingObj.val? -1:1);
    }
};

void func() {
    aClass anObj(0), anotherObj(1);
    if(anObj <= anotherObj) {
        /* Do something */
    }
    if(anObj >= anotherObj) {
        /* Do something else */
    }
}
```

In this example, the overload of `operator<=` returns a boolean value but the overload of `operator>=` does not return a boolean value. However, in function `func`, the operators <= and >= are used as if a boolean value is returned from the overloaded operators. Because the overload of `operator>=` does not return the value zero, the second `if` statement is always true, a result that you might not expect.

# AUTOSAR C++14 Rule A13-3-1

A function that contains "forwarding reference" as its argument shall not be overloaded

## Description

### Rule Definition

*A function that contains "forwarding reference" as its argument shall not be overloaded.*

### Rationale

Suppose that you define a template function `func` with a forwarding reference parameter `T&&` like this:

```
template <typename T> void func(T&& param) {}
```

Suppose that you overload this template function with another function:

```
void func(int param) {}
```

When the function `func` is called, it is difficult to tell whether the call resolves to the template function or the overload, without working through the intricacies of the overload resolution mechanism. A developer or reviewer can easily mistake which function is called after the overload resolution. For instance, the function call:

```
short var;
//...
func(var);
```

resolves to the template function because it is an exact match after template instantiation, but a developer or reviewer might think that the overload is called because the type `short` promotes to `int`.

To avoid this issue, do not overload on template functions that take forwarding references. For template constructors, you can constrain the constructors to not match the overloads (using `std::enable_if`). When constrained this way, there is no scope for confusion between the template constructor and its overloads.

### Polyspace Implementation

The checker flags definitions of template functions that contain forwarding references (template parameters with type `T&&`) if those functions are also overloaded. Events below the checker result show the locations of the overloads. If an overload is an implicitly defined member function such as a constructor, the corresponding event points to the containing class.

The checker shows you all template functions with forwarding references that are overloaded. If you determine that an overload cannot cause confusion, add a comment to your result or code to avoid another review. See “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” or “Address Results in Polyspace Access Through Bug Fixes or Justifications”.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Template Function with Forwarding Reference Overloaded

```
#include <cstdint>

template <typename T>
void func(T&& t) noexcept(false) //Noncompliant
{
}

void func(
  std::int32_t&& t) noexcept
{
}
```

In this example, the function `func(std::int32_t &&)` overloads the template function with the same name, and violates the rule.

### Template Constructor Overloaded by Implicit Constructor

```
#include <type_traits>

class A
{
public:
    template<typename T>
    A(T &&value) {} //Noncompliant
};

class B
{
public:
    template<typename T,
    std::enable_if_t<! std::is_same<std::remove_cv_t<
    std:: remove_reference_t<T>>, B>::value> * = nullptr>
    B(T &&value) {} //Compliant
};

A getObjA();
B getObjB();

void func() {
    A objA = getObjA();
    B objB = getObjB();
}
```

In this example, class `A` has a template constructor that is overloaded by the implicit move constructor of class `A`. The overloading violates the rule.

Class `B` circumvents this problem by constraining the template constructor to not match the implicit constructor. In this example, the implicit constructor move constructor is called when the function `getObjB` returns an object of type `B`.

# AUTOSAR C++14 Rule A13-5-1

If "operator[]" is to be overloaded with a non-const version, const version shall also be implemented

## Description

### Rule Definition

*If "operator[]" is to be overloaded with a non-const version, const version shall also be implemented.*

### Rationale

Typically, you overload the subscript operator `operator[]` to provide read and write access to individual elements of an array or similar structure contained in a class. If you implement a non-`const` overload of `operator[]`, you must also implement a `const` version of this overload. Otherwise, you cannot use `operator[]` to read elements of a `const` object.

This rule allows the implementation of a `const` overload of `operator[]` for read-only access without the corresponding non-`const` overload.

### Polyspace Implementation

Polyspace flags the definition of the non-`const` member function if no corresponding `const` version of the member function is implemented.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `const` Version of non-`const` Member Function not Implemented

```
#include <memory>
#include <iostream>

class MyList
{
private:
    static constexpr std::int32_t maxSize = 10;
    std::int32_t container[maxSize];

public:
    std::int32_t& operator[](std::int32_t index) //compliant, non-const version
    {
        return container[index];
    }
    const std::int32_t& operator[](std::int32_t index) const //compliant, const version
    {
        return container[index];
    }
};
```

```
class MyList_nc
{
private:
    static constexpr std::int32_t maxSize = 10;
    std::int32_t container[maxSize];

public:
    std::int32_t& operator[](std::int32_t index) //non-compliant, non-const version only
    {
        return container[index];
    }

};

void func() noexcept
{
    MyList list;
    list[2] = 3; // Uses non-const version of operator[]
    std::cout << list[2] << std::endl;

    const MyList clist = {};
    std::cout << clist[2] << std::endl; // Uses const version of operator[]

}
```

In this example, the overloads of `operator[]` in class `MyList` are compliant because both the `const` and non-`const` versions of the overload are implemented. In class `MyList_nc`, the member function is not compliant because only the non-`const` version was implemented.

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A13-5-2

All user-defined conversion operators shall be defined explicit

## Description

### Rule Definition

*All user-defined conversion operators shall be defined explicit.*

### Rationale

If you do not define a user-defined conversion operator with the `explicit` specifier, compilers can perform implicit and often unintended type conversions from the class type with possibly unexpected results.

The implicit conversion can occur, for instance, when a function accepts a parameter of a type different from the class type that you pass as argument. For instance, the call to `func` here causes an implicit conversion from type `myClass` to `int`:

```
class myClass {} {
  ...
  operator int() {...}
};
myClass myClassObject;

void func(int) {...}
func(myClassObject);
```

### Polyspace Implementation

The checker flags declarations or in-class definitions of user-defined conversion operators that do not use the `explicit` specifier.

For instance, `operator int() {}` can convert variable of the current class type to an `int` variable both implicitly and explicitly but `explicit operator int() {}` can only perform explicit conversions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Missing `explicit` Keyword on Conversion Operator

```
#include <cstdint>

class MyClass {
public:
    explicit MyClass(int32_t arg): val(arg) {};
    operator int32_t() const { return val; }  //Noncompliant
    explicit operator bool() const {   //Compliant
        if (val>0) {
          return true;
        }
        return false;
     }
private:
    int32_t val;
};

void useIntVal(int32_t);
void useBoolVal(bool);

void func() {
    MyClass MyClassObject{0};
    useIntVal(MyClassObject);
    useBoolVal(static_cast<bool>(MyClassObject));
}
```

In this example, the conversion operator `operator int32_t()` is not defined with the `explicit` specifier and violates the rule. The conversion operator `operator bool()` is defined explicit and does not violate the rule.

When converting to a `bool` variable, for instance, in the call to `useBoolVal`, the `explicit` keyword in the conversion operator ensures that you have to perform an explicit conversion from the type `MyClass` to `bool`. There is no such requirement when converting to an `int32_t` variable. In the call to `useIntVal`, an implicit conversion is performed.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A13-5-3

User-defined conversion operators should not be used

## Description

### Rule Definition

*User-defined conversion operators should not be used.*

### Rationale

User-defined conversion operators might be called when you neither want nor expect them to be called, which can result in unexpected type conversation errors. For instance, in this code snippet, the user-defined conversion operator converts type `customType` to `double` to allow mixed mode expressions:

```
class customType
{
    public:
    customType(int base, int exponent);
    //....
    operator double() const; // Conversion operator, convert customType to double
};

customType var1(2,5);
double var2 = 0.5 * var1; //Conversion operator called, converts var1 to double
```

While this conversion might be expected, if you attempt to print `var1` by using `cout << var1;` without defining `operator <<` for `customType` objects, the compiler uses the conversion operator to implicitly convert and print `var1` as a `double`.

To avoid these unexpected conversions, replace the conversion operator with an equivalent function. The function must then be called explicitly. If you cannot avoid using conversion operators in your application, see rule `AUTOSAR C++14 Rule A13-5-2`.

### Polyspace Implementation

Polyspace flags all calls to conversion operators.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of a User-Defined Conversion Operator

```
class customType
{
public:
    customType(int base, int exponent): b(base), exp(exponent) { /* ...*/}
    //....
    operator double() const;
    double as_double() const {/* ...*/}

private:
    int b; //base
    int exp; //exponent
};

int func(void)
{

    customType var1(2, 5);
    double var2 = 0.5 * var1; //Non-compliant
    double var3 = 0.5 * var1.as_double(); // Compliant

    return 0;
}
```

In this example, the conversion of `var1` to a `double` in the declaration of `var2` uses conversion operator `customType::operator double`. This conversion is non-compliant because it uses a user-defined conversion operator.

The type conversion in the declaration of `var3` is compliant because it uses a function to handle the conversion, and this function must be called explicitly. This ensures that the conversion is expected.

# AUTOSAR C++14 Rule A13-5-4

If two opposite operators are defined, one shall be defined in terms of the other

## Description

### Rule Definition

*If two opposite operators are defined, one shall be defined in terms of the other.*

### Rationale

Opposite operators have the same argument and return types but exactly complement each other. For instance, `operator==` checks if its arguments are equal and `operator!=` checks for the complementary relation, that is, inequality.

Defining opposite operators in terms of each other makes your code easier to maintain:

- If you define opposite operators independently of each other, each time you update one operator, you have to remember to update the other. For instance, if you update the definition of `operator==`. you have to also explicitly update the definition of `operator!=`.
- If you define opposite operators in terms of each other, updating only one operator is sufficient since that change implicitly updates the other operator.

### Polyspace Implementation

The checker raises a violation if one of the operators in the following pairs is not defined in terms of the other:

- `operator==`, `operator!=`
- `operator<`, `operator>=`
- `operator>`, `operator<=`

The checker flags one of the operators in the pair. The event list below the checker result shows the location of the other operator.

The checker considers two opposite operators as part of a pair only if they have the same argument and return types.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Opposite Operators Defined in Compliant and Noncompliant Ways

```
#include <cstdint>

class Info {
    public:
       explicit Info(std::uint32_t x, std::uint32_t y): x(x), y(y) {}
       friend bool operator==(const Info & lhs, const Info & rhs) {
           return ((lhs.x == rhs.x) && (lhs.y == rhs.y));
       }
       friend bool operator!=(const Info & lhs, const Info & rhs) { //Noncompliant
           return ((lhs.x != rhs.x) || (lhs.y != rhs.y));
       }
    private:
       std::uint32_t x;
       std::uint32_t y;
};

class Data {
    public:
       explicit Data(std::uint32_t x, std::uint32_t y): x(x), y(y) {}
       friend bool operator==(const Data & lhs, const Data & rhs) {
           return ((lhs.x == rhs.x) && (lhs.y == rhs.y));
       }
       friend bool operator!=(const Data & lhs, const Data & rhs) { //Compliant
           return !(lhs == rhs);
       }
    private:
       std::uint32_t x;
       std::uint32_t y;
};
```

In this example, the class `Info` defines the two opposite operators `operator==` and `operator!=` independently of each other. If you add another data member to the class or change to a different definition of equality, you have to explicitly update the definitions of both operators.

The class `Data` defines the same two operators, but `operator!=` is defined in terms of `operator==`. If you add a data member to the class later or change to a different definition of equality, you can change only the `operator==` operator. The `operator!=` operator will automatically reflect the change.

# AUTOSAR C++14 Rule A13-5-5

Comparison operators shall be non-member functions with identical parameter types and noexcept

## Description

### Rule Definition

*Comparison operators shall be non-member functions with identical parameter types and noexcept.*

### Rationale

Comparison operators must not compare objects that are of different types. If you pass objects of different types as arguments to a comparison operator, the operator must be able to convert one argument to the data type of the other.

Member functions have the inherent limitation that the implicit object parameter (the one referred to by the `this` pointer) cannot be converted to another data type. To support data type conversions when required, define comparison operators as non-member functions.

Comparison expressions are fundamental operations and must be noexcept. The comparison operators covered by this rule are:

- `==`
- `!=`
- `<`
- `<=`
- `>`
- `>=`

**Note** Declare comparison operators as `friend` to enable them to access internal data similar to a member function. This practice is allowed by the exception in rule A11-3-1.

### Polyspace Implementation

The checker flags comparison operators that are defined as member functions. The checker also flags non-member comparison operators that:

- Compare nonidentical parameter types, such as a `class` type and `int`.
- Are not declared with the `noexcept` specifier.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Noncompliant Member Function Declaration

The declaration of `nonComp::operator::==` is noncompliant because the comparison operator is declared as a member function.

```
#include <cstdint>

class nonComp
{
  public:
      explicit nonComp(std::uint32_t d): m_d(d)
      {}
      bool operator ==(const nonComp& rhs) noexcept  //Non-compliant; member function
      {
          return m_d == rhs.m_d;
      }

  private:
      std::uint32_t m_d;
};

class Compliant
{
  public:
      explicit Compliant(std::uint32_t d): m_d(d)
      {}
      friend bool operator ==(Compliant const& lhs, Compliant const& rhs) noexcept
      {
          return lhs.m_d == rhs.m_d;
      }
  private:
      std::uint32_t m_d;
};
// Compliant; non-member, identical parameter types, noexcept
```

The class `Compliant` declares `operator::==` as a `friend`, so this comparison operator is compliant.

### Noncompliant Declaration with Different Types

The first declaration of `operator::==` compares two different data types, because of which this comparison operator is noncompliant.

```
#include <cstdint>

class nonComp
{
    using Self = nonComp;
};

class MemberFunc
{
    using Self = MemberFunc;
};

bool operator ==(const nonComp& lhs, //noncompliant; comparison operator for different data types.
                 const MemberFunc& rhs) noexcept
{
    return true;
}

bool operator ==(const nonComp& lhs, const nonComp& rhs) noexcept
{
    return true;
} //compliant; because it compares the same data types.
```

The second declaration of `operator::==` compares the same data types, so this comparison operator is compliant.

### Noncompliant Declaration That Is Not Noexcept

`nonComp::operator::==` is not declared as a noexcept, so this comparison operator is noncompliant.

```
#include<cstdint>
class nonComp
{
  public:
    explicit nonComp(std::uint32_t d): m_d(d)
    {}
    friend bool operator ==(nonComp const& lhs, //Noncompliant; member function isn't noexcept
                            nonComp const& rhs)
    {
        return lhs.m_d == rhs.m_d;
    }

  private:
    std::uint32_t m_d;
};

class Compliant
{
  public:
    explicit Compliant(std::uint32_t d): m_d(d)
    {}
    friend bool operator ==(Compliant const& lhs, Compliant const& rhs) noexcept
    {
        return lhs.m_d == rhs.m_d;
    }

  private:
    std::uint32_t m_d;
};
// Compliant; non-member, identical parameter types, noexcept
```

`Compliant::operator::==` is declared as a noexcept, so this comparison operator is compliant.

# AUTOSAR C++14 Rule A13-6-1

Digit sequences separators ' shall only be used as follows: (1) for decimal, every 3 digits, (2) for hexadecimal, every 2 digits, (3) for binary, every 4 digits

## Description

### Rule Definition

*Digit sequences separators ' shall only be used as follows: (1) for decimal, every 3 digits, (2) for hexadecimal, every 2 digits, (3) for binary, every 4 digits.*

### Rationale

Since C++14, you can introduce a separator `'` to separate digits in a digit sequence for better readability. For consistency across your code, follow this convention when entering the digit sequence separator:

- In decimal values, starting from the right, place the separator after every three digits, for instance, `3'000'000`.
- In hexadecimal values, starting from the right, place the separator after every two digits, for instance, `0xF'FF'0F`.
- In binary values, starting from the right, place the separator after every four digits, for instance, `0b1001'0011'0100`.

If you are consistent across your code, a developer or code reviewer can follow your code more easily and possibly estimate the order of magnitude of a value from the digit sequence separators.

### Polyspace Implementation

This checker follows the specifications of the AUTOSAR C++14 rule.

For integers, the checker starts checking from the right. For instance, the checker raises a violation on the value `45'30'00`, because starting from the right, the digit sequence separator appears after two digits instead of the expected three.

For floating-point numbers, the checker begins the check from the decimal point and proceeds outwards. The checker checks:

- The part before the decimal starting from the right.
- The part after the decimal starting from the left.

For floating-point numbers with a mantissa and exponent, the same rule as integers applies to the exponent. For instance, in the decimal notation, the checker checks exponents starting from the right and raises a violation if the digit sequence separators are placed, for instance, after every two digits instead of three.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Placement of Digit Sequence Separators in Integers

```
#include <cstdint>

std::uint32_t largeNum = 3'0000'0000; //Noncompliant
std::uint32_t smallerNum = 3'000'000;  //Compliant
std::uint32_t evenSmallerNum = 3'00'00; //Noncompliant

std::uint32_t largeHexNum = 0xFF'FF'FF'FF; //Compliant
std::uint32_t smallerHexNum = 0xFFF'FFF; //Noncompliant
```

In this example, the placement of digit sequence separators is compliant if the separators follow the expected convention:

- In decimal numbers, starting from the right, the separator is placed after every three digits.
- In hexadecimal numbers, starting from the right, the separator is placed after every two digits.

### Placement of Digit Sequence Separators in Floating-Point Numbers

```
#include <cstdint>

float PI = 3.1'415'926'53; //Noncompliant
float pi = 3.141'592'653; //Compliant;

float one_LB_to_KG = 0.45'359'237; //Noncompliant
float one_lb_to_kg = 0.453'592'37; //Compliant
```

In this example, the same floating-point number is assigned to two different variables but the placement of the digit sequence separators is different. The placement is compliant if the separators follow the expected convention:

- For digits after the decimal, starting from the left, the separator is placed after every three digits.
- For digits before the decimal, starting from the right, the separator is placed after every three digits.

  For floating-point numbers, the need for a digit sequence separator before a decimal is typically a rare occurrence. For instance, if you store a floating point-number in normalized form, the mantissa has only one digit before the decimal.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A14-1-1

A template should check if a specific template argument is suitable for this template

## Description

### Rule Definition

*A template should check if a specific template argument is suitable for this template.*

### Rationale

A template defines the operations of a class or function for generic template types. If these operations require that the template types have specific characteristics, for instance the data type must be copy constructible, check the template arguments to ensure that they are suitable and have the required characteristics. Typically, you use `static_assert` assertions to perform this check at compile time, for instance, `static_assert(std::is_copy_constructible<T>)`.

### Polyspace Implementation

Polyspace flags template classes, structs, unions, and functions unless one of the following is true:

- The template contains at least one `static_assert` assertion, even if that assertion does not test the characteristics of the template parameters.
- The template is explicitly fully specialized even when it does not contain any `static_assert` assertions.

Polyspace does not flag template declarations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Template Does Not Check Template Arguments

In this example, templates `specializedClass`, `func_def`, and `myStruct` are noncompliant because these templates do not do not contains any `static_assert` statement and they are not fully specialized. Polyspace reports violations of this rule on the noncompliant templates.

Polyspace does not flag:

- The class template `myTemplate` because it uses `static_assert` to check whether the template type is copy-constructible. If the instantiation of `myTemplate<myClass>` in function `F()` is uncommented, the assertion results in a compile-time error.
- The `struct` template `floatStruct` because this template uses a `static_assert` statement that checks if the input type is `float`.
- The class template `specializedClass<std::int32_t>` because it is explicitly fully specialized.

- The function template declaration `func_decl` because the template is not implemented.

```
#include <cstdint>
#include <type_traits>

template<typename T>
class myTemplate  // Compliant. Use of static_assert
{

    static_assert(std::is_copy_constructible<T>(),
                  "Template type not copy constructible.");
    //...

};
template<typename T>
class specializedClass //Non-compliant
{
};

template<typename T>
struct myStruct //Non-compliant
{
    //...
};
template<typename T>
struct floatStruct //Compliant
{
    static_assert(std::is_floating_point<T>::value, "Expecting a floating point type");
};
template<>
class specializedClass<std::int32_t>  // Compliant. Explicit full specialization
{
};

class myClass  //Not a template
{
public:
    myClass() = default;
    myClass(myClass const&) = delete;

};

class myOtherClass  //Not a template
{

};

template<typename T>
void func_decl(T const& obj) noexcept(false); // Compliant. Template declaration

template <typename T>
void func_def(T const& obj) noexcept(false)  //Non-compliant
{

}

void F()
{

    //myTemplate<myClass> a; // myClass is not copy constructible. Compile-time error.
    myTemplate<myOtherClass> b; //myOtherClass is copy constructible.
}
```

# AUTOSAR C++14 Rule A14-5-2

Class members that are not dependent on template class parameters should be defined in a separate base class

## Description

### Rule Definition

*Class members that are not dependent on template class parameters should be defined in a separate base class.*

### Rationale

To access a member of a template class, you have to instantiate the template. If the member is not dependent on the template parameter, this instantiation step is not necessary. For instance, the members `anotherMember` and `someotherMember` of this template class `aClass` do not depend on the parameter `T`:

```
template <typename T>
class aClass {
   T aMember
   int anotherMember;
   int someotherMember
}
```

However, to access these members, you have to instantiate the template class `aClass`. To avoid the unnecessary template instantiation, do not include these members in the template declaration.

Including this member in the template declaration also causes unnecessary code bloat. Compilers generate a separate copy of a template class for each instantiation of a template. If a class member is not dependent on the template parameter, an identical copy of this member is created for each template instantiation.

### Polyspace Implementation

The checker flags data members of template classes that are not dependent on template parameters. The checker does not flag member functions.

If multiple data members of a template are flagged by this checker, create a base class for the template that aggregates these data members.

In some cases, you might not want to strictly adhere to this rule. For instance, if only a single member of the template class is not dependent on the template parameter, you might not want to create a separate base class for this member. If you do not want to fix the issue, add comments to your result or code to avoid another review. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Template Classes That Have Unnecessary Members

```
#include <cstdint>

template <typename T>
class aDataArray {
    T data[100];
    int32_t metadata[2]; //Noncompliant
    int32_t info;        //Noncompliant
};

class metadataArray {
    int32_t metadata[2];
    int32_t info;
};

template <typename T>
class anotherDataArray: public metadataArray { //Compliant
    T data[100];
};
```

In this example, the template class `aDataArray` includes data members `metadata` and `info` that are not dependent on the type parameter of the template, `T`. The template class `anotherDataArray` avoids the unnecessary instantiation. This class is derived from a base class `metadataArray`, which aggregates data members that are not dependent on a type.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A14-5-3

A non-member generic operator shall only be declared in a namespace that does not contain class (struct) type, enum type or union type declarations

## Description

### Rule Definition

*A non-member generic operator shall only be declared in a namespace that does not contain class (struct) type, enum type or union type declarations.*

### Rationale

This rule forbids placing generic operators in the same namespace as class (struct) type, enum type, or union type declarations. If the class, enum or union types are used as template parameters, the presence of generic operators in the same namespace can cause unexpected call resolutions.

Consider the namespace NS that combines a class B and a generic form of operator==:

```
namespace NS {
   class B {};
   template <typename T> bool operator==(T, std::int32_t);
}
```

If you use class B as a template parameter for another generic class, such as this template class A:

```
template <typename T> class A {
    public:
      bool operator==(std::int64_t);
}

template class A<NS::B>;
```

the entire namespace NS is used for overload resolution when operators of class A are called. For instance, if you call operator== with an int32_t argument, the generic operator== in the namespace NS with an int32_t parameter is used instead of the operator== in the original template class A with an int64_t parameter. You or another developer or code reviewer might expect the operator call to resolve to the operator== in the original template class A.

### Polyspace Implementation

For each generic operator, the rule checker determines if the containing namespace also contains declarations of class types, enum types, or union types. If such a declaration is found, the checker flags a rule violation on the operator itself.

The checker also flags generic operators defined in the global namespace if the global namespace also has class, enum or union declarations.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Generic Operator in Same Namespace as Class Type

```
#include <cstdint>

template <typename T> class Pair {
    std::int32_t item1;
    std::int32_t item2;
    public:
      bool operator==(std::int64_t ItemToCompare);
      bool areItemsEqual(std::int32_t itemValue) {
          return (*this == itemValue);
      }
};

namespace Operations {
    class Data {};
    template <typename T> bool operator==(T, std::int32_t); //Noncompliant
}

namespace Checks {
    bool checkConsistency();
    template <typename T> bool operator==(T, std::int32_t); //Compliant
}

template class Pair<Operations::Data>;
```

In this example, the namespace `Operations` violates the rule because it contains the class type `Data` alongside the generic `operator==`. The namespace `Checks` does not violate the rule because the only other declaration in the namespace, besides the generic `operator==`, is a function declaration.

In the method `areItemsEqual` in `template class Pair<Operations::Data>`, the == operation invokes the generic `operator==` method in the `Operations` namespace. The invocation resolves to this `operator==` method based on the argument data type (`std_int32_t`). This method is a better match compared to the `operator==` method in the original template class `Pair`.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A14-7-1

A type used as a template argument shall provide all members that are used by the template

## Description

### Rule Definition

*A type used as a template argument shall provide all members that are used by the template.*

### Rationale

A template can define operations on a generic type through one or more member variables or member functions. If the type that you use to instantiate the template does not provide all of the members that the template uses, your program might be ill-formed and might contain syntax or semantic errors.

For example, in the following code, template `TmplClass` declares a member function `someProperty()` but type `myType` does not. The instantiation of `TmplClass` by using `myType` is noncompliant and, as a result of the missing `someProperty()` function, `inst.func();` causes a compilation error.

```
template <typename T>
class TmplClass
{
public:
    void func()
    {
        T t;
        t.someProperty();
    }
};
struct myType {
};

void Instance() noexcept
{
    TmplClass<myType> inst; //Non-compliant
// inst.func(); //compilation error, struct myType has no member function someProperty()
}
```

### Polyspace Implementation

- Polyspace flags `class`, `struct`, or `union` template instantiations when the template parameter does not contain all of the members that the template uses.

  If you review results in the Polyspace desktop or web interfaces, in the template definition, the software highlights the members that are missing from the template parameter.
- Polyspace does not flag:
  - Function template instantiations.
  - Template instantiations that use an incomplete type as the template parameter.
  - Template instantiations that use a template parameter, where the missing member is a member type (nested type) or a member template.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Template Argument Does Not Provide All Members Used by Template

```
class IncompleteType;
class MyClass
{

    struct MyStruct {
        int Field1;
        int Field2;
    };

    struct MyStructArray {
        int Field3[12];
    };

public:
    MyStruct property1;
    int property2[10];
    MyStruct property3[10];
    MyStructArray property4;

};

template <typename T>
class TemplClass
{
public:
    void fooA()
    {
        T t;

        t.property1 = {1, 2};
        t.property2[5] = 5;
        t.property3[2].Field1 = 6;
        t.property4.Field3[4] = 10;

    }
};

class MyType
{
public:
    int rank;
};

class MyOtherType
{
public:
    int property;
};

template <typename T1, typename T2>
class TemplClass2Param
{
    void func()
    {
        T1 t1;
        T2 t2;
        t1.rank = 5;
        t2.rank2 = 6;
    }
};

void instantiate(void)
{
    TemplClass<MyClass> var; // Compliant
    TemplClass<IncompleteType> varFromIncomplete; // Compliant
    TemplClass2Param<MyType, MyOtherType> otherVar; //Non-compliant

}
```

In this example, the first instantiation of template `TmplCass` by using template parameter `MyClass` is compliant because `MyClass` provides all the members that the template uses.

Polyspace does not flag the second instantiation of `TmplCass` that uses incomplete type `IncompleteType`.

The instantiation of `TmplClass2Param` is noncompliant because one of the template parameters (`MyOtherType`) does not provide a member variable `rank2` that the template uses.

### Member Type or Member Template Missing from Template Parameter Used for Instantiation

```
class MyClass
{
  public:
    int var;
    void foo(int);
    typedef int nestedtype; // member type
    template<typename T>
    void tmpl_func() { }  //member template
};

template <typename T>
class TmplClass {
  public:
    void func() {
        T t;
        int j = t.var;
        t.foo(j);
        typename T::otherNestedType newvar; //member type not in MyClass
        newvar = 5;

        t.template other_tmpl_func<int>(); //member template not in MyClass
    }
};

void bar (void) {
    TmplClass<MyClass> instance;    // Compliant
}
```

In this example, template parameter `MyClass` does not have a member type `otherNestedType` or a member template `other_tmpl_function`, but the instantiation `TmplClass<MyClass> instance` is not flagged.

# AUTOSAR C++14 Rule A14-7-2

Template specialization shall be declared in the same file (1) as the primary template (2) as a user-defined type, for which the specialization is declared

## Description

### Rule Definition

*Template specialization shall be declared in the same file (1) as the primary template (2) as a user-defined type, for which the specialization is declared.*

### Rationale

Observing this rule avoids situations where the behavior is undefined. For instance, if a compiler sees a partial specialization of a template *after* it has instantiated the template, the behavior is undefined. If you specialize a template in the same file as the template, this situation is less likely to occur.

You can also easily extend compile-time interfaces through specialization since the template and its specialization are in the same file and part of the same translation unit. The same reasoning applies to the requirement that a template specialization must be in the same file as the type for which the template is specialized.

### Polyspace Implementation

The checker checks each template specialization and raises a violation if:

- The specialization is not in the same file as the template that is specialized.
- The specialization is not in the same file as the user-defined type for which the template is specialized.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# AUTOSAR C++14 Rule A14-8-2

Explicit specializations of function templates shall not be used

## Description

### Rule Definition

*Explicit specializations of function templates shall not be used.*

### Rationale

Explicit specialization of function templates can cause unexpected issues with overload resolution in C++. Overload resolution:

- First searches for a non-template, plain-old-function that has a matching parameter list.
- If such a function is not available, overload resolution selects the closest matching function template.
- After a function template is selected, the compiler searches for a suitable specialization of the template.

Specializing a template does not change the order of the overload resolution process, which can result in confusing and unexpected behavior. Consider code snippet:

```
//(a) base template
template<class T> void f( T );

//(b) specialization of (a)
template<> void f<>(int*);
//...

//(c) overloads (a)
template<class T> void f( T* );

//...
main(){
    int *p;
    f( p );
}
```

When `f()` is called with an `int*` in `main()`, you might expect the specialization for `int*`, marked (b), to be called. The compiler resolves the call to `f()` as follows:

1. The compiler searches for a plain-old-function with input type `int*`.
2. Because there is no such function, the compiler searches for a function template that has the closest matching parameter list.
3. The template (c), which takes a generic pointer as input, is the closest match for `f(int*)`.
4. The template (c) is not specialized. The overload resolution process stops and calls the template in (c).

Even though a specialized template for `int*` type input is defined in (b), the overload resolves to the template in (c) instead, which can be unexpected.

When you specialize an overloaded function template, the overload resolution process can get more confusing. Which among the overloaded templates gets specialized depends on the order of declaration. Consider the code snippet:

```
//(a)
template <typename T> void F1(T t){}
//(b)
template <typename T> void F1(T* p){}
//(x): Specialization of template
template <> void F1<>(uint16_t* p){}
```

You cannot determine whether (x) specializes (a) or (b) from the declaration alone. it depends on the declaration order. For instance, in the preceding case (x) specializes (b). But in this case, (x) specializes (a):

```
//(a)
template <typename T> void F1(T t){}
//(x): Specialization of template
template <> void F1<>(uint16_t* p){}
//(b)
template <typename T> void F1(T* p){}
```

To avoid confusing code and unexpected behavior, avoid specializing function templates. If you must specialize a function template, then write a single function template that delegates to a class template. For example, in this code, a function template `f()` delegates to the class `f_implementation`.

```
template<class T> class f_implementation;

template<class T> void f( T t ) {
    FImpl<T>::f( t ); //Don't specialize function template
}

template<class T> class f_implementation {
    static void f( T t ); // Specializing class templates is permissible.
}
```

Delegating to a class template also enables partial specialization.

### Polyspace Implementation

If you explicitly specialize a function template, Polyspace flags the function template.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Specializing Function Templates

This example shows how Polyspace flags specialized function templates.

```
#include <cstdint>
#include <memory>
#include <iostream>
```

```
//(a)
template <typename T> void F1(T t){
  std::cout << "(a)" << std::endl;
}
//(x) specializes (a)
template <> void F1<>(uint16_t* p){// Noncompliant
  std::cout << "(x)" << std::endl;
}
//(b) overloads (a)
template <typename T> void F1(T* p){// Compliant
  std::cout << "(b)" << std::endl;
}
//(y) specializes (b)
template <> void F1<>(uint8_t* p){// Noncompliant
  std::cout << "(c)" << std::endl;
}
//(d) plain old function overloads (a) and (b)
void F1(uint8_t* p){                    // Compliant
  std::cout << "(d)" << std::endl;
}

int main(void)
{
    auto sp8 = std::make_unique<uint8_t>(3);
    auto sp16 = std::make_unique<uint16_t>(3);
    F1(sp8.get()); //calls (d), might expect (y)
    F1(sp16.get()); //calls (b), might expect (x)
    return 0;
}
```

When the function `F1()` is called in main, overload resolution determines which instance of `F1()` is called.

- When F1() is invoked with pointers to `uint8_t`, the compiler calls the plain-old-function (d) because it takes precedence. You might incorrectly expect the specialization (y) to be called.
- When F1() is invoked with pointers to `uint16_t`, the compiler calls the overloaded template (b) because it is the closest matching template. You might incorrectly expect the specialization (x) to be called.

Specializing function templates can cause confusion and unexpected results. Polyspace flags the specialized function templates (x) and (y).

# AUTOSAR C++14 Rule A15-0-2

At least the basic guarantee for exception safety shall be provided for all operations. In addition, each function may offer either the strong guarantee or the nothrow guarantee

## Description

### Rule Definition

*At least the basic guarantee for exception safety shall be provided for all operations. In addition, each function may offer either the strong guarantee or the nothrow guarantee.*

### Rationale

To facilitate recovery from an exception while preserving the invariant of the relevant objects, programs must be designed to have exception safety. The C++ standard allows these levels of exception safety:

- Basic Exception Safety: This level of exception safety requires that after raising an exception, the basic invariants of all objects are maintained in a valid state and no memory is leaked. If an operation has basic exception safety, then you can destroy or assign to an object after the operations, even if an exception has been raised. The operations in standard library offers at least basic exception safety.
- Strong Exception Safety: This level of exception safety requires that after raising an exception, the state of the program remains as it was before the exception. Operations with strong exception safety either succeed or exit with an exception and have no effects on the program.
- `nothrow`: This level of safety requires that an exception cannot occur in an operation.

Without at least the basic exception safety, exceptions might corrupt the state of a program or create memory leaks. The AUTOSAR C++14 standard requires that a program must offer at least the basic exception safety for all operations, strong exception safety for key operations, and `nothrow` guarantee for some operations.

### Polyspace Implementation

Polyspace raises a violation of this rule if any of these conditions are true:

- An exception violates a class invariant: This condition is met if a non-`noexcept` member function attempts to raise an exception after modifying any of the fields in the class. For instance, Polyspace flags a `throw()` statement or a `new` statement if they are used after modifying the internal state of a class.
- An exception leaves dynamic memory in an invalid state: This condition is met if an exception is raised without deallocating the dynamic memory that is already allocated. For instance, Polyspace flags an exception raising statement if it is outside a `try` block or inside a `catch` block and the allocated resources are not deallocated before the statement. Exception raising statements might include:
  - A `throw` statement
  - Calls to functions containing `throw` statements
  - Calls to constructors containing `throw` statements.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Modifying Object Invariant Before Raising Exceptions

```
#include <cstdint>
#include <cstring>
template<typename T=int>
class myArray
{
public:
    myArray(){/*...*/}
    myArray(const myArray& rhs)
    {
        DeepCopyNC(rhs);
        DeepCopy(rhs);
    }
    ~myArray()
    {
        delete[] array;
    }
    void DeepCopyNC(const myArray& rhs) // Noncompliant
    {
        if (this != &rhs) {
            delete[] array;
            array = nullptr;
            len = rhs.len;

            if (len > 0) {

                array = new T[len];
                std::memcpy(array, rhs.array, len * sizeof(T));
            }
        }
    }
    void DeepCopy(const myArray& rhs) // Compliant
    {
        T* eTmp = nullptr;

        if (rhs.len > 0) {
            eTmp = new T[rhs.len];
            std::memcpy(eTmp, rhs.array, rhs.len * sizeof(T));
        }

        delete[] array;
        array = eTmp;
        len = rhs.len;
    }

private:
    T* array;
    std::size_t len;
};
```

```
extern     myArray<> c1{};
void foo(){

    myArray<> c2{c1};

}
```

This example shows a generic class template `myArray` that manages a raw array. The copy constructor of this class shows two implementations of deep copy. In the function `DeepCopyNC()`, the memory operations are performed after modifying the `this->array` and `this->len` fields. If the memory operation exits with an exception, the invariant of the original class is violated. Because the class invariant is violated by an exception, the function `DeepCopyNC()` does not have basic exception safety. Polyspace flags it. To provide basic exception safety, modify the class invariant only when the memory operation succeeds, as shown in `DeepCopy`.

### Deallocate Resource Before Raising Exception

```
#include<cstdlib>
#include<exception>
 class complex_ptr{

    complex_ptr(){
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            throw std::exception(); //Noncompliant
        }
    }
    ~complex_ptr(){
        free(real);
        free(imag);
    }
    private:
    double* real;
    double* imag;

};
class complex_ptr2{

    complex_ptr2() {
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            deallocate();
            throw std::exception(); //Compliant
        }
    }
    void deallocate(){
        free(real);
        free(imag);
    }
    ~complex_ptr2(){
        deallocate();
    }
    private:
    double* real;
    double* imag;
};
void foo(void){
    complex_ptr Z;
    complex_ptr2 X;
    //...
}
```

In this example, the class `complex_ptr` is responsible for allocating and deallocating two raw pointers to `double`. The constructor `complex_ptr::complex_ptr()` terminates with an exception when a memory allocation operation fails. The class goes out of scope before deallocating the already allocated resources, resulting in a memory leak. Because an exception causes a memory leak, this code does not have basic exception safety. Polyspace flags the `throw` statement in the constructor.

Similar to `complex_ptr`, the constructor of class `complex_ptr2` raises an exception when a memory allocation operation fails. Before raising the exception, the constructor deallocates the allocated memory by calling `deallocate()`. This constructor provides basic exception safety and is compliant with this rule.

### Handle Exceptions Arising from Object Construction

```
#include<exception>
extern int rd;

struct magnitude {
    magnitude() {
        //...
        throw std::exception();
    }
};

class complex_num {
public:
    complex_num() {
        theta = new int;
        r = new magnitude();//Noncompliant
    }
    magnitude* r;
    int* theta;
};

void foo() {
    complex_num t;
}
```

In this example, the constructor of `complex_num`constructs an `int` and a `magnitude` object. The constructor of a `magnitude` object might raise an exception, causing the already allocated `theta` to leak. Because an exception might lead to memory leak, this code does not have basic exception safety. Polyspace flags the call to `magnitude()`. To provide basic exception safety, construct the `magnitude` object within a `try-catch` block.

# AUTOSAR C++14 Rule A15-0-3

Exception safety guarantee of a called function shall be considered

## Description

### Rule Definition

*Exception safety guarantee of a called function shall be considered.*

### Rationale

The exception safety level of a function affects the function behavior. Functions that have a basic exception safety do not modify the class invariant when they exit with an exception. Functions that have a strong exception safety restores the class invariant to the state it was before the function call.

If a function provides neither of these exception safety, calling it might lead to unexpected behavior. For instance, an external function might exit with an exception for a specific input. When a client uses this function, the exception might be unexpected, resulting in a memory leak or program termination.

### Polyspace Implementation

The `emplace()` method uses constructors of objects to construct them in-place within the containers. An exception arising from this method leaves the constructor in an invalid state. If the called constructors contain `throw()` statements, or calls a function that raises exception, Polyspace flags the `emplace()` method.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using Emplace with Inputs That Raise Exceptions

```
#include<exception>
#include<vector>

class ratio{
public:
    ratio(double in1=1, double in2=1):num{in1}, denom{in2}{
        if(in2==0)
        throw std::invalid_argument("Denominator cannot be zero");

    }
private:
    double num;
    double denom;

};

void foo(){
    std::vector<ratio> v;
    v.reserve(10);
    std::vector<ratio>::const_iterator cit;
    //...
    v.emplace(cit, 1,0);//Noncompliant
}
```

In this example, creating a `ratio` with a zero denominator causes an exception. Because the `emplace()` method might leave the vector `v` in an invalid state, Polyspace flags the call to the `emplace()` method.

# AUTOSAR C++14 Rule A15-0-7

Exception handling mechanism shall guarantee a deterministic worst-case time execution time

## Description

### Rule Definition

*Exception handling mechanism shall guarantee a deterministic worst-case time execution time.*

### Rationale

Compilers, such as GCC or CLang, use dynamic memory allocation in the implementations of their exception handling mechanism. Dynamic memory allocation during exception handling results in a nondeterministic worst-case execution time. Such exception handling functions might raise memory allocation errors during run time. Avoid dynamic memory allocation in exception handling functions. Implement the exception handling functions so that memory is allocated before the run time.

### Polyspace Implementation

Violations of this rule are raised when the exception handling functions in your code allocates or deallocates memory dynamically. Polyspace recognizes the commonly used dynamic memory allocation functions and exception handling functions, including:

- `__cxa_allocate_exception`
- `__cxa_throw`
- `__cxa_free_exception`
- `__cxa_begin_catch`
- `__cxa_end_catch`
- Stack unwinding functions, such as `_Unwind_RaiseException`, `_Unwind_Resume`, `_Unwind_DeleteException`.

To check user-defined exception handling implementations, specify the user-defined exception handling and dynamic memory managing functions by using the analysis option `-code-behavior-specifications`. In the code behavior specification XML file, specify a function as an exception handling function by using the behavior `EXCEPTION_HANDLING`. Specify a function as a dynamic memory managing function by using the behavior `MANAGES_MEMORY`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Dynamic Memory Allocation in Exception Handling Functions

```
#include <cstdlib>
extern "C" void * __cxa_allocate_exception(size_t thrown_size) {
  return new char[thrown_size];   //Noncompliant
}

char bigBuffer[10*1024];
char* bigBufferPtr = bigBuffer;

extern "C" void* __cxa_begin_catch(void* unwind_arg) {
  char* ptr = bigBufferPtr;       // Compliant

  bigBufferPtr += *(int*)unwind_arg;

  return (void*)ptr;
}
```

In this example, the operator `new` allocates dynamic memory in the exception handling function `__cxa_allocate_exception`. Polyspace flags the use of dynamic memory allocation in the exception handling function. The best practice is to allocate memory elsewhere and use the allocated memory during exception handling. For instance, in the exception handling function `__cxa_begin_catch`, there is no dynamic memory allocation. Instead, memory is allocated statically in `bigBuffer`, which is then used in the function. This method of memory allocation for exception handling purposes is compliant with this rule.

`AUTOSAR C++14 Rule A18-5-7`

# AUTOSAR C++14 Rule A15-1-1

Only instances of types derived from std::exception should be thrown

## Description

### Rule Definition

*Only instances of types derived from std::exception should be thrown.*

### Rationale

Raising generic objects as exceptions can make your code difficult to read and reuse. Consider this code where exceptions are raised in two different `try-catch` blocks.

```
try{
    //..
    throw 1; // 1 means logic error;
}
catch(...){
    //...
}
//...
try{
    //...
    throw  std::logic_error{"Logic Error"};
}
catch(std::exception& e){
    //..
}
```

In the first code block, the cause or the meaning of this exception is not clear. An ambiguous exception such as this one can make the code difficult to read and reuse. These type of generic exceptions might also clash with exceptions raised elsewhere in the code, making the exceptions more difficult to handle. This rule states that such generic objects are not acceptable as exception objects.

In the second code block, the meaning and cause of the exception is clearly communicated by raising a specific and unique type of object as an exception. Such `throw` statements also match standard conventions. Clearly communicating the developer intent, adhering to the standard conventions, and raising unique type of exceptions make the code easy to read, understand, and reuse.

The class `std::exception` provides a consistent interface to raise unique exceptions corresponding to specific errors. It is standard convention to use this interface for raising exceptions. To make your code readable and reusable, raise objects of specific types that are derived from `std::exception` as the exception. Generic objects of type `std::exception` cannot be unique. Such exceptions violate this rule.

### Polyspace Implementation

- Polyspace flags a `throw` statement if the type of the raised object is not a class that is publicly derived from `std::exception`.

- If the raised object is part of a multiple inheritance hierarchy, then Polyspace flags the object if none of the base classes derive publicly from `std::exception` or if the base classes do not include `std::exception`.
- If you use a `throw;` statement without an argument in a catch block, Polyspace does not flag the `throw;` statement.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Raise Exception by Using Classes That Are Publicly Derived from `std::exception`

This example shows how Polyspace flags `throw` statements that raise objects of a noncompliant class hierarchy.

```
#include <stdexcept>
#include <memory>

class ConventionalException : public std::logic_error{
public:
    using std::logic_error::logic_error;
};
class CustomException {};
class CustomException_derived : public CustomException {};
class PrivateDerived : private std::exception {};
class ProtectedDerived : protected std::exception {};
class MultipleInheritenceCompliant :
    public ConventionalException, public CustomException {
public:
    MultipleInheritenceCompliant()
    : ConventionalException("Logic Error and Data Error") {
    }
};
class MultipleInheritenceNoncompliant :
    public ProtectedDerived, public CustomException {};

void Foo() {
    throw std::exception();   // Noncompliant
    throw CustomException(); // Noncompliant
    throw CustomException_derived(); // Noncompliant
    throw PrivateDerived();       // Noncompliant
    throw ProtectedDerived();     // Noncompliant
    throw MultipleInheritenceCompliant(); // Compliant
    throw MultipleInheritenceNoncompliant(); // Noncompliant
    throw ConventionalException{"Logic Error"};//Compliant
    throw std::make_shared<std::exception> // Noncompliant
    (std::logic_error("Logic Error"));
}
```

- Polyspace flags the statement `throw std::exception()` because it raises a generic `std::exception` object, which might not be unique in your code.

- Polyspace flags the statement `throw CustomException()` because the class `CustomException` does not derive from `std::exception`. Polyspace flags the statement `throw CustomException_derived()` for the same reason.
- Polyspace flags the statement `throw PrivateDerived()` because the class `PrivateDerived` derives from `std::exception` privately. You cannot catch this exception by using a `catch(std::exception& e)` block because of the private inheritance between `std::exception` and `PrivateDerived`. Polyspace flags the statement `throw ProtectedDerived()` for the same reason.
- Polyspace flags the statement `throw MultipleInheritenceNoncompliant()` because the class `MultipleInheritenceNoncompliant` does not publicly derive from `std::exception`.
- Polyspace flags the statement `throw std::make_shared<std::exception>(std::logic_error("Logic Error"))` because this statement raises a `std::shared_ptr` object as an exception which does not derive from `std::exception`.
- Polyspace does not flag the statements `throw MultipleInheritenceCompliant()` and `throw ConventionalException{"Logic Error"}` because these statements raise objects of classes that are publicly derived from `std::exception`.

### Avoid `throw` Statements in Catch Blocks That Accept `std::exception` Objects

This example shows how Polyspace flags `throw` statements in a catch block.

```
#include <memory>
#include <stdexcept>
class MyException : public std::logic_error
{
public:
    using std::logic_error::logic_error;
    // Implementation
};
void catch_and_rethrow() {
    try {
        /* ... */
    }catch (std::exception e) {
        throw; // Compliant
        throw e; // Noncompliant
    }catch (std::exception& e) {
        throw e; // Noncompliant
        throw;   // Compliant
    }catch (MyException& Error) {
        throw Error; // Compliant
    }
}
```

- Empty `throw;` statements in catch blocks might raise different types of exceptions depending on the run-time context. Because Polyspace analyzes the `throw;` statements without any run-time context-specific information, it cannot determine what kind of object an empty `throw;` statement might raise. Polyspace does not flag `throw;` statements in catch blocks.
- Polyspace flags the statements `throw e` because they raise the `std::exception` object `e` as an exception. Avoid such `throw` statements in catch blocks that accept references to or instances of the `std::exception` class.
- Polyspace does not flag the statement `throw Error` because it raises an object of class `MyException` that derives from `std::exception`.

# AUTOSAR C++14 Rule A15-1-2

An exception object shall not be a pointer

## Description

### Rule Definition

*An exception object shall not be a pointer.*

### Rationale

If your `throw` expression is a pointer to a dynamically allocated object, the deallocation point of the allocated resource becomes ambiguous. Such ambiguity might lead to a memory leak. Throwing pointers as exceptions might allow functions to access objects after their lifetime ends, which results in an undefined behavior.

Avoid using pointers as exceptions. Raise exceptions by copy instead.

### Polyspace Implementation

The checker raises a violation if a `throw` statement throws an exception of pointer type.

The checker does not raise a violation if a NULL pointer is thrown as exception. Throwing a NULL pointer is forbidden according to `AUTOSAR C++14 Rule M15-1-2`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Raising Pointers as Exceptions

```
extern int flag;
class A{/**/};
void foo(void){
    A a;
    A* a_pointer = new A;
    A& a_ref = a;
    if(flag==0){
        throw a;
    }

    else if(flag==2){
        throw a_pointer;//Noncompliant
    }

    else if(flag==-1){
        throw a_ref;
    }
    else if(flag==-2){
        throw &a; //Noncompliant
    }
}
```

In this example, the function `foo()` throws several exceptions. Polyspace flags the `throw` statements where the `throw` operand is a pointer. Raising exceptions by copy or by reference is compliant with this rule.

### Topics

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A15-1-3

All thrown exceptions should be unique

## Description

### Rule Definition

*All thrown exceptions should be unique.*

### Rationale

If the same object is raised as exceptions in multiple places, handling these exceptions and debugging the code can be difficult. Raising unique exception objects simplifies the debugging process. Consider this code where multiple exceptions are raised.

```
void f1(){
    //...
    throw std::logic_error("Error");
}
void f2(){
    //...
    throw std::logic_error("Error");
}
void f3(){
    //...
    throw std::logic_error("f3: Unexpected Condition");
}
int main(){
    try{
        f1();
        f2();
        f3();
        catch(std::logic_error& e){
            std::cout << e.what() << '\n';
        }
    }
}
```

The functions `f1()` and `f2()` raise the same exception, while `f3()` raises a unique exception. During debugging, you cannot determine if an exception arises from `f1()` or `f2()`. You know when an exception arises from `f3()`. To make the debugging process simpler, raise unique exceptions. An exception is unique if either of these conditions is true:

- The exception type does not occur elsewhere in your project.
- The error message or the error code does not occur elsewhere in your project.

### Polyspace Implementation

Polyspace highlights `throw` statements that raise the same class, enum value, integer, or constant literal as exceptions, and flags the final throw statement that raise the same object. You might want to raise the same exception in multiple places by using a preconstructed exception object. Polyspace does not flag `throw` statements that raise such preconstructed exception objects. If you raise the same literal object in multiple places, Polyspace does not flag it if the literal is not a constant or if the literal is hidden behind a variable.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Raise Unique Exceptions

This example shows how Polyspace flags nonunique exceptions.

```
#include <iostream>
#include <sstream>
#include <stdexcept>
#include <string>

int readLog();
enum ENUM {
    ENUM_VALUE_13 = 13,
    ENUM_VALUE_14 = 14,
};
const char* value_gen(int i) {
    if (i % 2 == 0) return "value_gen-0";
    else return "value_gen-1";
}
class CustomException : public std::invalid_argument {
public:
    CustomException() : std::invalid_argument(value_gen(readLog())) {}
};
int foo0(){
    //...
        throw std::logic_error("Invalid Logic"); // Compliant
    //...
        throw std::runtime_error("Runtime Error"); // Compliant
}
int foo1(){
    //...
        throw std::logic_error(value_gen(0));
    //...
        throw std::logic_error(value_gen(2));
}
int foo2(){
//..
        throw CustomException();
//..
        throw CustomException(); // Noncompliant
}

    int foo3(){
    const int localConstInt42 = 42;
    //..
        throw 42;
    //...
        throw localConstInt42; //Noncompliant
}
int foo4(){
    //..
        throw "RUNTIME_ERROR";
    //...
        throw "RUNTIME_ERROR"; // Noncompliant
}
int foo5(){
    //...
        throw ENUM_VALUE_14;
    //...
        throw ENUM_VALUE_14; // Noncompliant
}
```

- The function `foo0()` raises two different types of objects as exceptions. Polyspace does not flag the `throw` statements in `foo0()`.
- The function `foo1()` raises two exceptions that evaluate to be the same object during run-time. Because Polyspace analyzes the exception objects without runtime information, the exceptions appear unique and Polyspace does not flag the throw statements.
- The function `foo2()` raises two exceptions that evaluate to be different objects at run-time. Because Polyspace analyzes the exception objects without run-time information, the exceptions appear nonunique. Polyspace highlights the throw statements in `foo2()` and flags the final the throw statement.
- The function `foo3()` raises three exceptions by using objects that are the same at compile time. Polyspace highlights the throw statements in `foo3()` and flags the final the throw statement. For the same reason, the final `throw` statements in `foo4()` and `foo5()` are flagged.

# AUTOSAR C++14 Rule A15-1-4

If a function exits with an exception, then before a throw, the function shall place all objects/ resources that the function constructed in valid states or it shall delete them.

## Description

### Rule Definition

*If a function exits with an exception, then before a throw, the function shall place all objects/ resources that the function constructed in valid states or it shall delete them.*

### Rationale

When a function exits with an exception, any resource or memory that the function allocated might not be properly deallocated. Consider this code:

```
FILE* FilePtr;
//...
void foo(){
    FilePtr = fopen("some_file.txt", "r");
//...
    if(/*error condition*/)
    throw ERROR_CODE;

    delete FilePtr;
}
```

The allocated file pointer is intended to be deallocated before the function finishes execution. But when an exception takes place, the function exits without deleting the pointer, which results in a memory leak. To avoid memory leaks, a function must set all resources that it allocates to a valid state before it goes out of scope. For instance, in the preceding code example, the function must delete the pointer `FilePtr` before the `throw` statement.

Instead of manually tracking the allocation and deallocation of resources, the best practice is to follow the "Resource Acquisition Is Initialization" (RAII) or the "Constructor Acquires, Destructor Releases" (CADre) design pattern. In this pattern, resource allocation is performed in constructors and resource deallocation is performed in destructors. The lifecycle of resources are controlled by scope-bound objects in this pattern. When functions reach the end of their scope, the acquired resources are properly released. Consider this code:

```
void releaseFile(std::FILE* fp) { std::fclose(fp); }
std::unique_ptr<std::FILE, decltype(&releaseFile)> FilePtr;
//...
void foo(){
    FilePtr(std::fopen("some_file.txt"),&releaseFile);
//...
    if(/*error condition*/)
    throw ERROR_CODE;
}
```

Here, the unique pointer `FilePTR` invokes the function `releaseFile` to delete the allocated resource once the function `foo` reaches the end of its scope, whether normally or because of an unhandled exception.

C++ smart pointers such as `std::unique_ptr` and `std::shared_ptr` follow the RAII pattern. They simplify managing the lifecycle of resources during exception handling. Avoid using raw pointers whenever possible.

### Polyspace Implementation

Polyspace flags an uncaught `throw` statement in a if the statement might result in resource leak. For instance,

- A `throw` statement outside a `try` block is flagged if the allocated resources are not deallocated before the statement.
- A `throw` statement in a `catch` block is flagged if the resources are not deallocated before raising the exception.

Polyspace does not flag a `throw` statement if it is within a `try` block that has an appropriate handler or if the exception is raised before allocating resources.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Deallocate Resources Before `throw` Statements

```
#include <cstdint>
#include <memory>
#include <stdexcept>
extern int sensorFlag() noexcept;
namespace Noncompliant{
    void func(){
        int* intPtr = new int;
        int data = sensorFlag();
        if(data==-1)//Error
        throw std::runtime_error("Unexpected value");//Noncompliant
        //...
        delete intPtr;
    }
}
namespace Compliant{
    void func(){
        int* intPtr = new int;
        int data = sensorFlag();
        if(data==-1){//Error
            delete intPtr;
            throw std::runtime_error("Unexpected value");//Compliant
        }
        //...
        delete intPtr;
    }
}
namespace BestPractice{
    void func(){
        std::unique_ptr<int> intPtr = std::make_unique<int>();
        int data = sensorFlag();
        if(data==-1){//Error
            throw std::runtime_error("Unexpected value");//Compliant
        }
        //...

    }
}
```

In this example, the function `Noncompliant::func()` manages the raw pointer `inPtr`. The function allocates memory for it, and then releases the memory after some operations. The function exits with an exception when `data` is `-1`. In this case, the function exits before releasing the allocated memory, resulting in a memory leak. To prevent memory leak, the allocated memory must be released before raising the exception, as shown in `Compliant::func`.

The best practice is to follow the RAII design pattern and use `unique_ptr` instead of a raw pointer. `BestPractice::func` shows an implementation of `func` that follows the RAII pattern. In this case, the memory lifecycle is managed by the object itself. That is, once `func` is out of scope, the smart pointer `intPtr` deletes itself and releases the memory. Because the memory management is performed correctly by the smart pointer, `BestPractice::func` is simpler and safer.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A15-1-5

Exceptions shall not be thrown across execution boundaries

## Description

### Rule Definition

*Exceptions shall not be thrown across execution boundaries.*

### Rationale

An execution boundary separates code in your projects that are compiled by different compilers or different versions of a compiler. For example, you might use different compilers to compile your code and a library function. In this case, the execution boundary exists between the call site in your executable and the function implementation in the library.

Exception handling requires interoperability between the functions that raise the exception and the functions that handle the raised exceptions. Code on two sides of an execution boundary might implement exception handling by using incompatible interfaces. For instance:

```
// lib.h
void foo() noexcept(false);
//lib.cpp
void foo() noexcept(false){
  //...
  throw -1;
}
//App.cpp
#include"lib.h"
int main(){
  try{
    foo();
  }catch(int& e){
    //handle exception
  }
}
```

If you compile the library file `lib.cpp` by using GCC and compile the application `App.cpp` by using Microsoft Visual Studio, then these two portions of your code use incompatible exception-handling interfaces. The exception arising from the library is not caught, which terminates the application unexpectedly.

Avoid raising exceptions in code that you intend to reuse as a library in different projects. Instead of raising exceptions, return different error codes to handle unexpected situations.

As an exception, raising exceptions across an execution boundary is compliant with this rule if the codes on the two sides of the boundary are guaranteed to use the same exception handling interface

### Polyspace Implementation

Polyspace raises a violation of this rule if a library interface function raises an exception. Violations are not raised if a `new` operator in a such a function raises an `std::bad_alloc` exception.

To use this checker correctly, you must specify those functions in your code that are part of a library interface. Declare a function *`foo()`* as a library interface function by setting their `visibility` attribute. For instance:

- GNU and Clang compiler: `void __attribute__((visibility("default"))) foo(){/*...*/}`
- Visual Studio: `void __declspec(dllexport) foo(){/**.../}`

If you do not explicitly specify a function as visible, Polyspace assumes that it is not part of a library interface.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use `noexcept` Library Functions

```
#include<exception>
int FLAG;
void __attribute__((visibility("default"))) foo(int rd) noexcept(false) {//Noncompliant
    if (rd==-1)
        throw std::exception();
}

int __attribute__((visibility("default"))) bar(bool rd) noexcept(true) {
    if (rd==-1){
        FLAG = 52;
        return -1;
    }
}
```

In this example, the `visibility` attribute of the function `foo()` is set to `default`, which indicates that this function belongs in a library interface. Because `foo()` might be used in projects that have different exception handling mechanisms, exceptions raised by `foo()` might remain unhandled. Avoid raising exceptions from library interface functions. Instead, use other methods for handling errors, as shown in `bar`. The library function `bar` sets an error flag and returns an error code when a logic error occurs in the code.

# AUTOSAR C++14 Rule A15-2-1

Constructors that are not noexcept shall not be invoked before program startup

## Description

### Rule Definition

*Constructors that are not noexcept shall not be invoked before program startup.*

### Rationale

In C++, the compiler responds to an exception by following these steps:

- The compiler tries to match the exception with a handler in the current scope or a higher scope.
- If the exception matches with a handler, then the handler accepts the exception and begins stack unwinding. During stack unwinding, The program execution moves from the scope that produces the exception to the outer scopes in reverse order. The program execution then invokes the destructors for each variable on the stack that are not destroyed yet. After stack unwinding, program execution resumes from the line immediately after the triggered handler.
- If the exception does not match a handler, then the compiler terminates the execution in an implementation-defined manner. That is, the exact process of program termination depends on the particular set of software and hardware that you use. For instance, the compiler might invoke `std::terminate()`, which in turn might invoke `std::abort()` to abnormally abort the execution. Based on the implementation, the stack might not be unwound before the program is aborted. If the stack is not unwound before program termination, then the destructors of the variables in the stack are not invoked, leading to resource leak and security vulnerabilities.

Before program startup, the constructors of static or global objects are invoked to construct and initialize these objects. If such a constructor raises an exception, the compiler might abnormally terminate the code execution without unwinding the stack. Consider this code where the constructor of the static object `obj` might cause an exception.

```
class A{
    A(){

        //...
    }
};

static A obj;

main(){
    //...
}
```

The static object `obj` is constructed by calling `A()` before `main()` starts. Because `A()` is called before program startup, no exception handler can be matched with exceptions raised by `A()`. Based on the implementation, such an exception can result in program termination without stack unwinding, leading to memory leak and security vulnerabilities.

Because exceptions raised by constructors of static or global objects cannot be matched to an exception handler, declare these constructors as `noexcept`.

### Polyspace Implementation

Polyspace flags statements where non-`noexcept` constructors of a static or global object are directly invoked. It also highlights the noncompliant constructors.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declare Constructors of Static or Global Objects as `noexcept`

This example shows how Polyspace flags constructors of static or global objects.

```
#include <cstdint>
#include <stdexcept>
#include <string>
class A
{
public:
    A() noexcept : x(0){}
    A(std::int32_t n) : x(n) {
        throw std::runtime_error("Unexpected error");
    }
    A(std::int32_t i, std::int32_t j) noexcept : x(i + j)
    {
        try {
            throw std::runtime_error("Error");
        }
        catch (std::exception& e) {
        }
    }
private:
    std::int32_t x;
};

static A a1;     // Compliant
static A a2(5);  // Noncompliant
static A a6(5);  // Ignored because unused
static A a3(5, 10); // Compliant
A a4(5);  //Noncompliant
A a5(5, 10); //Compliant
int foo_A(A a) { };

int bar_A(int value) {
    A a{value};   //Compliant
    return foo_A(a);
}
int value2b = bar_A(20);   // Compliant
std::string s{"Hello World"};//Noncompliant
int value2a = foo_A(20);   //Noncompliant
int convert(){
    return  foo_A(a2);
}
```

- Polyspace flags the statement `std::string s{"Hello World"};` because this statement invokes the non-`noexcept` constructor of the string `s` before program startup.
- Polyspace flags the statement `A a4(5);` because this statement invokes the non-`noexcept` constructor `A(std::int32_t n)` before program startup.
- Polyspace flags the statement `static A a2(5);` because this statement invokes the non-`noexcept` constructor `A(std::int32_t n)` before program startup.
- Polyspace flags the statement `int value2a = foo_A(20);` because the implicit conversion from `int` to `A` requires invoking the non-`noexcept` constructor `A(std::int32_t n)` before startup.
- Polyspace does not flag the statement `static A a6(5);`. Because `a6` is not used in this code, the compiler does not construct the object. As a result, the non-`noexcept` constructor `A(std::int32_t n)` is not invoked before program startup.
- Polyspace does not flag the statement `A a{value};` in the body of the function `bar_A()` because the object `a` is local, and it is not created during program startup.

# AUTOSAR C++14 Rule A15-2-2

If a constructor is not noexcept and the constructor cannot finish object initialization, then it shall deallocate the object's resources and it shall throw an exception

## Description

### Rule Definition

*If a constructor is not noexcept and the constructor cannot finish object initialization, then it shall deallocate the object's resources and it shall throw an exception.*

### Rationale

When a constructor abruptly terminates due to unhandled exception or failed dynamic resource allocation, it might leave some objects in a partially constructed object, which is undefined behavior. Before raising exceptions in class constructors, deallocate the already allocated resources. When allocating resources, specify the `new` operation as `std::nothrow`. Alternatively, perform the resource allocation in a `try` or `function-try` block to handle exceptions that might arise from a failed allocation.

### Polyspace Implementation

Polyspace flags a `throw` or `new` statement outside a `try` block in a non-`noexcept` class constructor if the statement might result in resource leak. For instance:

- A `throw` statement outside a `try` block is flagged if the allocated resources are not deallocated before the statement.
- A `new` statement is flagged if there are more than one `new` statement in succession and the latter ones is not specified as `std::nothrow` or wrapped in a `try` or `function-try` block.

Polyspace ignores classes that remain unused in your code.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Deallocate Resource Before Raising Exception

```
#include<cstdlib>
#include<exception>
 class complex_ptr{

    complex_ptr(){
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            throw std::exception(); //Noncompliant
        }
    }
    ~complex_ptr(){
        free(real);
        free(imag);
    }
    private:
    double* real;
    double* imag;

};
class complex_ptr2{

    complex_ptr2() {
        real = (double*)malloc(sizeof(double));
        imag = (double*)malloc(sizeof(double));
        if(real==nullptr || imag==nullptr){
            deallocate();
            throw std::exception(); //Compliant
        }
    }
    void deallocate(){
        free(real);
        free(imag);
    }
    ~complex_ptr2(){
        deallocate();
    }
    private:
    double* real;
    double* imag;

};
void foo(void){
    complex_ptr Z;
    complex_ptr2 X;
    //...
}
```

In this example, the class `complex_ptr` is responsible for allocating and deallocating two raw pointers to `double`. The constructor `complex_ptr::complex_ptr()` terminates with an exception when a memory allocation operation fails. The class goes out of scope before deallocating the already allocated resources, resulting in a partially constructed object. Polyspace flags the `throw` statement in the constructor.

Similar to `complex_ptr`, the constructor of class `complex_ptr2` raises an exception when a memory allocation operation fails. Before raising the exception, the constructor deallocates the allocated memory by calling `deallocate()`. This constructor is compliant with this rule.

#### Handle Exceptions Arising from `new` Operations in Constructors

```
#include<cstdlib>
#include <stdexcept>
#include <new>
 class complex_ptr{

    complex_ptr(): real(new double), imag(new double){ //Noncompliant
    }
    ~complex_ptr(){
        delete real;
        delete imag;
    }
    private:
    double* real;
    double* imag;

};

class complex_ptr2{

    complex_ptr2() try: real(new double), imag(new double){    //Compliant

    }catch(std::bad_alloc){
        //...
    }
    ~complex_ptr2(){
        delete real;
        delete imag;
    }
    private:
    double* real;
    double* imag;

};

void foo(void){
    complex_ptr Z;
    complex_ptr2 X;
    //...
}
```

In this example, the constructor of `complex_ptr` performs `new` operations that might raise exceptions. Because the constructor has no mechanism for handling these exceptions, they might cause the constructor to abruptly terminate. Such termination might leave the object in a partially defined state because the allocated resources are not deallocated. Polyspace flags the constructor. The constructor of `complex_ptr2` performs the new operations in a `function-try` block and handles potential exceptions in a `catch` block. This constructor is compliant with the rule because it handles the exceptions that might arise from the `new` operations.

# AUTOSAR C++14 Rule A15-3-3

Main function and a task main function shall catch at least: base class exceptions from all third-party libraries used, std::exception and all otherwise unhandled exceptions

## Description

### Rule Definition

*Main function and a task main function shall catch at least: base class exceptions from all third-party libraries used, std::exception and all otherwise unhandled exceptions.*

### Rationale

During the execution of `main()` or a task main function, different exceptions can arise. For instance:

- Explicitly raised exceptions of class `std::exception`
- Exceptions arising from the third-party libraries that you use
- Unexpected exceptions

If any of these exceptions cannot be matched to a handler, the compiler implicitly invokes the function `std::terminate()` to abnormally terminate program execution. Depending on the hardware and software that you use, this termination process might invoke `std::abort()` to abort program execution without deleting the variables in the stack. Such an abnormal termination results in memory leaks and security vulnerabilities.

Unhandled exceptions might cause an abnormal termination of the program execution, leading to memory leaks and security vulnerabilities. To avoid these issues, execute the operations of `main()` or task main functions in a `try-catch` block. In the catch blocks:

- Handle exceptions of type `std::exception` explicitly in appropriate catch blocks.
- Handle the base class of exceptions arising from third-party libraries.
- Handle unexpected exceptions in a `catch(...)` block.

### Polyspace Implementation

- Polyspace flags a `main()` function or a task main function if :
  - Unhandled exceptions are raised in the function. For example, exceptions that are raised outside the `try-catch` block or in a catch block might remain unhandled.
  - The function does not have a `try-catch` block.
  - The function does not have catch blocks to explicitly handle `std::exception` type exceptions.
  - The function does not have a catch-all or `catch(...)` blocks to handle unexpected exceptions.
- Polyspace does not check if exceptions from third-party libraries are handled.
- Polyspace flags a `main()` function or a task main function even if the unhandled exception might not be raised.

Polyspace detects the `main()` function. To specify a function as a task main function, use these compilation options:

- -entry-points <*name*>
- -cyclic-tasks <*name*>
- -interrupts <*name*>

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unhandled Exceptions in `main()` and Task Main Functions

This example shows how Polyspace flags `main()` and task main functions that do not handle all exceptions. To specify the functions `Noncompliant`, `Noncompliant2`, and `Compliant2` as task main functions, use the compile option `-entry-points Noncompliant,Noncompliant2,Compliant`.

```
#include <stdexcept>
void f_throw() {             // Compliant
  throw 1;
}
void Noncompliant()     // Noncompliant
{
  try {

  } catch (std::exception& e) {
      f_throw();             // throw
  } catch (...) {
      throw;
  }
}
int Noncompliant2()     // Noncompliant
{
  f_throw();              // throw
  try {

  } catch (std::exception& e) {
  } catch (...) {
  }
  return 0;
}
int Compliant()   // Compliant
{

  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }catch (...) {
    // Handle all unexpected exceptions
  }
  return 0;
}
int main()   // Noncompliant
{

  try {
    // program code
  } catch (std::runtime_error& e) {
    // Handle runtime errors
  } catch (std::logic_error& e) {
    // Handle logic errors
  } catch (std::exception& e) {
    // Handle all expected exceptions
  }
  return 0;
}
```

- The function `f_throw()` exits with an unhandled exception. Because this function is not a main or task main function, Polyspace does not flag it.
- The function `Noncompliant()` and `Noncompliant2()` are specified as task main functions. In these functions, `f_throw` raises an exception that is not handled. Because these task main functions do not handle all the exceptions that might arise, Polyspace flags them. Enclose operations that might raise an exception in a `try-catch` block to handle exceptions that might arise.
- The function `main()` does not have a `catch(...)` block to handle any unexpected exceptions. Because the `main()` function does not handle all the exceptions that might arise, Polyspace flags it.
- The function `Compliant` is specified as a task main function. This function has a `catch` for all the exceptions that might arise. Polyspace does not flag it.

# AUTOSAR C++14 Rule A15-3-4

Catch-all (ellipsis and std::exception) handlers shall be used only in (a) main, (b) task main functions, (c) in functions that are supposed to isolate independent components and (d) when calling third-party code that uses exceptions not according to AUTOSAR C++14 guidelines

## Description

### Rule Definition

*Catch-all (ellipsis and std::exception) handlers shall be used only in (a) main, (b) task main functions, (c) in functions that are supposed to isolate independent components and (d) when calling third-party code that uses exceptions not according to AUTOSAR C++14 guidelines.*

### Rationale

Catch-all handlers such as `catch(std::exception)` or `catch(...)` blocks match many different types of exceptions. If you handle an exception by using such a catch-all handler, you do not have detailed and specific information about the raised exception. Such catch-all handlers cannot take meaningful actions to handle the raised exceptions. These catch-all handlers are useful in processing unexpected exceptions by raising the exceptions again or by properly exiting from the application.

Because catch-all handlers are useful for specific purposes, it is inefficient to use them in every function. Use catch-all handlers in:

- Main functions
- Task main functions
- Functions that call a third-party function that might be noncompliant with AUTOSAR C++14 guidelines
- Functions that are designed to isolate independent components of your code

### Polyspace Implementation

Polyspace flags `catch(std::exception)` and `catch(...)` blocks in a function if none of these are true:

- The function is the `main()` function.
- The function is a task main function.
- The function calls an external or third-party function that might exit with an exception.

Polyspace detects the `main()` function. To specify a function as a task main function, use these compilation options:

- -entry-points <*name*>
- -cyclic-tasks <*name*>
- -interrupts <*name*>

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Catch-All Handlers in Task Main Functions

This example shows how Polyspace flags catch-all handlers in a task main function `EntryPoint` and a nonentry-point function `NonEntryPoint()`. To specify the function `EntryPoint` as a task main function, use the compile option `-entry-points EntryPoint`.

```
#include <stdexcept>
#define MYEXCEPTION std::exception &
class ExceptionBased: std::exception {
};
typedef std::exception MyException;
typedef std::exception & MyExceptionRef;

void NonEntryPoint()
{
    try {
        int i = 2;

        // ...
    } catch (int i) {                   // Compliant
    } catch (int &i) {                  // Compliant
    } catch (std::runtime_error e) {    // Compliant
    } catch (std::runtime_error& e) {   // Compliant
    } catch (std::exception *e) {       // Compliant
    } catch (std::exception e) {        // Noncompliant
    } catch (const std::exception& e) { // Noncompliant
    } catch(MyException e){             // Noncompliant
    } catch(ExceptionBased e){          // Compliant
    } catch (...) {                     // Noncompliant
    }
}
void EntryPoint() noexcept
{
    try {
        int i = 2;

        // ...
    } catch (MyException &e) {          // Compliant
    } catch (MyException e) {           // Compliant
    } catch (MyExceptionRef e) {        // Compliant
    } catch (ExceptionBased e) {        // Compliant
    } catch (const std::exception& e) { // Compliant
    } catch (MYEXCEPTION e) {           // Compliant
    }
}
```

The function `NonEntryPoint()` is not a `main()` or task main function. In this function, Polyspace flags these catch-all blocks:

- The `catch (std::exception e)` block matches the different types of exceptions that derive from the class `std::exception`. This catch-all handler is useful in a main or task main function. Because `NonEntryPoint()` is neither a `main()` nor a task main function, Polyspace flags the statement `catch (std::exception e)`. For the same reason, Polyspace flags the statement `catch (std::exception& e)`.

- `MyException` is a `typedef` of `std::exception`. The `catch(MyException e)` block matches the different types of exceptions that derive from the class `std::except`. Because `NonEntryPoint()` is neither a main nor a task main function, Polyspace flags the statement `catch(MyException e)`.
- Because `NonEntryPoint()` is neither a main nor a task main function, Polyspace flags the statement `catch(...)`

The function `EntryPoint()` is specified as a task main function. Polyspace does not flag the catch-all blocks in this function.

### Use Catch-All Handlers to Handle Exceptions Raised By Third-party Code

```
#include <stdexcept>
void Fextern_throw(void);
void Fextern_nothrow(void) noexcept(true);
void Foo0()
{
    try {
        Fextern_nothrow();
    } catch (...) {                 // Noncompliant
    }
}
void Foo1()
{
    try {
        try {
            Fextern_throw();
        } catch (...) {               // Compliant
        }
    } catch (std::exception& e) {   // Compliant
    }
}
void Foo2()
{
    try {
        try {
            Fextern_nothrow();
        } catch (...) {               // Noncompliant
            Fextern_throw();
        }
    } catch (std::exception& e) {   // Compliant
    }
}
```

- The function `Foo0()` calls the third-party function `Fextern_nothrow()`, which is specified as `noexcept(true)`. Because the third-party code is specified as `noexcept`, Polyspace flags the `catch(...)` block in `Foo0()`.
- The function `Foo1()` calls the third-party function `Fextern_throw()` that might raise an exception. Because the third-party code might raise an exception, Polyspace does not flag the catch-all handler blocks in `Foo1()`.
- The function `Foo2()` contains a nested `try-catch` block. In the inner block, the external function `Fextern_nothrow()` is called, which is specified as `noexcept(true)`. Polyspace flags the `catch(...)` block in the inner `try-catch` block. The catch-all block in the outer `try-catch` is compliant because this block handles the exceptions that might be raised by the external function `Fextern_throw()`.

# AUTOSAR C++14 Rule A15-3-5

A class type exception shall be caught by reference or const reference

## Description

### Rule Definition

*A class type exception shall be caught by reference or const reference.*

### Rationale

If a class type exception is caught by value, the exception object might be sliced. For instance:

```
class baseException();
class derivedException : public baseException {};

void foo() {
    try {
        //...
        throw derivedException();
    }
    catch (baseException e) { //slices the thrown exception
        //...
    }
}
```

When the catch block in `foo()` catches the `derivedException` object, you might expect the object to remain a `derivedException` object. Because the object is caught by value, it is sliced to a `baseException` object. Unintended object slicing risks unexpected code behavior at run time. To avoid object slicing, catch class type exceptions by reference or `const` reference.

### Polyspace Implementation

Polyspace flags catch statements where class type exceptions are caught by value.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Catch Exceptions by Reference

```
#include <exception>
#include <iostream>

class baseException : public std::exception {
public:
    baseException() : exception() {}
    const char* what() const noexcept(true) override {
        return "Base Exception Object";
    }
};

class derivedException : public baseException {
public:
    derivedException() : baseException() {}
    const char* what() const noexcept(true) override {
        return "Derived Exception Object";
    }
};

class exampleException{};

void foo() {
    try {
        throw derivedException();
    }
    catch (baseException e) { //Noncompliant
        std::cout << e.what();
    }
    catch (derivedException e) { //Noncompliant
        std::cout << e.what();
    }
    catch (exampleException e) { //Noncompliant
    }
    catch (baseException &e) { //Compliant
        std::cout << e.what();
    }
    catch (const baseException &e) { //Compliant
        std::cout << e.what();
    }
    catch (derivedException &e) { //Compliant
        std::cout << e.what();
    }
    catch (const derivedException &e) { //Compliant
        std::cout << e.what();
    }
}
```

In this example, Polyspace flags the `catch` blocks that catches exception objects by value. For instance:

- Catch blocks for exceptions of type `baseException`, `derivedException`, and `exampleException` are noncompliant because the thrown class type exception is caught by value. These blocks might slice the exception objects.
- Catch blocks for exceptions of type `baseException &`, `const baseException &`, `derivedException &`, and `const derivedException &` are compliant because the class type exception is caught by reference or `const` reference.

# AUTOSAR C++14 Rule A15-4-1

Dynamic exception-specification shall not be used

## Description

### Rule Definition

*Dynamic exception-specification shall not be used.*

### Rationale

Dynamic exception specification is the method of specifying how a function behaves in case of an exception by using a `throw(`*`<list of exceptions>`*`)` statement in the function declaration. Using dynamic exception specification has these issues:

- Performance cost: Because dynamic exception specifications are checked at runtime, it adds to overhead and might reduce code performance.
- Not suitable for generic programming: Because the precise type of exceptions raised by function or class templates are generally not known beforehand, it can be difficult to use `throw` statements in generic code.

For these reasons, avoid the `throw(`*`<list of exceptions>`*`)` statement to specify exceptions. Use the `noexcept` keyword instead. Because the `noexcept` statements are checked at compile time, it is suitable for generic programming and generally provides better performance than `throw` statements. The C++11 standard specifies that dynamic exception specification will be removed from C++ in the future.

### Polyspace Implementation

When a `throw(`*`<list of exceptions>`*`)` statement is used in a function declaration, Polyspace flags the `throw` statement. Polyspace does not flag `throw` statements that are used for raising an exception.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using `throw()` for Dynamic Exception Specification

```
#include <string>
// throw for raising exception is compliant
void F9 () throw(std::runtime_error) {   //Non-compliant
    throw (std::runtime_error("foo"));   //Compliant
}
// Both declaration and definition is flagged
void F11 () throw(std::runtime_error);   //Noncompliant
void F11 () throw(std::runtime_error) {} //Noncompliant
// Instantiated and Noninstantiated templates are flagged
```

```
template <class T>
void F10 () throw(std::runtime_error) {  //Noncompliant
    throw (std::runtime_error("foo"));   //Compliant
}

template <class T>
void F12 () throw(std::runtime_error);   //Noncompliant
template <class T>
void foo() noexcept(noexcept(T())) {}//Compliant

void bar () {
    foo<int>();  // noexcept(noexcept(int())) => noexcept(true)
    F10<std::string> ();                 //Compliant

}
```

Polyspace flags statements such as `throw(std::runtime_error)` that are used in the function declarations and definitions as dynamic exception specification. Avoid dynamic exception specification. Use the keyword `noexcept` instead. The template `foo` uses the `noexcept` keyword as the exception specification, which is compliant with this rule.

# AUTOSAR C++14 Rule A15-4-2

If a function is declared to be noexcept, noexcept(true) or noexcept(<true condition>), then it shall not exit with an exception

## Description

### Rule Definition

*If a function is declared to be noexcept, noexcept(true) or noexcept(<true condition>), then it shall not exit with an exception.*

### Rationale

You can specify that a callable entity does not raise an exception by specifying it as `noexcept`, or `noexcept(true)`, or `noexcept(<true condition>)`. The compiler expects that a `noexcept` function does not exit with an exception. Based on this assumption, the compiler omits the exception handing process for `noexcept` functions. When a `noexcept` function exits with an exception, the exception becomes unhandled.

If a `noexcept` function exits with an exception, the compiler invokes `std::terminate()` implicitly. The function `std::terminate()` terminates the program execution in an implementation-defined manner. That is, the exact process of program termination depends on the particular set of software and hardware that you use. For instance, `std:terminate()` might invoke `std::abort()` to abnormally abort the execution without unwinding the stack, leading to resource leak and security vulnerabilities.

Specify functions as `noexcept` or `noexcept(true)` only when you know the functions raise no exceptions. If you cannot determine the exception specification of a function, specify it by using `noexcept(false)`.

### Polyspace Implementation

If you specify a callable entity by using `noexcept`, `noexcept(true)`, or `noexcept(<true condition>)`, Polyspace checks the callable entity for unhandled exceptions and flags the callable entity if it might exit with an exception.

When a callable entity invokes other callable entities, Polyspace makes certain assumptions to calculate whether there might be unhandled exceptions.

- Functions: When a `noexcept` function calls another function, Polyspace checks whether the called function might raise an exception only if it is specified as `noexcept(<false>)`. If the called function is specified as `noexcept`, Polyspace assumes that it does not raise an exception. Some standard library functions, such as the constructor of `std::string`, use pointers to functions to perform memory allocation, which might raise exceptions. Because these functions are not specified as `noexcept(<false>)`, Polyspace does not flag a function that calls these standard library functions.
- External function: When a `noexcept` function calls an external function, Polyspace flags the function declaration if the external function is specified as `noexcept(<false>)`.
- Virtual function: When a function calls a virtual function, Polyspace flags the function declaration if the virtual function is specified as `noexcept(<false>)` in a derived class. For instance, if a

noexcept function calls a virtual function that is declared as noexcept(<true>) in the base class, and noexcept(<false>) in a subsequent derived class, Polyspace flags the declaration of the noexcept function.

- Pointers to function: When a noexcept function invokes a pointer to a function, Polyspace assumes that the pointer to function does not raise exceptions.

When analyzing whether a function raises unhandled exceptions, Polyspace ignores:

- Exceptions raised in destructors
- Exceptions raised in atexit() operations

Polyspace also ignores the dynamic context when checking for exceptions. For instance, a function might raise unhandled exceptions that arise only in certain dynamic contexts. Polyspace flags such a function even if the exception might not be raised.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Handle Possible Exceptions Within noexcept Functions

This example shows how Polyspace flags noexcept functions that might raise unhandled exceptions. Consider this code containing several noexcept functions. These functions invoke other callable entities like functions, external functions, and virtual functions.

```
#include <stdexcept>
#include <typeinfo>
void LibraryFunc();
void LibraryFunc_noexcept_false() noexcept(false);
void LibraryFunc_noexcept_true() noexcept(true);

void SpecFalseCT() noexcept  // Noncompliant
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}

class A {
public:
    virtual void f() {}
};

class B : A {
public:
    virtual void f() noexcept {}
};

class C : B {
public:
    virtual void f() noexcept {}
};

class D : A {
public:
    virtual void f() noexcept(false) { throw(2);}
};

void A1(A &a) noexcept {          // Noncompliant
    a.f();
}

void D2(D &d) noexcept {          //Compliant
    try {
        d.f();
    } catch (int i) {
    } catch (...) {
    }
}

void B2(B *b) noexcept {          // Compliant
    b->f();
}
template <class T>
T f_tp(T a) noexcept(sizeof(T)<=4)    // Noncompliant
{
    if (sizeof(T) >4 ) {
        throw std::runtime_error("invalid case");
    }
    return a;
}
void instantiate(void)
{
    f_tp<char>(1);
}
void f() noexcept {               //Noncompliant
    throw std::runtime_error("dead code");
}

void g() noexcept {               // Compliant
    f();
}
```

- Polyspace flags the declaration of the function template `f_tp` because:
  - The condition `sizeof(T)<=4` evaluates to `true` for `char` so the template becomes a `noexcept(true)` function.
  - Polyspace analyzes the `noexcept(true)` instance of the template statically. Polyspace deduces that the template might raise an exception because of the `throw` statement, even though the condition `sizeof(T)>4` is `false`. That is, Polyspace flags the template even though the `throw` statement is never reached.

  Polyspace ignores function templates that are not instantiated.

- Polyspace flags the noexcept function SpecFaleCT() because this function calls the noexcept(false) external function LibraryFunc_noexcept_false() without encapsulating it in a try-catch block. Any exceptions raised by this call to the external function might raise an unhandled exception.
- Polyspace flags the declaration of the noexcept function A1() because this function might call the noexcept(false) function D.f() when the input parameter a is of class D. Depending on the class of the input parameter, the noexcept polymorphic function A1() might raise an unhandled exception.
- Polyspace flags the function f() because it is a noexcept function that uses throw to raise an unhandled exception. Polyspace does not flag the noexcept function g() even though it calls f() because f() is specified as noexcept.
- Polyspace does not flag the noexcept function D2() even though it calls the noexcept(false) function D.f() because D2() handles the exceptions that might arise by using a catch(...) block.

# AUTOSAR C++14 Rule A15-4-3

The noexcept specification of a function shall either be identical across all translation units, or identical or more restrictive between a virtual member function and an overrider

## Description

### Rule Definition

*The noexcept specification of a function shall either be identical across all translation units, or identical or more restrictive between a virtual member function and an overrider.*

### Rationale

Translation units are the different source files that the compiler compiles. When a function has a different exception specification in different source files, it might result in undefined behavior. Similarly, a different exception specification of a polymorphic function in different levels of a class hierarchy might result in compilation failure in some cases. Depending on the software and hardware that you use, different exception specifications of a function in different places might cause a compilation failure or result in undefined behavior leading to security vulnerabilities.

To avoid undefined behavior and security vulnerabilities:

- Keep the same exception specification in all declarations of a function.
- If a virtual function is declared by using `noexcept` or `noexcept(true)` as the exception specification, declare the overrider functions in the derived classes by using the same specification.
- If a virtual function is declared by using `noexcept(false)` as the exception specification, declare the overrider functions in the derived classes by using either `noexcept(false)` or `noexcept(true)` as the exception specification.

### Polyspace Implementation

Polyspace flags the exception specification of a function if the function is declared with different exception specifications in different places in a file. Polyspace flags an overrider function in a derived class if it is specified as `noexcept(fale)` while the virtual function in the base class is specified as `noexcept`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Maintain Identical Exception Specification in Function Declarations

This example shows how Polyspace flags declarations of one function that has different exception specifications. In one file `file1.cpp`, the member functions of the classes `A` and `B` are declared.

```
//file1.cpp
```

```
class A
{
public:
    void F() noexcept;
    void G() noexcept(false);

};
class B
{
public:
    void W() noexcept;
    void R() noexcept(false);

};
```

In another file `file2.cpp`, the member functions of these classes are defined.

```
// file2.cpp
#include"file1.cpp"

void A::F() noexcept(false) //Noncompliant
{
    // Implementation
}
void A::G() noexcept //Noncompliant
{
    // Implementation
}

void B::W() noexcept //Compliant
{
    // Implementation
}
void B::R() noexcept(false) //Compliant
{
    // Implementation
}
```

To see the violations of this rule, run Polyspace and specify both `file1.cpp` and `file2.cpp` as source files by using the option `-sources`. Keep `file1.cpp` and `file2.cpp` in the same folder. For more details about specifying multiple source files, see `-sources`.

The compilation might fail, but Polyspace flags the functions with nonidentical exception specification.

- The function `A::F()` is declared in`file1.cpp` by using the exception specification `noexcept`, but it is declared by using the exception specification `noexcept(false)` in `file2.cpp`. Polyspace flags the nonidentical exception specification in the latter declaration. For the same reason, the exception specification of `A::G()` in `file2.cpp` is also flagged.
- The functions `B::W()` and `B::R()` are declared and defined by using the same exception specification in the two source files. These functions are compliant with this rule.

### Keep Exception Specification Identical or More Restrictive When Declaring Overrider Functions

This example shows how Polyspace flags the declaration of overrider functions that have less restrictive exception specifications.

```
class A
{
public:
    virtual void V1() noexcept = 0;
    virtual void V2() noexcept(false) = 0;
    virtual void V3() noexcept = 0;
};
class B : public A
{
public:
    void V1() noexcept(false) override //Noncompliant
    {
        // Implementation
    }
    void V2() noexcept override //Compliant
    {
        // Implementation
    }
    void V3() noexcept override //Compliant
    {
        // Implementation
    }
};
```

The pure virtual functions `A::V1()`, `A::V2()`, and `A::V3()` are implemented by the overriding functions `B::V1()`, `B::V2()`, and `B::V3()` respectively.

- Polyspace flags the function `B::V1()` because this overriding function is specified by using the less restrictive exception specification `noexcept(false)` compared to the base class virtual function `A::V1()`, which is specified by using `noexcept`.
- Polyspace does not flag `B::V2()` because this overriding function is specified by using the more restrictive specification `noexcept` compared to the base class virtual function `A::V2()`, which is specified by using `noexcept(false)`.
- Polyspace does not flag `B::V3()` because this overriding function is specified by using the same exception specification as the base class virtual function `A::V3()`.

# AUTOSAR C++14 Rule A15-4-4

A declaration of non-throwing function shall contain noexcept specification

## Description

### Rule Definition

*A declaration of non-throwing function shall contain noexcept specification.*

### Rationale

Specifying functions that do not raise exceptions by using the specifier `noexcept` or `noexcept(true)` enables the compiler to perform certain optimizations for these functions, such as omitting the exception handling process. Specifying the exception specification of functions clearly communicates that you expect the functions to not raise exceptions.

Specify functions that do not raise exceptions by using the specifier `noexcept`. If the exception specification of a function depends on a template argument, use `noexcept(<condition>)`. If the exception specification of a function is unknown, assume it raises exceptions.

### Polyspace Implementation

Polyspace flags the definition of a callable entity, such as function, class or function template, or class constructors if the following is true:

- The callable entity is defined. Polyspace does not flag functions that are declared but not defined. Polyspace checks function or class templates that have at least one instantiation.
- The callable entity raises no exceptions. In case of templates of classes and functions, at least one instantiation raises no exception. When checking callable entities for exceptions, Polyspace assumes external functions with no definitions behave as `noexcept(true)`. For more information about how Polyspace checks if a callable entity raises an exception, see the Polyspace Implementation section of `AUTOSAR C++14 Rule A15-4-2`.
- The callable entity has no exception specification.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Specify Nonthrowing Functions as `noexcept`

```
#include <iostream>
#include <stdexcept>
void F1();
void F2() noexcept;
void F3() noexcept(true);
void F4() noexcept(false);

void F5(){ //Noncompliant
```

```
    F2();
    F3();

}

void F6() noexcept    // Compliant
{
    try {
        F4();
    }catch (std::exception& e) {
        // Handle exceptions
    }
}

class NotThrowing {
public:
    NotThrowing() { // Noncompliant
        F2();
    }
};

class Throwing{
public:
    Throwing() { // Compliant
        F4();
    }
};
template <class T, bool B> void CompliantClasshandler() noexcept(B) { //Compliant
    //...
}

template <class T> void NoncompliantClasshandler() { // Noncompliant
    //...
}

int Factory() noexcept{
    Throwing a;
    NotThrowing b;
    NoncompliantClasshandler<Throwing>();
    NoncompliantClasshandler<NotThrowing>();
    CompliantClasshandler<Throwing, true>();
    CompliantClasshandler<NotThrowing, false>();
    return 1;
}
```

- The function `F5` does not raise exceptions but it is not marked as `noexcept` in the code. Polyspace flags the definitions of the function. The function `F6` does not raise exceptions and it is specified as `noexcept` in the code. Polyspace does not flag `F6`.
- Polyspace checks constructors of classes when the classes are used in the code. In this example, the classes `Throwing` and `NotThrowing` are instantiated and Polyspace checks their constructors.

  The constructor of the class `NotThrowing` does not raise exceptions but it is not specified as `noexcept` in the code. Polyspace flags the function. The constructor of the class `Throwing` raises exception and it is not specified as `noexcept` in the code. Polyspace does not flag this constructor.

- Polyspace checks function templates when the template is instantiated. In this example, Polyspace checks the templates `CompliantClasshandler` and `NoncompliantClasshandler` because they are instantiated in `Factory`.

  Because the instantiation of `NoncompliantClasshandler` in `Factory` with the class `NotThrowing` does not raise exception, and the template is not specified as `noexcept` in the code, Polyspace flags the definition of `NoncompliantClasshandler`. Polyspace does not flag the template `CompliantClasshandler` because it is specified by a conditionalized `noexcept` operator in the code.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A15-4-5

Checked exceptions that could be thrown from a function shall be specified together with the function declaration and they shall be identical in all function declarations and for all its overriders

## Description

### Rule Definition

*Checked exceptions that could be thrown from a function shall be specified together with the function declaration and they shall be identical in all function declarations and for all its overriders.*

### Rationale

In C++, there are no checked exceptions because the compiler does not force functions to specify or handle the exceptions that the functions might raise. Dynamic exception specification of the form `throw(<>)` is obsolete and error-prone. The exception specification prescribed in the C++ standard specifies only whether a function raises an exception or not by using the specifier `noexcept`. Because there is no official way to declare which exceptions might arise from a function, the AUTOSAR standard requires that each function declaration be accompanied by comments that document the exception handling of the function. This method of documenting the exceptions is similar to the JAVA exception handling mechanism.

Use comments to specify a list of exceptions that a static analysis tool must check. Before function declarations, use comments to document which of the checked exceptions are expected in the function.

For a class template, the possible exceptions depend on the template argument. Because you cannot predicts the possible exceptions arising from a class template, this rule does not apply for templates.

### Polyspace Implementation

Polyspace reports a violation of this rule when any of these conditions are true:

- A function raises a checked exception but does not document it before its declaration.
- A function does not raise all the checked exceptions that are documented in comments before its declaration.
- A function documents an unchecked exception.
- A function documents an exception but does not define it.

This checker ignores the class member functions that are not called in your code. Because this rule does not apply for templates, Polyspace does not report violations of this rule on templates.

When documenting the checked exception classes, separate different checked exception classes by using line breaks, except between the class declaration and the documenting comments. For example, in this code, a line break separates the checked exceptions class `A` and `B`. The documenting comment and declaration of each class are kept together:

```
/// @checkedException
class A{};
```

```
/// @checkedException
class B{};
```

#### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

#### Document Checked Exceptions by Using Comments

```
#include <cstdint>
#include <stdexcept>

class ObjectType1{};
class ObjectType2{};

/// @checkedException
class TypeError : public std::exception
{
    // Implementation
};

/// @checkedException
class DimMismatch : public std::exception
{
    // Implementation
};

/// @checkedException
class SizeError : public std::exception
{
    // Implementation
};

/// @throw TypeError Unexpetced Object Type as Input
/// @throw DimMismatch Container Dimension Mismatched
/// @throw SizeError    Object Size Too large
void Transform1(ObjectType1& substrate,
               ObjectType2& coating) noexcept(false) //Compliant
{
    // ...
    throw TypeError();
    // ...
    throw DimMismatch();
    // ...
    throw SizeError();
    // ...
}

/// @throw TypeError Unexpetced Object Type as Input
void Transform2(ObjectType1& substrate,//Noncompliant
             ObjectType2& coating) noexcept(false)
//The function raises SizeError
//but does not document it before its declaration.
```

```
{
    // ...
    throw TypeError();
    // ...
    throw SizeError();
    // ...
}

class ValidationError : std::exception

{
    // Implementation
};

/// @throw TypeError Unexpetced Object Type as Input
/// @throw DimMismatch Container Dimension Mismatched
/// @throw SizeError   Object Size Too large
/// @throw ValidationError Checksum is Negative
void Transform3(ObjectType1& substrate,//Noncompliant
               ObjectType2& coating) noexcept(false)
// The function does not raise all the @throw exceptions
// The function documents an unchecked exception ValidationError.
{
    // ...
    throw TypeError();
    // ...
    throw SizeError();
    // ...
}

/// @throw TypeError Unexpetced Object Type as Input
/// @throw LengthMismatch Array Length Mismatched
void Transform4(void){//Noncompliant
// The function does not define the documented exception LengthMismatch
    // ...
    throw TypeError();
    // ...

}
```

In this example, the functions list their checked exceptions at the beginning of the file by using the tag `@checkedException` in comments. These functions then specify which of these checked exceptions are raised in their bodies by using the comment tag `@throw` before their declarations.

- The function `Transform1` is compliant with this rule because it specifies three checked exceptions before its declaration and then raises the same checked exceptions in its body.
- The function `Transform2` is not compliant with this rule because it raises the checked exception`SizeError` but does not document the exception in the comments before the function declaration.
- The function `Transform2` violates the rule in two different ways:
  - The function documents the checked exception `DimMismatch` in the comments before the function declaration but does not raise it in the function body.
  - The function documents the exception `ValidationError` before its declaration, but the exception is not listed as a checked exception.

- The function `Transform4` is noncompliant because it documents an exception `LengthMismatch` but the code does not have the definition of this type.

# AUTOSAR C++14 Rule A15-5-1

All user-provided class destructors, deallocation functions, move constructors, move assignment operators and swap functions shall not exit with an exception. A noexcept exception specification shall be added to these functions as appropriate

## Description

### Rule Definition

*All user-provided class destructors, deallocation functions, move constructors, move assignment operators and swap functions shall not exit with an exception. A noexcept exception specification shall be added to these functions as appropriate.*

### Rationale

This rule states that certain functions must not exit with an exception.

- Destructors and deallocation functions: When an exception is raised, the compiler invokes the destructors and deallocation functions to safely delete the objects in the stack. If a destructor or a deallocation function exits with an exception at that time, the compiler terminates the program execution abnormally. Depending on the software or hardware that you use, abnormal program termination can result in resource leaks and security vulnerabilities. To prevent these issues, avoid destructors and deallocator functions that might exit with an exception. Default destructors and deallocators are `noexcept` functions. When you provide a custom destructor or deallocation function, specify them as `noexcept` and handle all exceptions within the function so that they do not exit with exceptions. For a polymorphic class hierarchy, this rule applies to the destructors of the base and all derived classes.
- Move constructors and move assignment operators: If a move constructor or a move assignment operator exits with an exception, it cannot be guaranteed that the program will revert to the state it was before the move operation. Avoid a move constructor or a move assignment operator that might exit with an exception. Specify these functions as `noexcept` because standard library functions might avoid move operations unless they are declared as `noexcept`. You can also declare these special member functions as `=default`. For more information on when you can declare the special member functions as `=default`, see `AUTOSAR C++14 Rule A12-0-1`.
- Swap functions: Developers expect that a swap function does not exit with an exception. If a swap function exits with an exception, standard library algorithms and copy operations might not work in your code as expected. Specify swap functions as `noexcept`. Avoid operations that might exit with an exception in swap functions.

When you use templates as generic move constructors, generic move assignment operators, and generic swap functions, these templates can have dynamic exception specifications without violating this rule.

### Polyspace Implementation

Polyspace flags a user-defined destructor, deallocation function, move constructor, move assignment operator, and swap function if it might raise an exception. If a function is named `swap` or `Swap` and takes a reference as input, Polyspace considers it a swap function.

Polyspace ignores functions that are declared but not defined.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Exceptions in Destructors and Deallocation Functions

This example shows how Polyspace flags destructors and deallocation functions that might raise an exception. Consider this code with two classes.

```
#include <stdexcept>
class Compliant
{
public:
    //...
    ~Compliant()  //Compliant
    {
        try {
            // ...
            throw std::runtime_error("Error");
        }
        catch (std::exception& e) {
        //...
        }
    }
};

class Noncompliant
{
public:
    //...
    ~Noncompliant()
    {
        throw std::runtime_error("Error"); //Noncompliant
    }
    static void operator delete(void* ptr, std::size_t sz)
    {
        // ...
        throw std::runtime_error("Error");    // Noncompliant
    }
};
```

- The destructor of `Compliant` raises an exception by using a `throw` statement. Because this exception is handled within the destructor function by using a `try-catch` block, `~Compliant()` is compliant with this rule.
- The destructor of `Noncompliant` also raises an exception by using a `throw` statement. Because this exception is not handled within the function, the destructor `~Noncompliant()` exits with an exception. Polyspace flags this `throw` statement in the destructor.
- The deallocation function `Noncompliant::delete()` does not comply with this rule because it does not handle the exception raised within the function. Polyspace flags the `throw` statement in the function.

### Avoid Exceptions in Move Operations

Polyspace flags move operators or move constructors if:

- They might exit with an exception
- They are not specified as `noexcept`

Consider this code where move operations are implemented for two classes.

```
#include <stdexcept>
class Compliant
{
    //...
public:
    Compliant(Compliant&& rhs) noexcept   //Compliant
    {
        try {
            // ...
            throw std::runtime_error("Error");
        }
        catch (std::exception& e) {
            //...
        }
    }

    Compliant& operator=(Compliant&& rhs) noexcept //Compliant
    {
        try {
            // ...
            throw std::runtime_error("Error");
        }
        catch (std::exception& e) {
            //...
        }
        return *this;
    }
};

class Noncompliant
{
public:
    //...
    Noncompliant(Noncompliant&& rhs) //Noncompliant
    {
        // ...
        throw std::runtime_error("Error");    //Noncompliant
    }
    Noncompliant& operator=(Noncompliant&& rhs) //Noncompliant
    {
        // ...
        throw std::runtime_error("Error");   //Noncompliant
        return *this;
    }

};
```

- The move assignment operator and move constructor of the class `Compliant` are specified as `noexcept` and these functions handle exceptions that arise within them. The move constructor and move assignment operator of `Compliant` are compliant with this rule.
- The move assignment operator and the move constructor of the class `Noncompliant` are not specified as `noexcept`. Polyspace flags the declaration of these functions.
- The move assignment operator and the move constructor of the class `Noncompliant` contain `throw` statement that raise exceptions without handling them within these functions. Polyspace flags these `throw` statements.

### Avoid Exceptions in Swap Functions

Consider this code containing two swap functions.

```
#include <stdexcept>
namespace Compliant{
    class C1{};
    void Swap(C1& lhs, C1& rhs) noexcept   //Compliant
    {
        // Implementation
    }
}
namespace Noncompliant{
    class C2{};
    void Swap( C2& lhs, C2& rhs ) noexcept(false) //Noncompliant
    {
        throw std::runtime_error( "Error" );   //Noncompliant
    }
}
```

- The function `Compliant::Swap()` is specified as `noexcept` and does not raise an exception. This swap function is compliant with this rule.
- The function `Noncompliant::Swap()` is specified as `noexcept(false)` and it exits with an exception. Polyspace flags the exception specification of the function and the `throw` statement.

# AUTOSAR C++14 Rule A15-5-2

Program shall not be abruptly terminated. In particular, an implicit or explicit invocation of std::abort(), std::quick_exit(), std::_Exit(), std::terminate() shall not be done

## Description

### Rule Definition

*Program shall not be abruptly terminated. In particular, an implicit or explicit invocation of std::abort(), std::quick_exit(), std::_Exit(), std::terminate() shall not be done.*

### Rationale

Functions such as `std::abort()`, `std::quick_exit()`, and `std::_Exit()` terminate the program immediately without invoking any exit handlers or calling any destructors for the constructed objects. The `std::terminate()` function implicitly calls `std::abort()` to terminate the program abruptly. Exceptions that are unhandled or cannot be handled might also cause abrupt termination of the program.

Depending on your environment, the compiler might not release the allocated resources and unwind the stack when the program is terminated abruptly, leading to issues such as memory leaks. Such abnormal program terminations might make the code vulnerable to denial-of-service attacks. Avoid terminating the program abruptly.

### Polyspace Implementation

Polyspace flags the operations that might result in abrupt termination of the program. For instance:

- The destructor of a class exits with an unhandled exception. See `AUTOSAR C++14 Rule A15-5-3`.
- The constructor of a global or a static object is invoked directly but it is not explicitly specified as `noexcept`. See `AUTOSAR C++14 Rule A15-2-1`.
- A `noexcept` function raises an unhandled exception. See `AUTOSAR C++14 Rule A15-4-2`.
- The argument of a `throw` statement raises an exception. See `AUTOSAR C++14 Rule M15-1-1`.
- Unsafe termination functions such as `std::_Exit`, `std::abort`, and `std::quick_exit` are explicitly invoked.
- The function `std::terminate` is explicitly invoked.
- A handler for abnormal termination is explicitly registered by using the functions `std::set_terminate` or `std::get_terminate`.
- A handler for normal termination that is registered to `std::atexit` raises an unhandled exception.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Handle Possible Exceptions Within noexcept Functions

This example shows how Polyspace flags `noexcept` functions that might raise unhandled exceptions. Consider this code containing several `noexcept` functions. These functions invoke other callable entities such as functions, external functions, and virtual functions.

```
#include <stdexcept>
#include <typeinfo>
void LibraryFunc();
void LibraryFunc_noexcept_false() noexcept(false);
void LibraryFunc_noexcept_true() noexcept(true);

void SpecFalseCT() noexcept  // Noncompliant
{
    try {
        LibraryFunc_noexcept_false();
    } catch (int &e) {
        LibraryFunc_noexcept_false();
    } catch (std::exception &e) {
    } catch (...) {
    }
}

class A {
public:
    virtual void f() {}
};

class B : A {
public:
    virtual void f() noexcept {}
};

class C : B {
public:
    virtual void f() noexcept {}
};

class D : A {
public:
    virtual void f() noexcept(false) { throw(2);}
};

void A1(A &a) noexcept {          // Noncompliant
    a.f();
}

void D2(D &d) noexcept {          //Compliant
    try {
        d.f();
    } catch (int i) {
    } catch (...) {
    }
}

void B2(B *b) noexcept {          // Compliant
    b->f();
}
template <class T>
T f_tp(T a) noexcept(sizeof(T)<=4)    // Noncompliant
{
    if (sizeof(T) >4 ) {
        throw std::runtime_error("invalid case");
    }
    return a;
}
void instantiate(void)
{
    f_tp<char>(1);
}
void f() noexcept {               //Noncompliant
    throw std::runtime_error("dead code");
}

void g() noexcept {               // Compliant
    f();
}
```

- Polyspace flags the declaration of the function template `f_tp` because:
  - The condition `sizeof(T)<=4` evaluates to `true` for `char` so the template becomes a `noexcept(true)` function.
  - Polyspace analyzes the `noexcept(true)` instance of the template statically. Polyspace deduces that the template might raise an exception because of the `throw` statement, even though the condition `sizeof(T)>4` is `false`. That is, Polyspace flags the template even though the `throw` statement is never reached.

  Polyspace ignores function templates that are not instantiated.
- Polyspace flags the `noexcept` function `SpecFaleCT()` because this function calls the `noexcept(false)` external function `LibraryFunc_noexcept_false()` without encapsulating it in a `try-catch` block. Any exceptions raised by this call to the external function might raise an unhandled exception.
- Polyspace flags the declaration of the `noexcept` function `A1()` because this function might call the `noexcept(false)` function `D.f()` when the input parameter `a` is of class `D`. Depending on the class of the input parameter, the `noexcept` polymorphic function `A1()` might raise an unhandled exception.
- Polyspace flags the function `f()` because it is a `noexcept` function that uses `throw` to raise an unhandled exception. Polyspace does not flag the `noexcept` function `g()` even though it calls `f()` because `f()` is specified as `noexcept`.
- Polyspace does not flag the `noexcept` function `D2()` even though it calls the `noexcept(false)` function `D.f()` because `D2()` handles the exceptions that might arise by using a `catch(...)` block.

### Avoid Expressions That Can Raise Exceptions in `throw` Statements

This example shows how Polyspace flags the expressions in `throw` statements that can raise unexpected exceptions.

```
int f_throw() noexcept(false);

class WithDynamicAlloc {
public:
    WithDynamicAlloc(int n) {
        m_data = new int[n];
    }
    ~WithDynamicAlloc() {
        delete[] m_data;
    }
private:
    int* m_data;
};

class MightThrow {
public:
    MightThrow(bool b) {
        if (b) {
            throw 42;
        }
    }
};

class Base {
    virtual void bar() =0;
};
class Derived: public Base {
    void bar();
};
class UsingDerived {
public:
    UsingDerived(const Base& b) {
        m_d =
        dynamic_cast<const Derived&>(b);
    }
private:
    Derived m_d;
};
class CopyThrows {
public:
    CopyThrows() noexcept(true);
    CopyThrows(const CopyThrows& other) noexcept(false);
};
int foo(){
    try{
        //...
        throw WithDynamicAlloc(10); //Noncompliant
        //...
        throw MightThrow(false);//Noncompliant
        throw MightThrow(true);//Noncompliant
        //...
        Derived d;
        throw  UsingDerived(d);// Noncompliant
        //...
        throw f_throw(); //Noncompliant
        CopyThrows except;
        throw except;//Noncompliant
    }
    catch(WithDynamicAlloc& e){
        //...
    }
    catch(MightThrow& e){
        //...
    }
    catch(UsingDerived& e){
        //...
    }
}
```

- When constructing a `WithDyamicAlloc` object by calling the constructor `WithDynamicAlloc(10)`, exceptions can be raised during dynamic memory allocation. Because the expression `WithDynamicAlloc(10)` can raise an exception, Polyspace flags the `throw` statement `throw WithDynamicAlloc(10);`
- When constructing a `UsingDerived` object by calling the constructor `UsingDervide()`, exceptions can be raised during the dynamic casting operation. Because the expression `UsingDerived(d)` can raise exceptions, Polyspace flags the statement `throw UsingDerived(d)`.
- In the function `MightThrow()`, exceptions can be raised depending on the input to the function. Because Polyspace analyzes functions statically, it assumes that the function `MightThrow()` can raise exceptions. Polyspace flags the statements `throw MightThrow(false)` and `throw MightThrow(true)`.
- In the statement `throw except`, the object `except` is copied by implicitly calling the copy constructor of the class `CopyThrows`. Because the copy constructor is specified as `noexcept(false)`, Polyspace assumes that the copy operation might raise exceptions. Polyspace flags the statement `throw except`.
- Because the function `f_throw()` is specified as `noexcept(false)`, Polyspace assumes that it can raise exceptions. Polyspace flags the statement `throw f_throw()`.

### Avoid Unsafe Termination Functions

```
#include<cstdlib>
class obj
{
public:
    obj() noexcept(false){}
    obj(const obj& a){/*...*/}
    ~obj(){/*...*/}
};
static obj staticObject;
void foo(){
    obj localObject;
    //...
    std::_Exit(-1);//Noncompliant
}
void bar(){
    obj localObject;
    //...
    std::abort;//Noncompliant
}
void foobar(){
    obj localObject;
    //...
    std::quick_exit(-1);//Noncompliant
}
```

In this example, unsafe termination functions are invoked to terminate the program. These functions do not perform the essential cleanup operations such as calling destructors. For instance, the destructors of the `staticObject` or the three instances of `localObject` are not invoked. Any resource allocated by these objects is leaked. Polyspace flags the use of such unsafe termination programs.

### Avoid Explicitly Calling `std::terminate`

```
#include<cstdlib>
#include<exception>
class obj
{
public:
    obj() noexcept(false){}
    obj(const obj& a){/*...*/}
    ~obj(){/*...*/}
};
static obj staticObject;

void foobar(){
    obj localObject;
    //...
    std::terminate();//Noncompliant
}
```

Invoking `std::terminate` explicitly might result in abrupt termination of the program without calling the destructors of the local and static objects. Polyspace flags the explicit calls to `std::terminate`.

### Avoid Unhandled Exceptions in Termination Handlers

```
#include <stdexcept>
void atexit_handler(){//Noncompliant
    throw std::runtime_error("Error in atexit function");
}
void main(){
    try{
        //...
        std::atexit(atexit_handler);
    }catch(...){

    }
}
```

The termination handler `atexit_handler` raises an uncaught exception. The function `atexit_handler` executes after the main finishes execution. Unhandled exceptions in this function cannot be handled elsewhere, leading to an implicit call to `std::terminate()`. Polyspace flags the function.

### Avoid Unhandled Exceptions in Constructors and Destructors

```
#include <stdexcept>
#include <new>
class obj
```

```
{
public:
    obj() noexcept(false){}
    obj(const obj& a){
        //...
        throw -1;
    }
    ~obj()
    {
        try{
            // ...
            throw std::runtime_error("Error2"); // Noncompliant
        }catch(std::bad_alloc& e){

        }
    }
};
obj globalObject; //Noncompliant
```

In this example, the constructor of the object `globalObject` is specified as `noexcept`. The destructor of the object explicitly raises an unhandled exception. These unhandled exception might arise before the execution starts or after the `main` function completes execution, which might result in an abrupt and unsafe termination by invoking `std::abort()`. Polyspace flags these operations.

# AUTOSAR C++14 Rule A15-5-3

The std::terminate() function shall not be called implicitly

## Description

### Rule Definition

*The std::terminate() function shall not be called implicitly.*

### Polyspace Implementation

The checker flags situations that might result in calling the function `std::terminate()` implicitly. These situations might include:

- An exception remains unhandled. For instance:
  - While handling an exception, it escapes through another function that raises an unhandled exception. For instance, a catch statement or exception handler invokes another function that raises an unhandled exception.
  - An empty `throw` statement raises an unhandled exception again.

  For more details, see `Uncaught exception`
- A class destructor raises an exception.
- A termination handler that is passed to `std::atexit` raises an unhandled exception.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Unhandled Exceptions

```
#include <stdexcept>
#include <new>
class obj
{
public:
    obj() noexcept(false){}
    obj(const obj& a){
        //...
        throw -1;
    }
    ~obj()
    {
        try{
            // ...
            throw std::runtime_error("Error2"); // Noncompliant
        }catch(std::bad_alloc& e){
        }
    }
};
obj globalObject;
void atexit_handler(){//Noncompliant
    throw std::runtime_error("Error in atexit function");
}
void main(){
    try{
        //...
        obj localObject = globalObject; //Noncompliant
        std::atexit(atexit_handler);
    }catch(std::exception& e){

    }
}
```

In this example, Polyspace flags unhandled exceptions because they result in implicit calls to `std::terminate()`.

- The destructor `~obj()` does not catch the exception raised by the `throw` statement. The unhandled exception in the destructor results in abrupt termination of the program through an implicit call to `std::terminate`. Polyspace flags the `throw` statement in the destructor of `obj`.
- The `main()` function does not handle all exceptions raised in the code. For instance, the `main` function has no `catch` blocks to handle the exception raised by the copy constructor of `obj`. This unhandled exception might result in an implicit call to `std::terminate()`. Polyspace reports a violation on the statement where the copy constructor is invoked.
- The termination handler `atexit_handler` raises an uncaught exception. The function `atexit_handler` executes after the main finishes execution. Unhandled exceptions in this function cannot be handled elsewhere, leading to an implicit call to `std::terminate()`. Polyspace flags the function.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A16-0-1

The preprocessor shall only be used for unconditional and conditional file inclusion and include guards, and using specific directives

## Description

### Rule Definition

*The preprocessor shall only be used for unconditional and conditional file inclusion and include guards, and using specific directives.*

### Rationale

Other than unconditional and conditional file inclusion and include guards, avoid the use of preprocessor directives. Use a safer alternative instead. For instance:

- Instead of:

  ```
  #define MIN(a,b) ((a < b)? (a) : (b))
  ```

  You can use inline functions and function templates.
- Instead of:

  ```
  #define MAX_ARRAY_SIZE 1024U
  ```

  You can use a constant object.

In these situations, preprocessor directives do not provide the benefits that the alternatives provide, such as linkage, type checking, overloading, and so on.

### Polyspace Implementation

The rule checker does not allow the use of preprocessor directives. The only exceptions are:

- `#ifdef`, `#ifndef`, `#if`, `#if defined`, `#elif`, `#else` and `#endif`, only if used for conditional file inclusion and include guards.
- `#define` only if used for defining macros to be used in include guards. For instance, in this example, the macro `__FILE_H__` prevents the contents of the header file from being included more than once:

  ```
  /* aHeader.h */

  #ifndef __FILE_H__
  #define __FILE_H__
     /* Contents of header file */
  #endif
  ```

  When `#ifdef`, `#define` and `#endif` are used as include guards in a header file, the entire content of the header file must be in the include guard.
- `#include`

The checker does not allow the `#define` directives in other contexts. If you use `#define`-s for purposes other than for include guards, do one of the following:

- To define macros when compiling your code, instead of `#define`-s, use compilation flags (such as the GCC option `-D`). When running a Polyspace analysis, use the equivalent Polyspace option `Preprocessor definitions (-D)`.
- To retain the use of `#define` in your code, justify the violation using comments in your results or code. See "Address Results in Polyspace User Interface Through Bug Fixes or Justifications".

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Compliant and Noncompliant Use of Preprocessor Directives

```
#include <cstdint>       //Compliant: unconditional file inclusion

#ifdef WIN32             //Compliant: include guard
   #include <windows.h>  //Compliant: conditional file inclusion
#endif

#ifdef WIN32     //Noncompliant
    std::int32_t func(std::int16_t x, std::int16_t y) noexcept;
#endif
```

In this example, the rule is not violated when preprocessor directives are used for unconditional and conditional inclusion and include guards. Otherwise, the rule is violated.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A16-2-2

There shall be no unused include directives

## Description

### Rule Definition

*There shall be no unused include directives.*

### Rationale

Unused include directives unnecessarily increase the code base size and introduce dependencies, which slows down the compilation process. To avoid this issue, remove unused include directives.

Remove unused include directives from the code.

### Polyspace Implementation

Polyspace reports a violation when a source file includes a header file that contains declarations of symbols that are not used in the source file. This rule checker does not check any external libraries.

Polyspace considers an include directive to be unused when you do not:

- Invoke macros defined in the included file or the included file's includes.
- Use data types defined in the included file or the included file's includes.
- Call or use references to an object or function defined in the included file or the included file's includes.
- Use an externally visible object provided by the included file outside of the file.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unused Include Directive Used In Source File

Because the source file does not use a symbol, macro, or data type defined in the `<algorithm>` header file, Polyspace reports a violation on the `<algorithm>` header file. Remove the unused include directive from the source file.

```
#include <algorithm>    //Noncompliant
#include <cstdint>
#include <iostream>

void main()
{
    int32_t num = 5;
    std::cout << "Hello world : " << num;
}
```

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A16-2-3

An include directive shall be added explicitly for every symbol used in a file

## Description

### Rule Definition

*An include directive shall be added explicitly for every symbol used in a file.*

### Rationale

To avoid a compilation failure, declare every symbol, macro, and data type before use and include their associated header files in the source file.

### Polyspace Implementation

Polyspace reports a violation when a source file contains a symbol, macro, or data type and the header file in which the symbol, macro, or data type is defined in is not included in the same source file.

Polyspace does not report a violation if the header file containing the required include directive shares a name with the source file.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Include Directive Not Explicitly Added

The source code in this example contains the type `int32_t`. Because the source code does not include the header file where `int32_t` is defined, `<cstdint>`, Polyspace flags this violation. This example results in a compilation failure.

```
#include <ostream>
#include <iostream>
#include <string_view>

void main()
{
    int32_t num = 5;    //Noncompliant
    std::cout << "Hello world : " << num;
}
```

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A16-6-1

#error directive shall not be used

## Description

### Rule Definition

*#error directive shall not be used.*

### Rationale

You typically use the `#error` directive by combining it with a `#if` or similar directive to make the compilation fail and issue a message when a condition is not met. However, you cannot apply `#error` to templates. Preprocessor directives do not obey linkage, type checker, overloading and other C++ features, and `#error` will not be evaluated as a per-instance template deduction.

Instead, use `static_assert` for compile-time error checking. Static assertions provide all the benefits of C++ features and make the code clearer.

### Polyspace Implementation

Polyspace flags all uses of the `#error` directive.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A16-7-1

The #pragma directive shall not be used

## Description

### Rule Definition

*The #pragma directive shall not be used.*

### Rationale

The use of the `#pragma` directive in your code results in implementation-defined behavior. The directive might also not be supported by certain compilers.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of `#pragma once` Directive

```
//header.h
#pragma once //Noncompliant

#ifndef HEADER_H_ //Compliant
#define HEADER_H_
// ...
// body of header file
//..
#endif
```

The `#pragma once` directive prevents the inclusion of `header.h` more than once. However, if you copy `header.h` into multiple project modules, the directive may or may not treat the copies as the same file depending on the implementation. To avoid double definitions, use the `#ifndef` include guard instead.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A17-0-1

Reserved identifiers, macros and functions in the C++ standard library shall not be defined, redefined or undefined

## Description

### Rule Definition

*Reserved identifiers, macros and functions in the C++ standard library shall not be defined, redefined or undefined.*

### Rationale

Defining, redefining, or undefining reserved identifiers, macros, and functions that are in the C++ standard library is not recommended. Undefined behavior might occur when defining, redefining, or undefining reserved words such as:

- `__LINE__`
- `__FILE__`
- `__DATE__`
- `__TIME__`
- `__STDC__`
- `errno`
- `assert`

### Polyspace Implementation

Polyspace flags the preprocessor directives that define, redefine, or undefine reserved C++ standard library identifiers, macros, and functions.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Defining, Redefining, and Undefining Reserved C++ Identifiers, Macros, and Functions

```
#define __TIME__ 3  //Noncompliant
#undef __TIME__   //Noncompliant

#define __cplusplus 3 //Noncompliant
#undef __cplusplus //Noncompliant

#define break 3 //Noncompliant
#undef break //Noncompliant
```

```
#define pow 3 //Noncompliant
#undef pow //Noncompliant

#define example 3 //Compliant
#undef example //Compliant

#define example 7 //Compliant
```

In this example, Polyspace flags preprocessor directives that define or undefine reserved C++ identifiers and macros. For instance:

- Defining and undefining `__TIME__` is noncompliant because `__TIME__` is a reserved C++ macro.
- Defining and undefining `__cplusplus` is noncompliant because `__cplusplus` is a reserved C++ macro.
- Defining and undefining `break` is noncompliant because `break` is a reserved C++ identifier.
- Defining and undefining `pow` is noncompliant because `pow` is a reserved C++ function.
- Defining, undefining, and redefining `example` is compliant because `example` is not a reserved C++ macro, identifier, or function.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A17-1-1

Use of the C Standard Library shall be encapsulated and isolated

## Description

### Rule Definition

*Use of the C Standard Library shall be encapsulated and isolated.*

### Rationale

The C Standard Library functions leave the responsibility for handling errors, data races and security issues to developers. For instance, some C Standard Library functions return specific values on errors. A developer calling one of those functions has to explicitly check its return value for those errors.

If all calls to C Standard Library functions are isolated and encapsulated in wrapper functions, the wrapper functions can be left to perform the checking. Callers of those wrapper functions are freed from the responsibility of handling specific error values from the C Standard Library function calls. Instead, the callers can handle errors from the wrapper function calls like any other exception.

### Polyspace Implementation

The checker flags functions that contain a call to a C Standard Library function and one of these C++-specific constructs:

- A call to a C++ Standard Library function.
- A `try` block.
- A `new` or `delete` operator.
- Range-based `for` loops.

These C++-specific constructs indicate that the call to the C Standard Library function is not fully encapsulated and isolated. The event list below a rule violation shows the locations of the C Standard Library function call and the C++-specific construct.

Note that when C Standard Library functions are redeclared in the `std` namespace, their specifications remain unchanged. The rationale for encapsulating continues to apply to `std::` versions of the C library functions. Therefore, the checker flags these versions, too.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### C Standard Library Function Call Not Isolated and Encapsulated

```
#include <cerrno>
#include <cstdio>
```

```
#include <cstring>
#include <iostream>
#include <stdexcept>

void func1() { //Compliant
    FILE* fptr;
    fptr = fopen("myfile.txt", "w");
    // C-style error handling
    if (fptr == NULL) {
        throw std::system_error(errno, std::system_category());
    }

    fclose(fptr);
}

void func1_caller() noexcept{
    // C++-style error handling
    try {
        func1();
    }
    catch(std::system_error& e) {
        std::cerr << "Error "<< e.code() << ": " << e.what();
    }
}

std::int32_t func2() { //Noncompliant
    FILE* fptr;
    fptr = fopen("myfile.txt", "w");
    // C-style error handling
    if (fptr == NULL) {
        std::cerr << "Error " << strerror(errno);
        return errno;
    }

    // C++-style error handling
    try {
        fclose(fptr);
    }
    catch (std::exception& e) {
        fclose(fptr);
    }
    return errno;
}
```

In this example, the call to the C Standard Library function `fopen()` is encapsulated in the wrapper function `func1()`. The wrapper function performs all the error handling required after the call. Functions calling `func1()`, for instance, `func1_caller()`, do not have to concern themselves about the `fopen()` errors and can handle exceptions from `func1()` like other exceptions.

Conversely, the function `func2()` does not fully encapsulate the `fopen()` call and returns the value of `errno`. Note that `fopen()` sets the value of `errno` after errors. Callers of `func2()` have to read the `errno` value via the `func2()` return and if the value indicates an error, perform any resource cleanup required.

The use of the `try` block in `func2()` indicates that the `fopen()` call is not fully isolated and encapsulated.

# AUTOSAR C++14 Rule A17-6-1

Non-standard entities shall not be added to standard namespaces

## Description

### Rule Definition

*Non-standard entities shall not be added to standard namespaces.*

### Rationale

Adding declarations or definitions to namespace `std` or its subspaces:or to `posix` or its subspaces, leads to undefined behavior. For instance, any addition within braces here leads to undefined behavior:

```
namespace std {
  ...
}
```

Likewise, explicitly specializing a member function or member class of a standard library leads to undefined behavior.

### Polyspace Implementation

The checker flags additions to the namespaces `std`, `posix`, or their subspaces, or specializations of class or function templates from these namespaces.

The rule specification allows exceptions to the specialization aspect of the rule for standard library templates that require a user-defined type. If you have a process that all rule violations must be justified and an issue flagged by the checker belongs to this category of exceptions, justify the issue using comments in your result or code. See:

- “Address Results in Polyspace User Interface Through Bug Fixes or Justifications” if you review results in the Polyspace user interface.
- “Address Results in Polyspace Access Through Bug Fixes or Justifications” if you review results in a web browser.
- “Annotate Code and Hide Known or Acceptable Results” if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

# AUTOSAR C++14 Rule A18-0-2

The error state of a conversion from string to a numeric value shall be checked

## Description

### Rule Definition

*The error state of a conversion from string to a numeric value shall be checked.*

### Rationale

Converting strings to a numeric value might result in error conditions, for instance, when the input string:

- Does not contain a number
- Contains a number, but is out of range
- Contains additional data after a number

If you use C standard library functions such as `atoi()`, the preceding input errors might result in undefined behavior. To avoid undefined behavior and undetected errors, check the error state of output when converting strings to a numeric value. Avoid using C standard library function. Use C++ standard library functions, such as `std::stoi()`, `std::stof()`, and `std::stol()` instead.

### Polyspace Implementation

Polyspace flags the C standard library string-to-number functions of `atoi()`, `atol()`, and `atof()`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Use C++ Library Functions for Converting Strings to Numeric Value

```
#include <cstdlib>
#include <iostream>
#include <string>

void foo() {
    std::string str1 = "7";
    std::string str2 = "3.1415";
    std::string str3 = "three";

    int myint1 = std::stoi(str1); //Compliant
    float myint2 = std::stof(str2); //Compliant
    long myint3 = std::stol(str3); //Compliant

    const char* str4 = "12";
    const char* str5 = "2.7182";
    const char* str6 = "undefinedError";
    int num4 = atoi(str4); //Noncompliant
    float num5 = atof(str5); //Noncompliant
    long num6 = atol(str6); //Noncompliant
    //...
}
```

In this example, Polyspace flags the use of C standard library functions for converting strings to numeric value. For instance:

- The string-to-number functions from the C standard library, such as `atoi()`, `atof()`, and `atol()` are noncompliant flagged because an invalid conversion results in undefined behavior.
- The string-to-number functions from the C++ standard library `std::stoi()`, `std::stof()`, and `std::stol()` are not flagged because an invalid conversion produces a `std::invalid_argument` exception, which is defined behavior.

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A18-1-1

C-style arrays shall not be used

## Description

### Rule Definition

*C-style arrays shall not be used.*

### Rationale

A C-style array is an array that is not wrapped in a class such as `std::array` when the array is declared. You can lose information about the size of a C-style array. For instance, an array that you pass to a function decays to a pointer to the first element of the array. This can lead to unsafe and difficult to maintain code.

The AUTOSAR standard allows declarations of `static constexpr` data members of a C-style array type. For example, this declaration is compliant.

```
class A
{
  public:
    static constexpr std::uint8_t array[] {0, 1, 2}; // Compliant by exception
};
```

### Polyspace Implementation

The rule checker does not flag C-style array arguments in function declarations because the rule violation still exists if you fix the function declaration and not the definition. A function might be declared in your code and defined in a library that you cannot access. The checker flags C-style array arguments in function definitions. For instance, in this code snippet, the checker flags the argument of `foo` but not the argument of `bar`.

```
extern void bar(char arg[]); //Declaration, checker raises no rule violation
int foo(char arg[]) // Definition, checker raises a rule violation
{
    return sizeof(arg); //Returns size of pointer, not size of array
}
void baz()
{
    char value[10]; //C-style array, checker raises a rule violation
    assert(sizeof(value) == foo(value));
}
```

The checker raises a flag on `arg` in the definition of `foo` even when there is no explicit C-style array definition for the argument. For example, declaring `char* value;` instead of `char value[10];` in `baz()` would still result in a rule violation on the argument of `foo`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Declaration of C-Style Array

```
#include <array>

void func()
{

    const std::uint8_t size = 10;
    std::int32_t a1[size]; //non-compliant
    std::array<std::int32_t, size> a2; //compliant

}
```

In this example, the rule is violated when you declare C-style array `a1`. To declare fixed-size stack-allocated arrays, use `std:array` instead.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A18-1-2

The std::vector<bool> specialization shall not be used

## Description

### Rule Definition

*The std::vector<bool> specialization shall not be used.*

### Rationale

The specialization of `std::vector` for the type `bool` can be made space-efficient in an implementation defined manner. For instance, `std::vector<bool>` does not necessarily store its elements as a contiguous array. As a result, the specialization does not work as expected with all standard library template (STL) algorithms, such as the index `operator[]()` which does not return a contiguous sequence of elements. You cannot safely modify distinct elements of STL container `std::vector<bool>`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Non-Compliant and Compliant Use of `std::vector` With `bool` Type

```
#include <cstdint>
#include <vector>

class BoolWrapper
{
public:
    BoolWrapper() = default;
    constexpr BoolWrapper(bool b) : b_(b) {}
    constexpr operator bool() const
    {
        return b_;
    }
private:
    bool b_{};
};

void Fn() noexcept
{
    std::vector<bool> v2; //non-compliant
    std::vector<BoolWrapper> v3{true, false, true, false}; //compliant
}
```

In this example, vector `v2` is non-compliant because it is declared with `std::vector<bool>`. A possible fix is to use `std::vector` with a value type `BoolWrapper` that wraps `bool`.

# AUTOSAR C++14 Rule A18-1-3

The std::auto_ptr shall not be used

## Description

### Rule Definition

*The std::auto_ptr shall not be used.*

### Rationale

The `std::auto_ptr` is a type of class template that predates the introduction of move semantics in the C++11 language standard. When you copy a source `std::auto_ptr` object into a target object, the source object is modified. The compiler transfers the ownership of the resources in the source object to the target object and sets the source object to a null-pointer. Because of this unusual copy syntax, using the source object after the copy operation might lead to unexpected behavior. Consider this code snippet where the use of `std::auto_ptr` results in a segmentation fault.

```
void func(auto_ptr<int> p) {
    cout<<*p;
    //...
}

int main()
{
    std::auto_ptr<int> s = new int(1);
    //..
    func(s); // This call makes s a null-pointer
    //...
    func(s); // exception, because s is null
    return 1;
}
```

The first call to `func()` copies the source `std::auto_ptr` object `s` to the argument `p`, transfers ownership of the pointer to `p`, and sets `s` to a null pointer. When `func()` is called again, the compiler tries to access the null-pointer `s`, causing a segmentation fault.

The `std::auto_ptr` type objects are also incompatible with any generic code that expects a copy operation to not invalidate the source object, such as the standard template library (STL). Avoid using `std::auto_ptr`. It is deprecated in C++11 and removed from C++17. The C++11 language standard introduces `std::unique_ptr` as a safer replacement for `std::auto_ptr`. Use `std::unique_ptr` instead of `std::auto_ptr`.

### Polyspace Implementation

Polyspace flags all instances of `std::auto_ptr` in your code, other than those in C style arrays.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using `std::auto_ptr`

This code shows how Polyspace flags `std::auto_ptr` in your code.

```
#include <cstdint>
#include <memory>
#include <vector>
#define AUTOPTROF(_TYPE) std::auto_ptr<_TYPE>
AUTOPTROF(int) v_int;                          // Noncompliant
typedef struct {
    std::auto_ptr<bool> vb;                    // Noncompliant
} T;
T vec;
typedef std::auto_ptr<int> my_int_auto_ptr;     // Noncompliant
void Fn() noexcept
{

    std::auto_ptr<std::int32_t> ptr1(new std::int32_t(10)); // Noncompliant
    std::unique_ptr<std::int32_t> ptr2 =
    std::make_unique<std::int32_t>(10);         // Compliant
    std::vector<std::auto_ptr<std::int32_t>> v;  // Noncompliant
}

int main(){
    //..
}
```

Polyspace flags the `std::auto_ptr` objects. Use `std::unique_ptr` instead of `std::auto_ptr`.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A18-1-4

A pointer pointing to an element of an array of objects shall not be passed to a smart pointer of single object type

## Description

### Rule Definition

*A pointer pointing to an element of an array of objects shall not be passed to a smart pointer of single object type.*

### Rationale

You must deallocate pointers to array elements by using `delete[]` instead of `delete`.

A pointer to an array element being passed to a smart pointer of single object type results in undefined behavior. Consider this code:

```
typedef A cArr[10];
std::unique_ptr<A> smartPtr1{new cArr};  //Noncompliant
```

`cArr` and its elements require `delete[]`. However, `smartPtr1` attempts to deallocate by using `delete`, resulting in undefined behavior.

Consider the following alternatives:

- Avoid using smart pointers to a pointer to an item in an array of objects. Instead use:
  - `std::array`
  - `std::vector`
  - `std::shared_ptr<std::vector<T>>`
- `std::unique_ptr<T[]>` and the corresponding overloads for `std::make_unique` .

  As of C++17, you can use `std::shared_ptr<T[]>`. The corresponding overloads for `std::make_shared` are not introduced until C++20.

Creating a custom deleter capable of handling an array of objects for the smart pointer of a single object type is considered noncompliant with this rule. This alternative can be error-prone, might no longer be supported in C++17, and is superseded by alternatives such as `std::unique_ptr<T[]>`.

### Polyspace Implementation

Polyspace raises this defect when you pass a pointer pointing to an element in an array of objects to a smart pointer of a single object. Polyspace also raises this defect if you pass a C-style array to a smart pointer of a single object.

Polyspace raises this defect when these conditions are met:

- You create a smart pointer by using `std::unique_ptr<T>` or `std::shared_ptr<T>`.
- You create an array of objects by using a C-style array or you create an array by using `std::make_unique` or `std::make_shared`.

- You use a function member of the smart pointer such as `release()` or `get()` to obtain the pointer to pass to the smart pointer.

You can pass the pointer to a smart pointer in several ways, including using a copy constructor, move constructor, or the `reset()` member function of the smart pointer.

When using a copy or move constructor, Polyspace flags the checker on the declared object name. In the case of a `reset()` member function, Polyspace flags the checker on the `reset()` member function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Passing Pointer of Element of an Array to Smart Pointer of Single Object

```
#include <cstdint>
#include <vector>
#include <memory>

size_t x = 10;
class A
{
};

void example()
{
    std::unique_ptr<A[]> uPoint = std::make_unique<A[]>(x);
    std::shared_ptr<A> smartPtr1{ uPoint.get() };            //Noncompliant

    std::unique_ptr<A> smartPtr2;
    smartPtr2.reset(uPoint.release());                        //Noncompliant

    std::shared_ptr<std::vector<A>> smartPtr3;                //Compliant
}
```

There are two noncompliant smart pointers in the preceding example, `smartPtr1` and `smartPtr2`.

Both examples are noncompliant as, in each, a pointer to an array element is passed to a smart pointer that manages a single object, resulting in undefined behavior.

### C-Style Array Compliant By Using Compliant Standard Library Template

```
#include <cstdint>
#include <iostream>
#include <memory>

class A {
};

void Ex2()
{
    typedef A cArr[10];
    std::unique_ptr<A> smartPtr1{ new cArr };      //Noncompliant
    std::shared_ptr<A> smartPtr2{ new cArr };      //Noncompliant

    cArr a;
    std::unique_ptr<A> smartPtr3{ a };             //Noncompliant
    std::unique_ptr<A[]> smartPtr4{ a };           //Compliant
}
```

Because the C-style array is passed to the constructor of a smart pointer of a single object, Polyspace flags it as noncompliant. It does not matter if you create the smart pointer by using `std::unique_ptr` or `std::shared_ptr`. Both options are noncompliant.

Use of a specialized standard library template such as `std::unique_ptr<T[]>` as used in the example is compliant as long as you are using a compatible code version.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A18-1-6

All std::hash specializations for user-defined types shall have a noexcept function call operator

## Description

### Rule Definition

*All std::hash specializations for user-defined types shall have a noexcept function call operator.*

### Rationale

`std::hash` specializations provided by the standard library have a guarantee of no exceptions. If you manually create a `std::hash` specialization, emulate this guarantee for your specialization. Define all specializations of `std::hash` for your custom data types as `noexcept`.

Otherwise, standard library containers that use your specialization of `std::hash` indirectly might throw uncaught exceptions. The exceptions are not caught because the standard library containers do not provide a way to use `try-catch` blocks for exceptions from `std::hash`.

### Polyspace Implementation

The checker flags specializations of the `std::hash` template with user defined types that do not have a `noexcept` specifier.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A18-5-1

Functions malloc, calloc, realloc and free shall not be used

## Description

### Rule Definition

*Functions malloc, calloc, realloc and free shall not be used.*

### Rationale

C-style memory allocation and deallocation using `malloc`, `calloc`, `realloc`, or `free` is not type safe and does not invoke class's constructors/destructor to create/delete objects.

For instance, `malloc` allocates memory to an object and returns a pointer to the allocated memory of type `void*`. A program can then implicitly cast the returned pointer to a different type that might not match the intended type of the object.

The use of these allocation and deallocation functions can result in undefined behavior if:

- You use `free` to deallocate memory allocated with operator `new`.
- You use operator `delete` to deallocate memory allocated with `malloc`, `calloc`, or `realloc`.

The rule is not violated when you perform dynamic memory allocation or deallocation using overloaded `new` and `delete` operators, or custom implementations of `malloc` and `free`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Non-Compliant Use of `malloc`

```
#include <cstdint>
#include <cstdlib>

void func()
{

    std::int32_t* p1 = static_cast<std::int32_t*>(malloc(sizeof(std::int32_t))); // Non-compliant
    *p1 = 0;

    free(p1); // Non-compliant

    std::int32_t* p2 = new std::int32_t(0); // Compliant

    delete p2; // Compliant
}
```

In this example, the allocation of memory for pointer `p1` using `malloc` and the memory deallocation using `free` are non-compliant. These operations are not type safe. Instead, use operators `new` and `delete` to allocate and deallocate memory.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A18-5-2

Non-placement new or delete expressions shall not be used

## Description

### Rule Definition

*Non-placement new or delete expressions shall not be used.*

### Rationale

Explicit use of nonplacement `new` or `delete` operators might result in memory leaks caused by unexpected exceptions or returns. Consider this code where memory is allocated for a pointer by explicitly calling `new` and deallocated by explicitly calling `delete`.

```
std::int32_t ThrowError(){
    std::int32_t errorCode;
    std::int31_t* ptr = new std::int32_t{0};
    //...
    if(errorCode!=0){
        throw std::runtime_error{"Error"};
    }
    //...
    if (errorCode != -1) {
        return 1;
    }
    delete ptr;
    return errorCode;
}
```

This code can lead to unexpected memory leak in certain conditions.

- If the first `if()` statement is `true`, then the function produces an exception and exits without deleting the pointer.
- If the second `if()` statement is `true`, then the function returns `1` and exits without deleting the pointer.

To avoid an unpredictable memory leak, do not use nonplacement `new` and `delete` operators. Instead, encapsulate dynamically allocated resources in objects. Acquire the resources in object constructors and release the resources in object destructors. This design pattern is called "Resource Acquisition Is Initialization" or RAII. Following the RAII pattern prevents a memory leak even when there are unexpected exceptions and returns.

Alternatively, use manager objects that manage the lifetime of dynamically allocated resources. Examples of manager objects in the standard library include:

- `std::unique_ptr` along with `std::make_unique`
- `std::shared_ptr` along with `std::make_shared`
- `std::string`
- `std::vector`

This rule does not apply to a `new` operator or a `delete` operator in user-defined RAII classes and managers.

### Polyspace Implementation

AUTOSAR C++14 permits explicit resource allocation by calling the `new` operator in two cases, when the allocated resource is immediately passed to:

- A manager object
- A RAII class that does not have a safe alternative to the `new` operator.

Polyspace flags all explicit uses of the `new` operator and the `delete` operator. If you have a process where a `new` operator can be permissible and there is no safer alternative, justify the issue by using comments in your result or code. See:

- "Address Results in Polyspace User Interface Through Bug Fixes or Justifications" if you review results in the Polyspace user interface.
- "Address Results in Polyspace Access Through Bug Fixes or Justifications" if you review results in a web browser.
- "Annotate Code and Hide Known or Acceptable Results" if you review results in an IDE.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Explicitly Calling `new` Operator and `delete` Operator

This code shows how Polyspace flags `new` or `delete` operators.

```
#include <cstdint>
#include <memory>
#include <vector>
#include <cstddef>

using namespace std;

int32_t Fn1()
{
    int32_t errorCode{0};
    int32_t* ptr =
    new int32_t{0}; //Noncompliant
    // ...
    if (errorCode != 0) {
        throw  runtime_error{"Error"}; // Possible Memory Leak
    }
    // ...
    if (errorCode != 0) {
        return 1; //Possible Memory Leak
    }
    // ...
    delete ptr; //Noncompliant
    return errorCode; // Possible Memory Leak
}

int32_t Fn2()
{
    int32_t errorCode{0};
    // Alternative to 'new'
    unique_ptr<int32_t> ptr1 = make_unique< int32_t>(0);
    unique_ptr<int32_t> ptr2(new  int32_t{0});   // Noncompliant
    shared_ptr<int32_t> ptr3 =
    make_shared<int32_t>(0);   //Compliant
    vector<int32_t> array;   // Compliant

    if (errorCode != 0) {
        throw  runtime_error{"Error"};   // No memory leaks
    }
    // ...
    if (errorCode != 0) {
        return 1; // No memory leaks
    }
    // ...
    return errorCode; // No memory leaks
}

class X
{
public:
    static void* operator new( size_t s)
    {
        return ::operator new(s);   // Noncompliant
    }

    static void* operator new[]( size_t s)
    {
        return ::operator new(s);   // Noncompliant
    }

    static void operator delete(void* ptr,  size_t s)
    {
        ::operator delete(ptr);   // Noncompliant
    }

    static void operator delete[](void* ptr,  size_t s)
    {
        ::operator delete(ptr);   // Noncompliant
    }
};

main(){
    X* x1    = new X;   // Noncompliant
    X* x2    = new X[2];   // Noncompliant
}
```

In `Fn1()`, the operators `new` and `delete` are explicitly called for resource management. Consequently, an unexpected exception or return can lead to a memory leak. Polyspace flags the `new` and `delete` operators. In `Fn2()`, manager objects are used for memory management. Even in cases of unexpected exceptions and returns, there are no memory leaks in `Fn2()`.

The class `X` contains custom overloads for `new` and `delete` operators. Polyspace flags all instances of `new` and `delete` operators in the definitions of the custom overloads. In main(), Polyspace also flags the overloaded new and delete operators.

# AUTOSAR C++14 Rule A18-5-3

The form of delete operator shall match the form of new operator used to allocate the memory

## Description

### Rule Definition

*The form of delete operator shall match the form of new operator used to allocate the memory.*.

### Rationale

- The `delete` operator releases a block of memory allocated on the heap. If you try to access a location on the heap that you did not allocate previously, a segmentation fault can occur.
- If you use the single-object notation for `delete` on a pointer that is previously allocated with the array notation for `new`, the behavior is undefined.

The issue can also highlight other coding errors. For instance, you perhaps wanted to use the `delete` operator or a previous `new` operator on a different pointer.

### Polyspace Implementation

The checker flags a defect when:

- You release a block of memory with the `delete` operator but the memory was previously not allocated with the `new` operator.
- You release a block of memory with the `delete` operator using the single-object notation but the memory was previously allocated as an array with the `new` operator.

This defect applies only to C++ source files.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Deleting Static Memory

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;

    delete[] ptr;
}
```

The pointer `ptr` is released using the `delete` operator. However, `ptr` points to a memory location that was not dynamically allocated.

#### Correction: Remove Pointer Deallocation

If the number of elements of the array ptr is known at compile time, one possible correction is to remove the deallocation of the pointer ptr.

```
void assign_ones(void)
{
    int ptr[10];

    for(int i=0;i<10;i++)
        *(ptr+i)=1;
}
```

#### Correction — Add Pointer Allocation

If the number of array elements is not known at compile time, one possible correction is to dynamically allocate memory to the array ptr using the new operator.

```
void assign_ones(int num)
{
    int *ptr = new int[num];

    for(int i=0; i < num; i++)
        *(ptr+i) = 1;

    delete[] ptr;
   }
```

### Mismatched new and delete

```
int main (void)
{
    int *p_scale = new int[5];

    //more code using scal

    delete p_scale;
}
```

In this example, p_scale is initialized to an array of size 5 using new int[5]. However, p_scale is deleted with delete instead of delete[]. The new-delete pair does not match. Do not use delete without the brackets when deleting arrays.

#### Correction — Match delete to new

One possible correction is to add brackets so the delete matches the new [] declaration.

```
int main (void)
{
    int *p_scale = new int[5];

    //more code using p_scale

    delete[] p_scale;
}
```

#### Correction — Match new to delete

Another possible correction is to change the declaration of p_scale. If you meant to initialize p_scale as 5 itself instead of an array of size 5, you must use different syntax. For this correction, change the square brackets in the initialization to parentheses. Leave the delete statement as it is.

```
int main (void)
{
    int *p_scale = new int(5);

    //more code using p_scale

    delete p_scale;
}
```

# AUTOSAR C++14 Rule A18-5-4

If a project has sized or unsized version of operator 'delete' globally defined, then both sized and unsized versions shall be defined

## Description

### Rule Definition

*If a project has sized or unsized version of operator 'delete' globally defined, then both sized and unsized versions shall be defined.*

### Rationale

The C++14 Standard defines a sized version of `operator delete`. For instance, for an unsized `operator delete` with this signature:

```
void operator delete (void* ptr);
```

The sized version has an additional size argument:

```
void operator delete (void* ptr, std::size_t size);
```

See the C++ reference page for `operator delete`.

The Standard states that if both versions of `operator delete` exist, the sized version must be called because it provides a more efficient way to deallocate memory. However, in some cases, for instance to delete incomplete types, the unsized version is used.

If you overload the unsized version of `operator delete`, you must also overload the sized version. You typically overload `operator delete` to perform some bookkeeping in addition to deallocating memory on the free store. If you overload the unsized version but not the sized one or the other way around, any bookkeeping you perform in one version will be omitted from the other version. This omission can lead to unexpected results.

### Polyspace Implementation

The checker flags situations where an unsized version of `operator delete` exists but the corresponding sized version is not defined, or vice versa.

The checker is enabled only if you specify a C++ version of C++14 or later. See `C++ standard version (-cpp-version)`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Missing Sized Overload of `operator delete[]`

```
#include <new>
#include <cstdlib>
```

```
int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
      global_store++;
   else
      global_store--;
}

void operator delete(void *ptr);
void operator delete(void* ptr) {
    update_bookkeeping(ptr, false);
    free(ptr);
}

void operator delete(void *ptr, std::size_t size);
void operator delete(void* ptr, std::size_t size) {
    //Compliant, both sized and unsized version defined
    update_bookkeeping(ptr, false);
    free(ptr);
}

void operator delete[](void *ptr);
void operator delete[](void* ptr) { //Noncompliant, only unsized version defined
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

In this example, both the unsized and sized version of `operator delete` are overloaded and complies with the rule. However, only the unsized version of `operator delete[]` is overloaded, which violates the rule..

# AUTOSAR C++14 Rule A18-5-5

Memory management functions shall ensure the following: (a) deterministic behavior resulting with the existence of worst-case execution time, (b) avoiding memory fragmentation, (c) avoid running out of memory, (d) avoiding mismatched allocations or deallocations, (e) no dependence on non-deterministic calls to kernel

## Description

### Rule Definition

*Memory management functions shall ensure the following: (a) deterministic behavior resulting with the existence of worst-case execution time, (b) avoiding memory fragmentation, (c) avoid running out of memory, (d) avoiding mismatched allocations or deallocations, (e) no dependence on non-deterministic calls to kernel.*

### Rationale

When you implement custom memory management functions, make sure that your implementation addresses these common memory management errors that can affect the stability and correctness of your application:

- Non-deterministic worst-case execution time (WCET) of allocation and deallocation operations.

  To provide a deterministic WCET, make sure that the function can be executed without context switching or system calls. A predictable WCET is essential in determining an appropriate scheduling scheme that meets the timing constraints in safety-critical embedded systems.
- Mismatched allocation and deallocation functions.

  Deallocating memory with a function that does not match the allocation function can cause memory corruption or undefined behavior.
- Invalid memory access.

  If you try to access memory that is logically or physically invalid, the operation results in undefined behavior or a segmentation fault.
- Out-of-memory errors.

  To avoid running out of memory, your executable should allocate all the memory needed by the program at startup.
- Memory fragmentation.

  Fragmentation occurs when memory is allocated over non-contiguous blocks. If the unallocated blocks are not large enough to accommodate future allocation requests, the remaining free memory might not be usable and your system might crash.

In addition to custom implementations for operators `new` and `delete`, you should provide custom implementations for low-level allocation and deallocation functions (`malloc/free`). Even if you do not use these low-level functions in your source code, they can occur in linked libraries in your project.

A custom implementation of `std::new_handler` must perform one of these operations:

- Make more memory available for allocations and return.
- Terminate the program without returning to the callee.
- Throw an exception of type `std::bad_alloc` or derived from `std::bad_alloc`.

### Polyspace Implementation

Polyspace checks for these memory management issues that might result in non-deterministic behavior:

- Use of C library function (`malloc/calloc/realloc/free`) to allocate or deallocate memory in local variable initializations.

  Polyspace does not flag the use of these functions when allocating or deallocating global variables.
- Use of non-placement `new` and `delete` operators.
- Use of function `dlsym()`. This function might call low-level allocation or deallocation functions such as `malloc` or `calloc`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Non-Deterministic Memory Management Functions

```
#define _GNU_SOURCE
#include <malloc.h>
#include <dlfcn.h>
#include <iostream>

class Point
{
public:
    Point(int x1 = 0, int y1 = 0): x(x1), y(y1)
    {
    }
    ~Point();
private:
    int x, y;
};

void func1()
{
    unsigned char buffer[sizeof(int) * 2];
    Point* p1 = new Point(0, 0); // Non-compliant
    Point* p2 = new (buffer) Point(1, 1); // Compliant

    int* p3 = (int*)malloc(sizeof(int)); // Non-compliant

    //Use pointers

    delete p1; // Non-compliant
    p2->~Point();
    free(p3); // Non-compliant
}

void* customAlloc(size_t size)
{
    void* (*myAlloc)(size_t) =
            (void* (*)(size_t))dlsym(RTLD_NEXT, "malloc"); // Non-compliant

    return myAlloc(size);

}
```

In this example, Polyspace flags these dynamic memory management operations:

- The allocation and deallocation of pointer `p1` with non-placement operators `new` and `delete`.
- The allocation and deallocation of local pointer `p3` with low-level functions `malloc` and `free`. Polyspace does not flag the use of these functions when allocating or deallocating global variables.
- The use of function `dlsym()` because the function calls `malloc`.

Polyspace does not flag the initialization of pointer `p2` because it uses a placement operator `new` which creates the pointer in a pre-allocated buffer.

# AUTOSAR C++14 Rule A18-5-7

If non-real-time implementation of dynamic memory management functions is used in the project, then memory shall only be allocated and deallocated during non-real-time program phases

## Description

### Rule Definition

*If non-real-time implementation of dynamic memory management functions is used in the project, then memory shall only be allocated and deallocated during non-real-time program phases.*

### Rationale

A real-time function is one with a known worst case execution time. That is, the execution time of real-time functions cannot exceed a specific and known value.

Inside a real-time function, you might be using functions that manage dynamic memory, such as `new` or `delete`. The execution time of these functions depends on how much memory the functions manage. Because their worst case execution time is not deterministic, using these functions in the real time phase of the application might result in unexpected behaviors, memory leaks, and memory fragmentation. Dynamic memory management in real time requires implementing deterministic implementations of these functions that have a known worst case execution time.

Avoid using non-real-time dynamic memory management functions in the real time phase of your application. Perform non-real-time memory operations in the non-real-time phase such as the initialization or the non-real-time state transitions.

### Polyspace Implementation

To check for violations of this rule, specify your real-time functions by using the analysis option `-code-behavior-specifications`. In the code behavior specification XML file, specify a function as a real-time function by using the behavior `REAL_TIME_FUNC`. Polyspace flags a specified real-time function if :

- The function allocates or deallocates dynamic memory by using a non-real-time implementation.
- The function calls a function that uses non-real-time dynamic memory management.

Polyspace assumes that these functions from the standard library use non-real-time implementation of dynamic memory management:

- The operators `new` and `delete`.
- `std::make_unique()`
- `std::vector::vector()`
- `std::vector::reserve()`
- `std::basic_string::basic_string()`

You might use other functions in your code that use non-real-time implementation of dynamic memory management. Specify these functions as non-real-time dynamic memory management function by using the behavior `MANAGES_MEMORY`.

To use this rule, specify at least one entry that has the behavior `REAL_TIME_FUNC`. If you use this checker without specifying the code behavior, Polyspace produces a warning.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Non-Real-Time Memory Operations in Real-Time Functions

```
#include <cstdlib>
#include <new>
#include<vector>
extern bool pollSensor();
extern int getSize();
extern int getSensorData();
int* allocateIntArray(int size){
    return new int[size];  //Noncompliant
}
void deallocateIntArray(int* data){
    delete data;  //Noncompliant
}
void AppMain(){
    int* Data = allocateIntArray(getSize());
    int index = 0;
    while(1){
        if(pollSensor()){
            Data[index] = getSensorData(); ;
            //...

        }
        deallocateIntArray(Data);
    }
}
void AppMainAlt(){
    std::vector<int> Data;  //Noncompliant
    while(1){
        if(pollSensor()){
            Data.push_back(getSensorData());
        }
    }
}
```

To run this example, specify the functions `AppMain` and `AppMainAlt` as real-time functions. For instance, save this the code behavior specifications XML code as *`code_behavior.xml`*:

```
<specifications>
    <functions>
        <function name="AppMain">
            <behavior name="REAL_TIME_FUNC"/>
        </function>
        <function name="AppMainAlt">
            <behavior name="REAL_TIME_FUNC"/>
        </function>
    </functions>
</specifications>
```

After specifying the code behavior, add this option when running the analysis:

In this example, Polyspace flags non-real-time memory management in real-time functions.

- The duration for the operation `new` in `allocateIntArray()` depends on the argument `size` and cannot be predetermined. Using this function in real time might result in a memory leak or a segmentation fault. Because `allocateIntArray()` is called from the real-time function `AppMain`, Polyspace raises a violation.
- The non-real-time deallocation operation in `deallocateIntArray()` might result in a memory leak or a segmentation fault if the function is used in real time. Because `deallocateIntArray()` is called from the real-time function `AppMain`, Polyspace flags it.
- Polyspace flags the non-real-time memory allocation operation `allocateIntArray` in the real-time function `AppMain`.
- Polyspace flags the vector declaration, which is a non-real-time memory allocation operation, in the real-time function `AppMainAlt`.

### Perform Dynamic Memory Allocation In Non-Real-Time Phase

```
#include <cstdlib>
#include <new>
#include<vector>
extern bool pollSensor();
extern int getSize();
extern int getSensorData();

void AppMain(std::vector<int>& Data){
    while(1){
        if(pollSensor()){
            Data.push_back(getSensorData());
        }
    }
}
int main(){
    std::vector<int> Data;
    Data.reserve(1024);
    AppMain(Data);
    return 0;
}
```

This example shows a best practice when using non-real-time memory management in a program that uses real-time functions. The memory allocation operation is performed in the function `main()`, which is not executed at real time. The real-time function is `AppMain()`, and this function does not perform any dynamic memory management. Separating memory management from real time functions might reduce the possibility of memory leaks, segmentation faults, and other unexpected behaviors.

# AUTOSAR C++14 Rule A18-5-8

Objects that do not outlive a function shall have automatic storage duration

## Description

### Rule Definition

*Objects that do not outlive a function shall have automatic storage duration.*

### Rationale

A dynamically allocated object results in additional allocation and deallocation costs and makes your program vulnerable to memory leaks if, for instance, the program returns due to an exception throw before the deallocation operation.

Instead, use an object with automatic storage duration, which has a lifetime that is bound to the enclosing scope of that object. The object is automatically destroyed when that scope exits.

The rule allows an exception for local objects that are dynamically allocated to optimize stack memory usage because the objects use a large amount of memory and might otherwise cause a stack overflow.

### Polyspace Implementation

Polyspace flags objects that are created in a function scope and that do not have automatic storage duration when any of the following is true:

- The object is a smart pointer (`std::shared_ptr` or `std::unique_ptr`) that is never copied, moved, reassigned, reset, or passed to a callee.

  The object is not flagged if it is a non-array and, at compilation time, its size is greater than 4 KB or its size is unknown.
- The object is dynamically allocated by using operators `new` or `new[]` and then deallocated through all possible paths within the function.

  The object is not flagged if it is a non-array and, at compilation time, its size is greater than 4 KB or its size is unknown.
- The object is a wrapper class that contains at least one data member with a fixed size larger than 16 KB.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Unnecessary Use of a Smart Pointer

```
#include <iostream>
#include <cstdint>
```

```
#include <array>
#include <utility>

constexpr std::size_t size4KB = 4 * 1024;

class MyLargeBoard
{
  public:
    constexpr static size_t size16KB = 16 * 1024;
    MyLargeBoard() {}
    MyLargeBoard(int s);
  private:
    std::array<uint8_t, size16KB> cells;

};

void Reset_ptr(std::shared_ptr<std::pair<int32_t, int32_t>>& ptr)
{
    ptr.reset();
}

void Func(int32_t x_coord, int32_t y_coord,
          std::pair<int32_t, int32_t>** param_ptr)
{
    std::shared_ptr<std::pair<int32_t, int32_t>>reused_ptr(*param_ptr);

    auto toResetPtr = //Compliant, smart pointer is reset
        std::make_shared<std::pair<int32_t, int32_t>>(x_coord, y_coord);
    auto unused_ptr = //Non-compliant
        std::shared_ptr<std::pair<int32_t, int32_t>>(reused_ptr);

    if (toResetPtr->first || toResetPtr->second) {
        Reset_ptr(toResetPtr);
    }

}

void SmartPtrLargeMem()
{
    //Large non-array object
    std::shared_ptr<MyLargeBoard>
        big_non_array(new MyLargeBoard); // Compliant
    //Large array of char
    std::unique_ptr<char []>
        big_array {new char[size4KB]{'1', '2', '3', '4'}}; //Non-compliant

}
```

In this example, Polyspace flags these smart pointers as noncompliant:

- Shared smart pointer `unused_ptr` because it is declared locally in `Func` and it is never copied, moved, reassigned, reset, or passed to a callee.
- `big_array` which manages the dynamically allocate array of `char` in `SmartPtrLargeMem`. In this context, the use of a standard C++ container such as `std::array` instead of `std::unique_ptr` is less memory intensive.

Polyspace does not flag:

- `reused_ptr` because it is used to initialize `unused_ptr` and `toResetPtr` because it is reset.
- `big_non_array` because it is a non-array object with one data member of size smaller than 16 KB. The rule allows an exception for such objects because dynamic allocation can help optimize stack memory usage, for instance on an embedded device with limited memory storage.

### Unnecessary Dynamic Memory Allocation

```
#include <iostream>
#include <cstdint>
#include <array>
#include <utility>

constexpr std::size_t size4KB = 4 * 1024;

class MyLargeBoard
```

```
{
public:
    constexpr static size_t size16KB = 16 * 1024;
    MyLargeBoard() {}
    MyLargeBoard(int s);
private:
    std::array<uint8_t, size16KB> cells;

};

class Mytype
{
public:
    Mytype(int s = 0) : a{s} {}
private:
    int a;
};

void ReadInput(Mytype* input);
bool IsInValidRange(Mytype* input);

void* func(Mytype** output)
{
    auto input1 = new Mytype(); //Non-compliant
    ReadInput(input1);

    auto input2 = new Mytype(); //Compliant
    if (IsInValidRange(input2)) {
        delete input2;
    } else {
        *output = input2;
    }

    Mytype input3; //Compliant
    ReadInput(&input3);

    delete input1;

    return nullptr;

}

void DynamicAllocLargeMem()
{
    //Large non-array object
    MyLargeBoard* big_non_array {new MyLargeBoard}; //Compliant
    //Large array of char
    char* big_array { new char[size4KB]{'1', '2', '3', '4'}}; //Non-compliant
    // ....

    delete big_non_array;
    delete[] big_array;

}
```

In this example, noncompliant local variable `input1` is dynamically allocated with operator `new` and then deallocated through all possible paths inside `func`. The unnecessary allocation and deallocation operations can be avoided by declaring a variable with automatic storage duration, such as `input3`, which is automatically deleted when `func` returns .

Polyspace also flags dynamically allocated array `big_array`. In this context, the use of a standard C ++ container such as `std::array` is less memory intensive.

Dynamically allocated variable `input2` is compliant because it is not deallocated though all possible paths inside `func`. The variable is escaped through `output` in the `else` branch.

Similarly, Polyspace does not flag `big_non_array` because it is a non-array object with one data member of size smaller than 16 KB. The rule allows an exception for such objects because dynamic allocation can help optimize stack memory usage, for instance on an embedded device with limited memory storage.

### Use of Wrapper Class With Large Size Data Members

```
#include <iostream>
#include <cstdint>
#include <array>
#include <vector>

class MyTable
{

public:
    constexpr static size_t size64KB = 65535;
    using arrayType = std::array<uint8_t, size64KB>;
    MyTable() :   tableSize{0} {}
    MyTable(const std::string& dbPath, uint32_t inputSize) : tableSize{inputSize}
    {

        // ...
    }
    uint8_t AverageCellVal() const noexcept;
private:
    arrayType table;
    uint32_t tableSize;
};

void AvgCellVal(const std::string& dbPath, uint32_t inputSize)
{
    std::vector<uint8_t> table1(inputSize);  // Compliant
    MyTable table2(dbPath, inputSize); // Non-compliant
    uint8_t averageCellV = table2.AverageCellVal();
    std::cout << "Average cell value in " << dbPath << ": " << averageCellV << '\n';
}

class DerivedMyTable : public MyTable
{
public:
    constexpr static size_t pathMaxSize = 2 * 1024; // 2 Kb
    DerivedMyTable() : MyTable() {}
    DerivedMyTable(const std::string& dbPath, uint32_t inputSize) : MyTable(dbPath, inputSize)
    {
        std::strncpy(__dbPath, dbPath.data(), pathMaxSize - 1);
        __dbPath[pathMaxSize - 1] = '\0';
    }
private:
    char __dbPath[pathMaxSize];  // OK
};

void func(const std::string& dbPath, uint32_t inputSize)
{
    DerivedMyTable table2_derived(dbPath, inputSize);  // Non-compliant

}
```

In this example, base class `MyTable` contains a data member `table` of type `arrayType` which corresponds to an array of size 64 KB. Polyspace flags the declaration of variable `table2` because it consumes a large amount of memory through `MyTable` and it is only used within `AvgCellVal()`.

Instead, you can use a less memory intensive C++ container such as `std::vector` to declare an automatic storage duration object such as `table1`.

Polyspace also flags `table2_derived`. Even if `DerivedMyTable` does not contain a data member with a large size in memory, it is derived from a base class that wraps an object that consumes a large size of memory.

# AUTOSAR C++14 Rule A18-5-9

Custom implementations of dynamic memory allocation and deallocation functions shall meet the semantic requirements specified in the corresponding "Required behaviour" clause from the C++ Standard

## Description

### Rule Definition

*Custom implementations of dynamic memory allocation and deallocation functions shall meet the semantic requirements specified in the corresponding "Required behaviour" clause from the C++ Standard.*

### Rationale

The C++ Standard (*[new.delete]*) specifies certain required behaviors for the dynamic allocation and deallocation functions. If you implement a global replacement allocation or deallocation function that does not meet these semantic requirements, other functions that rely on the required behaviors might behave in an undefined manner.

For instance, `void* operator new ( std::size_t count )` is expected to throw a `bad_alloc` exception if it fails to allocate the requested amount of memory. If you implement a replacement allocation function that returns `nullptr` instead of throwing, a function that expect the memory allocation to throw on failure might try to dereference a null pointer instead.

### Polyspace Implementation

Polyspace flags these replacement implementations of dynamic allocation and deallocation functions.

- Replacement `operator new` that returns `nullptr` when the expected behavior is to throw a `bad_alloc` exception on failure.
- Replacement `operator new` or `operator delete` that throw directly or indirectly on failure when the expected behavior is to not throw. Polyspace also highlights the location of the throw in your code.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### `operator new` Returns `nullptr` on Failure

```
#include<new>

extern void* custom_alloc(std::size_t);

void* operator new (std::size_t count) //Non-compliant
{
    return custom_alloc(count);
}

void func()
```

```
{
    int* ptr1;
    try {
        ptr1 = new int;
    } catch (const std::bad_alloc&) {
        //handle exception
    }

    //Use ptr1

}
```

In this example, the custom allocation function `custom_alloc`, which is defined elsewhere, might return `nullptr` on failure. Function `func`, which expects a `bad_alloc` exception if the memory allocation fails, might dereference a null pointer because `operator new` does not throw.

# AUTOSAR C++14 Rule A18-5-10

Placement new shall be used only with properly aligned pointers to sufficient storage capacity

## Description

### Rule Definition

*Placement new shall be used only with properly aligned pointers to sufficient storage capacity.*

### Rationale

The `new` operator allocates the required amount of memory for storing an object on the heap and constructs a new object in the allocated memory in a single operation. If you want to separate the allocation and the construction and place an object in preallocated memory on either the stack or the heap, you use placement `new`. Placement `new` has advantages over `new` in certain situations, for example, when you need to place the object at a known memory location.

The `new` operator automatically allocates the correct amount of aligned memory that the object requires. But when using placement `new`, you must manually make sure that the pointer you pass has sufficient allocated storage capacity and is properly aligned. Violating these constraints results in the construction of an object at a misaligned location or memory initialization outside of allocated bounds, which might lead to unexpected or implementation-dependent behavior.

### Polyspace Implementation

Suppose that a pointer `ptr` is preallocated `m` bytes of memory on the stack and has alignment `n`. For instance, if `ptr` is an array:

```
uint8_t ptr[5];
```

the allocated storage is `sizeof(uint8_t) * 5` and the alignment is `alignof(uint8_t)`. If you allocate more than `m` bytes to this pointer in a placement `new` expression or if the alignment required for the allocation is greater than `n`, the checker raises a violation. When determining the pointer alignment, the checker takes into account explicit alignments such as with `std::align`.

The checker does not consider pointers that are preallocated memory on the heap since the available storage depends on the memory availability, which is known only at run time.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Placement `new` Used with Insufficient Storage Capacity and Misaligned Pointers

```
#include <new>
#include<memory>
#include <cstdint>

void Foo()
```

```
{
  uint8_t c;
  uint64_t* ptr =
      new    // Non-compliant (insufficient storage, misaligned)
      (&c) uint64_t;
}

void Bar()
{
  uint8_t buf[sizeof(uint64_t)];
  uint64_t* ptr =
      new            // Non-compliant (sufficient storage, misaligned)
      (buf) uint64_t;
}

void Baz()
{
  void* buf;
  std::size_t sp = 64;
  std::align(alignof(uint64_t), sizeof(uint64_t), buf, sp);
  uint64_t* ptr =
      new            // Compliant (sufficient storage, aligned)
      (buf) uint64_t;
}
```

In the function `Foo`, the `&c` points to an `uint8_t` value and has one byte memory in stack with one-byte alignment. The pointer is passed to placement `new`, which constructs an instance of `uint64_t` that requires 8 bytes of memory and a 4-byte alignment. This usage violates the rule.

In the function `Bar`, the pointer `buf` is properly allocated and has sufficient storage capacity. But, because it points to the `uint8_t` data type, it has one-byte alignment. This usage still violates the rule.

The function `Baz` calls the `std::align` function to create a pointer with correct storage capacity (8 byte) and alignment (4-byte) for `uint64_t`. This usage complies with the rule.

# AUTOSAR C++14 Rule A18-5-11

"operator new" and "operator delete" shall be defined together

## Description

### Rule Definition

*"operator new" and "operator delete" shall be defined together.*

### Rationale

You typically overload `operator new` to perform some bookkeeping in addition to allocating memory on the free store. Unless you overload the corresponding `operator delete`, it is likely that you omitted some corresponding bookkeeping when deallocating the memory.

The defect can also indicate a coding error. For instance, you overloaded the placement form of `operator new[]`:

```
void *operator new[](std::size_t count, void *ptr);
```

but the non-placement form of `operator delete[]`:

```
void operator delete[](void *ptr);
```

instead of the placement form:

```
void operator delete[](void *ptr, void *p );
```

When overloading `operator new`, make sure that you overload the corresponding `operator delete` in the same scope, and vice versa. To find the `operator delete` corresponding to an `operator new`, see the reference pages for `operator new` and `operator delete`.

### Polyspace Implementation

The rule checker raises a violation when you overload `operator new` but do not overload the corresponding `operator delete`, or vice versa.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Mismatch Between Overloaded `operator new` and `operator delete`

```
#include <new>
#include <cstdlib>

int global_store;

void update_bookkeeping(void *allocated_ptr, bool alloc) {
   if(alloc)
```

```
      global_store++;
   else
      global_store--;
}

void *operator new(std::size_t size, const std::nothrow_t& tag);
void *operator new(std::size_t size, const std::nothrow_t& tag) //Noncompliant
{
    void *ptr = (void*)malloc(size);
    if (ptr != nullptr)
        update_bookkeeping(ptr, true);
    return ptr;
}

void operator delete[](void *ptr, const std::nothrow_t& tag);
void operator delete[](void* ptr, const std::nothrow_t& tag) //Noncompliant
{
    update_bookkeeping(ptr, false);
    free(ptr);
}
```

In this example, the overloads of operators `operator new` and `operator delete[]` are noncompliant because there are no overloads of the corresponding `operator delete` and `operator new[]` operators.

The overload of `operator new` calls a function `update_bookkeeping` to change the value of a global variable `global_store`. If the default `operator delete` is called, this global variable is unaffected, which might defy developer's expectations.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A18-9-1

The std::bind shall not be used

## Description

### Rule Definition

*The std::bind shall not be used.*

### Rationale

`std::bind` takes a callable object, such as a function object, and produces a forwarding call wrapper for this object. Calling the wrapper invokes the object with some of the object arguments bound to arguments you specify in the wrapper. For instance, in this code snippet, `foo` is called through `bar` with the first (second) argument of `bar` bound to the second (first) argument of `foo`.

```
int foo(int, int);
auto bar = std::bind(foo, _2, _1);
bar(10, 20); //call to foo(20, 10)
```

The use of `std::bind` results in a less readable function call. A developer that is unfamiliar with `foo` would need to see the declaration of `foo` to understand how to pass arguments to `bar`, and might confuse one function parameter with another. In addition, a compiler is less likely to inline a function that you create using `std::bind`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Non-Compliant Use of `std::bind`

```
#include <cstdint>polys
#include <functional>
class A
{
//...
};
void func(A const& a, double y) noexcept
{
//...
}
void func1() noexcept
{
    double arg2 = 0.0;
    auto bind_fn = std::bind(&func, std::placeholders::_1, arg2); // Non-compliant
    // ...
    A const a{};
    bind_fn(a);
}
void func2() noexcept
{
    auto lambda_fn = [](A const & a) -> void { // Compliant
        double arg2 = 0.0;
        func(a, arg2);
    }; // Compliant
    // ...
    A const a{};
    lambda_fn(a);
}
```

In this example, `func` is called through `bind_fn` with the only argument of `bind_fn` bound to the first argument of `func`. It might be unclear to a developer that `arg2` in the definition of `bind_fn` is the second argument of `func`. For a more readable code, use lambda expressions instead. The call to `func` with two arguments is clearer in the definition of `lambda_fn`.

# AUTOSAR C++14 Rule A18-9-2

Forwarding values to other functions shall be done via: (1) std::move if the value is an rvalue reference, (2) std::forward if the value is forwarding reference

## Description

### Rule Definition

*Forwarding values to other functions shall be done via: (1) std::move if the value is an rvalue reference, (2) std::forward if the value is forwarding reference.*

### Rationale

You can pass an object efficiently to a function by casting the object to an rvalue and taking advantage of move semantics.

- If you are forwarding an rvalue reference to a function, use `std::move` to cast the object to an rvalue.
- If you are forwarding a forwarding reference (or universal reference) to a function, use `std::forward` to cast the object to an rvalue if and only if the object is bound to an rvalue. A forwarding reference might be bound to an rvalue or an lvalue. For the purposes of this rule, objects with type `auto &&` are considered as forwarding references.

Using `std::move` with forwarding references might result in an unexpected modification of an lvalue. Using `std::forward` with rvalue references is possible but it is error-prone and might increase the complexity of your code.

### Polyspace Implementation

- Polyspace flags the use of `std::move` to forward a forwarding reference to a function, including objects of type `auto &&`.
- Polyspace flags the use of `std::forward` to forward an rvalue reference to a function.
- Polyspace does not flag the use of `std::move` or `std::forward` if no forwarding to a function takes place. For instance, in this code snippet, no defect is raised on the use of `std::move` with forwarding reference `b2` and the use of `std::forward` with revalue reference `b1`.

```
template <typename T1, typename T2>
void func(T1& b1, T2&& b2)
{
    const T1& b10 = std::forward<B>(b1);
    const T2& b20 = std::forward<B>(b2);
    const T1& b11 = std::move(b1);
    const T2& b21 = std::move(b2);
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Values Forwarded Incorrectly

```
#include <cstdint>
#include <string>
#include <utility>

class A
{
public:
    explicit A(std::string&& s)
        : str(std::move(s)) // Compliant
    {
    }

private:
    std::string str;
};

template <typename ...T>
void f1(T...t);

template <typename T1, typename T2>
void func(T1&& t1, T2& t2)
{
    f1(std::move(t1));            // Non-compliant
    f1(std::forward<T1>(t1));     // Compliant

    f1(std::forward<T2>(t2));     // Non-compliant
    f1(std::move(t2));            // Compliant
}

void func_auto(A& var)
{
    auto&& var1 = var;
    f1(std::move(var1));                    // Non-compliant
    f1(std::forward<decltype(var1)>(var1)); //Compliant
}

void main()
{
    int32_t i;
    func(0, i);
}
```

In this example, template function `func` forwards parameters `t1` and `t2` to function `f1`. Polyspace flags the use of `std::forward` with `t2` because this parameter is an rvalue reference (type T&).

Polyspace also flags the use of `std::move` with `t1` because this parameter is a forwarding reference (type T&&). If `t1` is initialized with an lvalue, the move might result in an unexpected modification of the parameter. Similarly, Polyspace flags the use of `std::move` in `func_auto` because objects of type `auto&&` are considered as forwarding references.

# AUTOSAR C++14 Rule A18-9-3

The std::move shall not be used on objects declared const or const&

## Description

### Rule Definition

*The std::move shall not be used on objects declared const or const&.*

### Rationale

When you use `std::move()` on an object, it is cast into an rvalue. The compiler then manages the resources in the object by calling the constructor or operator with the closest matching parameter list. If you call `std::move()` on a `const` or `const&` type object, the call returns a `const` or `const&` type rvalue. Because move constructors and operators do not take a `const` type argument, the compiler calls the copy constructor or operator instead of the move constructor or operator. Consider this code snippet where a `const` object is copied when you might expect a move after a call to `std::move()`.

```
class string{
    //...
public:
    string(const string& rhs);// copy contructor
    string(string&& rhs);     //move constructor
};

void print(string text) {
    cout<<text;
    //...
}

int main(){
    int const message = "Error";
    //..
    print(std::move(message))// the copy constructor is called
}
```

The return type of `std::move(message)` is the rvalue `const string&&`. Between the move and copy constructors of class `string`, only the copy constructor accepts `const` type argument. The compiler calls the copy constructor and copies the resources of `message` into `text`.

Because `std::move()` does not move a `const` or `const&` type object, avoid using `std::move()` on `const` or `const&` objects. If you intend to move resources from an object, do not declare it as `const` or `const&`.

### Polyspace Implementation

Polyspace flags use of `std::move()` on:

- Objects that are declared `const` or `const&`.
- Objects that are cast to `const` or `const&`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using `std::move()` on `const` and `const&` Objects

```
#include <cstdint>
#include <utility>
class A
{
    // Implementation
};
void F1(const int32_t &is_const, int32_t &is_non_const)
{
    const A a1{};
    int32_t target = 0;
    A a2 = a1;              // Compliant
    A a3 = std::move(a1);   // Noncompliant

    target =
    std::move((const int32_t &)is_non_const);// Noncompliant
    target =
    std::move(static_cast<const int32_t &>(is_non_const));// Noncompliant
    target =
    std::move(const_cast<int32_t &>(is_const));// Compliant
}
int main(){
    //...
}
```

- Polyspace flags the use of `std::move()` with `const` object `a1`. The compiler calls the copy constructor to copy `a1` to `a3`. You might expect the compiler to call the move constructor.
- Polyspace also flags the use of `std::move()` with the object `is_non_const` when it is cast to `const`. After the casting, the compiler calls the copy constructor to copy `is_non_const` to `target`. You might expect the compiler to call the move constructor.
- Polyspace does not flag the use of `std::move()`with the non-`const` object that results from casting the `const` object `is_const` into a non-`const` type by using `const_cast`. After casting, `is_const` is no longer a `const` object. The compiler calls the move constructor.

# AUTOSAR C++14 Rule A18-9-4

An argument to std::forward shall not be subsequently used

## Description

### Rule Definition

*An argument to std::forward shall not be subsequently used.*

### Rationale

You typically use `std::forward` in a function template to pass a forwarding reference parameter to another function. The resources of the parameter might be transferred to another object through a move operation, depending on the value category of the parameter.

For an rvalue parameter, the parameter is in an indeterminate state if it is moved from after the call to `std::forward` and it should not be reused.

For an lvalue parameter, If you reuse the parameter after the call to `std::forward`, modifications to the parameter might affect the argument of the caller function to which you pass the parameter.

### Polyspace Implementation

Polyspace flags the call to `std::forward` if the forwarded object is reused after the call. Polyspace also highlights the lines where the forwarded object is reused in your code.

Polyspace does not flag the call to `std::forward` if its argument is reused in a branch that cannot be reached after the call to `std::forward`. For instance, in this code snippet, the branch where the reuse of variable `t` occurs cannot be reached after the code enters the branch where `std::forward` is used.

```
template<typename T>
void func(T&& t)
{
  T&& p = t;

  switch(t) {
    case 0:
      p = std::forward<T>(t);
      break;
    case 1:
      t--; //t reused
      break;
  }
}
```

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Reuse of Parameter After Call to `std::forward`

```
#include <cstdint>
#include <iostream>
#include <utility>

namespace myTemplates
{

template <typename ...T>
void f1(T...t);

template<typename T>
void f2(T&& t2, bool b)
{
    if (b) {
        f1(std::forward<T>(t2)); // Compliant
    } else {
        t2++;  // else branch not entered
    }

}

template<typename T>
void f3(T&& t3)
{
    T&& p = std::forward<T>(t3); // Non-compliant

    switch (t3) {                // t3 reused
    case 0:
        t3++;                    // t3 reused
        break;
    case 1:
        t3--;                    // t3 reused
        break;
    default:
        break;
    }
}

template<typename T>
void f4(T&& t4)
{
    --t4;

    f1(std::forward<T>(t4)); // Non-compliant

    t4++;                    // t4 reused

    f1(std::forward<T>(t4)); // Non-compliant and t4 reused

    t4--;                    // t4 reused
}
template<typename T>
void f5(T&& t5)
{
    f1(t5,                   // t5 reused
       std::forward<T>(t5)); // Non-compliant
}

}

void main(void)
{
    int i;

    myTemplates::f2(i, true);
    myTemplates::f3(i);
    myTemplates::f4(i);
    myTemplates::f5(i);

}
```

In this example, Polyspace flags all the calls to `std::forward` where the forwarded parameter is reused after the call. In template function `f4`, the second call to `std::forward` counts as a reuse of the parameter `t4`. There are no violations of this rule in `f2` because `t2` is reused in the `else` branch which is never entered.

# AUTOSAR C++14 Rule A20-8-1

An already-owned pointer value shall not be stored in an unrelated smart pointer

## Description

### Rule Definition

*An already-owned pointer value shall not be stored in an unrelated smart pointer.*

### Rationale

You use smart pointers to ensure that the memory a pointer points to is automatically deallocated when the pointer is destroyed, for example if the pointer goes out of scope. When unrelated smart pointers manage the same pointer value, one of the smart pointers might attempt to deallocate memory that was already deallocated by the other smart pointer. This results in a double free vulnerability, which corrupts your program's memory management data structure.

A smart pointer owns the pointer value that is used to initialize the smart pointer. If a pointer value is already owned by a smart pointer such as `std::shared_ptr`, and then you use that smart pointer to initialize another smart pointer, for example with a copy operation, the two smart pointers are related. The underlying pointer value is managed by both smart pointers and the memory pointed to is not deallocated until all the smart pointers are destroyed.

### Polyspace Implementation

Polyspace flags the use of an already-owned pointer as the argument of:

- A smart pointer constructor. For instance, in this code snippet, `raw_ptr` is already owned by `s_ptr1` and is used to initialize `s_ptr2`:

  ```
  char *raw_ptr = new char;
  std::shared_ptr<char> s_ptr1(raw_ptr);
  std::shared_ptr<char> s_ptr2(raw_ptr); //raw_ptr is already owned by s_ptr1
  ```
- A smart pointer reset operation. For instance, in this code snippet, the reset of `s_ptr2` replaces `raw_ptr2` with already-owned `raw_ptr1`:

  ```
  char *raw_ptr1 = new char;
  char *raw_ptr2 = new char;

  std::shared_ptr<char> s_ptr1(raw_ptr1);
  std::shared_ptr<char> s_ptr2(raw_ptr2);

  s_ptr2.reset(raw_ptr1); // s_ptr2 releases raw_ptr2 and owns already owned raw_ptr1
  ```

Polyspace checks only smart pointer types `std::shared_ptr` and `std::unique_ptr` and considers that user-defined allocators and deleters have standard allocation and deallocation behavior.

A pointer is already owned by a smart pointer if the pointer type is not `std::nullptr_t` and either:

- The pointer was used to initialize the smart pointer.
- The pointer was used as an argument to the smart pointer `reset()` member function.
- The pointer is the return value of the smart pointer `get()` member function.
- The pointer is the return value of the smart pointer `operator->` member function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Use of an Already-Owned Pointer

```
#include <memory>
#include <string>

struct Profile
{
    virtual ~Profile()=default;
};

struct Player : public Profile
{
    std::string name;
    std::int8_t rank;

    Player();
    Player(const std::string& name_, const std::int8_t& rank_) :
        name{ name_ }, rank{ rank_ } {}
};

void func(){

    Player * player = new Player("Richard Roll",1);
    std::shared_ptr<Player> player1(player);
    std::shared_ptr<Player> top_rank(player); //Non-compliant

}

void func2(){

    std::shared_ptr<Player> player1_shared =
        std::make_shared<Player>("Richard Roll",1);
    std::shared_ptr<Player> top_rank_shared(player1_shared); //Compliant

}
```

In this example, the use of pointer value `player` to construct smart pointer `top_rank` in function `func` is non-compliant. `player` is already owned by smart pointer `player1`. When `player1` is destroyed, it might attempt to delete pointer value `player` which was already deleted by `top_rank`.

If you intend to have multiple smart pointer manage the same pointer value, use `std::make_shared` to declare `player1_shared`, and then use copy construction to create related smart pointer `top_rank_shared`, as in `func2`. The underlying pointer value is not deleted until all smart pointers are destroyed.

If you do not intend to share the pointer value between smart pointers, use `std::make_unique` to construct a smart pointer of type `std::unique_ptr`. A `std::unique_ptr` can only be moved, which relinquishes ownership of the underlying managed pointer value.

# AUTOSAR C++14 Rule A20-8-2

A std::unique_ptr shall be used to represent exclusive ownership

## Description

### Rule Definition

*A std::unique_ptr shall be used to represent exclusive ownership.*

### Rationale

Raw pointers to heap memory suffer from two related problems:

- When a raw pointer goes out of scope, the pointed memory might not be deallocated and result in a memory leak. You have to remember to explicitly deallocate the memory (`delete` the pointer) before the pointer goes out of scope.
- If you pass a raw pointer to a function, it is unclear if the function takes exclusive ownership of the pointed resource and can deallocate the memory or must leave the deallocation to the caller. If the function deallocates the memory, there is a risk that another pointer pointing to the same memory location is now left dangling.

A `std::unique_ptr` object is a smart pointer that solves both problems and does not require significant additional overheads over raw pointers:

- You do not have to explicitly deallocate the pointed memory. The memory is deallocated before the pointer goes out of scope.
- The pointer has exclusive ownership of the pointed object. When you pass the pointer to a function by a move operation, the function assumes ownership of the memory through the pointer and implicitly deallocates the memory on completion (unless you pass the ownership to another function).

### Polyspace Implementation

The checker flags functions other than `main` that have raw pointers as parameters or return values.

The checker raises a violation of both this rule and `AUTOSAR C++14 Rule A20-8-3`.

- If you want the function to take exclusive ownership of the pointed object, convert the raw pointer to `std::unique_ptr` type.
- If you want the function to take shared ownership of the pointed object, convert the raw pointer to `std::shared_ptr` type.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Raw Pointers as Function Parameters

```
#include <memory>
#include <cstdint>
#include <thread>
constexpr std::uint32_t SIZE=100;

class Resource {
  public:
    bool lookup(std::int32_t);
  private:
    std::int32_t arr[SIZE];
};

bool doesValueExist(Resource *aResource, std::int32_t val) { //Noncompliant
    return aResource->lookup(val);
}

bool doAllSmallerValuesExist(std::unique_ptr<Resource> aResource, std::int32_t val) {
//Compliant
    bool valueExists = true;
    for(std::int32_t i = 0; i <= val; i++) {
        valueExists = aResource->lookup(i);
        if(!valueExists)
            break;
    }
    return valueExists;
}

std::int32_t getAVal();

void main(void) {
    Resource *aResourcePtr = new Resource;
    auto anotherResourcePtr = std::make_unique<Resource>();
    bool valueFound, allSmallerValuesFound;

    //Initialize resources

    valueFound = doesValueExist(aResourcePtr, getAVal());
    allSmallerValuesFound = doAllSmallerValuesExist(std::move(anotherResourcePtr), getAVal());
}
```

In this example, the function `doesValueExist` takes a raw pointer to a `Resource` object as parameter and violates the rule.

The function `doAllSmallerValuesExist` performs similar operations on a `Resource` object but takes an `std::unique_ptr` pointer to the object as parameter.

# AUTOSAR C++14 Rule A20-8-3

A std::shared_ptr shall be used to represent shared ownership

## Description

### Rule Definition

*A std::shared_ptr shall be used to represent shared ownership.*

### Rationale

Raw pointers to heap memory suffer from two related problems:

- When a raw pointer goes out of scope, the pointed memory might not be deallocated and result in a memory leak. You have to remember to explicitly deallocate the memory (`delete` the pointer) before the pointer goes out of scope.
- If you pass a raw pointer to a function, it is unclear if the function takes exclusive ownership of the pointed resource and can deallocate the memory or must leave the deallocation to the caller. If the function deallocates the memory, there is a risk that another pointer pointing to the same memory location is now left dangling.

A `std::shared_ptr` object is a smart pointer that solves both problems.

- You do not have to explicitly deallocate the pointed memory. The memory is deallocated before the last pointer pointing to the memory location goes out of scope.
- The pointer has shared ownership of the pointed object. When you pass the pointer to a function, the function assumes ownership of the memory through the pointer and implicitly deallocates the memory on completion as long as no other pointer is pointing to the object.

Although a `std::shared_ptr` object has some overhead over a raw pointer, the use of this object avoids possible memory leaks later.

### Polyspace Implementation

The checker flags functions other than `main` that have raw pointers as parameters or return values.

The checker raises a violation of both this rule and `AUTOSAR C++14 Rule A20-8-2`.

- If you want the function to take exclusive ownership of the pointed object, convert the raw pointer to `std::unique_ptr` type.
- If you want the function to take shared ownership of the pointed object, convert the raw pointer to `std::shared_ptr` type.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Raw Pointers as Function Parameters

```
#include <memory>
#include <cstdint>
#include <thread>
constexpr std::uint32_t SIZE=100;

class Resource {
    public:
       bool lookup(std::int32_t);
    private:
       std::int32_t arr[SIZE];
};

bool doesValueExist(Resource *aResource, std::int32_t val) { //Noncompliant
    return aResource->lookup(val);
}

bool doAllSmallerValuesExist(std::shared_ptr<Resource> aResource, std::int32_t val) {
//Compliant
    bool valueExists = true;
    for(std::int32_t i = 0; i <= val; i++) {
        valueExists = aResource->lookup(i);
        if(!valueExists)
            break;
    }
    return valueExists;
}

std::int32_t getAVal();

void main(void) {
    Resource *aResourcePtr = new Resource;
    auto anotherResourcePtr = std::make_shared<Resource>();
    bool valueFound, allSmallerValuesFound;

    //Initialize resources

    valueFound = doesValueExist(aResourcePtr, getAVal());
    allSmallerValuesFound = doAllSmallerValuesExist(anotherResourcePtr, getAVal());
}
```

In this example, the function `doesValueExist` takes a raw pointer to a `Resource` object as parameter and violates the rule.

The function `doAllSmallerValuesExist` performs similar operations on a `Resource` object but takes an `std::shared_ptr` pointer to the object as parameter.

"Check for and Review Coding Standard Violations"

# AUTOSAR C++14 Rule A20-8-4

A std::unique_ptr shall be used over std::shared_ptr if ownership sharing is not required

## Description

### Rule Definition

*A std::unique_ptr shall be used over std::shared_ptr if ownership sharing is not required.*

### Rationale

A resource can be owned by a single `std::unique_ptr` object. In contrast, a resource can be shared by several `std::shared_ptr` objects. Using `std::unique_ptr` when resource sharing is not required has these advantages:

- An `std::shared_ptr` object keeps an internal count of objects that share a resource. Copy assigning or copy constructing an `std::shared_ptr` object increments this use count. An `std::unique_ptr` does not keep this count, making it a more efficient alternative.
- The resource owned by an `std::unique_ptr` object has a predictable life cycle. Unless its ownership is moved to a different `std::unique_ptr` object, the resource is released when the object goes out of scope. The resource managed by an `std::shared_ptr` object has an unpredictable life cycle. It is not released until all the objects that share it are out of scope.

Using `std::shared_ptr` objects makes your code inefficient and difficult to debug. Avoid using `std::shared_ptr` objects unless ownership sharing is required. Instead, use `std::unique_ptr` objects as smart pointers.

### Polyspace Implementation

Polyspace raises a violation of this rule when replacing a `std::shared_ptr` object in your code by an `std::unique_ptr` object is possible. For instance, a violation is raised when either of these conditions are true:

- An `std::shared_ptr` is not used in a copy construction or copy assignment. The internal reference count remains at one. Consider this code:

  ```
  #include <memory>
  class A();
  void bar(std::shared_ptr<A> sp);
  void foo(){
  auto sp = std::make_shared<A>();//count==1
  bar(sp);
  }
  ```

  No `std::shared_ptr` objects are copy constructed or copy assigned. The object `sp` does not share its resources. Declaring this object as an `std::unique_ptr` might be more efficient. See “Avoid Using shared_ptr Objects If They are Not Copied” on page 26-544.
- `std::shared_ptr` objects are sequentially copied to create a chain of `N` shared pointers, but the first `(N-1)` shared pointers are not dereferenced or passed to a function. Because these `(N-1)` shared pointers are not used, moving their resources and declaring the pointers as unique pointers might be more efficient. For instance, in this code:

```
#include <memory>
class obj();
void foo(){
    auto A = std::make_shared<obj>();
    auto B = A;//count==2
    auto C = B;//count==3
    //…
    auto X = *C;
}
```

A chain of shared pointers is created by copying A into B and then copying B into C. Because A and B are not dereferenced, declaring A, B, and C as `std::unique_ptr` objects does not result in loss of functionality and makes the code more efficient. See "Avoid Using shared_ptr Objects When They Are Copied Once But Not Dereferenced" on page 26-545.

As an exception, Polyspace does not raise a violation if you use an `std::shared_ptr` object as an argument of certain standard atomic operation.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see "Diagnose Why Coding Standard Violations Do Not Appear as Expected".

## Examples

### Avoid Using shared_ptr Objects If They are Not Copied

```
#include <memory>
#include <cstdint>
#include <thread>

struct A {
    A(std::uint8_t xx, std::uint8_t yy) : x(xx), y(yy) {}
    std::uint8_t x;
    std::uint8_t y;
};
void Bar(std::shared_ptr<A> obj) {/**/ }

void Func1()
{
    auto spA = std::make_shared<A>(3,5); //Noncompliant
}

void Func2(void)
{
    std::shared_ptr<A> spA = std::make_shared<A>(3,5);
    //Compliant, object accesses in parallel
    std::thread th1{&Bar, spA};
    std::thread th2{&Bar, spA};
    th1.join();
    th2.join();
}
```

In this example:

- An `std::shared_ptr` object `spA` is declared in `Func1()` but it does not share its resources. Polyspace flags `spA` as noncompliant. The best practice is to declare such pointers as `std::unique_ptr` objects.
- An `std::shared_ptr` object `spA` is declared in `Func2()` and then used in two different threads simultaneously. Polyspace does not raise a violation because `spA` is used in multiple threads at the same time.

### Avoid Using shared_ptr Objects When They Are Copied Once But Not Dereferenced

```
#include <memory>
#include <cstdint>
#include <thread>
#include<iostream>

class Resource {
public:
    Resource(){}
};
class Interface{
public:
    Interface(std::shared_ptr<Resource> obj):R(obj){}
    std::shared_ptr<Resource> R;
};
void foo(){
    auto user1 = std::make_shared<Resource>();//Noncompliant
    auto user2 = user1;
    auto user3 = user2;
    Interface ti1(user3);
}
void foo2(){
    auto user1 = std::make_shared<Resource>();//Compliant
    auto user2 = user1;
    auto user3 = user2;
    //...
    auto X = *user2;
}
void bar(){
    auto user1 = std::make_unique<Resource>();
    auto user2 = std::move(user1);
    auto user3 = std::move(user2);
    //Interface ti1(user3);
}
```

In this example, a cheap interface class `Inteface` contains a pointer to an expensive object of class `Resource`.In `foo()`, three shared pointers `user1`, `user2`, and '`user3` are created by copying `user1` into `user2` and then copying `user2` into `user3`. The developer intent might be to create three separate `Interface` objects by using these shared pointers. Perhaps inadvertently, only one `Interface` object is created by using `user3`. Because `user1` and `user2` do not access their resource, it is possible to move the resource from one pointer to the other until `user3` owns the resource. It might be more efficient to replace these shared pointers in by unique pointers, as shown in `bar()`. Polyspace raises a violation on `foo()`.

The function `foo2()` contains a similar chain of copied shared pointers. Because `user2` accesses its resources, moving its resources to `user3` results in loss of functionality. In this case, it is not possible to replace the shared pointers by unique pointers. Polyspace does not raise a violation.

### Use Temporary Objects to Avoid Creating shared_ptr Objects That Do Not Share Resources

```
#include <memory>
class A{A();};
extern void foo(std::shared_ptr<A> sp);
void func1(){
    auto var = std::make_shared<A>();//Noncompliant
    foo(var);
    //...
}

void func2(){
    foo(std::make_shared<A>());//Compliant
    //...
}

void func3(){
    auto up = std::make_unique<A>();
    foo (std::shared_ptr<A>(std::move(up)));//Compliant
}
```

In this example, the external function `foo()` accepts an `std::shared_ptr` as input. In `func1`, to call `foo()`, the `std::shared_ptr` object `var` is created, but this object does not share ownership of its resources. Polyspace raises a violation.

To resolve this defect, modify `foo()` to accept a `unique_ptr`. If modifying `foo()` is not feasible, there are two alternative solutions.

- You might create a temporary `std::shared_ptr` object and pass it directly to `foo()`, as shown in `func2`.
- You might create a `std::unique_ptr` object and then convert it to a `std::shared_ptr` object when passing it to `foo()`, as shown in`func3`.

# AUTOSAR C++14 Rule A20-8-5

std::make_unique shall be used to construct objects owned by std::unique_ptr

## Description

### Rule Definition

*std::make_unique shall be used to construct objects owned by std::unique_ptr.*

### Rationale

Instead of allocating memory by using the `new` operator and converting the resulting raw pointer to an `std::unique_ptr` object, for instance:

```
class numberClass {
   public:
     numberClass(int n): number(n){}
   private:
     int number;
}
int aNumber=1;
std::unique_ptr<numberClass> numberPtr (new numberClass(aNumber));
```

Create a `std::unique_ptr` object directly using the `std::make_unique` function. For instance:

```
auto numberPtr = std::make_unique<numberClass>(aNumber);
```

Using `std::make_unique` is preferred because:

- The creation of the `std::unique_ptr` object using `std::make_unique` is exception-safe. Otherwise, an exception can occur between the dynamic memory allocation with the `new` operator and the subsequent conversion, leading to a memory leak. An exception causes a memory leak only in certain contexts, for instance, when the `std::unique_ptr` object is created in an argument of a multi-parameter function and another function argument evaluation throws an exception.
- You can use a more concise syntax. You do not have to repeat the data type of the object that is dynamically allocated.

### Polyspace Implementation

The checker flags the creation of an `std::unique_ptr` object (or `boost::unique_ptr` object) from the raw pointer returned by the `new` operator.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A20-8-6

std::make_shared shall be used to construct objects owned by std::shared_ptr

## Description

### Rule Definition

*std::make_shared shall be used to construct objects owned by std::shared_ptr.*

### Rationale

Instead of allocating memory by using the `new` operator and converting the resulting raw pointer to an `std::shared_ptr` object, for instance:

```
class numberClass {
   public:
     numberClass(int n): number(n){}
   private:
     int number;
}
int aNumber=1;
std::shared_ptr<numberClass> numberPtr (new numberClass(aNumber));
```

Create a `std::shared_ptr` object directly using the use `std::make_shared` function. For instance:

```
auto numberPtr = std::make_shared<numberClass>(aNumber);
```

Using `std::make_shared` is preferred because:

- The creation of the `std::shared_ptr` object is performed in a single dynamic memory allocation and improves run-time performance. Otherwise, creating a raw pointer by using the `new` operator requires one dynamic memory allocation and converting the raw pointer to an `std::shared_ptr` object requires a second allocation. The second allocation creates a control block that keeps track of the reference count of the shared resource and makes the `std::shared_ptr` object aware of all pointers to the shared resource.
- The creation of the `std::shared_ptr` object using `std::make_shared` is exception-safe. Otherwise, an exception can occur between the dynamic memory allocation with the `new` operator and the subsequent conversion, leading to a memory leak. An exception causes a memory leak only in certain contexts, for instance, when the `std::shared_ptr` object is created in an argument of a multi-parameter function and another function argument evaluation throws an exception.
- You can use a more concise syntax. You do not have to repeat the data type of the object that is dynamically allocated.

### Polyspace Implementation

The checker flags the creation of an `std::shared_ptr` object (or `boost::shared_ptr` object) from the raw pointer returned by the `new` operator.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Check Information

`Check AUTOSAR C++ 14 (-autosar-cpp14)`

### Topics

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A20-8-7

A std::weak_ptr shall be used to represent temporary shared ownership.

## Description

### Rule Definition

*A std::weak_ptr shall be used to represent temporary shared ownership.*

### Rationale

A `std::shared_ptr` is deallocated when the reference count drops to zero. If the code creates a reference cycle by using multiple `std::shared_ptr`, the reference count of any `std::shared_ptr` involved in the cycle can never drop to zero. This can cause a memory leak.

Use `std::weak_ptr` to break up reference cycles. A `std::weak_ptr` can point to a `std::shared_ptr` but does not increase the reference count.

### Polyspace Implementation

Polyspace raises this defect when assigning by using the assignment operator of `std::shared_ptr`. If the right side is a class or struct field of type `std::shared_ptr` that is instantiated with a template that has only a `std::shared_ptr` template argument, Polyspace flags this defect.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Potential Reference Cycles When Using std::shared_ptr

```
#include <memory>

template <template <typename> class T, typename U>
struct Base {
  T<U> sPoint;
};

template <typename T>
using Ex1 = Base<std::shared_ptr, T>;

struct spExampleA;
struct spExampleB : public Ex1<spExampleA> {};
struct spExampleA : public Ex1<spExampleB> {};

void example()
{
  std::shared_ptr<spExampleB> sp1 = std::make_shared<spExampleB>();
  std::shared_ptr<spExampleA> sp2 = std::make_shared<spExampleA>();
  sp1->sPoint = sp2;             // Noncompliant
  sp2->sPoint = sp1;             // Noncompliant

}
```

The preceding code creates a reference cycle with `std::shared_ptr`. In the example, neither `sp1` nor `ps2` can have their reference count drop to 0 and be deallocated. Use `std::weak_ptr` instead of `std::shared_ptr` to break reference cycles.

Arguments to character-handling functions shall be representable as an unsigned char

## Description

### Rule Definition

*Arguments to character-handling functions shall be representable as an unsigned char.*

### Rationale

You cannot use plain `char` variables as arguments to character-handling functions declared in `<cctype>`, for instance, `isalpha()` or `isdigit()`. On certain platforms, plain `char` variables can have negative values that cannot be represented as `unsigned char` or EOF, resulting in undefined behavior.

### Polyspace Implementation

The check raises a flag when you use a signed or plain `char` variable with a negative value as argument to a character-handling function.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

“Check for and Review Coding Standard Violations”

# AUTOSAR C++14 Rule A23-0-1

An iterator shall not be implicitly converted to const_iterator

## Description

### Rule Definition

*An iterator shall not be implicitly converted to const_iterator.*

### Rationale

The C++11 standard introduces member functions such as `cbegin` and `cend` that returns const iterators to containers. To create const iterators, use these member functions instead of functions such as `begin` and `end` that return non-const iterators and then require implicit conversions.

For instance, consider the `std::list` container:

```
std::list<int> aList = {0, 0, 1, 2};
```

You can use the `begin` and `end` member functions of the container to create const iterators, for instance in a `for` loop:

```
for(std::vector<int>::const_iterator iter{aList.begin()}, end{aList.end()};
    iter != end;
    ++iter) {...}
```

However, the functions `begin` and `end` return non-const iterators and for assignment to the const iterators `iter` and `end` respectively, an implicit conversion must happen. Instead, take advantage of the new C++11 functions `cbegin` and `cend` that directly returns const iterators:

```
for(std::vector<int>::const_iterator iter{aList.cbegin()}, end{aList.cend()};
    iter != end;
    ++iter) {...}
```

If you use these functions, you can also replace the explicit type specification of the iterators with `auto`:

```
for(auto iter{aList.cbegin()}, end{aList.cend()};
    iter != end;
    ++iter) {...}
```

### Polyspace Implementation

The checker flags conversions from type `iterator` to `const_iterator` or `reverse_iterator` to `const_reverse_iterator`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Implicit Conversions to Const Iterators

```
#include <cstdint>
#include <vector>

void func(std::vector<int32_t> & values, int32_t aValue) {
    std::vector<int32_t>::const_iterator iter1 =
                 std::find(values.begin(), values.end(), aValue); //Noncompliant
    std::vector<int32_t>::const_iterator iter2 =
                 std::find(values.cbegin(), values.cend(), aValue);  //Compliant
}
```

In this example, the first `std::find` function call uses as arguments the return values of the `begin` and `end` methods of an `std::vector` container `values`. These methods return iterators of type `std::vector<intr32_t>::iterator`. Since the `std::find` template has the same return type as the types of the first two arguments, it also returns an iterator of type `std::vector<intr32_t>::iterator`. The return value is assigned to a variable of type `std::vector<intr32_t>::const_iterator`, resulting in an implicit conversion.

The second call uses the `cbegin` and `cend` methods which return iterators of type `std::vector<intr32_t>::const_iterator` and avoid the implicit conversion.

# AUTOSAR C++14 Rule A23-0-2

Elements of a container shall only be accessed via valid references, iterators, and pointers

## Description

### Rule Definition

*Elements of a container shall only be accessed via valid references, iterators, and pointers.*

### Rationale

You access the elements of a container by dereferencing a reference, a pointer, or an iterator. When the size or shape of a container changes, the reference, pointer, or iterator might point to a different element or an invalid location. For instance, consider this code:

```
std::vector<int> v = {1,2,3,4,5,6,7};
std::vector<int>::iterator it = std::find(v.begin(), v.end(), 5);;
v.push_back(-1);
std::cout<<*it;
```

If the `push_back()` operation causes the vector v to reallocate memory to accommodate a larger size, the iterator `it` is no longer valid. Dereferencing the invalid iterator might produce unexpected results. If the invalidated iterator becomes a dangling pointer or an uninitialized pointer, you might not be able to dereference it safely.

The C++ standard defined which operations invalidate the iterators of the standard library containers. See Containers library. When performing actions that might invalidate an iterator, validate the iterator, for instance, by recalculating its position.

### Polyspace Implementation

Polyspace raises a violation of the rule when you access the elements of a container by using a pointer, reference, or iterator that has been invalidated.

Certain erasure operations, such as `std::deque::pop_back()` or `std::forward_list::pop_front()` invalidate the iterators to the erased elements. After the erasure, whether any iterators pointed to the erased elements is unknown. If invalidated iterators that point to the erased elements exist in your code, Polyspace does not flag them.

Certain operations return iterators through an `std::pair`. Polyspace does not track iterators that are part of an `std::pair`.

### Troubleshooting

If you expect a rule violation but Polyspace does not report it, see “Diagnose Why Coding Standard Violations Do Not Appear as Expected”.

## Examples

### Avoid Using Invalid Iterators

```
#include <iostream>
#include <vector>
```

```
#include <algorithm>
#include <list>
void foo()
{
    std::vector<int> v{0, 1, 2, 3, 4, 5, 6, 7};
    std::vector<int>::iterator it = std::find(v.begin(), v.end(), 5);
    v.push_back(8);
    std::cout<<*it; //Noncompliant
}

void bar()
{
    std::list<int> l{0, 1, 2, 3, 4, 5, 6, 7};
    std::list<int>::iterator it = std::find(l.begin(), l.end(), 5);
    l.remove(4);
    std::cout<<*it; //Compliant
}
```

In this example, the function `foo()` dereferences an iterator `it` after an insertion. The insertion might trigger a reallocation and invalidate `it`. Polyspace flags the dereferencing of an iterator that might be invalid.

The function `bar()` dereferences `it` after an erasure. The erasure does not invalidate the iterator and Polyspace does not flag the dereferencing.

## Description

### Rule Definition

*Non-static data members or captured values of predicate function objects that are state related to this object's identity shall not be copied.*

### Rationale

Predicate function objects take a single argument and use that argument to return a value that is testable as a boolean (true or false). Standard Template Library (STL) algorithms that accept a predicate function object may, depending on the algorithm implementation, make a copy of the function object. The invocation of the copy might cause unexpected results.

For example, suppose that you use an algorithm to remove one element from a list. To determine the element to remove, the algorithm uses a predicate function object that modifies a state related to the function object identity each time the function object is called. You might expect the predicate object to return true only once. If the algorithm makes a copy of the predicate object, the state of the copy is also modified and the copy returns true a second time, removing a second element from the list.

To avoid unexpected results, consider one of the following:

- Wrap the predicate function object in a `std::reference_wrapper<T>` before you pass it to the algorithm. If the wrapper object is copied, all copies refer to the same underlying predicate function object.
