If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Data Types: `single` | `double` | `fixed point`

Parameters

Input — Type of input

`Magnitude (default)` | `Angle` | `Magnitude and angle`

Specify the kind of input: a magnitude input, an angle input, or both.

Programmatic Use

Block Parameter: `Input`

Type: `character vector`

Values: `'Magnitude'` | `'Angle'` | `'Magnitude and angle'`

Default: `'Magnitude and angle'`

Angle — Phase angle of output

θ (default) | `real-valued scalar, vector, or matrix`

Constant phase angle of the output signal, in rad. To compute the CORDIC approximation, the input angle must be between:

- $[-2\pi, 2\pi)$ rad, for signed fixed-point types
- $[0, 2\pi)$ rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-1287.

Dependencies

To enable this parameter, set **Input** to **Magnitude**.

Programmatic Use

Block Parameter: `ConstantPart`

Type: character vector
Values: constant scalar
Default: '0'

Magnitude — Magnitude of output
 0 (default) | real-valued scalar, vector, or matrix

Constant magnitude of the output signal, specified as a real-valued scalar, vector, or matrix.

Dependencies

To enable this parameter, set **Input** to Angle.

Programmatic Use

Block Parameter: ConstantPart
Type: character vector
Values: real-valued scalar, vector, or matrix
Default: '0'

Approximation method — CORDIC or none

None (default) | CORDIC

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines for the input angle:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ rad.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ rad.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	None or CORDIC	Same as input
Signed, fixed point	CORDIC	$\text{fixdt}(1, WL + 2, FL)$ where WL and FL are the word length and fraction length of the magnitude
Unsigned, fixed point	CORDIC	$\text{fixdt}(1, WL + 3, FL)$ where WL and FL are the word length and fraction length of the magnitude

Programmatic Use

Block Parameter: ApproximationMethod

Type: character vector
Values: 'None' | 'CORDIC'
Default: 'None'

Number of iterations — Number of iterations for CORDIC algorithm

11 (default) | positive integer, less than or equal to word length of fixed-point input

Number of iterations to perform the CORDIC algorithm. The range of possible values depends on the data type of the input:

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: NumberOfIterations

Type: character vector

Values: positive integer, less than or equal to word length of fixed-point input

Default: '11'

Scale output by reciprocal of gain factor — Scale real and imaginary parts of complex output

on (default) | off

Select this check box to scale the real and imaginary parts of the complex output by a factor of (1/CORDIC gain). This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output, $X + iY$. However, scaling the output adds two extra multiplication operations, one for X and one for Y .

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: ScaleReciprocalGainFactor

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

CORDIC

CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so increases the expense of the computation and adds latency.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See "Generated Model and Validation Model" (HDL Coder).

For a block that has additional latency, the **Approximation method** is CORDIC. The number of additional cycles iterations is +1.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

The Magnitude-Angle to Complex block supports only the HDL code generation for a floating-point data type.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Magnitude-Angle to Complex block supports fixed-point and base integer data types when you set **Approximation method** to CORDIC.

Manual Switch

Switch between two inputs

Libraries:
Simulink / Signal Routing

Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. You control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

To programmatically toggle the switch, set the `set_param sw` property to `'0'` or `'1'`. For example, to connect the second input to the output:

```
set_param(gcf, 'sw', '0')
```

To connect the first input to the output:

```
set_param(gcf, 'sw', '1')
```

Note Double-clicking the Manual Switch block does not open the block dialog box. Instead, it toggles the input choice.

Ports

Input

Port_1 — First input signal

scalar | vector

First of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_2 — Second input signal

scalar | vector

Second of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port 1 — Output signal

scalar | vector

Output signal propagated from either the first or second input signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To view the block parameters, right-click the block and select **Block Parameters (ManualSwitch)**.

Allow the two inputs to differ in size (Results in variable-size output signal) — Allow inputs of different sizes

off (default) | on

Select this check box to allow inputs with different sizes and propagate the selected input signal size to the output signal. If you clear the box, the block expands scalar inputs to have the same dimensions as nonscalar inputs. See “Scalar Expansion of Inputs and Parameters”.

Programmatic Use

Parameter: varsize

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Switch | Multipoint Switch | Manual Variant Source | Manual Variant Sink

Manual Variant Sink

Switch between multiple variant choices at output

Libraries:
Simulink / Signal Routing

Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

The block can have two or more output ports and has one input port. Each output port is associated with a variant control. To change the number of output ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at output, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

Note

- Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.
 - Changing the active choice during compile, simulation, or paused states is not supported.
-

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal passed to the active output port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — First variant output
scalar | vector

First variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth variant output
scalar | vector

nth variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices — Number of output choices
2 (default) | scalar

Specify the number of variant output ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Manual Variant Source

Switch between multiple variant choices at input

Libraries:
Simulink / Signal Routing

Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control. To change the number of input ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at input, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

Note

- Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the output choice.
 - Changing the active choice during compile, simulation, or paused states is not supported.
-

Ports

Input

Port_1 — First variant input signal

scalar | vector

First variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_n — nth variant input signal

scalar | vector

nth variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal
scalar | vector

Output signal passed from the active variant input signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

Number of choices — Number of input choices
2 (default) | scalar

Specify the number of variant input ports.

Programmatic Use

Block Parameter: NumChoices

Type: character vector

Value: integer

Default: '2'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Math Function

Perform mathematical function

Libraries:

Simulink / Math Operations
HDL Coder / Math Operations

Description

The Math Function block performs many common mathematical functions.

You can select one of these functions from the **Function** parameter list in Math Function block.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	e^u	exp
log	Natural logarithm	$\ln u$	log
2^u	Power of base 2	2^u	2.^u (see power)
10^u	Power of base 10	10^u	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$ u ^2$	real(u).^2 + imag(u).^2 (see real, imag, and power)
square	Power 2	u^2	u.^2 (see power)
pow	Power	$\text{sign}(u) * u ^v$ (default, applied only for even-order roots) or u^v	power
conj	Complex conjugate	\bar{u}	conj
reciprocal with Exact method	Reciprocal	$1/u$	1./u (see rdivide)
reciprocal with Newton-Raphson method	Reciprocal	See "Newton-Raphson Reciprocal Algorithm Method" on page 1-1306	None
hypot	Square root of sum squares	$(u^2+v^2)^{0.5}$	hypot
rem	Remainder after division	—	rem

Function	Description	Mathematical Expression	MATLAB Equivalent
mod	Modulus after division	—	mod
transpose	Transpose	u^T	<code>u.'</code> (see “Array vs. Matrix Operations”)
hermitian	Complex conjugate transpose	u^H	<code>u'</code> (see “Array vs. Matrix Operations”)

Tip To perform square root calculations, use the Sqrt block.

The block output is the result of the operation of the function on the input or inputs. The functions support these types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
exp	Yes	Yes	Not applicable
log	Yes	Yes	Not applicable
2 ^u	Yes	Yes	Not applicable
10 ^u	Yes	Yes	Not applicable
log10	Yes	Yes	Not applicable
magnitude ²	Yes	Yes	Not applicable
square	Yes	Yes	Not applicable
pow	Yes	Yes	Not applicable
conj	Yes	Yes	Not applicable
reciprocal with Exact method	Yes	Yes	Not applicable
reciprocal with Newton-Raphson method	Yes	Yes	Not applicable
hypot	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
rem	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	Not applicable

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
mod	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	Not applicable
transpose	Yes	—	Yes
hermitian	Yes	—	Yes

The name of the function and the appropriate number of input ports appear on the block.

Tip Use the Math Function block when you want vector or matrix output.

Newton-Raphson Reciprocal Algorithm Method

The reciprocal function that has the Newton-Raphson algorithm method calculates the reciprocal by using the Newton-Raphson approximation method. The function uses recursive approximation to find better approximations to the roots of a real-value function.

The reciprocal of a real number a is defined as a zero of the function:

$$f(x) = \frac{1}{x} - a.$$

Simulink chooses an initial estimate in the range $0 < x_0 < \frac{2}{a}$, because this is the domain of convergence for the function.

To successively calculate the roots of the function, specify the **Number of iterations** parameter. The process is repeated as follows:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i + (x_i - ax_i^2) = x_i \cdot (2 - ax_i)$$

$f'(x)$ is the derivative of the function $f(x)$.

Data Type Support

This table lists the input data types that each function of the block can support.

Function	Single	Double	Half*	Boolean	Built-In Integer	Fixed Point
exp	Yes	Yes	Yes	—	—	—
log	Yes	Yes	Yes	—	—	—
2 ^u	Yes	Yes	Yes	—	—	—
10 ^u	Yes	Yes	Yes	—	—	—
log10	Yes	Yes	Yes	—	—	—

Function	Single	Double	Half*	Boolean	Built-In Integer	Fixed Point
magnitude^2	Yes	Yes	Yes	—	Yes	Yes
square	Yes	Yes	Yes	—	Yes	Yes
pow	Yes	Yes	Yes	—	—	—
conj	Yes	Yes	Yes	—	Yes	Yes
reciprocal with Exact method	Yes	Yes	Yes	—	Yes	Yes
reciprocal with Newton-Raphson method (for more information, see “Output” on page 1-1308)	Yes	Yes	—	—	Yes	Yes
hypot	Yes	Yes	Yes	—	—	—
rem	Yes	Yes	Yes	—	Yes	—
mod	Yes	Yes	Yes	—	Yes	—
transpose	Yes	Yes	Yes	Yes	Yes	Yes
hermitian	Yes	Yes	Yes	—	Yes	Yes

For more information on half-precision arithmetic operations, see “The Half-Precision Data Type in Simulink” (Fixed-Point Designer).

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. Supported modes accept real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs. See Description on page 1-1304.

Dependencies

Data type support for this block depends on the **Function** that you select and the size of the inputs. For more information, see “Data Type Support” on page 1-1306.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_2 — Input signal
scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. Supported modes accept real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs.

Dependencies

To enable this port, set **Function** to `hypot`, `rem`, or `mod`.

Data type support for this block depends on the **Function** that you select, and the size of the inputs. For more information, see “Data Type Support” on page 1-1306.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Result of the operation of the function on the input or inputs
`scalar` | `vector` | `matrix`

Output signal specified as a scalar, vector, or matrix. The dimensions of the block output depend on the **Function** that you select and the size of the inputs. The block output is real or complex, depending on what you select for **Output signal type**. See Description on page 1-1304.

reciprocal with Newton-Raphson Method

The `reciprocal` with Newton-Raphson method output data type depends on the input data type:

Input Data Type	Output Data Type
<code>single</code>	<code>single</code>
<code>double</code>	<code>double</code>
<code>built-in integer</code>	<code>built-in integer</code>
<code>built-in fixed-point</code>	<code>built-in fixed-point</code>
<code>fi (value, 0, word_length, fraction_length)</code>	<code>fi (value, 0, word_length, word_length-fraction_length-1)</code>
<code>fi (value, 1, word_length, fraction_length)</code>	<code>fi (value, 1, word_length, word_length-fraction_length-2)</code>

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Function — Math function

`exp (default)` | `log` | `2^u` | `10^u` | `log10` | `magnitude^2` | `square` | `pow` | `conj` | `reciprocal` | `hypot` | `rem` | `mod` | `transpose` | `hermitian`

Specify the mathematical function. For more information about the options for this parameter, see Description on page 1-1304.

Dependency

Setting **Function** to `pow` enables the **Signed power** parameter.

Programmatic Use**Block Parameter:** Operator**Type:** character vector**Values:** 'exp' | 'log' | '2^u' | '10^u' | 'log10' | 'magnitude^2' | 'square' | 'pow' | 'conj' | 'reciprocal' | 'hypot' | 'rem' | 'mod' | 'transpose' | 'hermitian'**Default:** 'exp'**Algorithm method** — Algorithm method for reciprocal function

Exact (default) | Newton-Raphson

Algorithm method for reciprocal function, specified as Exact or Newton-Raphson. To calculate reciprocal with the Newton-Raphson approximation method, select Newton-Raphson. Otherwise, select Exact.

DependencySetting **Function** to reciprocal enables this parameter.**Programmatic Use****Block Parameter:** AlgorithmType**Type:** character vector**Values:** 'Exact' | 'Newton-Raphson'**Default:** 'Exact'**Signed power** — Power signedness

on (default) | off

When calculating power, specified as on or off, take into account sign of the input signal.. This parameter applies only for even-order roots, such as $u^{1/2}$, $u^{1/4}$, and so forth.

- on — Calculate power of the absolute value of the input, multiplied by the sign of the input.
- off — Calculate power of the actual input value. If the first input is negative and the second input is an even-order root, returns nan.

DependencySetting **Function** to pow enables this parameter.**Programmatic Use****Block Parameter:** SignedPower**Type:** character vector**Values:** 'on' | 'off' |**Default:** 'on'**Output signal type** — Complexity of output signal

auto (default) | real | complex

Specify the output signal type of the Math Function block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
exp, log, 2 ^u , 10 ^u , log10, square, pow, reciprocal, conjugate, transpose, hermitian	real	real	real	complex
	complex	complex	error	complex
magnitude squared	real	real	real	complex
	complex	real	real	complex
hypot, rem, mod	real	real	real	complex
	complex	error	error	error

Programmatic Use**Block Parameter:** OutputSignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Number of iterations** — Number of Newton-Raphson iterations

3 (default) | scalar

Number of Newton-Raphson iterations, specified as a scalar.

Dependencies

To enable this parameter, set:

- **Function** to reciprocal.
- **Algorithm method** to Newton-Raphson.

Programmatic Use**Block Parameter:** Iterations**Type:** character vector**Values:** '3' | scalar**Default:** '3'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime

Type: string scalar or character vector

Default: "- 1"

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Same as first input (default) | Inherit: Inherit via internal rule |
 Inherit: Inherit via back propagation | double | single | half | int8 | uint8 | int16 |
 uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) |
 fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

- To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.
- For the `magnitude^2` and `square`, when input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal rule` output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single-precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as first input' |
 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' |
 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' |
 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as first input'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Choose the behavior when integer overflow occurs

`on` (default) | `boolean`

Action	Rationale	Overflows	Example
Select Saturate on integer overflow check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Overflows	Example
Do not select Saturate on integer overflow check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. The code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, `conj`, `reciprocal`, or `hermitian`.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Value: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

R2023a: Math Function Block Supports 2^u

The Math Function block now supports the 2^u function. The MATLAB equivalent is `2.^u` (see power).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Function	Architecture	Description
conj	ComplexConjugate	Calculate complex conjugate.
hermitian	Hermitian	Calculate hermitian.
transpose	Transpose	Calculate array transpose. See Math Function in the Simulink documentation.

Reciprocal Architecture

You can generate HDL code for single-precision floating-point data types in native floating-point mode by using Math architecture for reciprocal function. The reciprocal function in the Math Function block also supports the architectures listed in the table.

Architecture	Parameters	Additional Cycles of Latency	Description
Reciprocal	None	0	Calculate reciprocal as $1/N$, using the HDL divide (/) operator to implement the division.
ReciprocalRsqrBasedNewton	Iterations	Signed input: Iterations + 5 Unsigned input: Iterations + 3	Use the iterative Newton method. Select this option to optimize area. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, HDL Coder generates a message.

Architecture	Parameters	Additional Cycles of Latency	Description
ReciprocalRsqrBasedNewtonSingleRate	Iterations	Signed input: (Iterations * 4) + 8 Unsigned input: (Iterations * 4) + 6	Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation. The default value for Iterations is 3. The recommended value for Iterations is from 2 through 10. If Iterations is outside the recommended range, the coder generates a message.
ShiftAdd	UsePipelines	Signed input: (Input word length + 4) Unsigned input: (Input word length + 4)	Perform reciprocal operation on a fixed-point input by using a non-restoring division algorithm that performs multiple shift and add operations to compute the reciprocal. This architecture provides improved accuracy compared to the Newton-Raphson approximation method. When you use this architecture, to achieve a higher maximum clock frequency on the target FPGA device, leave the UsePipelines HDL block property to on. When you use fixed-point data types, following criteria must be satisfied for generating the HDL code: <ul style="list-style-type: none"> • Input word length (WL) must be less than or equal to 63. • [WL input + Abs (FL Sum)] must be less than or equal to 63. Where, FL Sum is given by, FL sum = FL input + FL output

When you set the algorithm method to Exact, you can select these options in HDL Block properties of this block.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

HDL code generation also supports the Newton-Raphson algorithm method for reciprocal function. Select the **Algorithm method** as Newton-Raphson to use these architectures for reciprocal function in the Math Function block.

Architecture	Additional Cycles of Latency	Description
ReciprocalNewton (default)	Iterations + 1	<p>Use the multirate implementation of the iterative Newton method. Select this option to optimize area for your design.</p> <p>The default value for Iterations is 3.</p> <p>The recommended value for Iterations is from 2 through 10. If Iterations value is outside the recommended range, HDL Coder displays a message.</p>
ReciprocalNewtonSingleRate	(Iterations * 2) + 1	<p>Use the single rate pipelined Newton method. Select this option to optimize speed for your design, or if you want a single rate implementation.</p> <p>The default value for Iterations is 3.</p> <p>The recommended value for Iterations is between 2 and 10. If Iterations value is outside the recommended range, HDL Coder displays a message.</p>

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Native Floating Point	
CheckResetToZero	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> such that the quotient <code>a/b</code> is close to an integer, this setting treats <code>a</code> as an integral multiple of <code>b</code> , and <code>rem(a, b) = 0</code> . This result is numerically accurate and matches the simulation results. Calculating this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “CheckResetToZero” (HDL Coder).
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MaxIterations	Use this property for the <code>mod</code> and <code>rem</code> functions of the Math Function block. If you have numbers <code>a</code> and <code>b</code> that are significantly large integers, you can increase MaxIterations to match the simulation results. Calculating this result uses additional resources and increases the area footprint on the target FPGA device. For more information, see “MaxIterations” (HDL Coder).

Supported Datatypes and Functions in Native Floating-Point

In the Math Function block, these functions are the supported functions with Native Floating-Point.

Math Functions	Supported Floating-Point Datatypes			Complex Data Support
	Half	Single	Double	
<code>exp</code>	No	Yes	No	No
<code>log</code>	No	Yes	Yes	No
<code>2^u</code>	No	Yes	No	No
<code>10^u</code>	No	Yes	No	No
<code>log10</code>	No	Yes	No	No
<code>magnitude^2</code>	No	Yes	Yes	Yes
<code>square</code>	No	Yes	No	Yes
<code>pow</code>	No	Yes	No	No
<code>conj</code>	No	Yes	No	Yes
<code>reciprocal</code>	Yes	Yes	Yes	No
<code>hypot</code>	No	Yes	No	No
<code>rem</code>	No	Yes	No	No
<code>mod</code>	No	Yes	No	No

Math Functions	Supported Floating-Point Datatypes			Complex Data Support
	Half	Single	Double	
transpose	Yes	Yes	Yes	Yes
hermitian	No	Yes	No	Yes

Restrictions

When you use a `reciprocal` implementation:

- Input must be scalar and must have integer or fixed-point (signed or unsigned) data type.
- The output must be scalar and have integer or fixed-point (signed or unsigned) data type.
- Only the Zero rounding mode is supported.
- The **Saturate on integer overflow** option on the block must be selected.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The Math Function block only supports fixed-point conversion in certain configurations. For more information, see the Block Support Table.

MATLAB Function

Include MATLAB code in models that generate embeddable C code

Libraries:

Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function executes for simulation and generates code for a Simulink Coder target. If you are new to Simulink and MATLAB products, see “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” for an overview.

Double-clicking the MATLAB Function block opens the **MATLAB Function Block Editor**, where you write the MATLAB function. The example model `call_stats_block2` discussed in “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” uses the following function in the **MATLAB Function Block Editor**:

```
function [mean,stdev] = stats(vals)

% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,"-+");

function mean = avg(array,size)
mean = sum(array)/size;
```

The function specifies the input and output data in the function declaration statement as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the `call_stats_block2` model.

You can also define variables, add an input trigger, and create function call outputs by using the Model Explorer or the **Symbols** pane. For more information, see “Create and Define MATLAB

Function Block Variables”, “Manage the Input Trigger of a MATLAB Function Block”, and “Manage Function Call Outputs of a MATLAB Function Block”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.

See “Best Practices for Defining Variables for C/C++ Code Generation”.

- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations”.
- Matrix operations like `size`, and `length`
- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

For more information, see “Functions and Objects Supported for C/C++ Code Generation”.

Note Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few eps initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

Note New MATLAB Function blocks do not include the `%#codegen` directive, but check for errors as if it is included. Adding the `%#codegen` directive to a MATLAB Function block does not affect error checking. For more information see “Compilation Directive `%#codegen`”.

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Use MATLAB Engine to Execute a Function Call in Generated Code” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the **Symbols** pane, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Define and Modify Variable Data Types”, “Specify Size of MATLAB Function Block Variables”, and “Configure MATLAB Function Block Parameter Variables” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, clear the **Allow direct feedthrough** property. Nondirect feedthrough semantics ensure that outputs rely only on the current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops. For more information, see “Use Nondirect Feedthrough in a MATLAB Function Block”.

Ports

Input

u — Input port

scalar | vector | matrix

Input port, specified as a scalar, vector, or matrix. Each input variable that you create has a corresponding input port.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “Data Type Override with MATLAB Function Block” (Fixed-Point Designer).

Dependencies

To create input ports, open the block and create input variables in the **Symbols** pane. See “Create and Define MATLAB Function Block Variables”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | string | fixed point | enumerated | bus

Output

y — Output port

scalar | vector | matrix

Output port, specified as a scalar, vector, or matrix. Each output variable that you create has a corresponding output port.

Dependencies

To create output ports, open the block and create output variables in the **Symbols** pane. See “Create and Define MATLAB Function Block Variables”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | string | fixed point | enumerated | bus

Parameters

Main

Show port labels — Display options for port labels

FromPortIcon (default) | none | FromPortBlockName | SignalName

Select how to display port labels on the MATLAB Function block icon.

- none - Do not display port labels.
- FromPortIcon - Display the name of the input and output variables.
- FromPortBlockName - Display the name of the input and output variables.
- SignalName - If the signal connected to the port is named, display the signal name. Otherwise, display the name of the variables.

Programmatic Use

Parameter: ShowPortLabels

Type: string scalar or character vector

Value: "none" | "FromPortIcon" | "FromPortBlockName" | "SignalName"

Default: "FromPortIcon"

Read/Write permissions — Levels of access to contents of block

ReadWrite (default) | ReadOnly | NoReadOrWrite

Control user access to the contents of the MATLAB Function block.

- ReadWrite - Enable opening and modifying of MATLAB Function block contents.
- ReadOnly - Enable opening of the MATLAB Function block.
- NoReadOrWrite - Disable opening or modifying of the MATLAB Function block.

Note When you attempt to view the contents of a MATLAB Function block whose **Read/Write permissions** parameter is NoReadOrWrite, the block does not respond. For example, when you double-click the MATLAB Function block, Simulink does not open the table contents and does not display messages.

Programmatic Use

Parameter: Permissions

Type: string scalar or character vector

Value: "ReadWrite" | "ReadOnly" | "NoReadOrWrite"

Default: "ReadWrite"

Minimize algebraic loop occurrences — Option to eliminate artificial algebraic loops

off (default) | on

Whether the block attempts to eliminate artificial algebraic loops that include the atomic unit during simulation.

- **off** - Do not try to eliminate any artificial algebraic loops that include the atomic unit.
- **on** - Try to eliminate any artificial algebraic loops that include the atomic unit.

Programmatic Use

Parameter: MinAlgLoopOccurrences

Type: string scalar or character vector

Value: "off" | "on"

Default: "off"

Sample time (-1 for inherited) — Specify time interval

-1 (default) | [Ts 0]

Specify whether variables in this block must run at the same rate or can run at different rates.

- If variables in the MATLAB Function block can run at different rates, specify the sample time as inherited (-1).
- If variables must run at the same rate, specify the sample time, T_s , corresponding to this rate.

Programmatic Use

Parameter: SystemSampleTime

Type: string scalar or character vector

Value: "-1" | "[Ts 0]"

Default: "-1"

Code Generation

Function packaging — Select code format

Auto (default) | Inline | Nonreusable function | Reusable function

Select the code format that the block generates.

Auto

Simulink Coder chooses the optimal format for your system based on the type and number of instances of the MATLAB Function block that exist in the model.

Inline

Simulink Coder inlines the MATLAB Function block unconditionally.

Nonreusable function

Simulink Coder explicitly generates a separate function in a separate file. MATLAB Function blocks with this setting generate functions that might have arguments depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0. These functions are not reentrant.

Reusable function

Simulink Coder generates a function with arguments that allows reuse of MATLAB Function block code when a model includes multiple instances of the MATLAB Function block.

This option generates a function with arguments that allows MATLAB Function block code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a MATLAB Function block across referenced models. In this case, the MATLAB Function block must be in a library.

Tips

- When you want to represent multiple instances of a MATLAB Function block as one reusable function, you can designate each of the instances as **Auto** or as **Reusable function**. It is best to use one or the other, as using both creates two reusable functions, one for each designation. The outcomes of these choices differ only when reuse is not possible. Selecting **Auto** does not allow control of the function or file name for the MATLAB Function block code.
- The **Reusable function** and **Auto** options both determine whether multiple instances of a MATLAB Function block exist and the code can be reused. The options behave differently when it is impossible to reuse the code. In this case, **Auto** yields inlined code, or if circumstances prohibit inlining, separate functions for each block instance.

- If you select `Reusable` function while your generated code is under source control, set **File name options** to `Use subsystem name`, `Use function name`, or `User specified`. Otherwise, the names of your code files change when you modify your model, which prevents source control on your files.

Dependency

- This parameter requires Simulink Coder.
- Setting this parameter to `Nonreusable` function or `Reusable` function enables the following parameters:
 - **Function name options**
 - **File name options**
 - Memory section for initialize/terminate functions (requires Embedded Coder and an ERT-based system target file)
 - Memory section for execution functions (requires Embedded Coder and an ERT-based system target file)
- Setting this parameter to `Nonreusable` function enables **Function with separate data** (requires a license for Embedded Coder and an ERT-based system target file).

Programmatic Use

Parameter: `RTWSystemCode`

Type: string scalar or character vector

Value: `"Auto"` | `"Inline"` | `"Nonreusable function"` | `"Reusable function"`

Default: `"Auto"`

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>half^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>
Direct Feedthrough	<code>yes^a</code>
Multidimensional Signals	<code>yes^a</code>
Variable-Size Signals	<code>yes^a</code>
Zero-Crossing Detection	<code>no</code>

^a Actual data type or capability support depends on block implementation.

Version History

Introduced in R2011a

R2020a: 64-bit integer type support for MATLAB Function block

MATLAB Function blocks now support 64-bit integer data. The block implements `int64` and `uint64` data types as fixed-point numbers with a word length of 64 bits and a fraction length of 0.

R2019b: String support for MATLAB Function block

Simulink strings are now supported in MATLAB Function blocks.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. Actual data type or capability support depends on block implementation. For best practices of using the MATLAB Function block, see:

- “Design Guidelines for the MATLAB Function Block” (HDL Coder)
- “Generate Instantiable Code for Functions” (HDL Coder)
- “Optimize MATLAB Loops” (HDL Coder)
- “Pipeline MATLAB Expressions” (HDL Coder)

HDL Architecture

MATLAB Function (Default)	This is the default architecture for MATLAB Function blocks with fixed-point data types. When you use this architecture, you can use speed and area optimizations for blocks that surround the MATLAB Function block. The code inside the MATLAB Function block is not optimized.
MATLAB Datapath	This is the default architecture for MATLAB Function blocks with floating-point data types. When you use this architecture, the code generator treats the MATLAB Function block like a regular Subsystem block. By enabling this architecture for fixed-point types, you can use speed and area optimizations for blocks inside the MATLAB Function block and across the MATLAB Function block with other Simulink blocks. This capability enables you to specify additional properties for the MATLAB Function block that you would specify for a Subsystem such as ClockRatePipelining and FlattenHierarchy .

HDL Block Properties

AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “BalanceDelays” (HDL Coder).

ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “ClockRatePipelining” (HDL Coder).
ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is <code>none</code> . See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove MATLAB Function block hierarchy from generated HDL code. The default is <code>inherit</code> . To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).
InstantiateFunctions	Generate a VHDL entity or Verilog module for each function. The default is <code>off</code> . See also “InstantiateFunctions” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is <code>none</code> . If you set Architecture to <code>MATLAB Datapath</code> , you can only unroll loops. If you want to use loop streaming with the <code>MATLAB Datapath</code> architecture, you can use the streaming optimization by specifying a StreamingFactor . See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is <code>off</code> . See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is <code>0</code> . See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is <code>0</code> , which implements fully parallel data paths. To specify this property, set Architecture to <code>MATLAB Datapath</code> . See also “Streaming” (HDL Coder).

VariablesToPipeline	Warning VariablesToPipeline is not recommended. Use <code>coder.hdl.pipeline</code> instead.
	Insert a pipeline register at the output of the specified variable or variables. Specify the list of variables as a character vector, with spaces separating the variables. To specify this property, set Architecture to MATLAB Function .

Data Type Support

HDL code generation supports half-precision data types for these functions in MATLAB Function block:

all	and, &	any	cast	conj	ctranspose
end	=	eq	==	ge, >=	gt, >
half	inf	int8	int16	int32	int64
isa	iscolumn	isempty	isequal	isfinite	isfloat
isinf	isinteger	islogical	isnan	isnumeric	isreal
isrow	isscalar	isvector	le, <=	length	logical
lt, <	max	min	minus, -	NaN	ndims
ne, ~=	not	numel	or,	plus, +	prod
reshape	single	size	sqrt	sum	times, .*
transpose	uint8	uint16	uint32	uint64	uminus
uplus	vertconcat	-	-	-	-

Complex Data Support

This block supports code generation for complex signals.

See also “Complex Data Type Support” (HDL Coder).

Tunable Parameter Support

HDL Coder supports both tunable and non-tunable parameters with the following data types:

- Scalar
- Vector
- Complex
- Structure
- Enumeration

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder) and “Design Guidelines for the MATLAB Function Block” (HDL Coder)

Restrictions

- If the block contains a System object™, block inputs cannot have non-discrete (constant or Inf) sample time.

- HDL Coder does not support a MATLAB Function that contains the same variable as the input and output of the function. For example, this MATLAB code is not supported.

```
function y = myFun(y)
    %#codegen
```

```
y = 3 * y;
```

- The block supports floating-point data types only in the Native Floating Point mode.

For the MATLAB language subset supported for HDL code generation from a MATLAB Function block, see “Supported MATLAB Data Types, Operators, and Control Flow Statements” (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

MATLAB System

Include System object in model

Libraries:

Simulink / User-Defined Functions
HDL Coder / User-Defined Functions

Description

The MATLAB System block brings existing System objects (based on `matlab.System`) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations”, like `plus`, `minus`, and `power`
- Matrix operations, like `size` and `length`
- Advanced matrix operations, like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions, like `sin`, `cos`, `sinh`, and `cosh`

By default, the MATLAB System block recognizes 1-D input signals and propagates 1-D output signals as 2-D. Use the `supports1DVectorsImpl` method to enable the block to recognize and propagate 1-D inputs and outputs as 1-D signals.

System Objects

To use the MATLAB System block, you must first have a new System object or use an existing one. For more information, see “Integrate System Objects Using MATLAB System Block”.

Ports

Input

In — Signal input to a MATLAB System block

scalar | vector | matrix

The MATLAB System block accepts inputs of the types listed in the Block Characteristics table. For more information, see “Data Types Supported by Simulink”.

For information on fixed-point support for this block, see “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output of a MATLAB System block
`scalar` | `vector` | `matrix`

Signal output of a MATLAB System block that the System object returns.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

System Object Name — Name of the System object
`cell array` (default)

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

Programmatic Use

Block Parameter: `System`

Type: `character vector`

Value: `name of the System object`

Default: `' '`

New — Create a System object from a template

`Basic` (default) | `Advanced` | `Simulink Extension`

Select one of the options for a System object template.

Basic

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

Advanced

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

Simulink Extension

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

Simulate using — Select the simulation mode
Code generation (default) | Interpreted Execution

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System Objects accept a maximum of 32 inputs.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Dependency — Dependency parameter for MATLAB System block
auto (default)

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

Saturate on integer overflow — Specify whether overflows saturate

Off (default) | On

On

Overflows saturate to either the minimum or maximum value that the data type can represent. For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.

- Consider clearing this check box when you want to optimize efficiency of your generated code. Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Treat these inherited Simulink signal types as fi objects — Specify fi data types

Fixed-point (default) | Fixed-point & Integer

Select which inherited data types to treat fi data types,

Fixed-point

Treat fixed-point data types as fi data types.

Fixed-point & Integer

Treat fixed-point and integer data types as fi data types.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

MATLAB System fimath — Specify fixed-point settings to use

Same as MATLAB (default) | Specify Other

Select which fixed-point math settings to use.

Same as MATLAB

Use the current MATLAB fixed-point math settings.

Specify Other

Enable the edit box for specifying the desired fixed-point math settings. For information on setting fixed-point math, see `fimath`.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Block Characteristics

Introduced in R2013b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

You can define a System object and use it in a MATLAB System block for HDL code generation.

Tunable Parameter Support

HDL Coder supports tunable parameters with the following data types:

- Numeric
- Fixed point
- Character
- Logical

When using tunable parameters with the MATLAB System block, the tunable parameter should be a Simulink.Parameter object with the StorageClass set to ExportedGlobal.

```
x = Simulink.Parameter
x.Value = 1
x.CoderInfo.StorageClass = 'ExportedGlobal'
```

For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

If you use a predefined System object, the HDL block properties available are the same as the properties available for the corresponding block.

By default, the following HDL block properties are available.

ConstMultiplierOptimization	Canonical signed digit (CSD) or factored CSD optimization. The default is none. See also “ConstMultiplierOptimization” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
LoopOptimization	Unroll, stream, or do not optimize loops. The default is none. See also “LoopOptimization” (HDL Coder).
MapPersistentVarsToRAM	Map persistent arrays to RAM. The default is <code>off</code> . See also “MapPersistentVarsToRAM” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is <code>default</code> , which generates reset logic. See also “ResetType” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
VariablesToPipeline	<p>Warning <code>VariablesToPipeline</code> is not recommended. Use <code>coder.hdl.pipeline</code> instead.</p> <p>Insert a pipeline register at the output of the specified MATLAB variable or variables. Specify the list of variables as a character vector, with spaces separating the variables.</p>

Restrictions

- The DUT subsystem must be single-rate.
- Inputs cannot have non-discrete (constant or `Inf`) sample time.
- To find predefined System objects that are supported for HDL code generation when you use them in the MATLAB System block, see “Predefined System Objects Supported for HDL Code Generation” (HDL Coder).
- If you use a user-defined System object, it must support HDL code generation. For information about user-defined System objects and requirements for HDL code generation, see “HDL Code Generation for System Objects” (HDL Coder).

See also “Generate Code for User-Defined System Objects” (HDL Coder) and “HDL Code Generation for System Objects” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Matrix Concatenate

Concatenate input matrices of same data type for iterative processing

Libraries:

Simulink / Math Operations
 Simulink / Matrix Operations
 DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations
 HDL Coder / Math Operations

Alternative Configurations of Matrix Concatenate Block:

Vector Concatenate

Description

The Matrix Concatenate block concatenates input signals to create a nonscalar signal that you can iteratively process with a subsystem, for example, a for-each, while-iterator, or for-iterator subsystem.

You can use multiple Matrix Concatenate blocks to create the output signal in stages, but the result is flat along each concatenation dimension, as if you used a single block to concatenate the signals.

The signals in the output signal appear in the same order as the input signals for the block along the concatenation dimension. For a description of the port order for various block orientations, see “Identify Port Location on Rotated or Flipped Block”.

You must use a Vector Concatenate or Matrix Concatenate block to define an array of buses. For more information, see “Group Nonvirtual Buses in Arrays of Buses”.

Examples

Horizontally Concatenate Matrices

When a Matrix Concatenate block receives 2-D matrices with the same number of rows, you can horizontally concatenate the matrices, placing them side-by-side in the output matrix. To horizontally concatenate the matrices, set the **Concatenate dimension** block parameter to 2.

For example, simulate the `ex_concatenate_horizontal` model.

Copyright 2010-2022 The MathWorks, Inc.

The input matrices $\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ and $\begin{bmatrix} 5 & 6 \end{bmatrix}$ are horizontally concatenated to create the output matrix $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 3 & 4 \end{bmatrix}$.

Vertically Concatenate Matrices

When a Matrix Concatenate block receives 2-D matrices with the same number of columns, you can vertically concatenate the matrices, placing them on top of each other in the output matrix. To vertically concatenate the matrices, set the **Concatenate dimension** block parameter to 1.

For example, simulate the `ex_concatenate_vertical` model.

Copyright 2010-2022 The MathWorks, Inc.

The input matrices $\begin{bmatrix} 1 & 2 & 3 & 4 \end{bmatrix}$ and $\begin{bmatrix} 5 & 6 \end{bmatrix}$ are vertically concatenated to create the output matrix $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 \end{bmatrix}$.

Perform Multidimensional Matrix Concatenation

When a Matrix Concatenate block receives 2-D matrices, you can perform multidimensional matrix concatenation. To do so, set the **Concatenate dimension** block parameter to 3.

For example, simulate the `ex_concatenate_multidims` model.

Copyright 2010-2022 The MathWorks, Inc.

The dimension of each input matrix is [2x2], and the dimension of the output matrix is [2x2x2].

Ports

Input

Port_1 — First input to concatenate

scalar | vector | matrix | array

First input to concatenate, specified as a scalar, vector, matrix, or array.

- Inputs must be of the same data type.
- Matrix and array inputs are supported only when you set **Mode** to **Multidimensional array**.

When the data type is a `Simulink.Bus` object, the inputs must be nonvirtual buses.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Port_N — Nth input to concatenate

scalar | vector | matrix | array

Nth input to concatenate, specified as a scalar, vector, matrix, or array.

- Inputs must be of the same data type.
- Matrix and array inputs are supported only when you set **Mode** to **Multidimensional array**.

Dependencies

To add input ports, set **Number of inputs** to an integer greater than or equal to 2.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Concatenation of input signals

scalar | vector | matrix | array

Concatenation of input signals along specified dimension. Outputs have the same data type as the input.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

To edit block parameters interactively, use the **Property Inspector**. From the Simulink Toolstrip, on the **Simulation** tab, in the **Prepare** gallery, select **Property Inspector**.

Number of inputs — Number of input ports

2 (default) | positive integer

Specify the number of inputs for the block as a real-valued, positive integer, less than or equal to 65536.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	NumInputs
Values:	'2' (default) positive integer
Data Types:	char string

Example: `set_param(gcb, 'NumInputs', '3')`

Mode — Type of concatenation

Vector | Multidimensional array

Select whether the block operates in vector or multidimensional array concatenation mode. The default **Mode** of the Vector Concatenate block is **Vector**. The default **Mode** of the Matrix Concatenate block is **Multidimensional array**.

- When you select **Vector**, the block performs vector concatenation.
- When you select **Multidimensional array**, the block performs matrix concatenation.

Mode Setting	Input Signals	Output Signal
Vector	<ul style="list-style-type: none"> • Vectors • Row vectors (1-by-M matrices) • Column vectors (M-by-1 matrices) • Combination of vectors and either row or column vectors 	<p>When all inputs are vectors, the output is a vector.</p> <p>If any of the inputs are row or column vectors, the output is a row or column vector, respectively.</p>
Multidimensional array	Signals of any dimensionality (scalars, vectors, and matrices)	<p>The output is always an array.</p> <p>Trailing dimensions are assumed to be 1 for lower dimensionality inputs. For example, if the output is 4-D and the input is [2×3] (2-D), this block treats the input as [2×3×1×1].</p> <p>Concatenation is on the dimension that you specify with the Concatenate dimension parameter.</p>

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	Mode
Values:	'Vector' 'Multidimensional array'

Example: `set_param(gcb, 'Mode', 'Vector')`

Concatenate dimension — Output dimension along which to concatenate input arrays

scalar integer

Specify the output dimension along which to concatenate the input arrays.

- 1 — Concatenate inputs vertically. The vertical matrix concatenation stacks the input matrices on top of each other in the output matrix. When you insert a Vector Concatenate block and set **Mode** to `Multidimensional array`, the default is 1.
- 2 — Concatenate inputs horizontally. The horizontal matrix concatenation places the input matrices side-by-side in the output matrix. When you insert a Matrix Concatenate block, the default is 2.
- 3 or more — Perform multidimensional concatenation on the inputs.

The input matrices must have compatible sizes for concatenation. Vertical concatenation requires the input matrices to have the same number of columns. Horizontal concatenation requires input matrices to have the same number of rows.

Dependencies

To enable this parameter, set **Mode** to `Multidimensional array`.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	<code>ConcatenateDimension</code>
Values:	scalar integer
Data Types:	<code>char</code> <code>string</code>

Example: `set_param(gcb, 'ConcatenateDimension', '2')`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>half</code> <code>image</code> <code>integer</code> <code>single</code>
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Vector Concatenate — Concatenate input vectors of same data type for iterative processing

The Vector Concatenate block sets **Mode** to `Vector`.

Matrix Square

Compute square of input matrix

Libraries:
Simulink / Matrix Operations

Description

The Matrix Square block computes the square of an M -by- N input matrix, u , by premultiplying with the Hermitian transpose. The equivalent MATLAB code is:

$$y = u' * u$$

The block treats length- M unoriented vector inputs as an M -by-1 matrix. When the input is an M -by- N matrix, the output of the block is an N -by- N matrix.

Applications

The Matrix Square block can be used in a variety of applications:

- General matrix squares — The Matrix Square block computes the output matrix, y , without explicitly forming u' . It is therefore more efficient than other methods for computing the matrix square.
- Sum of squares — When the input is a column vector ($N=1$), the operation of the block is equivalent to a multiply-accumulate (MAC) process, or inner product. The output is the sum of the squares of the input, and is always a real scalar.
- Correlation matrix — When the input is a row vector ($M=1$), the output, y , is the symmetric autocorrelation matrix, or outer product.

Ports

Input

Port_1 — Input matrix

M -by-1 matrix | 1-by- N matrix | M -by- N matrix

Input matrix, specified as an M -by-1, 1-by- N , or M -by- N matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output matrix

M -by- M matrix | N -by- N matrix

Output matrix, returned as an N -by- N or M -by- M matrix.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Output minimum — Minimum output value for range checking

`[]` (default) | scalar

Minimum output value for range checking that Simulink checks. Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMin`

Type: character vector

Values: `'[]'` | scalar

Default: `'[]'`

Output maximum — Maximum output value for range checking

`[]` (default) | scalar

Maximum output value for range checking that Simulink checks. Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMax`

Type: character vector

Values: `'[]'` | scalar

Default: `'[]'`

Output data type — Output data type

Inherit: `Inherit via internal rule` (default) | `Inherit via back propagation` | `Inherit: Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the output data type for this block.

You can select one of these options:

- A rule that specifies how to inherit a data type, such as `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule” (DSP System Toolbox).
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as input' | 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | fixdt(1,16,0) | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Output data type locking

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output data type** you specify on the block mask. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode (DSP System Toolbox) for fixed-point operations.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Behavior when integer overflow occurs

off (default) | on

Select this check box to have overflows saturate to the maximum or minimum value that the data type can represent. If you clear this check box, the block wraps all overflows. See Precision and Range (DSP System Toolbox) for more information.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. The code generation process can generally detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Mode** — Category of data to specify

Inherit (default) | Built in | Fixed point | Expression

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Built in**— Lets you specify a built-in data type.
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Dependencies

To enable this parameter, click >> at the **Output data type** parameter.

Signedness — Specify signed or unsigned

Signed (default) | Unsigned

Specify the **Signedness** for the **Output** data type.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Scaling — Method for scaling fixed-point data

Binary point (default)

Specify the **Scaling** for the **Output** data type.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Dependencies

To enable this parameter, click the **Show data type assistant** button, and set **Mode** to `Built in` or `Fixed point`.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Fraction length — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set:

- **Mode** to `Fixed point`
- **Scaling** to `Binary point`

Block Characteristics

Data Types	double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Output input from previous time step

Libraries:

Simulink / Discrete
HDL Coder / Discrete

Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be a scalar, vector, matrix, or N-D array. If the input is non-scalar, the block holds and delays all elements of the input by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

Tip Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver `ode15s` or `ode113`.
 - The input to the block changes during simulation.
-

When the Memory block inherits a discrete sample time, the block is analogous to the Unit Delay block. However, the Memory block does not support state logging. If logging the final state is necessary, use a Unit Delay block instead.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> • “Engine Timing Model with Closed Loop Control” on page 13-152 (Compression subsystem)

Block	Purpose of the Block	Reference Examples
Memory on page 1-1350	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> • “Building a Clutch Lock-Up Model” on page 13-156 (Friction Mode Logic/Lockup FSM subsystem) • “Capture the Velocity of a Bouncing Ball with the Memory Block” on page 12-89
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> • “Developing the Apollo Lunar Module Digital Autopilot” on page 13-215 • “Radar Tracking Using MATLAB Function Block” on page 13-244

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Elements”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Modify Sample Times for Nonvirtual Buses” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value 0. In this case, all the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be continuous or discrete, containing real, or complex values of any data type Simulink supports.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Input delayed by one major integration time step

scalar | vector | matrix | N-D array

Output is the input from the previous time step.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Main

Initial condition — Initial condition

0 (default) | scalar | vector | matrix | N-D array

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: scalar | vector

Default: '0'

Inherit sample time — Inherit sample time

off (default) | on

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this check box has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: [0, 1].
- If the solver is a fixed-step solver, the [0, 1] sample time converts to the solver step size after sample-time propagation.

Programmatic Use

Block Parameter: `InheritSampleTime`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization — Output the input during linearization and trim

off (default) | on

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering, use the following commands.

First compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

Next, terminate the compilation with this command.

```
model([],[],[],'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use

Block Parameter: `LinearizeMemory`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Treat as a unit delay when linearizing with discrete sample time — Linearize to unit delay for discrete inputs

off (default) | on

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

Programmatic Use**Block Parameter:** LinearizeAsDelay**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes****State name** — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Merge

Combine multiple signals into single signal

Libraries:
Simulink / Signal Routing

Description

The Merge block combines inputs into a single output. The output value at any time is equal to the most recently computed output of its driving blocks. Specify the number of inputs by setting the **Number of inputs** parameter.

Use a Merge block to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

- Always use conditionally executed subsystems to drive Merge blocks, without any intervening blocks.
- Ensure that at most one of the driving conditionally executed subsystems executes at any time step.
- Ensure that all input signals have the same sample time.
- Do not branch a signal that is input to a Merge block.
- Do not log a signal that is input to a Merge block.
- Do not specify the block execution priority of a Merge block. For more information, see “Specify Block Execution Priority and Tag”.
- For all conditionally executed subsystem Output blocks that drive Merge blocks, set **Output when disabled** to held.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.
- The Merge block supports merging signals in different tasks to a root Output block.

For each input of a Merge block, the topmost nonvirtual source must be a conditionally executed subsystem (not including a For Iterator or While Iterator subsystem).

The next diagram shows valid Merge block usage, merging signals from two conditionally executed subsystems.

Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to these restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- The **Allow unequal port widths** check box must be cleared.
- All inputs must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

All signals in a nonvirtual bus input to a Merge block must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus.

Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the output from the S-Function block is reusable. Simulink displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts`.

Multi-tasked Root Outputs

A Merge block connected to a root Outputport block allows merging signals in different tasks by allowing those signals to write to the root Outputport block simultaneously. A Union sample time of the sources is assigned to the Merge block.

All the sources of the Merge block that are in the same task should be inside conditionally executed subsystems that should not output simultaneously in the same time step.

Limitations

- All signals that connect to a Merge block are functionally the same signal. Therefore, they are subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.

- Run-time diagnostics do not run if the inputs to a Merge block are from a single initiator. For example, a single initiator could be a Stateflow chart executing function-call subsystems that are connected to a Merge block.
- Do not set the outputs of conditionally executed subsystems being merged to reset when disabled. This action can cause multiple subsystems to update the block at the same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the block by computing its output.

To prevent this behavior, set the Output block parameter **Output when disabled** to held for each conditionally executed subsystem being merged.

- A Merge block does not accept input signals whose elements have been reordered or partially selected, as shown in the next diagram.

- Do not connect input signals to the block that have been combined outside of a conditionally executed subsystem.

You can use an array of buses as an input signal to a Merge block with these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Initial condition** — You can specify this parameter using:
 - The value θ . In this case, each of the individual signals in the array of buses use the initial value θ .
 - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
 - A scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Ports

Input

Port_1 — First input signal
scalar | vector

First input signal merged with the other input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Port_n — nth input signal
scalar | vector

nth input signal merged with the other input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Output signal
scalar | vector

Output signal merged from the input signals.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Number of inputs — Number of input signals to merge

2 (default) | integer

Specify the number of input signals to merge. The block creates a port for each input signal.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer

Default: '2'

Initial output — Initial output value

[] (default) | scalar | vector

Specify the initial value of the output signal. If you do not specify an initial output value, then initial output depends on the initialization mode and the driving blocks.

In “Simplified Initialization Mode”, for an unspecified (empty matrix []) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see “Initialize Signal Values”. In “Classic Initialization Mode”, for an unspecified (empty matrix []) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering for these sources can vary, initialization can be inconsistent for the simulation and the code generation of a model.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector

Values: scalar | vector

Default: '[]'

Allow unequal port widths — Allow inputs of unequal dimensions

off (default) | on

Select this parameter to allow the block to accept inputs having different numbers of elements from each other or from the output. The block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$$\max(w_1+o_1, w_2+o_2, \dots, w_n+o_n)$$

where w_1, \dots, w_n are the widths of the input signals and o_1, \dots, o_n are the offsets for the input signals.

If you clear this parameter, the Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs.

Note Do not select this parameter unless your model is using Classic Initialization Mode.

Programmatic Use

Block Parameter: AllowUnequalInputPortWidths

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Input port offsets — Offset for input signals

[] (default) | vector

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

Dependencies

To enable this parameter, select **Allow unequal port widths**.

Programmatic Use

Block Parameter: InputPortOffsets

Type: character vector

Values: scalar | vector

Default: '[]'

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.

- The source of the constant value is a grounded signal.
- The source of the constant value is a constant block with a non-tunable parameter.
 - There is only one constant block that feeds the Merge block.
 - All other input signals to the Merge block are from conditionally executed subsystems.
 - The Merge block and output blocks of all conditionally executed subsystems does not specify any initial outputs.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).

Entity Transport Delay

Introduce a delay in propagation of a SimEvents message

Libraries:
Simulink / Continuous
SimEvents

Description

The Entity Transport Delay block delays an entity for a period of time, named *transport delay*. The first input is the entity that is transported from point A to point B on a constant-length moving surface whose speed changes over time. The value from the second input is the *instantaneous delay*. The speed of the surface is the reciprocal of instantaneous delay. The product of instantaneous delay and the speed is 1.

The block calculates the implemented transport delay by the distance-speed-time relationship, where the surface length (distance) is equal to the integral of the variable surface speed over the duration of the transport delay (time). For more information about this calculation, see Variable Transport Delay.

The Entity Transport Delay block connects SimEvents to Simulink using the input from a Simulink signal and computing the transport delay as a continuous process, and applying this delay to an entity in a discrete-event process. For an example that uses the Entity Transport Delay block, see “Modeling Cyber-Physical Systems” on page 13-634.

Ports

Input

Port_1 — Input entity
SimEvents entity

SimEvents entity or message. For more information on entities in SimEvents, see “Entities in a SimEvents Model” (SimEvents).

t_i — Instantaneous delay
scalar | vector | matrix

Instantaneous delay in the transport of the SimEvents entity. t_i is the reciprocal of the speed of the entity. For more information on the calculation of instantaneous delay, see “Variable Transport Delay” on page 1-2399.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | bus

Output

Port_1 — Delayed entity
SimEvents entity

SimEvents entity with the instantaneous delay t_i applied to it.

n — Number of delayed entities
real scalar

Secondary output signal of the block, which displays the number of entities processed in a time step.

Dependencies

To enable this port, enable the **Output number of entities in block, n** parameter

Data Types: double

Parameters

Capacity — Specify the capacity of the block

inf (default) | scalar

Specify capacity to accept entities to be delayed.

Programmatic Use

Block Parameter: Capacity

Type: character vector

Values: 'inf' | real scalar

Default: 'inf'

Output number of entities in block, n — Outputs the number of delayed entities present in the block

off (default) | on

Number of entities present in the block that are being delayed.

Programmatic Use

Block Parameter: ShowNumberEntitiesInBlock

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Message Merge

Combine message paths

Libraries:
Simulink / Messages & Events

Description

The Message Merge block graphically combines multiple message lines into a single message line. Merging message lines does not change the messages themselves. You can specify the number of message lines to merge.

Use this block when you want to merge multiple incoming messages and output to a single destination such as a queue or a message storage block.

Ports

Input

Port_1 — Input message line to merge
scalar | vector | matrix

Input message port for messages entering the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Port_2 — Input message line to merge
scalar | vector | matrix

Input message port for messages entering the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port — Output message line
scalar | vector | matrix

Output message port for messages exiting the block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Number of input ports — Specify the number message lines to combine

2 (default) | scalar

Determines the number of message input ports to be combined.

Programmatic Use

Block Parameter: NumberInputPorts

Type: character vector

Values: '2' | scalar

Default: '2'

Send | Queue | Entity Input Switch (SimEvents) | Entity Output Switch (SimEvents)

Topics

“Establish Message Send and Receive Interfaces Between Software Components”

Receive, Message Receive

Receive messages

Libraries:

Simulink / Messages & Events
SimEvents

Description

The Receive block extracts data from received messages and writes them to the output signal port. If there are no new messages when the block executes, the block uses the **Value source when queue is empty** value. Receive and Message Receive blocks are identical blocks.

- Select `Hold last value` to hold data read from the last message.
- Select `Use initial value` to write default data.

Ports

Input

Port_1 — Input message

scalar | vector | matrix

The input port for the message.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_S — Show whether a message was received

scalar

Outputs 1 if the block receives a message successfully, and 0 otherwise.

Dependencies

To enable this port, select the check box labeled **Show receive status**.

Data Types: double

Port_1 — Output signal

scalar | vector | matrix

Output port for the signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Use internal queue — Select to use an internal queue
on (default for SimEvents) | off (default for Simulink)

Select this check box if you use an internal queue to receive messages.

Programmatic Use

Block Parameter: UseInternalQueue

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Overwrite the oldest element if queue is full — Specify queue overwriting policy
on (default for Simulink) | off (default for SimEvents)

Select this check box to choose between two queue overwriting policies.

- If you select the check box, an incoming message overwrites the oldest if the queue is full.
- If you clear the check box, the block does not accept new messages if the queue is full.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueOverwriting

Type: character vector

Values: 'on' | 'off'

Default: 'on' (for Simulink) and 'off' (for SimEvents)

Queue length — Specify the length of the message queue
16 (default) | scalar

Specify message queue capacity. The queue length can be specified as a positive integer between 1 and $2^{26}-1$ (both included).

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueLength

Type: character vector

Values: '16' | scalar

Default: '16'

Queue type — Specify message queue sorting policy
FIFO (default) | LIFO | Priority

The block supports three message sorting policies:

- First-in-first-out (FIFO) — The oldest message in the storage departs first.
- Last-in-first-out (LIFO) — The newest message in the storage departs first.
- Priority — Messages or entities are sorted based on their priority.

The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

Note Priority queue accepts only non-bus scalar and it does not support fixed point data type.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: QueueType

Type: character vector

Values: 'FIFO' | 'LIFO' | 'Priority'

Default: 'FIFO'

Priority order — Specify message queue priority

Ascending (default) | Descending

Choose the direction of sorting messages based on priority.

- Ascending — Messages with smaller priority values appear in front of the queue.
- Descending — Messages with greater priority values appear in front of the queue.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue** and **Queue type > Priority**.

Programmatic Use

Block Parameter: PriorityOrder

Type: character vector

Values: 'Ascending' | 'Descending'

Default: 'Ascending'

Show receive status — Show whether a message was received

off (default) | on

Select this check box to show whether a message was received. If this check box is selected the block outputs 1 if it receives a message successfully, and 0 otherwise.

Programmatic Use

Block Parameter: ShowQueueStatus

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Initial value — Set initial data value

[] (unspecified) (default) | scalar | vector | matrix

Enter an initial data value for the queue before the arrival of the first message. The default value [] (unspecified) is treated as 0 with data type double.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Elements”.

Programmatic Use

Block Parameter: InitialValue

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Value source when queue is empty — Value source for empty queue

Hold last value (default) | Use initial value

Specify the value to receive when received message queue is empty.

- Hold last value (default) — Holds data read from the last message.
Initially, if the block tries to receive a message and fails, it outputs the initial value.
- Use initial value — Writes default data.

Dependencies

This parameter is visible when you select the box labeled **Use internal queue**.

Programmatic Use

Block Parameter: ValueSourceWhenQueueIsEmpty

Type: character vector

Values: 'Hold last value' | 'Use initial value'

Default: 'Hold last value'

Sample time (-1 for inherited) — Specify the time interval between samples

-1 (default) | scalar

To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: '-1' | scalar

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no

Multidimensional Signals	yes
Variable-Size Signals	no

Simulink / Messages & Events
SimEvents

Description

The Send block reads the value of an input signal, and sends a message that carries this value. In message-based communication, a message is a discrete-item of interest that carry data of any type that Simulink supports. Send and Message Send blocks are identical blocks.

Ports

Input

Port_Enable — External enable signal
scalar

Input port to enable the block to send a message. For any input value that is greater than 0 send is enabled. For any value less than or equal to 0, the send is disabled.

Dependencies

To enable this port, select the box labeled **Show enable port**.

Data Types: double

Port_1 — Input signal
scalar | vector | matrix

This block accepts inputs of any type that Simulink supports, including enumerated types and converts the input signal to a message. For more information, see “Data Types Supported by Simulink”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_1 — Output message
scalar | vector | matrix

The block outputs a message with constant priority 20.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Parameters

Show enable port — Display the enable port
off (default) | on

Select this check box to display enable port. For any input value that is greater than 0 send is enabled. For any value less than or equal to 0, the send is disabled.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2016a

Extended Capabilities

C/C++ Code Generation

Topics

“Simulink Messages Overview”

Message Triggered Subsystem, Message Polling Subsystem

Subsystem whose execution is controlled by message input

Libraries:
Simulink / Messages & Events

Description

This block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes based on message input. The block has different names based on the timing of execution.

- A Message Triggered Subsystem block executes whenever a message is available at the control port, independent of the block sample time.
- A Message Polling Subsystem block periodically checks for messages and executes if a message is available at the control port.

Inside the subsystem, a Trigger block displays an output port that outputs a data signal carrying the message payload.

Message Triggered Subsystem

A Message Triggered Subsystem block enables event-based message triggers. The block executes whenever a message is available at the control port, independent of sample time. The block contains a Trigger block with the **Trigger type** set to message and the **Trigger time** set to on message available.

The block operates in two modes, scheduled and immediate.

- In scheduled mode, execution order of a subsystem can be scheduled in the Schedule Editor to model asynchronous behavior. You can defer subsystem execution to follow a specific Simulink task while staying at the same time step. A Queue block in front of the trigger port can buffer messages before they enter the subsystem. When a message arrives at the Queue block, it raises an event that triggers the subsystem to pull the message from the Queue block based on the schedule. If there is no Queue block between the message source and the trigger port, Simulink treats the trigger port as having an internal, overwriting-type queue with a capacity of 1, similar to the Receive block. The trigger port can be connected to a root-level Inport block for modeling a software component. Message-trigger subsystem can be placed in an export-function model, for example, a function-call subsystem.

To use scheduled mode, select the **Schedule as aperiodic partition** check box in the Trigger block.

- In immediate mode, the subsystem executes as soon as a message is available at the control port, which pushes the message to the subsystem without a queue buffering the message.

To use immediate mode, clear the **Schedule as aperiodic partition** check box in the Trigger block.

Message Polling Subsystem

A Message Polling Subsystem block executes conditionally at each time step based on whether a message is available at the control port. The block contains a Trigger block with the **Trigger type** set to `message` and the **Trigger time** set to `on sample time hit`.

The block tries at each time step to pull a message from the queue in front of the control port. If there is no Queue block between the message source and the control port, Simulink treats the control port as having an internal, overwriting-type queue with a capacity of 1, similar to the Receive block. If the queue is not empty, a message is pulled and the subsystem executes, with the message payload as input. Only one message is pulled at each time step. If more than one message is in the queue at the current time step, the next message is pulled at the next time step. If the queue is empty, the subsystem does not execute at that time step. You can set the sample time in the block dialog box of the Message Polling Subsystem block. See “Sample time” on page 1-0 .

Ports

Input

Trigger — Control signal and data input
scalar | vector | matrix

Placing a Trigger block with the **Trigger type** set to `message` in a Subsystem block adds an external message input port to the block.

Use the Trigger port to control execution of the subsystem and to pass data to the subsystem.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output
scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an external output port to the block. The port label on the Subsystem block matches the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

For the Message Triggered Subsystem and Message Polling Subsystem block parameters, see Subsystem.

For the Trigger block parameters, see Trigger.

^a Actual data type or capability support depends on block implementation.

Version History

Introduced in R2022a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation. Code generation for the scheduled mode is only supported when connecting the control port to a root Inport block and placing the message-triggered subsystem in an export-function model.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

MinMax

Output minimum or maximum input value

Libraries:

Simulink / Math Operations

HDL Coder / Math Operations

Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You choose whether the block outputs the minimum or maximum values by setting the **Function** parameter.

The MinMax block ignores any input value that is NaN, except when every input value is NaN. When all input values are NaN, the output is NaN, either as a scalar or the value of each output vector element.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

- When the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.
- When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To support matrix input, you must set the **Number of input ports** parameter to an integer greater than one. All nonscalar inputs must have the same dimensions.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — N-th input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block

outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To provide more than one input signal, set the **Number of input ports** to an integer greater than 1.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Minimum or maximum values of inputs

scalar | vector | matrix

When the block has one input, the output is a scalar value, equal to the minimum or maximum of the input elements. When the block has multiple inputs, the output is a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Function — Specify minimum or maximum

min (default) | max

Specify whether to apply the function min or max to the input.

Programmatic Use

Block Parameter: Function

Type: character vector

Values: 'min' | 'max'

Default: 'min'

Number of input ports — Specify number of input ports

1 (default) | positive integer

Specify the number of inputs to the block.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: positive integer

Default: '1'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector | string**Values:** 'off' | 'on'**Default:** 'on'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Signal Attributes****Require all inputs to have the same data type** — Inputs must have the same data type

off (default) | on

Select this check box to require that all inputs have the same data type.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Output minimum** — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal` rule output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Inherit via back propagation'` | `'Inherit: Same as first input'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
default Tree	0	Generates a tree structure of comparators.
Cascade	1, when block has a single vector input port.	This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder). Cascade architecture will be removed in future releases.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
InstantiateStages	Generate a VHDL entity or Verilog module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).

General	
SerialPartition	Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also "SerialPartition" (HDL Coder).

Note To enable the **LatencyStrategy** setting for the MinMax block, you must specify Tree as the **HDL Architecture**.

Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also "LatencyStrategy" (HDL Coder).

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

MinMax Running Resettable

MinMax Running Resettable

Determine minimum or maximum of signal over time

Libraries:

Simulink / Math Operations

Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs u . You specify whether the block outputs the running minimum or maximum with the **Function** parameter.

The block can reset its state based on an external reset signal R . When the reset signal R is nonzero (`true`), the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal as a scalar, vector, or matrix. Based on what you specify for the **Function** parameter, the block outputs the minimum or maximum value of all past inputs u .

If you specify a scalar value for the **Initial condition** parameter, the block expands the parameter to have the same dimensions as nonscalar input u .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

R — Reset signal

scalar | vector | matrix

The input port accepting the reset signal as a scalar, vector, or matrix. When the reset signal is nonscalar, it must have the same dimensions as input signal u . As long as the reset signal has a value of zero, the block outputs the running minimum or maximum value of input u . Whenever the reset signal has a nonzero value (`true`), the block resets the output to the value of the **Initial condition** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

Output

y — Running minimum or maximum value
 scalar | vector | matrix

Output signal, specified as a scalar, vector, or matrix, where each output element equals the running minimum or maximum value of the corresponding input elements. Output signal **y** has the same data type and dimensions as input signal **u**.

When the block receives a nonzero (**true**) reset signal, the block resets the output to the value of the **Initial condition** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Function — Specify minimum or maximum

`min` (default) | `max`

Specify whether the block outputs the running minimum or maximum value of the corresponding input elements.

Programmatic Use

Block Parameter: `Function`

Type: character vector

Values: `'min'` | `'max'`

Default: `'min'`

Initial condition — Value to reset output to

`0.0` (default) | scalar or vector

Specify the initial condition value. When the reset input signal **R** is **true**, the block resets the output to the value you specify.

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar or vector

Default: `'0.0'`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	no

MinMax

Model

Reference another model to create model hierarchy

Libraries:

Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Model block references the specified model. It displays input and output ports that correspond to the top-level input and output ports of the referenced model. These ports allow you to connect the referenced model to other blocks in the parent model.

To determine whether the Model block is better suited for your goal than another block with similar functionality, see “Choose Among Types of Model Components” and “Compare Capabilities of Model Components”.

For instructions on how to reference a model with a Model block, see “Reference Existing Models”.

By default, the Model block displays a representation of the contents of the referenced model. For more information, see “Preview Content of Model Components”. To see the contents of a referenced model, double-click the Model block.

If you have a Simulink Coder license, you can conceal the implementation details of a referenced model by protecting the model. To protect a model, see “Protect Models to Conceal Contents” (Simulink Coder). To reference a protected model, see “Reference Protected Models from Third Parties”.

Ports

Input

Port_1 — Input that corresponds to root-level blocks of referenced model
scalar | vector | matrix | array | bus

The Model block has an input port for each input port of the model it references. The input ports of referenced models are defined by Inport and In Bus Element blocks. The name of the Model block port matches the name of the corresponding port in the referenced model. The input signal, message, or function call for each Model block port must be valid for the corresponding port in the referenced model. For more information, see “Model Reference Interface and Boundary”.

Tips

- Signal attributes in a referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in a referenced model, define block parameters for root-level Inport and In Bus Element blocks.
- Function calls connected to an input port pass into the referenced model. To conditionally execute the referenced model based on a function call, see **Function Call** on page 1-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Output that corresponds to root-level blocks of referenced model
 scalar | vector | matrix | array | bus

The Model block has an output port for each output port of the model it references. The output ports of referenced models are defined by Outport and Out Bus Element blocks. The name of the port on the Model block matches the name of the corresponding port in the referenced model. The output signals and messages of a Model block are the signals and messages connected to the Outport and Out Bus Element blocks in the referenced model. See “Model Reference Interface and Boundary”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Control

Conditional Execution

Enable — Control signal that enables referenced model
 scalar | vector | matrix

The enable port appears at the top of the Model block. The port label is an icon that represents an enable signal.

The control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add an Enable block to the top level of the referenced model.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Trigger — Control signal that triggers referenced model
 scalar | vector | matrix

The trigger port appears at the top of the Model block. The port label is an icon that represents a trigger signal.

The control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add a Trigger block to the top level of the referenced model and set its **Trigger type** to **rising**, **falling**, or **either**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Function Call — Control signal for function-call event

scalar

The function-call port appears at the top of the Model block. The port label displays the name of the referenced model as a function.

The function-call control signal that connects to the port determines when to execute the referenced model. For more information, see “Conditionally Execute Referenced Models”.

Dependencies

To enable this port, add a Trigger block to the top level of the referenced model and set its **Trigger type** to **function-call**.

Model Events Simulation

initialize — Control signal for model initialize event

scalar

The initialize event port provides a function-call control signal that triggers a model initialize event, which initializes the states of the referenced model.

The referenced model can contain an Initialize Function block that corresponds to the model initialize event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

Dependencies

To enable this port, select **Show model initialize port** on page 1-0 .

reset — Control signal for model reset event

scalar

A reset event port provides a function-call control signal that triggers a model reset event, which resets the states of the referenced model.

The referenced model must contain a Reset Function block that corresponds to each model reset event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

To specify the port name, use the **Event name** parameter of the Event Listener block in the Reset Function block.

Dependencies

To enable this type of port, select **Show model reset ports** on page 1-0 .

reinit — Control signal for model reinitialize event
scalar

A reinitialize event port provides a function-call control signal that triggers a model reinitialize event, which reinitializes the states of the referenced model.

The referenced model must contain a Reinitialize Function block that corresponds to each model reinitialize event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

To specify the port name, use the **Event name** parameter of the Event Listener block in the Reinitialize Function block.

Dependencies

To enable this type of port, select “**Show model reinitialize ports**” on page 1-0 .

terminate — Control signal for model terminate event
scalar

The terminate event port provides a function-call control signal that triggers a model terminate event, which reads and saves the states of the referenced model.

The referenced model can contain a Terminate Function block that corresponds to the model terminate event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

Dependencies

To enable this port, select **Show model terminate port** on page 1-0 .

D — Control signal for scheduling periodic events
scalar

Periodic event ports provide function-call control signals that specify when to execute the model. For an example, see “Test Rate-Based Model Simulation Using Function-Call Generators”.

Each port label displays information about the periodic event, such as the sample time of the corresponding Inport block. For example, the Model block in this image displays periodic event ports and references a model with two discrete rates: 0.01 and 0.1.

Dependencies

To enable this type of port, set **Schedule rates with** on page 1-0 to Ports.

Parameters

To interactively modify Model block parameters, select the Model block. Then, in the Simulink Toolstrip, on the **Model Block** tab, click **Block Parameters**.

Main

Specify fundamental information for the Model block.

Model name — File name of referenced model

' ' (default) | character vector

Specify the file name of the referenced model. The file name must be a valid MATLAB identifier for a model, as defined in “Choose Valid Model File Names”. The file extension is optional.

To select the model that you want to reference, click **Browse**. To view the specified model, click **Open Model**.

Programmatic Use

You can query the name of the referenced model in different formats:

- **ModelFile** — Model name with file extension. When you do not specify a file extension, the first match that Simulink finds on the MATLAB path determines the file extension.
- **ModelNameDialog** — Model name with or without file extension, depending on whether you specify a file extension.
- **ModelName** — Model name without file extension. If you specify a model name with a file extension for **ModelName**, Simulink retains the file extension by setting **ModelNameDialog** and **ModelFile**.

Parameter: `ModelNameDialog`

Type: character vector

Value: ' ' | '<filename>'

Default: ' '

Simulation mode — Simulation mode for model reference

Normal (default) | Accelerator | Software-in-the-loop (SIL) | Processor-in-the-loop (PIL)

Specify the simulation mode for the Model block. The simulation mode for the Model block can be different than the simulation mode of its referenced model and of other models in the model hierarchy.

- **Normal** — Execute the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- **Accelerator** — Create a MEX file for the referenced model. Then, execute the referenced model by running the S-function.
- **Software-in-the-loop (SIL)** — This option requires an Embedded Coder license. Generate production code based on the **Code interface** parameter setting. The code is compiled for and executed on the host platform.

- **Processor-in-the-loop (PIL)** — This option requires an Embedded Coder license. Generate production code based on the **Code Interface** parameter setting. This code is compiled for and executed on the target platform. A target connectivity API implementation supports the exchange of data between the host and target at each time step during the PIL simulation.

The corners of the Model block indicate the simulation mode of the Model block. For normal mode, the corners have empty triangles. For accelerator mode, the corner triangles are filled in. For SIL and PIL modes, the corners are filled in and the word (SIL) or (PIL) appears on the block icon.

Although you can specify any simulation mode for a model, when you reference that model, the Model block specifies the simulation mode of the referenced model instance. The simulation mode of a parent model can override the simulation mode of a Model block.

For more information, see “Choose Simulation Modes for Model Hierarchies”.

Programmatic Use

Parameter: SimulationMode

Type: character vector

Value: 'Normal' | 'Accelerator' | 'Software-in-the-loop' | 'Processor-in-the-loop'

Default: 'Normal'

Code interface — Option to generate code from top model or referenced model

Model reference (default) | Top model

Specify whether to generate the code from the top model or the referenced model for SIL and PIL simulation modes. To deploy the generated code as part of a larger application that uses the referenced model, specify `Model reference`. To deploy the generated code as a standalone application, specify `Top model`.

- `Model reference` — The code is generated from the referenced model as part of a model hierarchy. Code generation uses the `slbuild('model', 'ModelReferenceCoderTarget')` command.
- `Top model` — The code is generated from the top model with the standalone code interface. Code generation uses the `slbuild('model')` command.

Dependencies

To enable this parameter, set **Simulation mode** on page 1-0 to either `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.

Programmatic Use

Parameter: CodeInterface

Type: character vector

Value: 'Model reference' | 'Top model'

Default: 'Model reference'

Model Events Simulation

Control when the referenced model executes and changes states.

Show model initialize port — Option to display initialize event port

off (default) | on

Select this parameter to display the initialize event port. Clear this parameter to remove the port.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution.

Programmatic Use

Block parameter: ShowModelInitializePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model reinitialize ports — Option to display reinitialize event ports

off (default) | on

Select this parameter to display the reinitialize event ports. Clear this parameter to remove the ports.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution and contains a Reinitialize Function block.

Programmatic Use

Block parameter: ShowModelReinitializePorts

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model reset ports — Option to display reset event ports

off (default) | on

Select this parameter to display the reset event ports. Clear this parameter to remove the ports.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution and contains a Reset Function block.

Programmatic Use

Block parameter: ShowModelResetPorts

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model terminate port — Option to display terminate event port

off (default) | on

Select this parameter to display the terminate event port. Clear this parameter to remove the port.

Dependencies

To enable this parameter, reference a model that is not configured for conditional execution. Then, select **Show model initialize port** on page 1-0 .

Programmatic Use

Block parameter: ShowModelTerminatePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Schedule rates — Option to schedule periodic events

off (default) | on

Control the execution of the referenced model with periodic events.

Depending on the value of the **Schedule rates with** parameter, selecting this parameter will either display the periodic event ports on the Model block or create partitions to use with the **Schedule Editor**. When the **Schedule rates with** parameter is not visible, its default value (Ports) applies.

Clearing this parameter hides the periodic event ports and does not create partitions.

Dependencies

To enable this parameter, reference a model with discrete sample times that is not configured for conditional execution and is not an export-function model. When the parent model is rate based and the referenced model is an export-function model, **Schedule rates** is automatically selected.

Programmatic Use

Block parameter: ScheduleRates

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Schedule rates with — Option to create partitions or periodic event ports

Ports (default) | Schedule Editor

Create ports or partitions.

- **Ports** — Display periodic event ports for discrete rates in the referenced model.

To manually specify port rates, use the `set_param` function to set the `AutoFillPortDiscreteRates` parameter of the Model block to 'off'. Then, specify the port rates with the `PortDiscreteRates` parameter.

- **Schedule Editor** — Create partitions for the referenced model to use with the **Schedule Editor**.

Dependencies

To enable this parameter:

- The parent model must not be an export-function model.
- The parent model must not use a fixed-step solver and single-tasking mode.
- Select **Schedule rates**. When the parent model is rate based and the referenced model is an export-function model, **Schedule rates** is automatically selected.
- Clear **Show model initialize port**, **Show model reset ports**, and **Show model reinitialize ports**.

Programmatic Use**Block parameter:** ScheduleRatesWith**Type:** character vector**Value:** 'Ports' | 'ScheduleEditor'**Default:** 'Ports'**Instance Parameters**

Specify instance-specific values for model arguments.

Instance parameters — Display instance parameters and specify values for referenced model

[number](#) | [workspace variable](#) | [mathematical expression](#) | [structure or structure field](#)

Display instance parameters and specify instance-specific values. Instance parameters are block parameters that have been configured in the referenced model to use a different value for each instance of the model.

To specify instance-specific values, use the **Value** column in the table. To specify that a parameter value can be overridden by the parent model, select the **Argument** check box. For more information about configuring instance parameters in a referenced model and specifying instance-specific values at the Model block, see “Parameterize Instances of a Reusable Referenced Model”.

When changing instance-specific values, you can use a partial structure that has fields that correspond to only the instance parameters whose values you want to change. Instance parameters not included in the partial structure retain their values. In the structure, include the instance parameter names and values, specified as character vectors.

Programmatic Use**Block parameter:** ParameterArgumentValues**Type:** structure**Value:** structure**Default:** structure with no fields**Block parameter:** InstanceParameters**Type:** structure array**Value:** structure with fields: Name, Value, Path, and Argument.**Solver**

Configure local solver parameters using a combination of the configuration parameters for the referenced model and the block parameters for each Model block that references the model.

Referenced Model Configuration Parameters

Use local solver — Option to use local solver in referenced model

[link to referenced model configuration parameter](#)

This parameter provides a hyperlink that opens the Configuration Parameters dialog box for the model referenced by the block. In the Configuration Parameters dialog box, select or clear the **Use local solver when referencing model** configuration parameter for the referenced model. When you select **Use local solver when referencing model**, the referenced model uses a local solver.

When you configure a referenced model to use a local solver, the local solver computes the state values for the referenced model during simulation. Using a local solver can improve simulation performance by allowing you to:

- Specify a larger step size for a component with slower dynamics compared to the rest of the system.
- Select a different solver that is more appropriate for the referenced model.

For more information, see “Use Local Solvers in Referenced Models”.

Solver — Option to select local solver
[link to referenced model configuration parameter](#)

This parameter provides a hyperlink that opens the Configuration Parameters dialog box for the model referenced by the block. In the Configuration Parameters dialog box, select a value for the **Solver** parameter to specify the solver to use as the local solver for the referenced model.

The local solver must be a fixed-step solver.

Dependencies

To enable this parameter, select **Use local solver when referencing model** in the model configuration parameters for the model referenced by this block.

Step size — Option to specify step size for local solver
[link to referenced model configuration parameter](#)

This parameter provides a hyperlink that opens the Configuration Parameters dialog box for the model referenced by the block. In the Configuration Parameters dialog box, specify the value for the **Fixed-step size (fundamental sample time)** parameter of the referenced model to specify the step size for the local solver.

The local solver step size must be an integer multiple of the parent solver step size.

Dependencies

To enable this parameter, select **Use local solver when referencing model** in the model configuration parameters for the model referenced by this block.

Model Block Parameters

Input signal handling — Extrapolation method for local solver inputs

Auto (default) | Zero-order hold

Because the local solver execution is decoupled from the execution of the parent solver, the local solver extrapolates values from outside the model reference and provides interpolated values to the parent solver. For more information, see “Use Local Solvers in Referenced Models”.

Use this parameter to specify how the local solver extrapolates values from outside the model reference.

- **Auto** — Use default input handling, which includes numerical compensation that improves data exchanges between the top and local solvers.
- **Zero-order hold** — Use the last value calculated by the parent solver.

Specifying **Auto** input handling generally increases the accuracy of simulation results. The **Auto** input handling is more computationally intensive than the **Zero-order hold** input handling.

Consider using **Zero-order hold** input handling in any of these situations:

- When simulation results are acceptable with Zero-order hold input handling and performance is a concern
- When the referenced model does not have input ports
- When input port values do not affect continuous state computations
- When a significant part of the derivative is based on the state itself, for example, from feedback loops in the model
- To improve local solver stability for a given step size

Dependencies

To enable this parameter, select **Use local solver when referencing model** in the model configuration parameters for the model referenced by this block.

Programmatic Use

Block parameter: InputSignalHandling

Type: string | character vector

Value: 'Auto' | 'Zero-order hold'

Default: 'Auto'

Output signal handling — Interpolation method for outputs from local solver

Use solver interpolant (default) | Zero-order hold

Because the local solver execution is decoupled from the execution of the parent solver, the local solver extrapolates values from outside the model reference and provides interpolated values to the parent solver. For more information, see “Use Local Solvers in Referenced Models”.

Use this parameter to specify the interpolation method the local solver uses to provide values to the parent solver.

- **Use solver interpolant** — Use the interpolant of the local solver to calculate the interpolated state and output signal values.
- **Zero-order hold** — Use the last value calculated by the local solver before the current time for the top solver.

In general, using the solver interpolant for output handling increases accuracy. Zero-order hold output handling reduces computational complexity but also reduces accuracy.

Dependencies

To enable this parameter, select **Use local solver when referencing model** in the model configuration parameters for the model referenced by this block.

Programmatic Use

Block parameter: OutputSignalHandling

Type: character vector

Value: 'Use solver interpolant' | 'Zero-order Hold'

Default: 'Use solver interpolant'

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Tips

To programmatically determine whether a Model block references a protected model, use the `get_param` function to query the read-only `ProtectedModel` parameter of the Model block. If the referenced model is protected, the function returns 'on'. If the referenced model is unprotected, the function returns 'off'.

Version History

Introduced before R2006a

R2019a: Specifying variant models in Model blocks is no longer supported

Warns starting in R2019a

Starting in R2019a, specifying variant models in Model blocks is no longer supported. The Model Variants block, which was a Model block preconfigured to specify variant models, is also no longer supported. Loading a model that contains these blocks converts them to Variant Subsystem blocks that contain Model blocks that represent the variant choices.

Variant Subsystem blocks provide these advantages:

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

The Variant Subsystem block parameter **Analyze all choices during update diagram and generate preprocessor conditionals** behaves differently from the Model block parameter **Generate preprocessor conditionals**. Instead of causing simulation and update diagram to compile the active variant only, the Variant Subsystem block parameter compiles all variants.

If you have scripts that use Model block parameters for variants, you must update them to use Variant Subsystem block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information about using the Model block for HDL code generation and best practices and limitations, see “Model Referencing for HDL Code Generation” (HDL Coder).

See also “Generate Black Box Interface for Referenced Model” (HDL Coder) and “Generate Parameterized Code for Referenced Models” (HDL Coder).

HDL Architecture

Architecture	Description
ModelReference (default)	When you want to generate code from a referenced model and any nested models, use the ModelReference implementation. For more information, see “How To Generate Code for a Referenced Model” (HDL Coder).
BlackBox	Use the BlackBox implementation to instantiate an HDL wrapper, or black box interface, for legacy or external HDL code. If you specify a black box interface, HDL Coder does not attempt to generate HDL code for the referenced model. For more information, see “Generate Black Box Interface for Referenced Model” (HDL Coder).

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ReferenceModelPrefix	Prefix of the referenced model to insert in the generated code. The code generator applies this prefix to submodel file names and HDL identifiers. The default prefix is <code>modelName_</code> where <code>modelName</code> is the name of the referenced model. Note <ul style="list-style-type: none"> • If you specify an empty prefix, the code generator does not add a prefix to submodel file names. This can cause HDL compilation errors due to naming collisions between the models. • If you use the referenced model as the DUT, the code generator ignores the prefix that you specify.
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Model Info

Display model properties and text in model

Libraries:

Simulink / Model-Wide Utilities
HDL Coder / Model-Wide Utilities

Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

Parameters

Specify Text and Properties to Display — Content and format of the text to display
no default

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text **Model Info**.
- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

The block adds a token of the form `%<modelpropertyname>` to the edit box. In the text the block mask displays, Simulink replaces the token with the value of the property.

- 1 For example, if you select **Description** in the **Model properties** list and click the right arrow button, then the token `%<Description>` appears in the right edit box.
- 2 You could add some explanatory text before the model property, e.g. **“Model description:”**.
- 3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See “Access Model Information Programmatically” for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use a project. See “Source Control in Projects”.

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Model Info block is ignored during code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

When using Model Info blocks in models targeted for HDL code generation, consider using only ASCII characters in the text that you enter to display on the Model Info block. If you have non-ASCII characters in the generated HDL code, RTL simulation and synthesis tools can fail to compile the code.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Multiport Switch

Select output signal based on control signal

Libraries:

Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to Select Data Input	Out-of-Range Condition
Integer value	None	Zero-based contiguous	Zero-based indexing	The control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The control input does not correspond to any specified data port index.
Not an integer value	The block truncates the value to an integer by rounding to zero.	Zero-based contiguous	Zero-based indexing	The truncated control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The truncated control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1408.

Multiport Switch Configured as an Index Vector Block

An Index Vector is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block, set **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

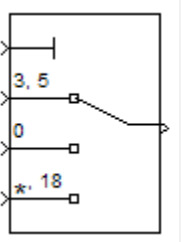

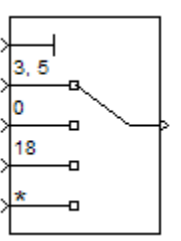

How the Block Handles an Out-of-Range Control Input

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

Note If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

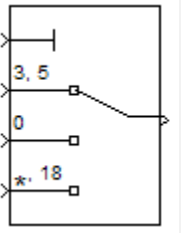

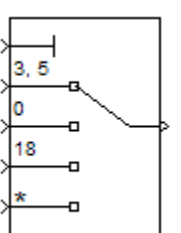

Behavior for Simulation

The following behavior applies only to simulation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port and do not report any warning or error.	Use the last data port and report a warning.	Report an error and stop simulation.
Additional data port 	Use the additional data port with a * label and do not report any warning or error.	Use the additional data port with a * label and report a warning.	Report an error and stop simulation.

Behavior for Code Generation

The following behavior applies to code generation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
Last data port 	Use the last data port.	Use the last data port.	Use the last data port.
Additional data port 	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes (Results in variable-size output signal)” on page 1-0 . For more information about variable-size signals, see “Variable-Size Signal Basics”.

Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-1408.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	<ul style="list-style-type: none"> Set Data port order to Specify indices. Set Data port indices to use this value for the last data port. Set Data port for default case to Last data port. 	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles invalid values that the enumerated type does not explicitly represent.
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Last data port. Set Diagnostic for default case to None. 	This block configuration avoids unnecessary diagnostic action.
The block does not have a data input port for every value of the enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to Additional data port. 	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

Limitations

- If the data inputs to the Multiport Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name mismatch** diagnostic to error. See “Model Configuration Parameters: Connectivity Diagnostics” for more information.
- For arrays of buses, **Number of data ports** must be set to a value of 2 or greater.

Ports

Input

Port_1 — Control signal
scalar

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-1410.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1408.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data port, an error occurs.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `image`

1 — First data input

`scalar` | `vector` | `matrix` | N-D array

First data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1409
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string` | `image`

2 — Second data input

`scalar` | `vector` | `matrix` | N-D array

Second data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1409
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable this port, set **Number of data ports** to an integer greater than 1.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `string` | `image`

N — Nth data input

scalar | vector | matrix | N-D array

Nth data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1409
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable the **N**th input port, set **Number of data ports** to an integer value greater than or equal to **N**.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | string | image

*** — Data port for out-of-range inputs**

scalar | vector | matrix | N-D array

Input data port for out-of-range control signal inputs, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type. If any two signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1409.

Dependencies

To create an additional data port for out-of-range control signal inputs, set **Data port for default case** to **Additional data port**. When you set **Data port for default case** to **Last data port**, the block uses the last data port for output when the control signal value does not match any data port indices.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Output**Port_1** — Selected data input, based on control signal value

scalar | vector | matrix | N-D array

The block outputs one of the data inputs, selected according to the control signal value. The output has the same dimensions as the corresponding data input. The output data type is the data type of the input port that requires the largest memory space. When you select the **Allow different data input sizes** check box, the output of the block is a variable size signal.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | string | image

Parameters

Main

Data port order — Type of ordering for data input ports

One-based contiguous | Zero-based contiguous | Specify indices

Specify the type of ordering for your data input ports.

- **Zero-based contiguous** — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- **One-based contiguous** — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block
- **Specify indices** — Block uses noncontiguous indexing for ordering data ports.

Tips

- When the control port is of enumerated type, select **Specify indices**.
- If you select **Zero-based contiguous** or **One-based contiguous**, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs.

If the Block Has Unused Data Ports and Data Port Order Is:	The Block Produces:
Zero-based contiguous or One-based contiguous	A warning
Specify indices	An error

Dependencies

Selecting **Zero-based contiguous** or **One-based contiguous** enables the **Number of data ports** parameter.

Selecting **Specify indices** enables the **Data port indices** parameter.

Programmatic Use

Block Parameter: DataPortOrder

Type: character vector

Values: 'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'

Default: 'One-based contiguous' (Multiport Switch) 'Zero-based contiguous' (Index Vector)

Number of data ports — Number of data input ports

1 | 3 | integer between 1 and 65535

Specify the number of data input ports to the block. The total number of input ports is the number you specify, plus one for the control signal input port, and plus one more if you set **Data port for default case** to Additional data port.

Dependencies

To enable this parameter, set **Data port order** to Zero-based contiguous or One-based contiguous.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: integer between 1 and 65536

Default: '3' (Multiport Switch) '1' (Index Vector)

Data port indices — Array of indices for data ports

{1,2,3} (default) | array of indices

Specify an array of indices for your data ports. The block icon changes to match the data port indices you specify.

Tips

- To specify an array of indices that correspond to all values of an enumerated type, enter the name of the type.

For example, `MyColors` is a valid entry if `MyColors` is the name of an enumerated type.

- To enter specific values of an enumerated type, use the *type_name.enumerated_name* format. Do not enter the underlying integer value.

For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.

- To indicate that more than one value maps to a data port, use brackets.

For example, the following entries are both valid:

- `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
- `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

Dependencies

To enable this parameter, set **Data port order** to Specify indices.

Programmatic Use

Block Parameter: DataPortIndices

Type: character vector

Values: array of indices

Default: '{1,2,3}'

Data port for default case — Port to use for out-of-range inputs

Last data port (default) | Additional data port

Specify whether to use the last data port for out-of-range inputs, or to use an additional port. An asterisk (*) next to the port name indicates the port the block uses when the control port value does not match any data port indices.

- **Last data port** — Block uses the last data port for output when the control port value does not match any data port indices.
- **Additional data port** — Block uses an additional data port for output when the control port value does not match any data port indices.

Tip

If you set this parameter to **Additional data port** and **Number of data ports** is 3, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

Programmatic Use

Block Parameter: DataPortForDefault

Type: character vector

Values: 'Last data port' | 'Additional data port'

Default: 'Last data port'

Diagnostic for default case — Diagnostic action when control port value does not match data port indices

Error (default) | Warning | None

Specify the diagnostic action to take when the control port value does not match any data port indices.

- **None** — Produce no response.
- **Warning** — Display a warning and continue the simulation.
- **Error** — Terminate the simulation and display an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-1408.

Programmatic Use

Block Parameter: DiagnosticForDefault

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'Error'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

Require all data port inputs to have the same data type — Require all inputs to have the same data type

off (default) | on

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see *Optimize using the specified minimum and maximum values (Embedded Coder)*.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first data input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | string | Simulink.ImageType(480,640,3) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule**—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:
 - Specify the output data type explicitly.
 - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Uses the data type of the driving block.
- **Inherit: Same as first data input** — Uses the data type of the first data input port.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | Simulink.ImageType(480,640,3) | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer round function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB fix function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.
For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.
For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.
Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector
Values: 'off' | 'on'
Default: 'off'

Allow different data input sizes (Results in variable-size output signal) — Allow input signals with different sizes

off (default) | on

Select this check box to allow input signals with different sizes.

- On — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- Off — Requires that all nonscalar data input signals be the same size.

Programmatic Use

Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Mode — Select data type mode

Inherit (default) | Built in | Fixed Point

Select the category of data to specify.

- Inherit — Inheritance rules for data types. Selecting Inherit enables a second menu/text box to the right where you can select the inheritance mode.
- Built in — Built-in data types. Selecting Built in enables a second menu/text box to the right where you can select a built-in data type.
- Fixed point — Fixed-point data types. Selecting Fixed point enables additional parameters that you can use to specify a fixed-point data type.
- Expression — Expressions that evaluate to data types. Selecting Expression enables a second menu/text box to the right, where you can enter the expression.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, click the **Show data type assistant** button.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- When you select Inherit, Simulink inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.
- When you select Off, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, set **Mode** to `Built in` or `Fixed point`.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Signedness — Specify signed or unsigned

`Signed (default)` | `Unsigned`

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only.

- `Signed`, specifies the fixed-point data as signed.
- `Unsigned`, specifies the fixed-point data as unsigned.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Mode** to `Fixed point`.

Scaling — Method for scaling fixed-point data

`Best precision (default)` | `Binary point` | `Slope and bias`

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Word length — Bit size of the word that holds the quantized integer

`16 (default)` | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Fraction length — Specify fraction length for fixed-point data type

`0 (default)` | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Binary point`.

Slope — Specify slope for the fixed-point data type

2^{θ} (default) | positive, real-valued scalar

Specify slope for the fixed-point data type. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Slope and bias`.

Bias — Specify bias for the fixed-point data type

θ (default) | real-valued scalar

Specify bias for the fixed-point data type as any real number. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Slope and bias`.

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

General	
CodingStyle	Specify whether to generate HDL code with case statements or if-else statements. By default, HDL Coder generates if-else statements. See also “CodingStyle” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

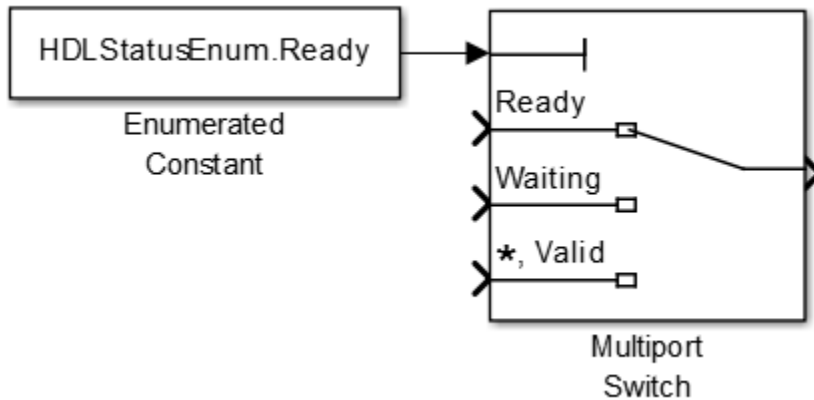

Setting Data Port Indices Using Specify Indices mode

You can specify the data port indices to the input port using specify indices mode. To configure the Multiport Switch block with specify indices mode, set the **Data port order** block parameter to `Specify indices`. Then, enter the port indices in the **Data port indices** block parameter. For a model targeted for HDL code generation, you can use these input data types for the control input in a specify indices mode:

- Fixed-point and floating-point types
- Signed and unsigned integer types
- Enumerated types
- Vector, matrix, and bus types

Using an Enumerated Type as Port Index

You can set **Data port order** to `Specify indices`, and enter enumeration values for the **Data port indices**. For example, you can connect the Enumerated Constant block to the Multiport Switch control port and use the enumerated types as data port indices.

Restrictions

You must avoid using of NaN or out of range values at the control port. It can cause simulation mismatch in the validation model.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

“Variable-Size Signal Basics”

MultiStateImage

Display image reflecting input value

Libraries:
Simulink / Dashboard

Description

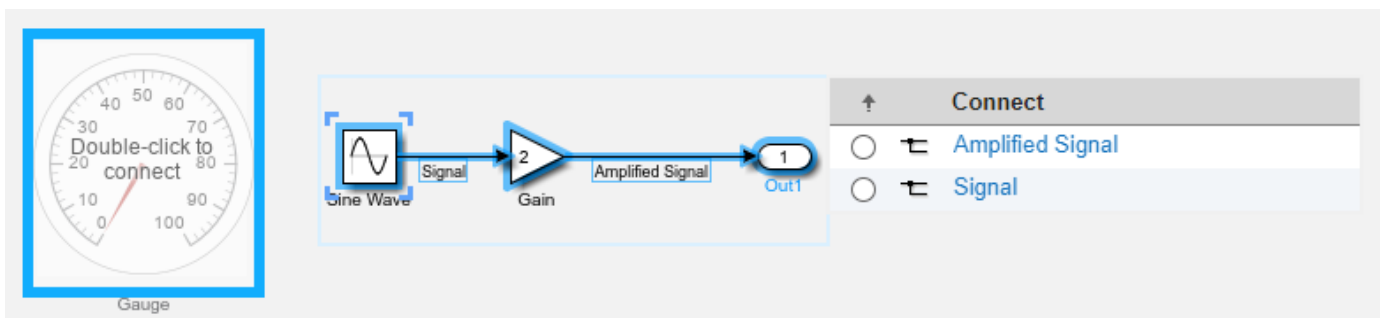

The MultiStateImage block displays an image to indicate the value of the input signal. You can use the MultiStateImage block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and images to provide the information you want during simulation.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.
- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Connection — Signal to connect and display
signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Scale Mode — Specify how to scale image

Fill with fixed aspect ratio (default) | Fixed | Fill

Specify how to scale the image.

Fill with fixed Aspect Ratio scales the image to the size of the block while retaining its original aspect ratio.

Fixed displays the image with its fixed true size.

Fill adjusts the image to fill the block.

Programmatic Use

Block Parameter: ScaleMode

Type: string or character vector

Values: 'Fill with fixed aspect ratio' | 'Fixed' | 'Fill'

Default: 'Fill with fixed aspect ratio'

States — Match values with images to display
scalar and image

States match an image to display with a value of the connected variable or parameter. Each state consists of a **State** and an image, displayed as a **Thumbnail** in the **States** table for the MultiStateImage block.

- **State** — Connected variable or parameter value that causes the MultiStateImage block to display the corresponding image.
- **Thumbnail** — Image to display when the connected variable or parameter value matches the corresponding **State**.

Click the **+** button to add another state.

Programmatic Use

To programmatically configure **State** and **Thumbnail** parameter values for the MultiStateImage block, use the **States** parameter. Specify the value for the **States** parameter as an array of structures with the fields:

- **State** — State value.
- **Size** — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as a `uint64`.
- **Image** — Character array of Base64 encoded image data.
- **Thumbnail** — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Include a structure in the array for each state you want to specify for the block. In the example, the `myBase64Image` and `myBase64Thumbnail` variables contain character vectors of the Base64 image data for the block image and thumbnail..

```
state1.State = 1;
state1.Size = [uint64(400) uint64(400)];
state1.Image = myBase64Image;
state1.Thumbnail = myBase64Thumbnail;
state2.State = 2;
state2.Size = [uint64(400) uint64(400)];
state1.Image = myBase64Image2;
state1.Thumbnail = myBase64Thumbnail2;
msiStates = [state1 state2];
```

Block Parameter: States**Type:** structure array

The block displays the default image when the connected signal value does not correspond to any of the specified states. Specify the `DefaultImage` parameter as a structure containing the fields:

- **Size** — 1-by-2 vector containing the width and height for the image in that order, in pixels, specified as `uint64`.
- **Image** — Character array of Base64 encoded image data.
- **Thumbnail** — Character array of Base64 encoded image data for the thumbnail image to display in the **States** table in the block dialog.

Block Parameter: DefaultImage**Type:** structure**Label** — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Block Characteristics**

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no

Mux

Combine input signals of same data type and complexity into virtual vector

**Libraries:**

Simulink / Commonly Used Blocks
Simulink / Signal Routing
HDL Coder / Commonly Used Blocks
HDL Coder / Signal Routing

Description

The Mux block combines inputs with the same data type and complexity into a virtual vector. You can use multiple Mux blocks to create a mux signal in stages, but the result is flat as if you used a single Mux block.

Ideally, use Mux blocks to group only function-call signals.

While a Mux block can create a virtual vector from signals that have the same data type and complexity, other blocks group signals in ways that provide more flexibility and efficiency.

- To group signals or messages, use a Bus Creator block instead of a Mux block. The Bus Creator block creates virtual buses, which give you the flexibility to group elements of different data types and complexity. Virtual buses also let you access elements by name instead of by index. If a block requires a virtual vector instead of a virtual bus, model compilation converts the bus to a vector.
- To concatenate input signals, use a Vector Concatenate block instead of a Mux block. The Vector Concatenate block creates a nonvirtual vector, which improves the efficiency of generated code.

For a comparison of mux signals, virtual buses, and concatenated signals, see “Choose Among Composite Interfaces”.

Ports

Input

Port_1 — Input signal to include in mux signal

scalar | vector

Input signal to include in the mux signal, specified as a scalar or vector.

The input signals for a Mux block can be any combination of scalars and vectors, but they must have the same data type and complexity or be function-call signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | image

Output

Port_1 — Output mux signal

vector

Output mux signal composed of the combined input signals, returned as a vector.

The elements of the output mux signal take their order from the port order of the input signals. For a description of the port order for various block orientations, see “Identify Port Location on Rotated or Flipped Block”.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `image`

Parameters

Number of inputs — Number of input signals

2 (default) | scalar | vector | cell array | comma-separated list of signal names

The number of input signals, specified as a scalar, vector, cell array, or comma-separated list of signal names. Some of these formats allow you to specify the signal names and sizes, as described in this table.

Format	Block Behavior
Scalar	The number of inputs to the Mux block. When you use this format, the block accepts scalar or vector signals of any size. The software assigns each input the name <code>signalN</code> , where N is the input port number.
Vector	The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input. A positive value specifies that the corresponding port can accept only vectors of that size. For example, <code>[2 3]</code> specifies two input ports of sizes 2 and 3, respectively. If an input signal width does not match the expected width, an error message appears. A value of -1 specifies that the corresponding port can accept scalars or vectors of any size.
Cell array	The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input. A scalar value N specifies a vector of size N. A value of -1 means that the corresponding port can accept scalar or vector signals of any size.
Comma-separated list of signal names	A list of signal names separated by commas. The software assigns each name to the corresponding port and signal. For example, if you enter <code>position, velocity</code> , the Mux block has two inputs, named <code>position</code> and <code>velocity</code> .

Tips

If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, the software adds a port and updates the parameter.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	Inputs
Values:	'2' (default) character vector string scalar
Data Types:	char string

Example: `set_param(gcb, 'Inputs', '5')`

Example: `set_param(gcb, 'Inputs', '[2 3]')`

Example: `set_param(gcb, 'Inputs', '{3}')`

Example: `set_param(gcb, 'Inputs', 'position,velocity')`

Display option — Block icon appearance

`bar` (default) | `signals` | `none`

Block icon appearance, specified as `bar`, `signals`, or `none`.

- `bar` — Displays no text
- `signals` — Displays the input signal names
- `none` — Displays the type of block (Mux)

Resize the block as necessary to fit the text on the block icon.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	DisplayOption
Values:	'bar' (default) 'signals' 'none'

Example: `set_param(gcb, 'DisplayOption', 'signals')`

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

Buses are not supported for HDL code generation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Neighborhood

Control block for Neighborhood Processing Subsystem

Description

The Neighborhood block serves as a control block for the Neighborhood Processing Subsystem block. The Neighborhood Processing Subsystem block iterates over an input matrix. At each iteration, the inport inside the subsystem receives a small matrix representing a configurable window of elements around one element of the input matrix. Use the Neighborhood block parameters to configure the behavior of the Neighborhood Processing Subsystem block, such as the window dimensions, the size of the output matrix, and the region of interest (ROI) over which to iterate.

Parameters

Neighborhood size — Dimensions of neighborhood window

[3 3] (default) | array of positive scalars

Configure the dimensions of the neighborhood window that the subsystem receives at each iteration. The dimensions of the neighborhood cannot exceed the dimensions of the region of interest that you specify with the **Processing width** and **Processing offset** parameters.

For example, consider this input matrix:

$$\begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 6 & 7 & 8 & 9 & 10 \\ 11 & 12 & 13 & 14 & 15 \\ 16 & 17 & 18 & 19 & 20 \\ 21 & 22 & 23 & 24 & 25 \end{bmatrix}.$$

If you set **Neighborhood size** to [3 3], then on the seventh iteration, the Neighborhood Processing Subsystem block receives this 3-by-3 window that surrounds the seventh element:

$$\begin{bmatrix} 1 & 2 & 3 \\ 6 & 7 & 8 \\ 11 & 12 & 13 \end{bmatrix}.$$

Programmatic Use

Block Parameter: NeighborhoodSize

Type: array

Values: [3 3] | '<array>'

Default: [3 3]

Stride — Number of input matrix elements to skip between iterations

[1 1] (default) | array of positive scalars

Configure the Neighborhood Processing Subsystem block to skip a number of elements in the input matrix between each iteration. For example, the value [1 2] configures the subsystem to iterate over alternating columns from the input matrix and the value [3 1] configures the subsystem to iterate over every third row from the input matrix. Larger **Stride** values produce smaller output matrices because the Neighborhood Processing Subsystem block processes fewer elements.

See the difference between the **Stride** parameter values of [1 1] and [2 3].

Programmatic Use

Block Parameter: Stride

Type: array

Values: [1 1] | '<array>'

Default: [1 1]

Processing offset — Offset of each iteration

[0 0] (default) | array of positive scalars

Configure a distance by which to offset each iteration of the algorithm. This distance defines the top left boundary the ROI within the input matrix.

For example, consider this input matrix:

1	2	3	4	5
6	7	8	9	10
11	12	13	14	15
16	17	18	19	20
21	22	23	24	25

If you use the default **Processing offset** parameter value of [0 0], then the first iteration uses a neighborhood around the element 1, the second iteration centers around element 2, and so on. If you set the **Processing offset** parameter value to [1 2], then the Neighborhood Processing Subsystem block offsets the center of each iteration by 1 along the vertical axis and 2 along the horizontal axis. The first iteration centers on element 8, the second iteration centers on element 9, and so on. Because the region of interest cannot extend outside the input matrix, the output matrix is smaller than the input matrix.

Use the **Processing offset** and **Processing width** parameters together to process only a subsection of an input matrix. For an example, see “Specify Region of Interest for Neighborhood Processing”.

Programmatic Use

Block Parameter: ProcessingOffset

Type: array

Values: [0 0] | '<array>'

Default: [0 0]

Processing width — Subsection of input matrix to process

-1 (default) | array of scalars

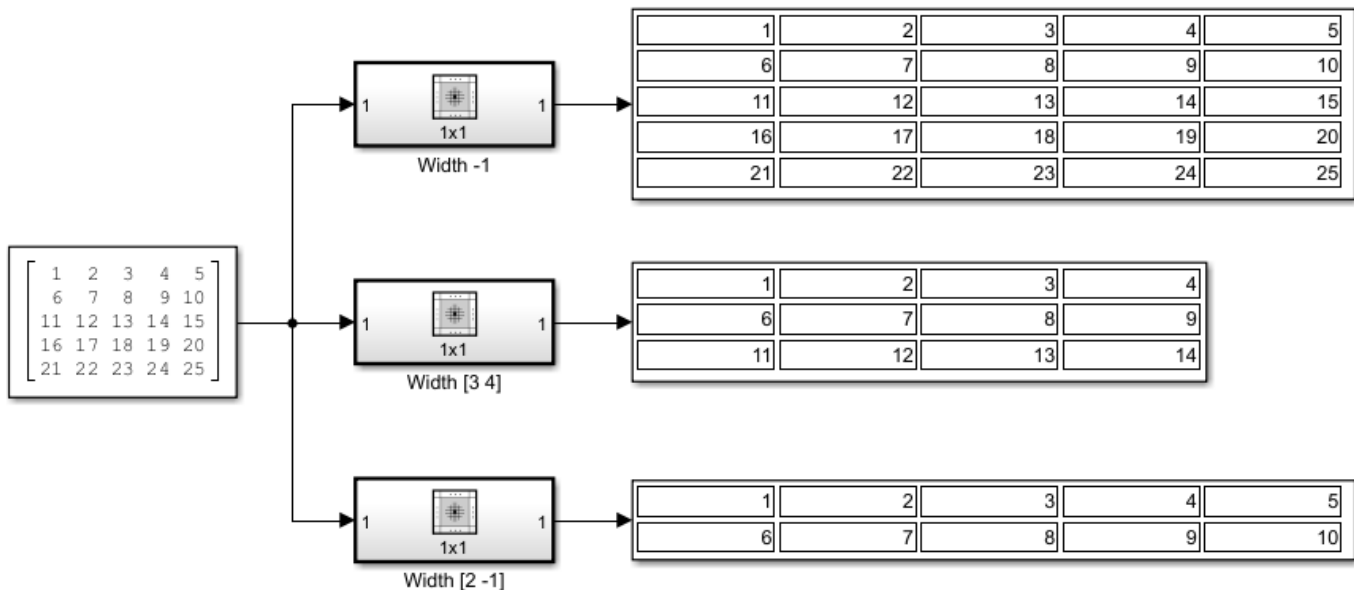

Configure the dimensions of the ROI of the input matrix to process. The dimensions of the **Processing width** parameter cannot exceed the dimensions of the input matrix.

For example, consider this input matrix:

$$\begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 6 & 7 & 8 & 9 & 10 \\ 11 & 12 & 13 & 14 & 15 \\ 16 & 17 & 18 & 19 & 20 \\ 21 & 22 & 23 & 24 & 25 \end{bmatrix}.$$

If you use the default **Processing width** parameter value of -1, then the Neighborhood Processing Subsystem block iterates over the entire input matrix. In this example, this behavior is equivalent to a **Processing width** parameter value of [5 5]. If you use a **Processing width** parameter value of [3 4], then the Neighborhood Processing Subsystem block iterates over only the top left 3-by-4 region of the input matrix.

You can use the value -1 within a **Processing width** parameter vector value to configure the Neighborhood Processing Subsystem block to iterate over the full length of a particular dimension. In the preceding example, if you use a **Processing width** parameter value of [2 -1], then the Neighborhood Processing Subsystem block iterates over the top 2-by-5 region of the input matrix.

Use the **Processing offset** and **Processing width** parameters together to define the top left and bottom right boundaries of a region of interest. For an example, see “Specify Region of Interest for Neighborhood Processing”.

Programmatic Use

Block Parameter: ProcessingWidth

Type: array

Values: -1 | '<array>'

Default: -1

Output size — Dimensions of output matrix

Same (default) | Full | Valid

Configure which ROI elements you want the Neighborhood Processing Subsystem block to iterate over by selecting the value Same, Full, or Valid. This determines the dimensions of the output matrix.

Each example graphic shows a 5-by-5 region of interest with three highlighted subsections.

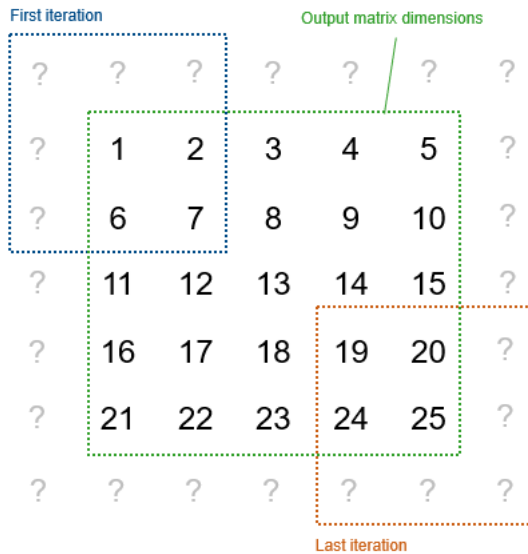

- The blue top left subsection represents the neighborhood that the Neighborhood Processing Subsystem block processes in the first iteration.
- The orange bottom right subsection represents the neighborhood of the last iteration.
- The green center subsection represents the dimensions of the output matrix, which spans the centers of the first and last iterations.

For settings that use padded values, the example graphics denote padded values as ?.

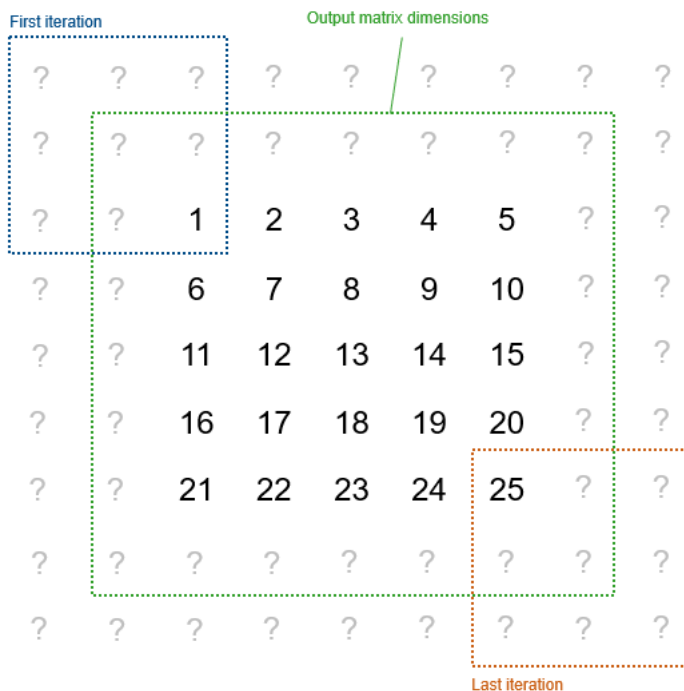

Each example graphic assumes a **Neighborhood size** parameter value of [3 3], which defines a 3-by-3 neighborhood. Because each example graphic assumes the default value of [0 0] for the **Processing offset** parameter and the default value of -1 for the **Processing width** parameter, the region of interest is the full input matrix. For information about how the Neighborhood Processing

Subsystem block pads values when you configure a region of interest, see “Use Neighborhood Processing Subsystem Block Padding Options with Region of Interest”.

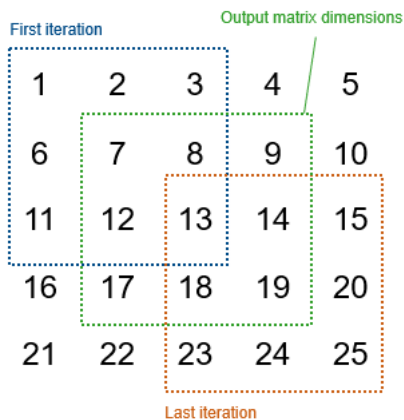

- **Same** -- The output matrix has the same dimensions as the region of interest. For elements near the edges, the neighborhood extends beyond the input matrix. Use the **Padding option** parameter to configure how to pad elements outside the input matrix.

- **Full** -- The output matrix is larger than the region of interest. The matrix includes an element for every neighborhood that includes at least one element from the region of interest, even if the neighborhood center is outside the region of interest. Use the **Padding option** parameter to configure how to pad elements outside the input matrix.

- **Valid** -- The output matrix is smaller than the region of interest. The output matrix includes only the elements whose neighborhoods fall entirely within the region of interest.

Programmatic Use

Block Parameter: OutputSize

Type: character vector

Values: 'Same' | 'Full' | 'Valid'

Default: 'Same'

Padding option — Values to use outside of input matrix

Constant (default) | Replicate | Symmetric | Circular

Configure how to pad values outside the input matrix. When you select the value **Full** or **Same** for the **Output size** parameter, some neighborhoods extend beyond the input matrix and use padded matrix element values.

To fully illustrate the logic of each padding option, each example graphic shows the 5-by-5 input matrix padded with 5-by-5 matrices. In practice, not every padded value is necessarily part of a neighborhood, depending on the **Neighborhood size** and **Output size** parameters. For example, if you set **Neighborhood size** to [3 3] and **Output size** to **Same**, the subsystem uses only the innermost layer of padded values.

- **Constant** -- Use a configurable constant value for elements outside the input matrix. For example, this matrix uses a constant value of 0.

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Neighborhood Processing Subsystem

Create algorithm that follows the neighborhood pattern

Libraries:
Simulink / Matrix Operations

Description

The Neighborhood Processing Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that follows the neighborhood pattern. At each simulation time step, the subsystem iterates over each element of an input array. For each element, the subsystem processes a neighborhood of values surrounding that element. Use the subsystem for image processing. Certain image processing algorithms involve processing images in sections rather than processing the entire image at once.

Configuring Subsystem

The Neighborhood Processing Subsystem contains a Neighborhood block that acts as a control block for the subsystem. Specify the parameters of the Neighborhood block to configure the behavior of the subsystem.

The **Neighborhood size** parameter controls the dimensions of the neighborhood. For elements near the edges of the input matrix, the neighborhood can extend beyond the input matrix. The **Padding option** parameter controls how the subsystem treats values from outside the input matrix. You can configure the subsystem to pad these values with a constant or by reusing values from inside the matrix. If you use the Constant padding option, use the **Padding constant** parameter to set the constant value.

You can configure the Neighborhood Processing Subsystem block to process only certain elements of an input matrix. Use the **Stride** parameter to configure the Neighborhood Processing Subsystem block to skip a certain number of elements at each iteration. Use the **Processing offset** and **Processing width** parameters to define the top left and bottom right boundaries, respectively, of a region of interest (ROI) within the image. The Neighborhood Processing Subsystem block iterates over only that region.

The **Output size** parameter controls the size of the output matrix. The **Same** value configures the output matrix to be the same size as the ROI. The **Full** value produces a larger output matrix by calculating values for elements outside the ROI whose neighborhoods include at least one element from the ROI. The **Valid** value creates a smaller output matrix by calculating values for only the elements whose neighborhoods do not extend beyond the ROI. When you use this setting, the **Padding constant** parameter is disabled.

Example

Consider this model.

In this example, the Neighborhood Processing Subsystem block takes a 5-by-5 matrix and outputs a matrix of the same dimensions by using the Same output size option. The subsystem contains these blocks.

Inside the Neighborhood Processing Subsystem block, the inport does not receive the full 5-by-5 matrix. Instead, because the **Neighborhood size** parameter value is [3 3], the inport receives a smaller, 3-by-3 window of elements. The subsystem iterates over the elements of the input matrix, passing the neighborhood of each element to the inport at each iteration.

The model uses the Constant padding option with a padding value of 0. For neighborhoods that extend beyond the input matrix, the subsystem treats the external values as 0.

The output of the Neighborhood Processing Subsystem block receives a scalar which represents the derived value for the element at the center of the window. In this case, a Sum of Elements block with the **Sum over** parameter set to All dimensions produces a scalar for each window, representing the sum of the values in that window.

Run the model to populate the Display block.

Each value of the output matrix is the sum of the corresponding element and its eight direct neighbors in the input matrix. The inner elements are surrounded by values of 1, and so have the value 9. The outer elements have lower values because the selected padding method uses the value 0 for elements outside the input matrix.

Limitations

- The Neighborhood Processing Subsystem block does not support Switch blocks when you use normal simulation mode. To use a Switch block inside a Neighborhood Processing Subsystem block, use the accelerator or rapid accelerator simulation mode. For a workaround in normal simulation mode, see the “Tips” on page 1-1447 section.
- The Neighborhood Processing Subsystem block does not support row-major layout.

Ports

Input

In — Signal input to a subsystem
matrix

Use Inport blocks to get signals from the local environment.

Placing an Inport block in a Neighborhood Processing Subsystem block adds an external input port to the subsystem. The port label matches the name of the Inport block. Use the Neighborhood control block to configure which input signals to process using the neighborhood pattern.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Out — Signal output from a subsystem
matrix

Use Outport blocks to send signals to the local environment.

Placing an Outport block in a Neighborhood Processing Subsystem block adds an external output port from the subsystem. The port label matches the name of the Outport block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Tips

- To improve performance, consider setting the Measure function execution times (Embedded Coder) configuration parameter to `Coarse` (referenced models and subsystems only) when you run software-in-the-loop (SIL) or processor-in-the-loop (PIL) profiling on a model that contains a Neighborhood Processing Subsystem block. Neighborhood Processing Subsystem blocks process large amounts of data, which can cause poor performance when you use the `Detailed` (all function call sites) option. For more information, see “Create Execution-Time Profile for Generated Code” (Embedded Coder).
- Switch blocks are useful in Neighborhood Processing Subsystem blocks for image processing tasks such as thresholding. Thresholding can convert an image to black and white by converting every pixel value to 255 or 0, depending on whether the input pixel value is greater than a given threshold value. For example, this Neighborhood Processing Subsystem block performs thresholding by using a Switch block with a threshold value of 110.

To perform thresholding in normal simulation mode, consider using a Relational Operator block that uses the `>` operator to recreate the Switch block behavior.

The Relational Operator block returns a value of 1 if the input value is greater than the threshold and otherwise returns 0. By sending this value to a Gain block with a value of 255, the subsystem returns 255 or 0.

Introduced in R2022b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

If this block is not the DUT, the block property settings in the **Target Specification** tab are ignored. In the HDL Workflow Advisor, if you use the **IP Core Generation** workflow, these target specification block property values are saved with the model. If you specify these target specification block property values using `hdlset_param`, when you open HDL Workflow Advisor, the fields are populated with the corresponding values.

Target Specification	
AdditionalTargetInterfaces	<p>Additional target interfaces, specified as a character vector.</p> <p>To save this block property on the model, in the Set Target Interface task of the IP Core Generation workflow, corresponding to the DUT ports that you want to add more interfaces, select Add more.... You can then add more interfaces in the Add New Target Interfaces dialog box. Specify the type of interface, number of additional interfaces, and a unique name for each additional interface.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: '{{'AXI4-Stream', 'InterfaceID', 'AXI4-Stream1'}}'</p>
ProcessorFPGASynchronization	<p>Processor/FPGA synchronization mode, specified as a character vector.</p> <p>To save this block property on the model, specify the Processor/FPGA Synchronization in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: Free running (default) Coprocessing - blocking</p> <p>Example: 'Free running'</p>
TestPointMapping	<p>To save this block property on the model, specify the mapping of test point ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: '{{'TestPoint', 'AXI4-Lite', 'x"108"'}}'</p>
TunableParameterMapping	<p>To save this block property on the model, specify the mapping of tunable parameter ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: '{{'myParam', 'AXI4-Lite', 'x"108"'}}'</p>
AXI4RegisterReadback	<p>To save this block property on the model, specify whether you want to enable readback on AXI4 subordinate write registers in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see "Model Design for AXI4 Slave Interface Generation" (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>
AXI4SlaveIDWidth	<p>To save this block property on the model, specify the number of AXI manager interfaces that you want to connect the DUT IP core to by using the AXI4 Slave ID Width setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see "Define Multiple AXI Master Interfaces in Reference Designs to Access DUT AXI4 Slave Interface" (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>

Target Specification	
AXI4SlavePortToPipelineRegisterRatio	<p>To save this block property on the model, specify the number of AXI4 subordinate ports for which you want a pipeline register to be inserted by using the AXI4 Slave port to pipeline register ratio setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” (HDL Coder).</p> <p>Values: 'off' (default) 'on' '10' '20' '35' '50'</p>
GenerateDefaultAXI4Slave	<p>To save this block property on the model, specify whether you want to disable generation of default AXI4 subordinate interfaces in the Generate RTL Code and IP Core task of the IP Core Generation workflow.</p> <p>Values: 'on' (default) 'off'</p>
IPCoreAdditionalFiles	<p>Verilog or VHDL files for black boxes in your design. Specify the full path to each file, and separate file names with a semicolon (;).</p> <p>You can set this property in the HDL Workflow Advisor, in the Additional source files field.</p> <p>Values: '' (default) character vector</p> <p>Example: 'C:\myprojfiles \led_blinking_file1.vhd;C:\myprojfiles \led_blinking_file2.vhd;'</p>
IPCoreName	<p>IP core name, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core name field. If this property is set to the default value, the HDL Workflow Advisor constructs the IP core name based on the name of the DUT.</p> <p>Values: '' (default) character vector</p> <p>Example: 'my_model_name'</p>
IPCoreVersion	<p>IP core version number, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core version field. If this property is set to the default value, the HDL Workflow Advisor sets the IP core version.</p> <p>Values: '' (default) character vector</p> <p>Example: '1.3'</p>

Target Specification	
IPDataCaptureBuffer Size	<p>FPGA Data Capture buffer size, specified as a character vector. Use FPGA Data Capture to observe signals in a design when running on an FPGA.</p> <p>The buffer size uses values that are $128 \cdot 2^n$, where n is an integer. By default, the buffer size is 128 ($n=0$). The maximum value of n is 13, which means that the maximum value for buffer size is 1048576 ($=128 \cdot 2^{13}$).</p> <p>Values: ' ' (default) character vector</p> <p>Example: '1.3'</p>

Restrictions

If your DUT is a masked subsystem, you can generate code only if it is at the top level of the model.

For more information, see:

- “External Component Interfaces” (HDL Coder)
- “Generate Black Box Interface for Subsystem” (HDL Coder)

Out Bus Element

Specify output that connects to external port

Libraries:

Simulink / Ports & Subsystems
 Simulink / Sinks
 HDL Coder / Ports & Subsystems
 HDL Coder / Sinks

Alternative Configurations of Out Bus Element Block:

Bus Element Out

Description

The Out Bus Element block, also known as the Bus Element Out block, combines the functionality of an Outputport block and a Bus Creator block. This block is of the Outputport block type, and all Out Bus Element blocks that correspond with the same port share a dialog box.

Use an Out Bus Element block to pass a bus, nonbus signal, or message to an output port of a model component. To group elements in a bus at an output port, use multiple Out Bus Element blocks for the same port.

For interfaces that include buses composed of many bus elements, Out Bus Element blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Allow you to more easily make incremental changes to the interface.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Creator and From block configuration.

To convert an interface to use Out Bus Element blocks, see “Simplify Subsystem and Model Interfaces with Bus Element Ports”.

The Out Bus Element block does not support mixing message and signal elements as inputs.

When you save output data to the workspace or a file, bus data defined by groups of root-level Out Bus Element blocks are logged along with root-level Outputport block data.

Examples

Create Output Bus Element Port

In a model component, each output bus element port is represented by one or more Out Bus Element blocks.

Open the example model named `CreateOutputBusElementPort`.

Copyright 2022 The MathWorks, Inc.

To add an output bus element port for a model, add an Out Bus Element port to the top level of the model. For example, double-click the canvas and start typing the block name. Then, select the Out Bus Element block.

To add an output bus element port to a subsystem, add an Out Bus Element block to the subsystem or click the edge of the Subsystem block and select **Create out bus port**.

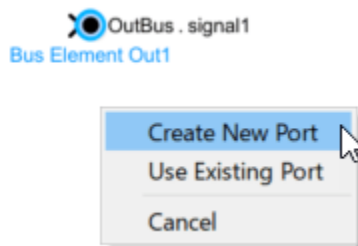

To open the subsystem, double-click the Subsystem block.

The subsystem contains a default Out Bus Element block that corresponds to the output port you created on the Subsystem block. The block label uses default values for its two interactive text fields: the port name (OutBus) and the bus element (signal1).

To create another output bus element port from inside a model component, hold **Ctrl** while you drag an existing Out Bus Element block to a new location. Upon releasing the pointer, click **Create New Port**.

An Out Bus Element block with a unique port name appears.

 OutBus . signal1

 OutBus1 . signal1

In this example, the new port is named `OutBus1`.

To edit the port name, click the port name in the block label. Then, enter a new name.

 ControlBus | signal1

Alternatively, set the **Port name** block parameter to the desired name for the port.

When multiple blocks are associated with the same port and you change the name of the port, all blocks that share the port update to reflect the new port name.

Output Signal Without Bus

When you have only one Out Bus Element block for a port, you can pass the block input to the output port without nesting it in a bus.

Open the example model named `SignalOutputBusPort`.

Copyright 2022 The MathWorks, Inc.

A Sine Wave block connects to an Out Bus Element block. Based on the block label, `OutBus . signal1`, the port output is a bus that contains an element named `signal1`. The dot in the block label indicates the bus hierarchy.

To pass the signal to the output port without nesting it in a bus, in the label of the Out Bus Element block, delete the text from the second text field. Then, click elsewhere on the canvas to commit the change.

 OutBus

To change the name of the port associated with the block, edit the first text field in the block label. In the block label, click `OutBus`.

 OutBus | signal1

Delete `OutBus` and enter `SineWave`. Ignore the placeholder text that shows where you can enter an element name.

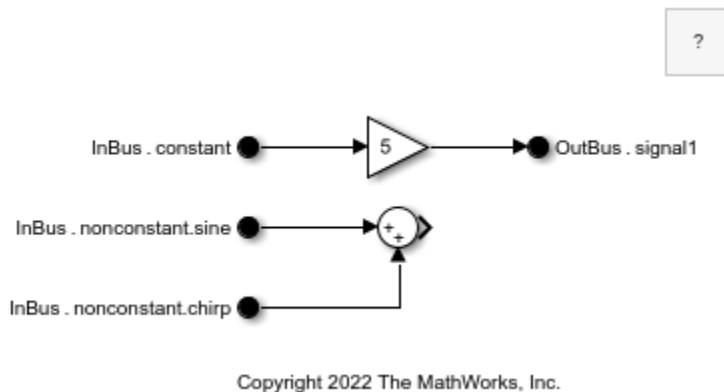

Alternatively, set the **Port name** block parameter to the desired name for the port.

Output Multiple Signals with One Port

To specify multiple elements for an output port, use an Out Bus Element block for each element that you want in the output. All element names associated with the same output port must be unique. The software does not support overlapping writes to the same port.

Open the example model named `SpecifyOutputElements`.

An Out Bus Element block writes to an element named `signal1` of a port named `OutBus`.

To rename an element, edit the second text field in the block label. For example, double-click `signal1` and enter `constant*5`.

Open the Property Inspector. Then, select the Out Bus Element block. Alternatively, double-click the block to open a dialog box.

The signal that the block selects is highlighted.

To add another element to the port, click **Add a new signal**.

An Out Bus Element block labeled `OutBus . signal1` appears in the block diagram.

In the Property Inspector or dialog box, double-click the name `signal1` and enter `sine+chirp`.

▼ OutBus

`constant*5`

`sine+chirp`

The corresponding block label updates.

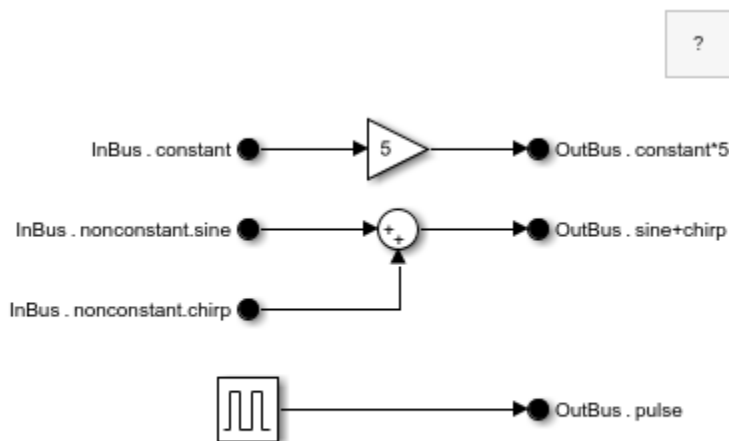

Connect the new Out Bus Element block to the unconnected port of the Sum block.

Create Multilevel Bus Hierarchy at Output Port

The default Out Bus Element block nests the output element in a bus. When the output port has many elements, organize the elements in nested buses within the output bus.

Open the example model named `OutputBusPortHierarchy`, which contains three Out Bus Element blocks.

Each dot in an Out Bus Element block label indicates a new level of hierarchy. To nest an element under another bus in the output bus, edit the second text field of the corresponding block label and add a dot after each nested bus in the hierarchy.

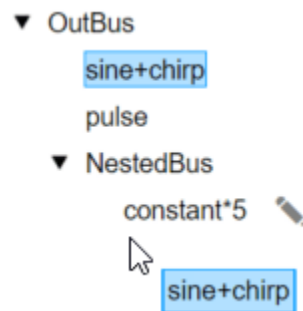

For example, click `constant*5`. Then, change it to `NestedBus.constant*5`.

This label creates an intermediate bus named `NestedBus` that contains `constant*5`.

To add elements to the new bus, you can similarly edit other block labels. Alternatively, double-click an Out Bus Element block or open the Property Inspector and select an Out Bus Element block.

To move elements within the output bus, select the elements to move and drag them to a new location. For example, drag the signal named `sine+chirp` into the nested bus.

The block label updates to indicate the new hierarchy.

To add a nested bus and leaf element to the output bus, along with the corresponding Out Bus Element block, click **Add a new sub-bus**.

The nested bus and element use default names.

Customize Appearance of In Bus Element and Out Bus Element Blocks

Use compact labels and block colors to customize the appearance of In Bus Element and Out Bus Element blocks.

Open the example model named `BusElementPortBlocks`.

The model contains:

- In Bus Element blocks that represent two unique bus element ports named `InBus` and `pulse`
- Out Bus Element blocks that represent a bus element port named `OutBus`

To reduce the size of the block labels, display only the leaf element names. Select an In Bus Element or Out Bus Element block, pause on the ellipsis, and in the action bar, click **Compact Notation**.

All In Bus Element and Out Bus Element blocks in the block diagram display shortened block labels that use only the leaf element name.

To show the full block label, in the action bar, you can click **Expanded Notation**. For this example, keep the compact block labels.

Block colors can help differentiate unique ports when the block labels are compact.

Open the Property Inspector. Then, select an In Bus Element block that corresponds with the port named InBus. For example, select the block labeled constant. Alternatively, double-click the block to open a dialog box.

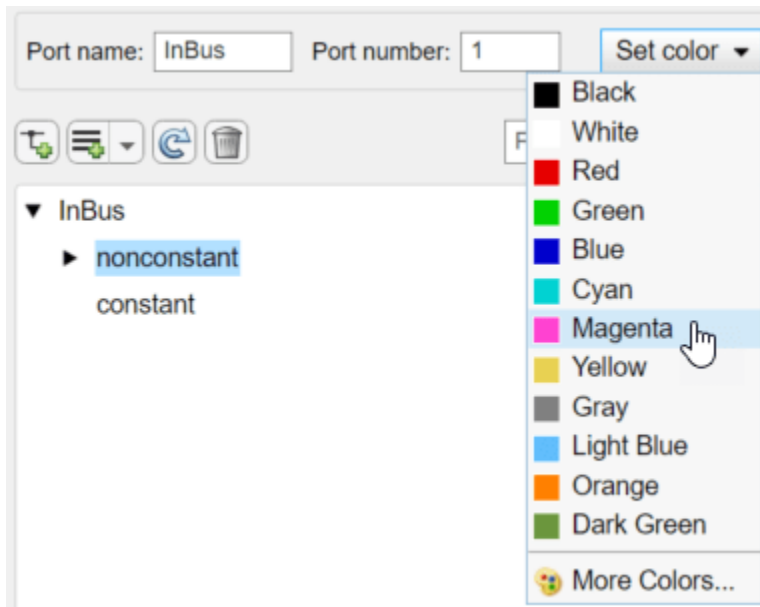

In the Property Inspector or dialog box, select InBus. Then, click **Set color** and select a color from the menu.

The blocks related to the port use the chosen color.

To identify the blocks that select the nested bus named nonconstant or its elements, select nonconstant. Then, click **Set color** and select a different color from the menu.

The blocks related to the nested bus use the chosen color.

Ports

Input

Port_1 — Full or partial output for external port

scalar | vector | matrix | array | bus

Connect a bus, signal, or message to pass to the corresponding external output port of the parent subsystem or model.

When multiple Out Bus Element blocks are associated with the same external port, the input to this block is an element of the bus at the output port. The second text field in the block label specifies the element name.

When one Out Bus Element block is associated with the external port, the input to this block is passed directly to the output port or nested in a bus at the output port. To pass the input of the block to the output port without nesting it in a bus, delete the text from the second text field in the block label.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To interactively edit the parameters of the block, the corresponding port, and the elements at the port, double-click the block or open the **Property Inspector** and select the block.

Port name — Name of output port

`OutBus` (default) | port name

Specify a port name that is not already in use by another block or port. The name appears on the parent Subsystem or Model block. The name also appears next to the block. Multiple blocks can access the same port.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	PortName
Values:	'OutBus' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/PortBlock','PortName','myBus')`

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	Port
Values:	'1' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/PortBlock','Port','5')`

Set color — Block background color

`Black` (default) | `White` | `Red` | `Green` | `Blue` | `Cyan` | `Magenta` | `Yellow` | `Gray` | `Light Blue` | `Orange` | `Dark Green` | `More Colors`

Specify the block background color. This specification sets the color of blocks associated with selected bus elements, or of all blocks associated with the port if you do not select any bus elements.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	BackgroundColor
Values:	'black' (default) 'white' 'red' 'green' 'blue' 'cyan' 'magenta' 'yellow' 'gray' 'lightBlue' 'orange' 'darkGreen' '[r,g,b]' where r, g, and b, are the red, green, blue values of the color in the range 0.0 to 1.0

Example: `set_param('mymodel/Subsystem1/PortBlock', 'BackgroundColor', 'magenta')`

Filter — Filter for set of displayed signals

no default

Specify a search term to use for filtering a long list of bus elements. Do not enclose the search term in quotation marks. The filter does a partial string search and supports regular expressions. To use a regular expression character as a literal, include an escape character (`\`). For example, to use a question mark, type `sig\?1`.

Attributes

To specify attributes, such as data type, pause on the name of a bus, signal, or message. Then, click the pencil button  that appears.

When you specify attributes, they appear next to the name of the bus, signal, or message. Click an attribute summary to edit the attributes of the bus, signal, or message.

▼ Bus (dt: Bus: BusObject, dims: 1)
 element1 (dt: double, dims: [1])

Data type — Data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

The data type of a bus, signal, or message can be inherited, specified directly, or expressed as a data type object such as a `Simulink.NumericType` object.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify `single` or `uint8`. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the `fixdt` function. For example, specify `fixdt(1,16,0)`.
- Enumerated data type — Use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.
- Bus data type — Use the name of the `Simulink.Bus` object preceded by `Bus:`. For example, specify `Bus: myBusObject`.
- Value type — Use the name of the `Simulink.ValueType` object preceded by `ValueType:`. For example, specify `ValueType: windVelocity`.

- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a `Simulink.NumericType` object whose `DataTypeMode` property is set to a value other than `'Fixed-point: unspecified scaling'`.

When you specify a `Simulink.ValueType` object as the data type, some parameters of the element are ignored. For example, the **Min**, **Max**, and **Unit** parameters are ignored. The software uses the corresponding properties of the `Simulink.ValueType` object. For example, suppose you set **Unit** to `ft/s` for an element. When the **Data type** of the element specifies a `ValueType` object that has `m/s` as its unit, the element uses `m/s` instead of `ft/s`.

When you specify a `Simulink.Bus` object as the data type, some parameters of the element are reset to their default values. For example, the **Min**, **Max**, and **Unit** parameters are reset. The software uses the corresponding properties of the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Tips

When you specify a bus using a `Simulink.Bus` object or a `Simulink.ValueType` object with a `Simulink.Bus` object data type, the Property Inspector and block dialog box display the elements defined by the corresponding `Simulink.BusElement` objects.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	<code>OutDataTypeStr</code>
Values:	<code>'Inherit: auto'</code> (default) <code>'double'</code> <code>'single'</code> <code>'half'</code> <code>'int8'</code> <code>'uint8'</code> <code>'int16'</code> <code>'uint16'</code> <code>'int32'</code> <code>'uint32'</code> <code>'int64'</code> <code>'uint64'</code> <code>'boolean'</code> <code>'fixdt(1,16)'</code> <code>'fixdt(1,16,0)'</code> <code>'fixdt(1,16,2^0,0)'</code> <code>'string'</code> <code>'Enum: <class name>'</code> <code>'Bus: <object name>'</code> <code>'ValueType: <object name>'</code> <code><data type expression></code>

Example: `set_param('mymodel/Subsystem1/myBus.signal1','OutDataTypeStr','int32')`

Data mode — Data mode of bus elements

`inherit` (default) | `signal` | `message`

Specify the data mode of the elements of the bus.

- `inherit` — Bus elements inherit their data modes.
- `signal` — Bus elements must be signals.
- `message` — Bus elements must be messages.

Dependencies

To enable this parameter, the block must be at the top level of a model.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	<code>DataMode</code>
Values:	<code>'inherit'</code> (default) <code>'signal'</code> <code>'message'</code>

Example: `set_param('mymodel/OutBus','DataMode','signal')`

Bus virtuality — Virtual or nonvirtual bus
`inherit` (default) | `virtual` | `nonvirtual`

Specify whether to inherit the bus virtuality or define the bus as virtual or nonvirtual. For more information, see “Composite Interface Guidelines”.

This parameter determines whether the blocks inherit or define the bus virtuality. If the blocks define the bus virtuality and the virtuality of the input bus does not match, compiling the model produces an error.

Dependencies

To enable this parameter, **Data type** must resolve to a `Simulink.Bus` object. For example, set **Data type** to a `Simulink.Bus` object or a `Simulink.ValueType` object that specifies a `Simulink.Bus` object as its data type.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	<code>BusVirtuality</code>
Values:	<code>'inherit'</code> (default) <code>'virtual'</code> <code>'nonvirtual'</code>

Example: `set_param('mymodel/Subsystem1/myBus.nestedBus','BusVirtuality','nonvirtual')`

Dimensions — Signal dimensions
`-1` (default) | `integer` | [`integer`, `integer`]

Specify the dimensions of a signal.

- `-1` — The signal can have any dimensions.
- `N` — The signal must be a vector of size `N`.
- [`R` `C`] — The signal must be a matrix having `R` rows and `C` columns.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to `1`. The software uses the dimensions specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the dimensions specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	<code>PortDimensions</code>
Values:	<code>'-1'</code> (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','PortDimensions','[1 3]')`

Dims mode — Option to allow only variable-size or fixed-size signals
 Inherit (default) | Fixed | Variable

Specify the type of signals allowed.

- **Inherit** — Allow variable-size and fixed-size signals.
- **Variable** — Allow only variable-size signals.
- **Fixed** — Allow only fixed-size signals. Do not allow variable-size signals.

When the signal is variable-sized, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to **Inherit**. The software uses the dimensions modes specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the dimensions mode specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	VarSizeSig
Values:	'Inherit' (default) 'No' 'Yes'

Example: `set_param('mymodel/Subsystem1/myBus.signal1','VarSizeSig','No')`

Unit — Physical unit

inherit (default) | unit supported by Simulink software

Specify the physical unit of the signal. For a list of supported units, in the MATLAB Command Window, enter `showunitslist`.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to **inherit**. The software uses the units specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the unit specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	Unit
Values:	'inherit' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','Unit','m/s')`

Complexity — Numeric type

auto (default) | real | complex

Specify the numeric type of the signal. To choose the numeric type of the signal, select **auto**. Otherwise, choose a real or complex signal type.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to **auto**. The software uses the complexity specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the complexity specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	SignalType
Values:	'auto' (default) 'real' 'complex'

Example: `set_param('mymodel/Subsystem1/myBus.signal1','SignalType','real')`

Minimum — Minimum value

[] (default) | scalar

Lower value of the range that the software checks.

This number must be a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see [Optimize using the specified minimum and maximum values \(Embedded Coder\)](#).

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to []. The software uses the minimum values specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the minimum value specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	OutMin
Values:	' [] ' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','OutMin','0')`

Maximum — Maximum value

[] (default) | scalar

Upper value of the range that the software checks.

This number must be a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to []. The software uses the maximum values specified by the `Simulink.BusElement` objects in the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the maximum value specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	OutMax
Values:	' [] ' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','OutMax','2')`

Description — Description of bus, bus element, signal, or message

no default

Use the description to document information about the bus, signal, or message, such as where it is used. This information does not affect processing.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to '' (empty). The software uses the description specified by the `Simulink.Bus` object.
- When **Data type** specifies a `Simulink.ValueType` object, the software ignores the value of this parameter. The software uses the description specified by the `Simulink.ValueType` object instead.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	Description
Values:	' ' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','Description','This signal is used by...')`

Output name — Name of output bus, signal, or message in parent subsystem or model
no default

Specify the name of the output bus, signal, or message in the parent subsystem or model. The name appears as a label on the line.

To display propagated labels for individual lines or all lines in a model, see “Display Propagated Signal Labels”.

Dependencies

- To enable this parameter:
 - The block must be at the top level of a model.
 - The element must be the top-level bus, signal, or message.
- When **Data type** specifies a `Simulink.Bus` object, the software sets this parameter to "" (empty).

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	OutputName
Values:	"" (default) character vector string scalar
Data Types:	char string

Example: `set_param('mymodel/OutBus','OutputName','model-output')`

Execution Attributes

To specify execution attributes, such as sample time, pause on the name of a bus, signal, or message.

Then, click Specify execution attributes .

Sample time — Sample time
-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another type of sample time, such as continuous (0) or inherited (-1). For more options, see “Types of Sample Time”.

By default, the signal inherits its sample time.

Programmatic Use

To programmatically set the attribute value for an element, use the `set_param` function, specifying the element as the block path of the model component with the element label.

Parameter:	SampleTime
Values:	'-1' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/myBus.signal1','SampleTime','0.01')`

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string

 `OutBus.signal1` **Bus Element Out** — Specify output that connects to external port

The Bus Element Out block differs from the Out Bus Element block by name only.

Libraries:

Simulink / Signal Routing
HDL Coder / Signal Routing

Version History

Introduced in R2017a

R2023a: Specify name of port output

For an Out Bus Element block at the top level of a model, use the **Output name** block parameter to specify the name of the top-level bus, signal, or message that appears in a parent subsystem or model.

R2023a: Property Inspector supports In Bus Element blocks

The **Property Inspector** supports In Bus Element and Out Bus Element blocks.

R2023a: Messages link to related In Bus Element blocks

Warning and error messages for In Bus Element and Out Bus Element blocks now link to the corresponding block in the block diagram, helping you quickly find the source of the warning or error. In previous releases, warning and error messages refer to a hidden block and do not provide a link.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used to simplify subsystem bus interfaces when you use the block in subsystems that generate HDL code, but it is not included in the hardware implementation.

To learn more about using buses for HDL code generation, see “Buses” (HDL Coder) and “Use Bus Signals to Improve Readability of Model and Generate HDL Code” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Output

Create output port for subsystem or external output

**Libraries:**

Simulink / Commonly Used Blocks

Simulink / Ports & Subsystems

Simulink / Sinks

HDL Coder / Commonly Used Blocks

HDL Coder / Ports & Subsystems

HDL Coder / Sinks

Description

Output blocks link signals from a system to a destination outside of the system. They can connect signals flowing from a subsystem to other parts of the model. They can also supply external outputs at the top level of a model hierarchy.

Output block port numbers are assigned according to these rules:

- Output blocks within a root-level system or subsystem are numbered sequentially, starting with 1.
- If you add an Output block, it is assigned the next available number.
- If you delete an Output block, other port numbers are automatically renumbered to ensure that the Output blocks are in sequence and that no numbers are omitted.

Output Blocks in a Subsystem

Output blocks in a subsystem represent outputs from the subsystem. A signal arriving at an Output block in a subsystem flows out of the associated output port on that Subsystem block. The Output block associated with an output port is the block whose **Port number** parameter matches the relative position of the output port on the Subsystem block. For example, the Output block whose **Port number** parameter is 1 sends its signal to the block connected to the topmost output port on the Subsystem block.

If you renumber the **Port number** of an Output block, the block becomes connected to a different output port. The block continues to send the signal to the same block outside the subsystem.

You can directly edit port labels on a Subsystem block. For more information, see “Edit Port Labels on Subsystems”.

Tip For models that include buses composed of many bus elements, consider using In Bus Element and Out Bus Element blocks. These blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport and the Out Bus Element block is of block type Output.

Top-Level Output Block in a Model Hierarchy

Output blocks at the top level of a model hierarchy have two uses. They can supply external outputs to the base MATLAB workspace, and they provide a means for the `linmod` and `trim` analysis functions to obtain output from the system.

To supply external outputs to the workspace, use the **Configuration Parameters > Data Import/Export** pane (see Exporting Output Data to the MATLAB Workspace) or the `sim` command. For example, if a system has more than one Output block and the save format is array, this command

```
[t,x,y] = sim(...);
```

writes `y` as a matrix, with each column containing data for a different Output block. The column order matches the order of the port numbers for the Output blocks.

If you specify more than one variable name after the second (state) argument, data from each Output block is written to a different variable. For example, if the system has two Output blocks, to save data from Output block 1 to `speed` and the data from Output block 2 to `dist`, specify this command:

```
[t,x,speed,dist] = sim(...);
```

Connecting Buses to Root-Level Outputs

A root-level Output block in a model can accept a virtual bus only if all elements of the bus have the same data type. The Output block automatically unifies the bus to a vector having the same number of elements as the bus, and provides that vector as output.

If you want a root-level Output block of a model to accept a bus that contains mixed types, set the Output block **Data type** to `Bus: <object name>`. If the bus is virtual, it is converted to nonvirtual, as described in “Virtual and Nonvirtual Bus Conversions”.

Associate Root-Level Output Block with Simulink.Signal Object

To associate a root-level Output block with a `Simulink.Signal` object, use the Model Data Editor. See “For Signals”.

Ports

Input

Port_1 — Output signal
scalar | vector

Input signal that flows through the output to an external subsystem or model.

An Output block can accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as its input.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Main

Port number — Position of port on parent block

1 (default) | real integer

Specify the order in which the port that corresponds to the block appears on the parent Subsystem or Model block.

- If you add a block that creates another port, the port number is the next available number.
- Deleting all blocks associated with a port deletes the port. Other ports are renumbered so that they are sequential and do not skip any numbers.
- Specifying a port number that exceeds the number of ports creates a port for that number and for any skipped sequential numbers.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	Port
Values:	'1' (default) character vector string scalar

Example: `set_param('mymodel/Subsystem1/PortBlock','Port','5')`

Signal name — Signal name

' ' (default) | character vector

Specify the name of the corresponding signal data in the generated code. Use this parameter to specify a name for the signal data when you apply a storage class to a root-level Outport block.

Programmatic Use

Block Parameter: SignalName

Type: character vector

Values: character vector

Default: ' '

Icon display — Icon display

Port number (default) | Signal name | Port number and signal name

Specify the information displayed on the block icon.

Programmatic Use

Block Parameter: IconDisplay

Type: character vector

Values: 'Signal name' | 'Port number' | 'Port number and signal name'

Default: 'Port number'

Specify output when source is unconnected — Specify unconnected output value

off (default) | on

Specify a constant output value for when source is not connected.

Dependencies

Available for unconnected Outport blocks inside a Variant Subsystem block.

Programmatic Use

Block Parameter: OutputWhenUnconnected

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Constant value — Output value when the block is not connected

0 (default) | scalar | vector

Specify a constant output value for when source is not connected.

Dependencies

Available in a Variant Subsystem block for an unconnected Outport block with **Specify output when source is unconnected** selected.

Programmatic Use

Block Parameter: OutputWhenUnconnectedValue

Type: character vector

Values: scalar | vector

Default: '0'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to create a vector of length N at the output if the **Constant value** parameter evaluates to an N-element row or column vector.

Dependencies

Available in a Variant Subsystem block on an unconnected Outport block when you select the **Specify output when source is unconnected** parameter.

Programmatic Use

Block Parameter: VectorParamsAs1DForOutWhenUnconnected

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Ensure output is virtual — Ensure that output is virtual

off (default) | on

Clear this parameter to allow Simulink to use a signal buffer on output port. This buffer, which is the equivalent of a Signal Copy block but is not displayed on the canvas, ensures consistent initialization of the Outport block signal.

If you select this parameter, Simulink tries to remove the signal buffer.

- If the signal buffer is not needed, Simulink removes the buffer.

- If the signal buffer is needed for data consistency and proper execution, Simulink displays an error indicating the buffer could not be removed.

Allow partial writes through Assignment blocks.

For more information regarding this parameter, including examples with conditional writes and partial writes, see “Ensure Output Port Is Virtual”.

Dependencies

This parameter applies to these blocks:

- Conditional subsystem
- Assignment
- Merge
- Model with root Output block

Programmatic Use

Block Parameter: EnsureOutputIsVirtual

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Source of initial output value — Source of initial output value

Dialog (default) | Input signal

Select the source of the initial output value of the block. Select `Dialog` to specify that the initial output value is the value of the **Initial output** parameter. Select `Input signal` to specify that the initial output value is inherited from the input signal. See “Conditional Subsystem Initial Output Values”.

Tips

- If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from the input signal, set this parameter to `Dialog` and specify `[]` (empty matrix) for the **Initial output** value. For more information, see “Conditional Subsystem Initial Output Values”.

Dependencies

Available for Output blocks inside a conditional subsystem.

Programmatic Use

Block Parameter: SourceOfInitialOutputValue

Type: character vector

Values: 'Dialog' | 'Input signal'

Default: 'Dialog'

Output when disabled — Output when disabled

held (default) | reset

Specify what happens to the block output when the subsystem is disabled. Select `held` to indicate that the output is held when the subsystem is disabled. Select `reset` to indicate that the output is reset to the value given by **Initial output** when the subsystem is disabled.

Dependencies

Available when you select `Dialog` as the value for the **Source of initial output** parameter for an Output block inside a conditional subsystem with valid enabling and disabling semantics. For example, the parameter is available for an Output block inside an Enabled Subsystem block and not for an Output block inside a Triggered Subsystem block.

If an Output block is inside a Function-Call Subsystem block, this parameter is only meaningful if the Function-Call Subsystem block is connected to a state in a Stateflow chart. For more information, see “Bind a Function-Call Subsystem to a State” (Stateflow).

When connecting the output of a conditional subsystem to a Merge block, set this parameter to `held`. Setting it to `reset` returns an error.

Programmatic Use

Block Parameter: `OutputWhenDisabled`

Type: character vector

Values: `'held'` | `'reset'`

Default: `'held'`

Initial output — Initial output for conditionally executed subsystems

`[]` (default) | scalar | structure

For conditionally executed subsystems, specify the block output before the subsystem executes and while it is disabled. Specify `[]` to inherit the initial output value from the input signal. For more information, see “Conditional Subsystem Initial Output Values”.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Elements”.

Tips

If the conditional subsystem is driving a Merge block, you do not need to specify an Initial Condition (IC) for the Output block. For more information, see “Underspecified initialization detection”.

Dependencies

Available when **Source of initial output value** is set to `Dialog` for an Output block in a conditional subsystem.

Limitations

- This block does not allow an initial output of `inf` or `NaN`.
- When the input is a virtual bus, an **Initial output** value `[]` is treated as `double(0)`.
- When the input contains a nonvirtual bus, **Initial output** does not support nonzero scalar values.

Programmatic Use

Block Parameter: `InitialOutput`

Type: character vector

Values: `[]` | scalar | structure

Default: `[]`

Signal Attributes

Minimum — Minimum output value

[] (default) | scalar

Lower value of the output range that the software checks.

This number must be a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the minimum values specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Maximum — Maximum output value

[] (default) | scalar

Upper value of the output range that the software checks.

This number must be a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the maximum values specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Data type** — Output data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as a `Simulink.NumericType` object.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify `single` or `uint8`. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the `fixdt` function. For example, specify `fixdt(1,16,0)`.
- Enumerated data type — Use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.
- Bus data type — Use the name of the `Simulink.Bus` object preceded by `Bus:`. For example, specify `Bus: myBusObject`.
- Simulink image data type — If you have Computer Vision Toolbox, use the constructor for the `Simulink.ImageType` object and specify the properties to describe the image. By default, the data type uses the `Simulink.ImageType(480,640,3)` expression that represents the rows, columns, and channels of the image respectively.
- Value type — Use the name of the `Simulink.ValueType` object preceded by `ValueType:`. For example, specify `ValueType: windVelocity`.
- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a `Simulink.NumericType` object whose `DataTypeMode` property is set to a value other than `'Fixed-point: unspecified scaling'`.

When you specify a `Simulink.ValueType` or `Simulink.Bus` object as the data type, some parameters of the Output block are ignored. For example, the **Min**, **Max**, and **Unit** parameters of the Output block are ignored. The software uses the corresponding properties of the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead. For example, suppose a block sets **Unit** to ft/s. When the **Data type** of the block specifies a `ValueType` object that has m/s as its unit, the block uses m/s instead of ft/s.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | 'Enum: <class name>' | 'Bus:

<object name>' | 'ValueType: <object name>' | '<data type expression>' |
Simulink.ImageType(480,640,3)
Default: 'Inherit: auto'

Lock output data type setting against changes by the fixed-point tools — Option to prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the output data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` object.

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Output as nonvirtual bus in parent model — Output as nonvirtual bus in parent model

off (default) | on

Specify the output bus to be nonvirtual in the parent model. Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

Clear this parameter if you want the bus emerging in the parent model to be virtual.

Tips

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see “Modify Sample Times for Nonvirtual Buses”.

To use a multirate signal for a virtual bus, in the root-level Outport block, set the **Sample time** parameter to inherited (-1).

- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus output of this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependencies

To enable this parameter, **Data type** must resolve to a `Simulink.Bus` object. For example, set **Data type** to a `Simulink.Bus` object or a `Simulink.ValueType` object that specifies a `Simulink.Bus` object as its data type.

Programmatic Use

Block Parameter: BusOutputAsStruct

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Unit (e.g., m, m/s², N*m) — Physical unit of the input signal to the block

inherit (default) | <Enter unit>

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a Simulink.ValueType or Simulink.Bus object. The software uses the units specified by the Simulink.ValueType object or the Simulink.BusElement objects in the Simulink.Bus object instead.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Port dimensions (-1 for inherited) — Port dimensions

-1 (default) | integer | [integer, integer]

Specify the dimensions that a signal must have to be connected to this Outport block.

-1	A signal of any dimensions can be connected to this port.
N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a Simulink.ValueType object. The software uses the dimensions specified by the Simulink.ValueType object instead.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '-1' | integer | [integer, integer]

Default: '-1'

Variable-size signal — Allow variable-size signals

Inherit (default) | No | Yes

Specify the type of signals allowed at the output of this port. To allow variable-size and fixed-size signals, select **Inherit**. To allow only variable-size signals, select **Yes**. To allow only fixed-size signals, select **No**.

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` object. The software uses the dimensions mode specified by the `Simulink.ValueType` object instead.

Programmatic Use

Parameter: `VarSizeSig`

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Signal type — Output signal type

auto (default) | real | complex

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select **auto**. Otherwise, choose a real or complex signal type.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the complexity specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use

Block Parameter: `SignalType`

Type: character vector

Values: 'auto' | 'real' | 'complex'

Default: 'auto'

Execution

Sample time (-1 for inherited) — Option to specify sample time

-1 (default) | scalar

Specify the discrete interval between sample time hits or specify another type of sample time, such as continuous (0) or inherited (-1). For more options, see “Types of Sample Time”.

By default, the block inherits its sample time based upon the context of the block within the model.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar

Default: '-1'

Block Characteristics

Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

General		
BalanceDelays	BalanceDelays Setting	Description
	on (default)	Detects introduction of delays on other paths in the DUT and inserts matching delays on the Outport block path.
	off	Disable delay balancing on output ports in your DUT subsystem to prevent HDL Coder from inserting matching delays when they are unnecessary. For example, disable BalanceDelays on an Outport block in your DUT subsystem when treating a manually added output port as a test point.
Note This property affects only DUT-level Outport blocks.		

General		
BidirectionalPort	BidirectionalPort Setting	Description
	on	Specify the port as bidirectional. The following requirements apply: <ul style="list-style-type: none"> • The port must be in a Subsystem block with black box implementation. • There must also be no logic between the bidirectional port and the corresponding top-level DUT subsystem port. For more information, see “Specify Bidirectional Ports” (HDL Coder).
	off (default)	Do not specify the port as bidirectional.
Target Specification		
IOInterface	Target platform interface type for DUT ports, specified as a character vector. The IOInterface block property is ignored for Inport and Outputport blocks that are not DUT ports. To specify valid IOInterface settings, use the HDL Workflow Advisor: <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. 2 Save the model. The IOInterface value is saved as an HDL block property of the port. For example, to view the IOInterface value, if the full path to your DUT port is hdlcoder_led_blinking/led_counter/LED, enter: hdlget_param('hdlcoder_led_blinking/led_counter/LED', 'IOInterface')	

Target Specification	
IOInterfaceMapping	<p>Target platform interface port mapping for DUT ports, specified as a character vector. The <code>IOInterfaceMapping</code> block property is ignored for Inport and Outport blocks that are not DUT ports.</p> <p>To specify valid <code>IOInterfaceMapping</code> settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, in the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, use the drop-down list to set the target platform interface type. 2 In the Bit Range / Address / FPGA Pin column, if you want to change the default value, enter a target platform interface mapping. 3 Save the model. <p>The <code>IOInterfaceMapping</code> value is saved as an HDL block property of the port.</p> <p>For example, to view the <code>IOInterfaceMapping</code> value, if the full path to your DUT port is <code>hdlcoder_led_blinking/led_counter/LED</code>, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED',... 'IOInterfaceMapping')</pre>
IOInterfaceOptions	<p>Target platform interface port mapping options for DUT ports, specified as a character vector. The <code>IOInterfaceOptions</code> block property is ignored for Inport and Outport blocks that are not DUT ports.</p> <p>To specify valid <code>IOInterfaceOptions</code> settings, use the HDL Workflow Advisor:</p> <ol style="list-style-type: none"> 1 In the HDL Workflow Advisor, on the Set Target > Set Target Interface step, in the Target platform interface table, in the Target Platform Interfaces column, map the input or output ports to an AXI4 subordinate interface. 2 In the Interface Options column, if you want to change the default initial value, click the Options button and enter a value for RegisterInitialValue. 3 Save the model. <p>The <code>IOInterfaceOptions</code> value is saved as an HDL block property of the port.</p> <p>For example, to view the <code>IOInterfaceOptions</code> value, if the full path to your DUT port is <code>hdlcoder_led_blinking/led_counter/LED</code>, enter:</p> <pre>hdlget_param('hdlcoder_led_blinking/led_counter/LED',... 'IOInterfaceOptions')</pre>

PLC Code Generation

Parameter Writer

Write to block parameter or model workspace variable

Libraries:
Simulink / Signal Routing

Description

The Parameter Writer block changes block parameter values by writing to one of the following:

- A parameter of a block that is tunable during simulation
- An instance parameter that belongs to a Model block that references a model
- A masked subsystem parameter
- A model workspace variable

A block with a parameter that can be written by a Parameter Writer block is called a parameter owner block. For the Parameter Writer block to find the supported parameters of a parameter owner block, the supported parameters must be enabled.

Use the Parameter Writer block with the Initialize Function, Reinitialize Function, and Reset Function blocks to respond to events. For example, an event could be reading the value from a hardware sensor and then updating a block parameter based on the sensor value.

For more information about using the Parameter Writer block, see Initialize and Reset Parameter Values.

Otherwise, a Parameter Writer block must be in the same task as either:

- The block whose parameter is directly written by the Parameter Writer block, which could be a built-in block such as a Gain block, a Model block, a masked subsystem block, or a User-Defined Functions block such as an S-Function block
- The block whose parameter is indirectly written through a model workspace variable

To write to a model workspace variable, mask parameter, or Model block instance parameter with a Parameter Writer block, the model workspace variable, mask parameter, or Model block instance parameter must be used by a parameter owner block or C MEX S-function with run-time tunable parameters.

For a Parameter Writer block in a masked subsystem, the Parameter Writer block and corresponding parameter owner block must have the same immediate parent masked subsystem.

When a Parameter Writer block writes to an instance parameter with storage class set to `Model default`, the code generator uses the default configuration for **Model parameter arguments** when generating code for the parameter. See “Specify Instance-Specific Parameter Values for Reusable Referenced Model” (Simulink Coder).

When you create a library block with a Parameter Writer block, you must also include the corresponding parameter owner block in the library block.

Identify Parameter Owner Blocks

You can determine whether a block is a supported parameter owner block by the value of the `IsParamOwnerBlock` block parameter. Use the `get_param` function with the block name or handle, `blk`, and the `IsParamOwnerBlock` block parameter.

```
get_param(blk, 'IsParamOwnerBlock')
```

The function returns 'on' if the block is a supported parameter owner block and 'off' otherwise.

A Parameter Writer block and the parameter owner block of the value that the block writes constitute a set of related blocks. You can select a Parameter Writer block to highlight the related parameter owner block or vice versa. When a related block is highlighted, blocks in the current model that contain the related block are also highlighted. For example, an Initialize Function block is highlighted when it contains a Parameter Writer block that is related to the selected block. The blocks that are highlighted in the model canvas are also highlighted in the miniature map.

To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select the **Related Blocks** button  from the action bar. Window focus goes to the open diagram or new tab that shows the related block.

Limitations

A Parameter Writer block cannot be placed in a Simulink function.

Ports

Input

In — Parameter value
scalar | vector

Parameter value written by the block.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Validate parameter — Option to validate parameter during normal mode simulation

on (default) | off

Locally enable parameter validation for this block.

When parameter validation is disabled for a Parameter Writer block, normal mode simulation of the block is faster.

Tips

To globally enable or disable parameter validation for Parameter Writer blocks, use the **Parameter Writer block validation** configuration parameter.

Dependencies

To disable parameter validation for this block, the block must not directly or indirectly change the value of a Model block instance parameter. For example, the block must not change the value of a model workspace variable or mask parameter that specifies the value of a Model block instance parameter.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	IsParameterValidationOn
Values:	'on' (default) 'off'

Example: `set_param(gcb, 'IsParameterValidationOn', 'off')`

Access model workspace parameter — Option to write to model workspace variable instead of block parameter

off (default) | on

Select this parameter to write to a model workspace variable, as specified by the **Model workspace parameter name** parameter.

Clear this parameter to write to a tunable block parameter, model instance parameter, or masked subsystem parameter, as specified by the **Parameter owner block** parameter.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	AccessWorkspaceVariable
Values:	'off' (default) 'on'

Example: `set_param(gcb, 'AccessWorkspaceVariable', 'on')`

Model workspace parameter name — Name of model workspace variable

no default

Specify the name of the model workspace variable whose value this block writes.

Dependencies

To enable this parameter, select the **Access model workspace parameter** parameter.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	WorkspaceVariableName
Values:	' ' (default) character vector string scalar

Example: `set_param(gcb, 'WorkspaceVariableName', 'var')`

Parameter owner block — Block path of parameter owner block and name of block parameter

no default

Specify the block path of the parameter owner block and the name of the parameter whose value this block writes.

The **Parameter Owner Selector Tree** provides the writable parameters in a hierarchical tree list. Expand the nodes on the path to the parameter owner block. Then, select the parameter under the parameter owner block.

Tips

If the name of a parameter owner block contains a slash (/), the slash appears as two slashes (//) in the Parameter Writer block parameters. This notation distinguishes the slash in the block name itself from slashes that separate names at different levels of the model hierarchy.

Dependencies

To enable this parameter, clear the **Access model workspace parameter** parameter.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

First, specify the block path of a parameter owner block using the `ParameterOwnerBlock` parameter.

Parameter:	ParameterOwnerBlock
Values:	' ' (default) character vector string scalar
Data Types:	char string

Example: `set_param(gcb, 'ParameterOwnerBlock', 'mymodel/Gain1')`

Then, specify the programmatic name of a block parameter of the parameter owner block using the `ParameterName` parameter.

Parameter:	ParameterName
Values:	' ' (default) character vector string scalar

Example: `set_param(gcb, 'ParameterName', 'Gain')`

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

R2023a: Disable parameter validation during normal mode simulation

Optionally, disable parameter validation that occurs during normal mode simulation for Parameter Writer blocks. When parameter validation is disabled for a Parameter Writer block, normal mode simulation of the block is faster.

To locally enable or disable parameter validation for a Parameter Writer block, use the **Validate parameter** block parameter.

To globally enable or disable parameter validation for Parameter Writer blocks, use the **Parameter Writer block validation** configuration parameter.

Permute Dimensions

Rearrange dimensions of multidimensional array dimensions

Libraries:
Simulink / Math Operations

Description

The Permute Dimensions block reorders the elements of the input signal by permuting its dimensions. You specify the permutation to be applied to the input signal using the **Order** parameter.

For example, to transpose a 3-by-5 input signal, specify the permutation vector [2 1] for the **Order** parameter. When you do, the block reorders the elements of the input signal and outputs a 5-by-3 matrix.

You can use an array of buses as an input signal to a Permute Dimensions block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix | N-D array

This port accepts scalar, vector, matrix, and N-dimensional signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_2 — Permutation of input signal
scalar | vector | matrix | N-D array

The block outputs the permutation of the input signal, according to the value of the **Order** parameter. The output has the same data type as the input.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Order — Permutation vector

[2, 1] (default) | N-element vector, where N is the number of dimensions of the input signal

Specify the permutation order to apply to the dimensions of the input signal. The value of this parameter must be an N-element vector where N is the number of dimensions of the input signal. The elements of the permutation vector must be a rearrangement of the values from 1 to N.

For example, the permutation vector [2 1] applied to a 5-by-3 input signal results in a 3-by-5 output signal, in other words, the transpose of the input signal.

Programmatic Use

Block Parameter: Order

Type: character vector

Value: N-element vector

Default: '[2 1]'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Permute Matrix

Reorder matrix rows or columns

Libraries:
Simulink / Matrix Operations

Description

The Permute Matrix block reorders the rows or columns of an M -by- N input matrix A as specified by indexing input P .

Ports

Input

A — Input matrix
scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

P — Index matrix
scalar | vector

Index matrix, specified as a scalar or vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated

Output

Port_1 — Output signal
vector | matrix

Output signal, specified as a vector or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

Permute — Permute method

Columns (default) | Rows

Method of constructing the output matrix by permuting rows or columns of the input.

When the **Permute** parameter is set to:

- **Rows** -- The block uses the rows of **A** to create a matrix that has the same column dimension. Input **P** is a length-*L* vector whose elements determine where each row from **A** must be placed in the *L*-by-*N* output matrix.

```
y = [A(P(1),:); A(P(2),:); A(P(3),:); ... ; A(P(end),:)] % Equivalent MATLAB code
```

For row permutation, the block treats the length-*M* unoriented vector input at the port **A** as an *M*-by-1 matrix.

- **Columns** -- The block uses the columns of **A** to create a matrix that has the same row dimension. Input **P** is a length-*L* vector whose elements determine where each column from **A** must be placed in the *M*-by-*L* output matrix.

```
% Equivalent MATLAB code y = [A(:,P(1)) A(:,P(2)) A(:,P(3)) ... A(:,P(end))]
```

For column permutation, the block treats the length-*N* unoriented vector input at port **A** as a 1-by-*N* matrix.

Programmatic Use

Block Parameter: mode

Type: character vector, string

Values: 'Columns' | 'Rows'

Default: 'Columns'

Index mode — Index mode

One-based (default) | Zero-based

When set to One-based, a value of 1 in the permutation vector **P** refers to the first row or column of the input matrix **A**. When set to Zero-based, a value of 0 in **P** refers to the first row or column of **A**.

Programmatic Use

Block Parameter: ZeroOneIdxMode

Type: character vector, string

Values: 'Zero-based' | 'One-based'

Default: 'One-based'

Invalid permutation index — Response to an invalid index value

Clip index (default) | Clip and warn | Generate error

Response to an invalid index value. When an index value in input **P** references a nonexistent row or column of matrix **A**, the block reacts as specified in this parameter. These options are available:

- **Clip index** -- Clip the index to the nearest valid value (1 or *M* for row permutation and 1 or *N* for column permutation) and *do not* issue an alert. Example: For a 3-by-7 input matrix, a column index of 9 is clipped to 7 and a row index of -2 is clipped to 1.
- **Clip and warn** -- Display a warning message in the MATLAB Command Window and clip the index as described in the preceding bullet.
- **Generate error** -- Display an error dialog box and terminate the simulation.

Tunable: Yes

Programmatic Use

Block Parameter: errmode

Type: character vector, string

Values: 'Clip index' | 'Clip and warn' | 'Generate error'

Default: 'Clip index'

Error when length of P is not equal to Permute dimension size — Error message for P length

off (default) | on

Option to display an error dialog box and terminate the simulation when the length of the permutation vector P is not equal to the number of rows or columns of the input matrix A.

You can choose to open an error dialog box and terminate the simulation by setting this parameter to on.

Programmatic Use

Block Parameter: checkDims

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

PID Controller

Continuous-time or discrete-time PID controller

Libraries:
Simulink / Continuous

Description

The PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the Discrete PID Controller block with the **Time domain** parameter set to **Continuous-time**.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

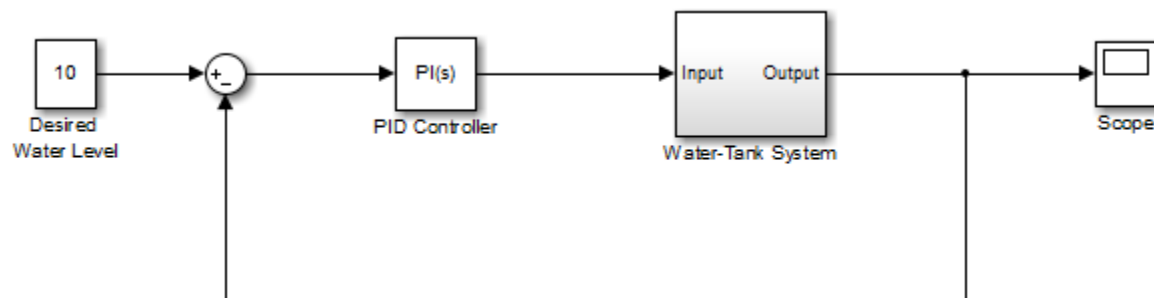

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Implement Variations in Separate Hierarchy Using Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see PID Controller (2DOF).

PID Gain Tuning

The PID controller coefficients are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

Ports

Input

Port_1(u) — Error signal input
scalar | vector

Difference between a reference signal and the output of the system under control, as shown.

When the error signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain
scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger
scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to **rising**.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the **I₀** and **D₀** ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than **none**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point` | `Boolean`

I₀ — Integrator initial condition
scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

D₀ — Filter initial condition
scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

up — Output saturation upper limit
scalar | vector

Upper limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions exceeds the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to **external**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

lo — Output saturation lower limit

scalar | vector

Lower limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions goes below the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to **external**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1}.$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(y) — Controller output
scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Controller — Controller type

PID (default) | PI | PD | P | I

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

P

Proportional action only.

I

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "PID", "PI", "PD", "P", "I"

Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P \left[1 + I\alpha(z) + D \frac{N}{1 + N\beta(z)} \right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify continuous-time or discrete-time controller

Continuous-time (default) | Discrete-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Continuous-time"

PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to **Discrete-time**.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) — Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method — Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the BackwardEuler or Trapezoidal methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
-

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} \cdot$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use

Block Parameter: FilterMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

internal

Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

external

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Programmatic Use

Block Parameter: ControllerParametersSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s + N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1 + N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to **PID**, **PD**, **PI**, or **P**.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to a type that has integral action.

Programmatic Use**Block Parameter:** I**Type:** scalar, vector**Default:** 1**Derivative (D)** — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes**Dependencies**To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.**Programmatic Use****Block Parameter:** D**Type:** scalar, vector**Default:** 0**Use filtered derivative** — Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D \frac{z - 1}{zT_s}$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: UseFilter

Type: string, character vector

Values: "on", "off"

Default: "on"

Filter coefficient (N) — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to internal and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: N

Type: scalar, vector

Default: 100

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

on (default) | off

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

internal (default) | external

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

internal

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator**

parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

external

Specify the initial conditions externally using block inputs. Additional input ports **I₀** and **D₀** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D₀** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: InitialConditionForIntegrator

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: InitialConditionForFilter

Type: scalar, vector

Default: 0

Differentiator — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to Discrete-time, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to internal.

Programmatic Use

Block Parameter: DifferentiatorICPrevScaledInput

Type: scalar, vector

Default: 0

Initial condition setting — Location at which initial condition is applied

Auto (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

Auto

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: InitialConditionSetting

Type: string, character vector

Values: "Auto", "Output"

Default: "Auto"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than none enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer” on page 12-104.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.

The Inner Loop subsystem contains the blocks shown in the following diagram.

Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see “Prevent Block Windup in Multiloop Control” on page 12-103.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain K_t . Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Saturation

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output, so that you do not need a separate Saturation on page 1-1896 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the output saturation limits using the **Lower limit** and **Upper limit** parameters. You can also specify the saturation limits externally as block input ports.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Source — Source for output saturation limits

internal (default) | external

Use this parameter to specify how to supply the upper and lower saturation limits of the block output.

internal

Specify the output saturation limits using the **Upper limit** and **Lower limit** parameters.

external

Specify the output saturation limits externally using block input ports. The additional input ports **up** and **lo** appear on the block. You can use the input ports to implement the upper and lower output saturation limits determined by logic or other calculations in the Simulink model and passed to the block.

Programmatic Use**Block Parameter:** SatLimitsSource**Type:** string, character vector**Values:** "internal", "external"**Default:** "internal"**Upper limit** — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** UpperSaturationLimit**Type:** scalar**Default:** Inf**Lower limit** — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use**Block Parameter:** LowerSaturationLimit**Type:** scalar**Default:** -Inf**Ignore saturation when linearizing** — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use**Block Parameter:** LinearizeAsGain**Type:** string, character vector**Values:** "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $K_b = I$, or for controllers with derivative action, $K_b = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The **back-calculation** anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to **back-calculation**.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Integrator saturation

Limit Output — Limit integrator output to specified saturation limits

off (default) | on

Enable this parameter to limit the integrator output to be within a specified range. When the integrator output reaches the limits, the integral action turns off to prevent integral windup. Specify the saturation limits using the **Lower limit** and **Upper limit** parameters.

Dependencies

To enable this parameter, set **Controller** to a controller type that has integral action.

Programmatic Use**Block Parameter:** LimitIntegratorOutput**Type:** string, character vector**Values:** "off", "on"**Default:** "off"**Upper limit** — Upper saturation limit for integrator

Inf (default) | scalar

Specify the upper limit for the integrator output. The integrator output is held at this value whenever it would otherwise exceed this value.

Dependencies

To enable this parameter, under **Integrator saturation**, select **Limit output**.

Programmatic Use**Block Parameter:** UpperIntegratorSaturationLimit**Type:** scalar**Default:** Inf**Lower limit** — Lower saturation limit for integrator

-Inf (default) | scalar

Specify the lower limit for the integrator output. The integrator output is held at this value whenever it would otherwise go below this value.

Dependencies

To enable this parameter, under **Integrator saturation**, select **Limit output**.

Programmatic Use**Block Parameter:** LowerIntegratorSaturationLimit**Type:** scalar**Default:** -Inf**Data Types**

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

Data Type	Minimum	Maximum
P product output:		
I product output:		
D product output:		
N product output:		
b product output:		
c product output:		
Sum output:		

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.

- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

State Attributes

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') — Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector**Default:** ''**State name** — Names for discrete-time filter and integrator states

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use**Parameter:** IntegratorStateIdentifier, FilterStateIdentifier**Type:** string, character vector**Default:** ""**State name must resolve to Simulink signal object** — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use**Block Parameter:** IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject**Type:** string, character vector**Values:** "off", "on"**Default:** "off"

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2009b

R2022b: Issues error when integrator and filter initial conditions lie outside saturation limits

Behavior changed in R2022b

The block now issues an error when the integrator or filter initial condition value lies outside the output saturation limits. In previous releases, the block did not issue an error when these initial conditions had such values.

If this change impacts your model, update the PID integrator or filter initial condition values such that they are within the output saturation limits.

R2021b: ReferenceBlock parameter returns different path

Behavior changed in R2021b

Starting in R2021b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller and Discrete PID Controller blocks now link to `'slpidlib/PID Controller'`. Previously, the blocks linked to `'pid_lib/PID Controller'`.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

R2020b: ReferenceBlock parameter returns different path

Behavior changed in R2020b

Starting in R2020b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller and Discrete PID Controller blocks now link to `'pid_lib/PID Controller'`. Previously, the blocks linked to `'simulink/Continuous/PID Controller'`.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to Continuous-time):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to Discrete-time):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on memcopy or memset functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

Restrictions

- HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to Discrete-time).

- If the **Integrator method** is set to `BackwardEuler` or `Trapezoidal`, you cannot generate HDL code for the block under either of the following conditions:
 - **Limit output** is selected and the **Anti-Windup Method** is anything other than none.
 - **Enable tracking mode** is selected.
- To generate HDL code:
 - Use a discrete-time PID controller. On the **Time domain** section, specify **Discrete-time**.
 - Leave the **Use filtered derivative** check box selected.
 - Specify the initial conditions of the filter and integrator internally. On the **Initialization** tab, specify **Source** as `internal`.

You can specify the filter coefficients internally and externally for HDL code generation. On the **Main** tab, for **Source**, you can use `internal` or `external`.
 - Set **External reset** to none.
 - When you use double inputs, do not set **Anti-windup Method** to clamping.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

PID Controller (2DOF)

Continuous-time or discrete-time two-degree-of-freedom PID controller

Libraries:

Simulink / Continuous

Description

The PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the Discrete PID Controller (2DOF) block with the **Time domain** parameter set to Continuous-time.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Implement Variations in Separate Hierarchy Using Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

Ports

Input

Ref — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.

When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_1(y) — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to external.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

N — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

b — Proportional setpoint weight

scalar | vector

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

c — Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.

When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the I_0 and D_0 ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than none.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | Boolean

I_0 — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has integral action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to external, and set **Controller** to a controller type that has derivative action.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

up — Output saturation upper limit

scalar | vector

Upper limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions exceeds the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to **external**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

lo — Output saturation lower limit

scalar | vector

Lower limit of the block output, provided from a source external to the block. If the weighted sum of the proportional, integral, and derivative actions goes below the value provided at this port, the block output is held at that value.

Dependencies

To enable this port, select **Limit output** and set the output saturation **Source** to **external**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

T_{DTI} — Discrete-integrator time

scalar

Discrete-integrator time, provided as a scalar to the block. You can use your own value of discrete-time integrator sample time that defines the rate at which the block is going to be run either in Simulink or on external hardware. The value of the discrete-time integrator time should match the average sampling rate of the external interrupts, when the block is used inside a conditionally-executed subsystem.

In other words, you can specify T_s for any of the integrator methods below such that the value matches the average sampling rate of the external interrupts. In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

$$\alpha(z) = \frac{T_s}{z - 1}.$$

Backward Euler

$$\alpha(z) = \frac{T_s z}{z - 1}.$$

Trapezoidal

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} \cdot$$

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page. For more information on conditionally executed subsystems, see “Conditionally Executed Subsystems Overview”.

Dependencies

To enable this port, set **Time Domain** to Discrete-time and select the **PID Controller is inside a conditionally executed subsystem** option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output

Port_1(u) — Controller output
scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as N independent PID controllers, where N is the number of signals in the input vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Controller — Controller type

PID (default) | PI | PD

Specify which of the proportional, integral, and derivative terms are in the controller.

PID

Proportional, integral, and derivative action.

PI

Proportional and integral action only.

PD

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "PID", "PI", "PD"

Default: "PID"

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y) \right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y) \right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: Controller

Type: string, character vector

Values: "Parallel", "Ideal"

Default: "Parallel"

Time domain — Specify continuous-time or discrete-time controller

Continuous-time (default) | Discrete-time

When you select **Discrete-time**, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting **Discrete-time** also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select **Continuous-time**.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use

Block Parameter: TimeDomain

Type: string, character vector

Values: "Continuous-time", "Discrete-time"

Default: "Continuous-time"

PID Controller is inside a conditionally executed subsystem — Enable the discrete-integrator time port

off (default) | on

For discrete-time PID controllers, enable the discrete-time integrator port to use your own value of discrete-time integrator sample time. To ensure proper integration, use the T_{DTI} port to provide a scalar value of Δt for accurate discrete-time integration.

Dependencies

To enable this parameter, set **Time Domain** to **Discrete-time**.

Programmatic Use

Block Parameter: UseExternalTs

Type: string, character vector

Values: "on", "off"

Default: "off"

Sample time (-1 for inherited) — Discrete interval between samples

-1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of -1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to Continuous-time.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to -1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Block Parameter: SampleTime

Type: scalar

Values: -1, positive scalar

Default: -1

Integrator method — Method for computing integral in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the integral term of the controller transfer function is $Ia(z)$, where $a(z)$ depends on the integrator method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1} \cdot$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1}.$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1}.$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: IntegratorMethod

Type: string, character vector

Values: "Forward Euler", "Backward Euler", "Trapezoidal"

Default: "Forward Euler"

Filter method — Method for computing derivative in discrete-time controller

Forward Euler (default) | Backward Euler | Trapezoidal

In discrete time, the derivative term of the controller transfer function is:

$$D \left[\frac{N}{1 + N\alpha(z)} \right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

Forward Euler

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1} .$$

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Bilinear approximation,

$$\alpha(z) = \frac{T_s z + 1}{2 z - 1} .$$

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to Discrete-time and enable **Use filtered derivative**.

Programmatic Use**Block Parameter:** FilterMethod**Type:** string, character vector**Values:** "Forward Euler", "Backward Euler", "Trapezoidal"**Default:** "Forward Euler"**Main****Source** — Source for controller gains and filter coefficient

internal (default) | external

internal

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

external

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight c is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the input signal u is multiplied by the externally supplied integrator gain, I , before integration. This implementation yields:

$$u_i = \int (r - y)I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D and the derivative setpoint weight c to be differentiated.

Programmatic Use**Block Parameter:** ControllerParametersSource**Type:** string, character vector

Values: "internal", "external"

Default: "internal"

Proportional (P) — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- **Parallel** — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output u is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where r is the reference signal, y is the measured plant output signal, and b and c are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- **Ideal** — The proportional gain multiplies the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y)\right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y)\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to `internal`.

Programmatic Use

Block Parameter: P

Type: scalar, vector

Default: 1

Integral (I) — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: I

Type: scalar, vector

Default: 1

Derivative (D) — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**, and set **Controller** to PID or PD.

Programmatic Use

Block Parameter: D

Type: scalar, vector

Default: 0

Use filtered derivative — Apply filter to derivative term

on (default) | off

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D \frac{z - 1}{z T_s} (cr - y) .$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to **Discrete-time**, and set **Controller** to a type that has a derivative term.

Programmatic Use**Block Parameter:** UseFilter**Type:** string, character vector**Values:** "on", "off"**Default:** "on"**Filter coefficient (N)** — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is Continuous-time, the pole location is $s = -N$.
- When **Time domain** is Discrete-time, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
Forward Euler	$z_{pole} = 1 - NT_s$
Backward Euler	$z_{pole} = \frac{1}{1 + NT_s}$
Trapezoidal	$z_{pole} = \frac{1 - NT_s/2}{1 + NT_s/2}$

The block does not support $N = \text{Inf}$ (ideal unfiltered derivative). When the **Time domain** is Discrete-time, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes**Dependencies**

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to internal and set **Controller** to PID or PD.

Programmatic Use**Block Parameter:** N**Type:** scalar, vector**Default:** 100**Setpoint weight (b)** — Proportional setpoint weight

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is $P(br-y)$, where r is the reference signal and y is the measured plant output. Setting b to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal**.

Programmatic Use

Block Parameter: **b**

Type: scalar, vector

Default: 1

Setpoint weight (c) — Derivative setpoint weight

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on $cr-y$, where r is the reference signal and y is the measured plant output. Thus, setting c to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting c to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of b and c changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to **internal** and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: **c**

Type: scalar, vector

Default: 1

Select tuning method — Tool for automatic tuning of controller coefficients

Transfer Function Based (PID Tuner App) (default) | Frequency Response Based

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

Transfer Function Based (PID Tuner App)

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**, and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

Frequency Response Based

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information

about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Enable zero-crossing detection — Detect zero crossings on reset and on entering or leaving a saturation state

`on (default) | off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: string, character vector

Values: "on", "off"

Default: "on"

Initialization

Source — Source for integrator and derivative initial conditions

`internal (default) | external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

Specify the initial conditions externally using block inputs. Additional input ports **I_o** and **D_o** appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at **D_o** instead of a filter initial condition.

Programmatic Use

Block Parameter: InitialConditionSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Integrator — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`

Type: scalar, vector

Default: 0

Filter — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`

Type: scalar, vector

Default: 0

Differentiator — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be NaN or Inf.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use**Block Parameter:** DifferentiatorICPrevScaledInput**Type:** scalar, vector**Default:** 0**Initial condition setting** — Location at which initial condition is applied

Auto (default) | Output

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

Auto

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use**Block Parameter:** InitialConditionSetting**Type:** string, character vector**Values:** "Auto", "Output"**Default:** "Auto"**External reset** — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than **none** enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset

Type: string, character vector

Values: "none", "rising", "falling", "either", "level"

Default: "none"

Ignore reset when linearizing — Force linearization to ignore reset

off (default) | on

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: IgnoreLimit

Type: string, character vector

Values: "off", "on"

Default: "off"

Enable tracking mode — Activate signal tracking

off (default) | on

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain K_t , specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.

For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 12-105.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 12-103.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: TrackingMode

Type: string, character vector

Values: "off", "on"

Default: "off"

Tracking coefficient (Kt) — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain Kt. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: Kt

Type: scalar

Default: 1

Saturation

Output saturation

Limit Output — Limit block output to specified saturation values

off (default) | on

Activating this option limits the block output, so that you do not need a separate Saturation on page 1-1896 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the output saturation limits using the **Lower limit** and **Upper limit** parameters. You can also specify the saturation limits externally as block input ports.

Programmatic Use

Block Parameter: LimitOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Source — Source for output saturation limits

internal (default) | external

Use this parameter to specify how to supply the upper and lower saturation limits of the block output.

internal

Specify the output saturation limits using the **Upper limit** and **Lower limit** parameters.

external

Specify the output saturation limits externally using block input ports. The additional input ports **up** and **lo** appear on the block. You can use the input ports to implement the upper and lower output saturation limits determined by logic or other calculations in the Simulink model and passed to the block.

Programmatic Use

Block Parameter: SatLimitsSource

Type: string, character vector

Values: "internal", "external"

Default: "internal"

Upper limit — Upper saturation limit for block output

Inf (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: UpperSaturationLimit

Type: scalar

Default: Inf

Lower limit — Lower saturation limit for block output

-Inf (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: LowerSaturationLimit

Type: scalar

Default: -Inf

Ignore saturation when linearizing — Force linearization to ignore output limits

off (default) | on

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: LinearizeAsGain

Type: string, character vector

Values: "off", "on"

Default: "off"

Anti-windup method — Integrator anti-windup method

none (default) | back-calculation | clamping

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

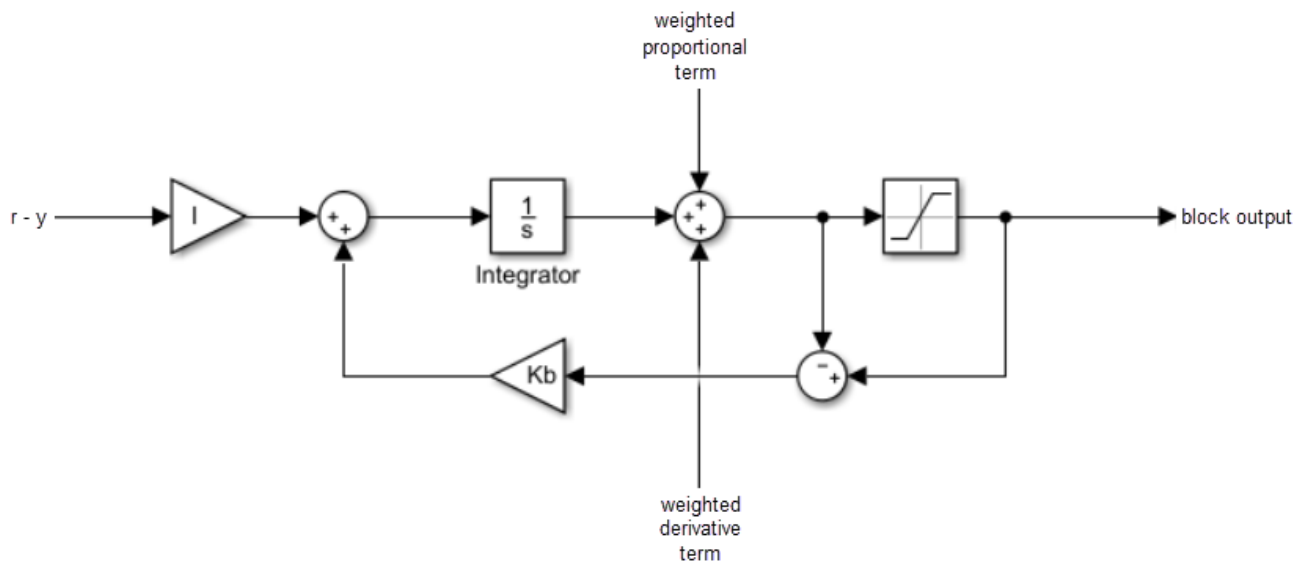

In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

none

Do not use an anti-windup mechanism.

back-calculation

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.

Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set $Kb = I$, or for controllers with derivative action, $Kb = \sqrt{I \cdot D}$. Back-calculation can be effective for plants with relatively large dead time [1].

clamping

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: AntiWindupMode

Type: string, character vector

Values: "none", "back-calculation", "clamping"

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The back-calculation anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb

Type: scalar

Default: 1

Integrator saturation

Limit Output — Limit integrator output to specified saturation limits

off (default) | on

Enable this parameter to limit the integrator output to be within a specified range. When the integrator output reaches the limits, the integral action turns off to prevent integral windup. Specify the saturation limits using the **Lower limit** and **Upper limit** parameters.

Dependencies

To enable this parameter, set **Controller** to a controller type that has integral action.

Programmatic Use

Block Parameter: LimitIntegratorOutput

Type: string, character vector

Values: "off", "on"

Default: "off"

Upper limit — Upper saturation limit for integrator

Inf (default) | scalar

Specify the upper limit for the integrator output. The integrator output is held at this value whenever it would otherwise exceed this value.

Dependencies

To enable this parameter, under **Integrator saturation**, select **Limit output**.

Programmatic Use

Block Parameter: UpperIntegratorSaturationLimit

Type: scalar
Default: Inf

Lower limit — Lower saturation limit for integrator

- Inf (default) | scalar

Specify the lower limit for the integrator output. The integrator output is held at this value whenever it would otherwise go below this value.

Dependencies

To enable this parameter, under **Integrator saturation**, select **Limit output**.

Programmatic Use

Block Parameter: LowerIntegratorSaturationLimit

Type: scalar

Default: - Inf

Data Types

The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click  to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as SumI2. (See **Model Explorer**.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use**Block Parameter:** SaturateOnIntegerOverflow**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**State Attributes**

The parameters in this tab are primarily of use in code generation.

State name (e.g., 'position') — Name for continuous-time filter and integrator states

' ' (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to Continuous-time.

Programmatic Use**Parameter:** IntegratorContinuousStateAttributes, FilterContinuousStateAttributes**Type:** character vector

Default: ''

State name — Names for discrete-time filter and integrator states
empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to Discrete-time.

Programmatic Use

Parameter: IntegratorStateIdentifier, FilterStateIdentifier

Type: string, character vector

Default: ""

State name must resolve to Simulink signal object — Require that state name resolve to a signal object

off (default) | on

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

- 1 Set **Time domain** to Discrete-time.
- 2 Specify a value for the integrator or filter **State name**.
- 3 Set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: IntegratorStateMustResolveToSignalObject, FilterStateMustResolveToSignalObject

Type: string, character vector

Values: "off", "on"

Default: "off"

More About

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

Prefilter Decomposition

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where C is a single degree-of-freedom PID controller and F is a prefilter on the reference signal.

Ref is the reference signal, y is the feedback from the measured system output, and u is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for F and C are

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN},$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)},$$

where b and c are the setpoint weights.

For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN},$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Feedforward Decomposition

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.

In this realization, Q acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for Q is

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}$$

The transfer functions for C are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Version History

Introduced in R2009b

R2022b: Issues error when integrator and filter initial conditions lie outside saturation limits

Behavior changed in R2022b

The block now issues an error when the integrator or filter initial condition value lies outside the output saturation limits. In previous releases, the block did not issue an error when these initial conditions had such values.

If this change impacts your model, update the PID integrator or filter initial condition values such that they are within the output saturation limits.

R2021b: ReferenceBlock parameter returns different path

Behavior changed in R2021b

Starting in R2021b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller (2DOF) and Discrete PID

Controller (2DOF) blocks now link to 'slpidlib/PID Controller (2DOF)'. Previously, the blocks linked to 'pid_lib/PID Controller (2DOF)'.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

R2020b: ReferenceBlock parameter returns different path

Behavior changed in R2020b

Starting in R2020b, the `get_param` function returns a different value for the `ReferenceBlock` parameter. The `ReferenceBlock` parameter is a property common to all Simulink blocks and gives the path of the library block to which a block links. The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks now link to 'pid_lib/PID Controller (2DOF)'. Previously, the blocks linked to 'simulink/Continuous/PID Controller (2DOF)'.

This change does not affect any other functionality or workflows. You can still use the previous path with the `set_param` function.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using “Model Discretizer” to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

Playback

Load data from workspace, file, or Simulation Data Inspector

Libraries:
Simulink / Sources

Description

Use the Playback block to load input data for simulation. The Playback block supports loading real or complex signals with fixed or variable dimensions, discrete and continuous signals, and messages. Using the Playback block, you can load data from:

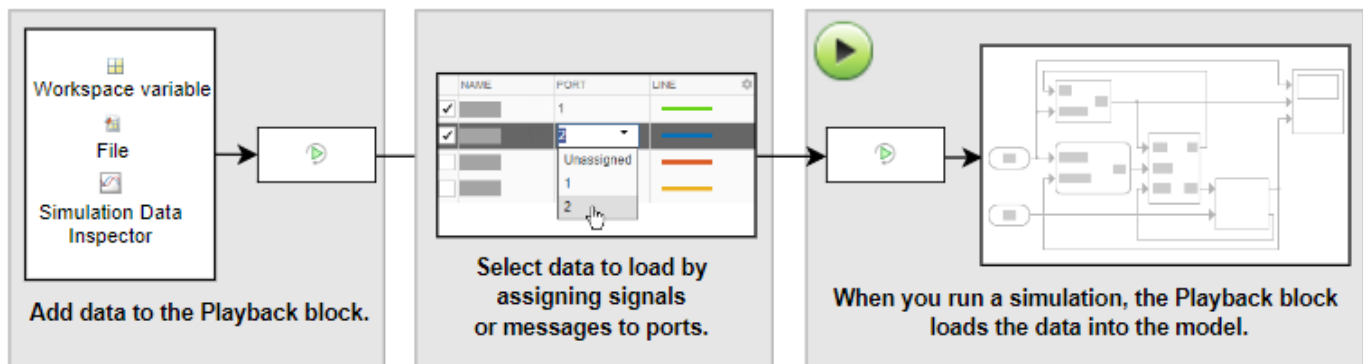

- Workspace variables of any data format supported by the Simulation Data Inspector
- Files in the same formats supported by the Record block and the Simulation Data Inspector such as MAT, MLDATX, and Microsoft Excel files
- Data from a custom file reader
- Runs in the Simulation Data Inspector

For more information about workspace variables and file formats supported by the Playback block, see “Import Data from the Workspace or a File”.

You can also use the Playback block in conjunction with the Record block as part of a record and playback workflow. Use the Record block to record data from physical devices or simulations. Then, use the Playback block to load the recorded data into a model. Using real or simulated data, you can then develop, test, and optimize the model. For more information about the Record block, see Record, XY Graph.

Add Data to Playback Block

You can add signals, messages, multidimensional signals, buses, and arrays of buses to the Playback block. To load data to a model using the Playback block, first add data to the block. Then, select the data to load by assigning signals or messages to ports. When you run a simulation, the Playback block loads data into the model.

To add signals to the Playback block for loading, double-click the block. When you double-click a Playback block that has no signals, the block shows a screen with options to add data.

You can choose from three ways to load data to your model:

- Load a workspace variable from the base workspace, model workspace, or mask workspace.
- Load data from a file. If the file is not on the MATLAB path or in your current directory, you can click the folder icon to browse for your data.
- Load data from the workspace, a file, or the Simulation Data Inspector using the Add Signals dialog box.

Use the Add Signals dialog box to access more options for loading data from the workspace or a file or to load data from the Simulation Data Inspector.

Add signals from:

Workspace

File

Data Inspector

NAME
<input checked="" type="checkbox"/> simin

Reference source:

Reference signals in source (no copy)

Save copy of signals in model

Assign ports:

Assign ports automatically

Do not assign ports

Refresh Add Cancel

When you load data from the workspace or a file, you can choose to reference the signals in the source or save a copy of the signals in the model. Loading signal data from the Simulation Data Inspector always saves a copy of the signals in the model.

Referencing the signal in the source links the signal in the Playback block to the variable or file that contains the signal data. If the data in the source variable or file changes, that change is reflected in the data loaded by the Playback block. When linking data, only metadata is stored on the block for each signal.

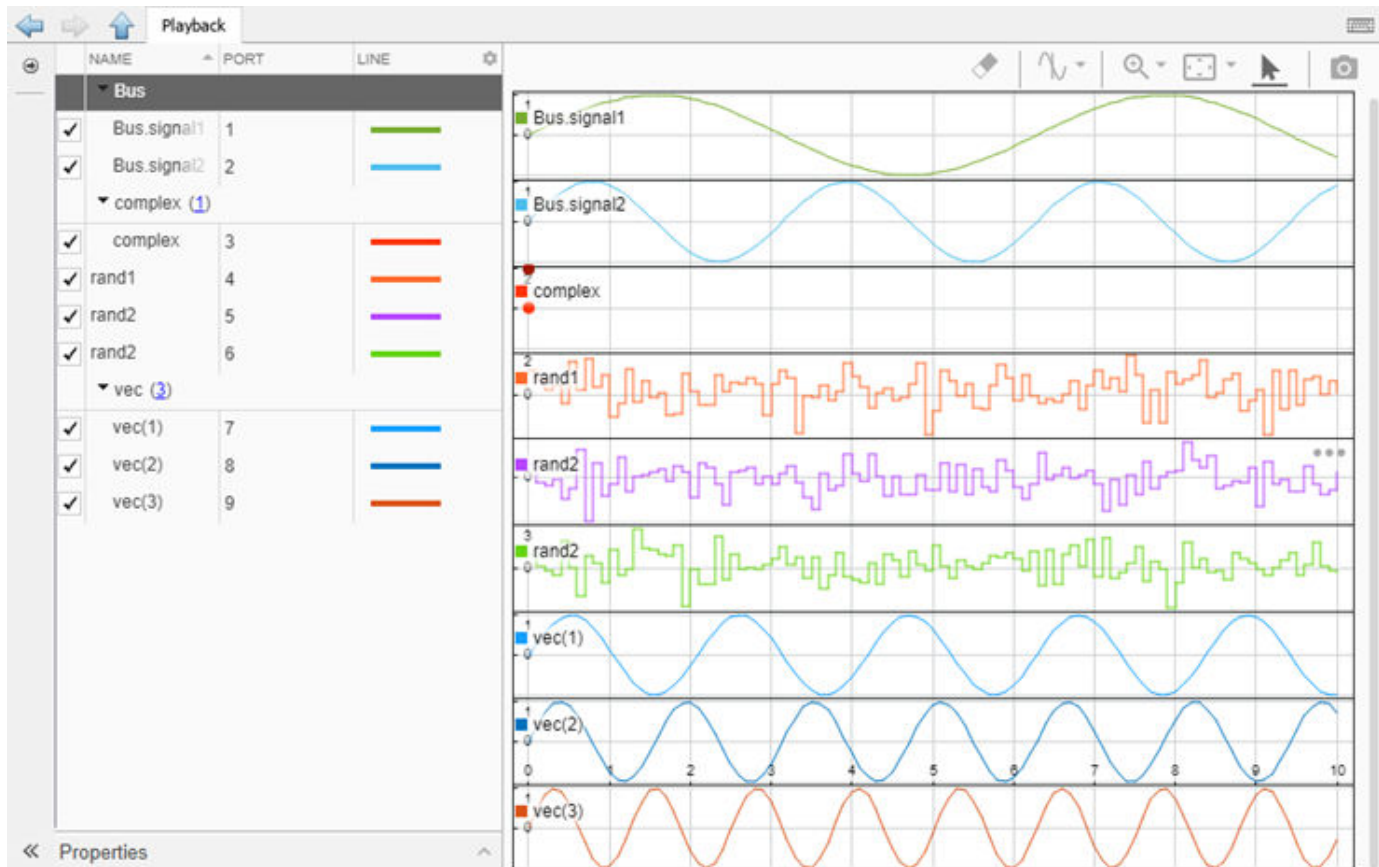

When you save a copy of the signals in the model, the Playback block loads from the copied data. Changes made to the original data source variable or file are not reflected in the Playback block output.

The Add Signals dialog box also allows you to choose whether to assign ports automatically or manually. If you choose to manually assign ports, you can create ports using the **Port Editor** and assign ports using the port column of the signal table.

NAME	PORT	LINE
▼ out		
▼ yout		
<input checked="" type="checkbox"/> Out1:1		—
<input checked="" type="checkbox"/> Out2:1	Unassigned	—
<input checked="" type="checkbox"/> Out3:1	1	—

Visualize Data

After you choose the signal data you want to load, you can use the Playback block to visualize the data using a sparklines plot.

By default, a sparkline is created for each signal loaded with the Playback block. If you load input data for a bus, a sparkline is created for each bus element. Multidimensional signals must be converted to channels or frames to visualize the data. Use the check boxes next to each signal name to control which signals are plotted.

Note You can select or clear the check boxes to change the appearance of the sparklines visualization without affecting which signals the Playback block loads to a model. To control which signals are loaded to the model, use the port column in the table of signals.

View and Edit Signals and Ports

You can view and edit signal properties using the **Properties** pane in the Playback block.

In the **Properties** pane, you can edit any row with a white background. The number of editable fields depends on whether you choose to reference the signal in the source or save a copy of the data in the model.

Port properties for the Playback block can be set separately from the signal properties using the **Port Editor**.

Port Editor: untitled/Playback

Number of Ports: + Add Port 🗑 Delete Port Filter contents

Port	Signal Source	Data Type	Complexity	Units	Sample Time	Dimensions	Dimension Mode
1	Bus.signal1	Inherit: auto	auto		-1		auto
2	Bus.signal2	Inherit: auto	auto		-1		auto
3	complex	Inherit: auto	auto		-1		auto
4	rand1	Inherit: auto	auto		-1		auto
5	rand2	Inherit: auto	auto		-1		auto

Using the **Port Editor**, you can add ports, delete ports, and edit port properties. You can also change port assignments using the signal table. By default, port properties are inherited from the signal. However, you can set a port property independently of the signal property. When compatible with the signal property, the port property determines the output of the Playback block. For example, you can convert the units of a signal with assigned measurement by setting the **Units** property for that port to a different unit of measurement. When the signal units and port units are compatible, the Playback block performs a unit conversion.

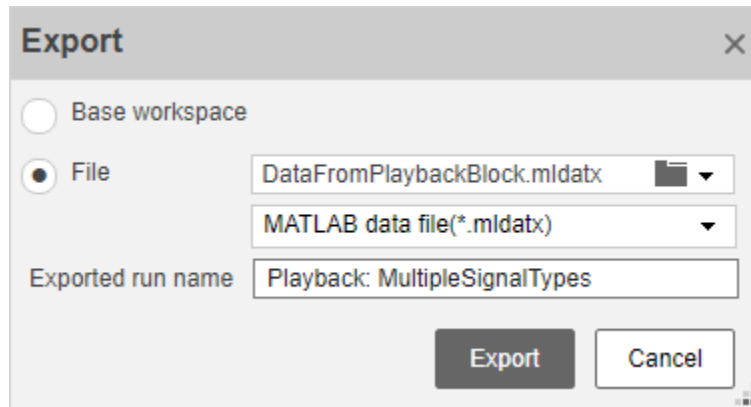

The Playback block supports multirate sample times, allowing you to set a different sample time for each port. Port sample times can also be set separately from the signal sample time.

Export Data Added to Playback Block

You can use the Playback block to aggregate data from the workspace, files, and the Simulation Data Inspector (linked to from the source or saved in the model) and export that data to the workspace or

a file. The Playback block exports all data added to the block, even signals that are not assigned to ports. To export all data added to the Playback block:

- 1 On the **Simulation** tab, in the **Share** section, click **Export**.
- 2 Select **Base workspace** or **File** to export the data to the workspace or to a file. You can choose to export the data to the workspace or to a MAT, MLDATX, or Microsoft Excel file.
- 3 Click **Export**.

If you choose to export data to an MLDATX file, you can specify the name of the run using the **Exported run name** text box.

If you choose to export data to an Excel file, click **Options** to select meta data to export and specify how time data is exported.

Ports

Output

Port_1 — Data loaded from workspace, file, or Simulation Data Inspector
scalar | vector | matrix | array

The Playback block supports loading real or complex signals with fixed or variable dimensions, discrete and continuous signals, and messages.

When you load bus data, the Playback block assigns a port to each element of the bus.

Data Types: single | double | half | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Parameters

Port Parameters

You can access port parameters through the **Port Editor**. Double-click the Playback block. In the **Simulation** tab, in the **Port** section, click **Port Editor**. Properties for each port can be set independently using the **Port Editor**.

Number of Ports — Number of output ports
0 (default) | integer in the range [0, 100]

When you add signals to the Playback block and automatically assign signals to ports, a new port is created for each signal or bus element you add. You can add or delete ports after adding signal data. The number of ports does not need to be equal to the number of signals you add to the block.

Programmatic Use

Block Parameter: NumPorts

Type: integer

Values: integer in the range [0, 100]

Default: 0

Data Type — Output data type for each port

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | string | boolean | fixdt(1,16,0) | fixdt(1,16,2^0,0) | ...

By default, the port data type is inherited from the source data type or from a downstream block.

You can set the data type of the port independently of the signal data type. For numerical data, the Playback block converts to the data type specified by the port. If a conversion is not possible, such as in the case of converting numerical data to a string, the software throws an error.

Programmatic Use

The size of the string array is equal to the number of ports. The index of each element is determined by the port number.

Block Parameter: OutDataTypeStr

Type: string array

Values: "Inherit: auto" | "double" | "single" | "half" | "int8" | "uint8" | "int16" | "uint16" | "int32" | "uint32" | "int64" | "uint64" | "string" | "boolean" | "fixdt(1,16,0)" | "fixdt(1,16,2^0,0)"

Default: "Inherit: auto"

Complexity — Complexity of each port

"auto" (default) | "real" | "complex"

You can specify the complexity for each port independently. Port complexity does not need to match the corresponding signal complexity. By default, the complexity of the port is "auto" and inherited from the signal data.

- If the signal data is real, the complexity of the port that loads the signal can be real or complex. If the port is set to "complex", the complex part of the signal is a signal ground.
- If the signal data is complex, the complexity of the port that loads the signal must be complex.

Programmatic Use

The size of the string array is equal to the number of ports. The index of each element is determined by the port number.

Block Parameter: PortComplexity

Type: string array

Values: "auto" | "real" | "complex"

Default: "auto"

Units — Physical units for each port

inherit (default) | supported physical unit

Physical units for each port, specified as a supported physical unit. To see a list of supported physical units, use the function `showunitslist`.

`showunitslist`

- If no unit is set on the port, the output units are inherited from the signal units.
- If different units are set on both the signal and the port, then the Playback block performs a unit conversion if the units are compatible.

The Playback block propagates units for each port.

Programmatic Use

The size of the string array is equal to the number of ports. The index of each element is determined by the port number.

Block Parameter: PortUnits

Type: string array

Values: " " | supported physical unit

Default: " "

Sample time — Output sample period and optional time offset

-1 | scalar | vector

The **Sample time** parameter specifies when the block computes a new output value during simulation. For details, see “Specify Sample Time”.

Specify the **Sample time** parameter as a scalar when you do not want the output to have a time offset. To add a time offset to the output, specify the **Sample time** parameter as a 1-by-2 vector where the first element is the sampling period and the second element is the offset.

By default, the **Sample time** parameter value is -1, which indicates that the port sample time is inherited from the signal. If the sample time of a port differs from the sample time of the associated signal, the Playback block interpolates data as needed using the interpolation setting of the signal.

Programmatic Use

The size of the string array is equal to the number of ports. The index of each element is determined by the port number.

Block Parameter: PortSampleTimes

Type: string array

Values: scalar | vector

Default: "-1"

Dimensions — Dimensions of each port

" " (default) | integer | integer array

To inherit the dimensions of a port from the data, leave the parameter empty. If the port does not have assigned data, setting the dimensions generates the ground.

The Playback block stores a multidimensional signal as a single signal with nonscalar sample values, a set of channels, or frames. For more information, see “Analyze Multidimensional Signal Data”.

Programmatic Use

The size of the cell array is equal to the number of ports. The index of each element is determined by the port number.

Block Parameter: PortDimensions**Type:** cell array**Values:** cell array of positive integers | cell array of vectors**Default:** empty 1×1 cell array**Dimension Mode** — Dimension mode of each port`"auto" (default) | "Fixed" | "Variable"`

Dimension mode of each port, returned as a string array where each element may be "auto", "Fixed", or "Variable".

- If the dimension mode is "auto", then the port inherits the dimension mode from the data.
- If the dimension mode is "Fixed", then the port allows only fixed-sized signals.
- If the dimension mode is "Variable", then the port allows only variable-sized signals.

Programmatic Use

The size of the string array is equal to the number of ports. The index of each element is determined by the port number.

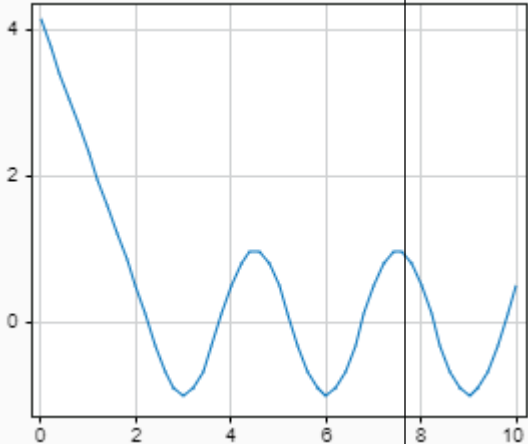

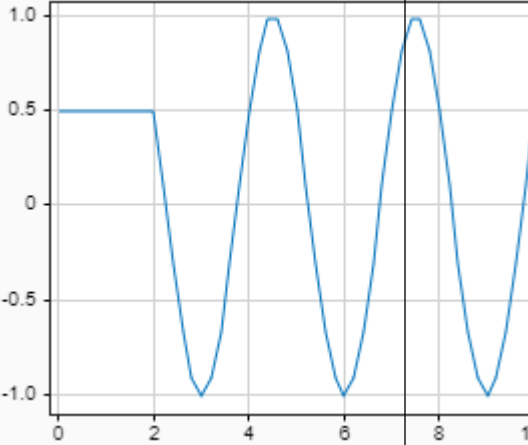

Block Parameter: PortDimsModes**Type:** string array**Values:** "auto" | "Fixed" | "Variable"**Default:** "auto"**Block Parameters**

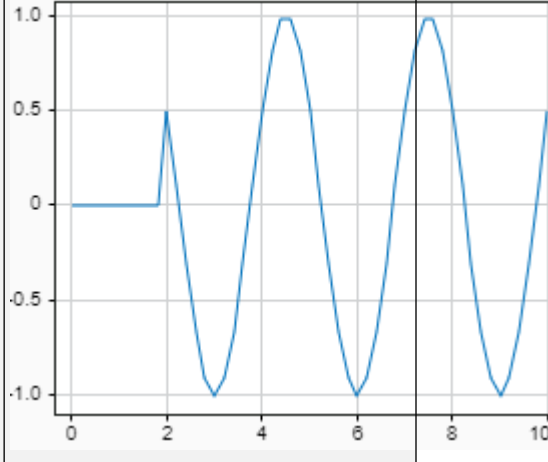

You can access block parameters through the **Parameter Settings**. Double-click the Playback block. In the **Simulation** tab, click **Parameter Settings** to configure block parameters.

Block parameter settings apply to all ports.

Before first point — Extrapolation method to determine block output before first data point in loaded data`Linear (default) | Hold First Value | Ground Value`

Extrapolation method used to determine output values for simulation times before the first sample in the file, workspace, or Simulation Data Inspector data.

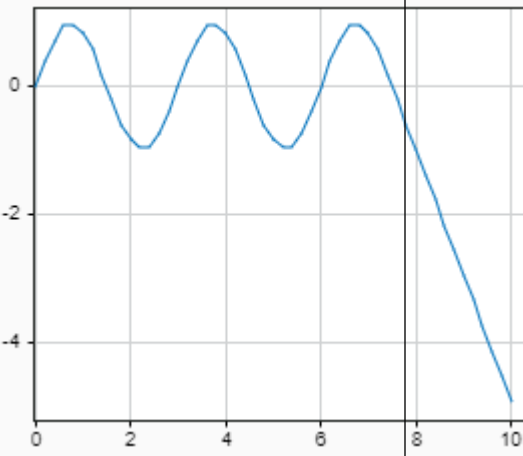

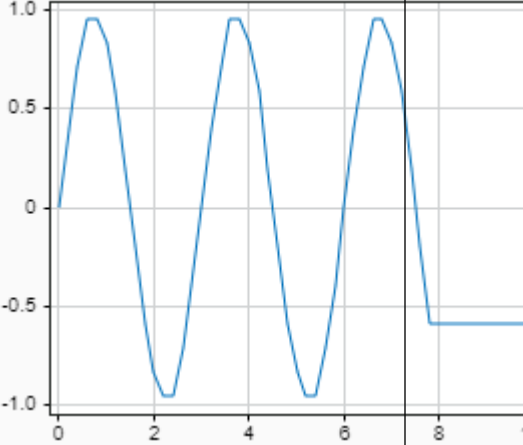

Method	Description	Example
<p>Linear</p>	<p>Extrapolated output depends on the type of data.</p> <ul style="list-style-type: none"> • For double data, the Playback block linearly extrapolates the output value using the first two samples. • For Boolean data, the Playback block uses the first data point value for the output value. • For all other built-in data types, the Playback block: <ol style="list-style-type: none"> 1 Upcasts the data to double 2 Linearly extrapolates the output value using the first two data samples 3 Downcasts the extrapolated data value to the original data type <p>If the data contains only one sample, the Playback block provides that value at the output.</p> <p>Do not use the Linear option when the Playback block loads enumerated or fixed-point data.</p> <p>The extrapolation setting is applied to all signals in a bus. If any signal in the bus contains enumerated or fixed-point data, do not use the Linear option.</p>	
<p>Hold First Value</p>	<p>The Playback block uses the first data value as the output value.</p>	

Method	Description	Example
Ground Value	<p>Extrapolated output depends on the type of data.</p> <ul style="list-style-type: none"> Built-in numeric types — 0 Boolean — false Fixed-point data types — Representation for value of 0, which may not be exactly 0 due to scaling and limited precision. Enumerated data types — Default value 	 <p>The graph displays a signal over time from 0 to 10. The signal is constant at 0.0 from t=0 to t=2. At t=2, it begins a periodic sine wave with an amplitude of 1.0 and a period of 4. The signal reaches 1.0 at t=4.5, -1.0 at t=6.5, 1.0 at t=8.5, and -1.0 at t=10.5. The y-axis is labeled from -1.0 to 1.0 in increments of 0.5, and the x-axis is labeled from 0 to 10 in increments of 2.</p>

Programmatic Use**Block Parameter:** ExtrapolationBeforeFirstDataPoint**Type:** character vector**Values:** 'Linear extrapolation' | 'Hold first value' | 'Ground value'**Default:** 'Linear extrapolation'**After last point** — Extrapolation method to determine block output after final data point in loaded data

Linear (default) | Hold Last Value | Ground Value

Extrapolation method used to determine output values for simulation times after the last sample in the file, workspace, or Simulation Data Inspector data.

Method	Description	Example
<p>Linear</p>	<p>Extrapolated output depends on the type of data.</p> <ul style="list-style-type: none"> • For double data, the Playback block linearly extrapolates the output value using the last two samples. • For Boolean data, the Playback block uses the last sample value for the output value. • For all other built-in data types, the Playback block: <ol style="list-style-type: none"> 1 Upcasts the data to double 2 Linearly extrapolates the output value using the last two data samples 3 Downcasts the extrapolated data value to the original data type <p>If the data contains only one sample, the Playback block uses that value as the output.</p> <p>Do not use the Linear option when the Playback block loads enumerated or fixed-point data.</p>	
<p>Hold Last Value</p>	<p>The Playback block uses the last data value as the output value.</p>	

Method	Description	Example
Ground Value	<p>The Playback block output value depends on the type of data.</p> <ul style="list-style-type: none"> Built-in numeric types — 0 Boolean — false Fixed-point data types — Representation for value of 0, which may not be exactly 0 due to scaling and limited precision. Enumerated data types — Default value 	

Programmatic Use**Block Parameter:** ExtrapolationAfterLastDataPoint**Type:** character vector**Values:** 'Linear extrapolation' | 'Hold last value' | 'Ground value'**Default:** 'Linear extrapolation'**Enable zero-crossing detection** — Zero-crossing detection

'off' (default) | 'on'

Zero-crossing detection locates discontinuities, or zero crossings, in the block output and prevents excessively small time steps near the discontinuities, which can slow down simulation. The Playback block detects zero crossings for a signal only when the sample time of the signal is continuous.

The loaded data creates a discontinuity in the block output when the data includes multiple samples with the same time. For example, for this input data, a discontinuity occurs at time 2.

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

The Playback block can also create discontinuities in the output based on how you configure interpolation and extrapolation.

- Setting **Before first point** to Ground Value can create a discontinuity at the first sample in the loaded data.
- Setting **After last point** to Ground Value can create a discontinuity at the last sample in the loaded data.

This block supports zero-crossing detection only in simulations that use a variable-step solver. When you use a fixed-step solver for simulation, the software does not detect or locate zero crossings for this block.

For more information, see “Zero-Crossing Detection”.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector**Values:** 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Algorithms

Interpolation

Interpolation is the process the Playback block uses to provide output values for simulation times that are between sample times in the loaded data. For the Playback block, you configure the interpolation as a signal property. To change the interpolation method for a signal or message:

- 1 Select the signal or message in the signal table.
- 2 In the **Properties** pane, select an option for the **Interp Method**.

You can choose linear interpolation, zero-order hold interpolation, or no interpolation.

Interpolation Method	Description
linear	<ul style="list-style-type: none"> • For <code>double</code> data, the Playback block linearly interpolates the output value using data values before and after the simulation time that needs an output value. • For all other built-in numeric data types, the Playback block: <ol style="list-style-type: none"> 1 Upcasts the data to <code>double</code> 2 Linearly interpolates the output value using data values before and after the simulation time that needs an output value 3 Downcasts the extrapolated data value to the original data type • For <code>Boolean</code> data, if the simulation time is between two workspace data points with different values, the Playback block positions the value transition halfway between the data points. For example, if the data transitions from <code>true</code> to <code>false</code>, the Playback block provides an output value of <code>true</code> for simulation times in the first half of the interval between the data points and an output value of <code>false</code> for simulation times in the latter half of the interval. <p>If the data only contains one sample, the Playback block provides that value at the output.</p> <p>Do not use the <code>Linear</code> interpolation option when the Playback block loads enumerated or fixed-point data.</p>
zoh	The Playback block holds each data value from one sample to the next. The output value for a simulation time between two samples in the data is the value of the sample that precedes the simulation time.
none (event-based)	The Playback block produces a message. For more information on messages, see “Simulink Messages Overview”.

The interpolation method affects the block output as well as the visualization. For example, this Playback block visualization shows three ways the Playback block can load the same data for a sine wave.

- The first sine wave uses linear interpolation.
- The second sine wave uses zero-order hold interpolation.
- The third sine wave is event-based and not interpolated.

Version History

Polynomial

Perform evaluation of polynomial coefficients on input values

Libraries:
Simulink / Math Operations

Description

The Polynomial block evaluates $P(u)$ at each time step for the input u . You define a set of polynomial coefficients in the form that the MATLAB `polyval` command accepts.

Ports

Input

Port_1 — Input signal
real scalar or vector

Value at which to evaluate the polynomial $P(u)$.

Data Types: `single` | `double`

Output

Port_1 — Evaluated polynomial value
real scalar or vector

Value of the polynomial $P(u)$ evaluated at the input signal.

Data Types: `single` | `double`

Parameters

Polynomial coefficients — Coefficients of polynomial to be evaluated

[+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001] (default) | real array

Specify polynomial coefficients in MATLAB `polyval` form. The first coefficient corresponds to x^N and the remaining coefficients correspond to decreasing orders of x . The last coefficient represents the constant for the polynomial.

Programmatic Use

Block Parameter: `coefs`

Type: real array

Default: [+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001]

Prelookup

Compute index and fraction for Interpolation Using Prelookup block

Libraries:

Simulink / Lookup Tables
HDL Coder / Lookup Tables

Description

The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint dataset. The Prelookup block works best with the Interpolation Using Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n-D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility and more efficient simulation and code generation than the n-D Lookup Table block. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Prelookup block, you must specify a set of breakpoint values. You choose whether to specify the breakpoint values directly on the dialog box or by feeding the values to a **bp** input port by setting the **Source** parameter to **Dialog** or **Input port**. Typically, this breakpoint data set corresponds to one dimension of the table data in an Interpolation Using Prelookup block. The Prelookup block generates a pair of outputs for each input value u by calculating:

- The index of the breakpoint set element that is less than or equal to u and forms an interval containing u
- The interval fraction in the range $0 \leq f < 1$, representing the normalized position of u on the breakpoint interval between the index and the next index value for in-range input

For example, if the breakpoint data set is $[0 \ 5 \ 10 \ 20 \ 50 \ 100]$ and the input value u is 55, the index is 4 and the fractional value is 0.1. Labels for the index and interval fraction appear as **k** and **f** on the Prelookup block icon. The index value is zero based.

The interval fraction can be negative or greater than 1 for out-of-range input. See the **Extrapolation method** block parameter for more information.

Ports

Input

Port_1 — Input signal, u
scalar | vector | matrix

The Prelookup block accepts real-valued signals of any numeric data type that Simulink supports, except Boolean. The Prelookup block supports fixed-point data types for signals and breakpoint data.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

bp — Breakpoint data

1-D vector of real-valued signals

The Prelookup block accepts real-valued signals as breakpoint data of any numeric data type that Simulink supports, except Boolean.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated

Output

k — Index of the interval containing the input, u

scalar | vector | matrix

The zero-based index, k , is a real-valued integer that specifies the interval containing the input, u .

Dependencies

To enable this port, set the **Output selection** to Index and fraction or Index only.

Data Types: int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

f — Fraction representing the normalized position of the input, u , within the interval, k

scalar | vector | matrix

Fraction, f , represents the normalized position of the input, u , within the interval k .

Dependencies

To enable this port, set the **Output selection** to Index and fraction.

Data Types: single | double | fixed point

Port_2 — Bus containing index, k , and fraction, f

bus

Outputting the index, k , and fraction f , as a bus object can help simplify the model.

Dependencies

To enable this port, set the **Output selection** to Index and fraction as bus.

Data Types: bus

Parameters**Main****Breakpoints data**

Specification — Choose how to enter breakpoint data

Explicit values (default) | Even spacing | Breakpoint object

If you set this parameter to:

- Explicit values, the **Source** and **Value** parameters are visible on the dialog box.
- Even spacing, the **First point**, **Spacing**, and **Number of points** parameters are visible on the dialog box.
- Breakpoint object, the **Name** parameter is visible on the dialog box.

Programmatic Use**Block Parameter:** BreakpointsSpecification**Type:** character vector**Values:** 'Explicit values' | 'Even spacing' | 'Breakpoint object'**Default:** 'Explicit values'**Source** — Specify source of breakpoint data

Dialog (default) | Input port

If you set **Source** to:

- Dialog, specify breakpoint data under **Value**.
- Input port, verify that an upstream signal supplies breakpoint data to the **bp** input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes from the **bp** input port.

DependenciesTo enable this parameter, set **Specification** to Explicit values.**Programmatic Use****Block Parameter:** BreakpointsDataSource**Type:** character vector**Values:** 'Dialog' | 'Input port'**Default:** 'Dialog'**Value** — Breakpoint data values

[10:10:110] (default) | vector of strictly monotonically increasing values containing two or more elements

Explicitly specify the breakpoint data. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify additional breakpoint attributes on the **Data Types** pane.

To open the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Note When you set **Specification** to Explicit values and **Source** to Input port, verify that an upstream signal supplies breakpoint data to the **bp** input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes (including data type) from the **bp** input port.

DependenciesTo enable this parameter, set **Specification** to Explicit values and **Source** to Dialog.

Programmatic Use**Block Parameter:** BreakpointsData**Type:** character vector**Values:** vector of strictly monotonically increasing values containing two or more elements**Default:** '[10:10:110]'**First point** — First point in evenly spaced breakpoint data

10 (default) | real-valued scalar

DependenciesTo enable this parameter, set **Specification** to Even spacing.**Programmatic Use****Block Parameter:** BreakpointsFirstPoint**Type:** character vector**Values:** real-valued scalar**Default:** '10'**Spacing** — Spacing between evenly spaced breakpoints

10 (default) | real-valued, positive scalar

DependenciesTo enable this parameter, set **Specification** to Even spacing.**Programmatic Use****Block Parameter:** BreakpointsSpacing**Type:** character vector**Values:** real-valued, positive scalar**Default:** '10'**Number of points** — Number of evenly spaced points

11 (default) | real-valued, positive scalar

DependenciesTo enable this parameter, set **Specification** to Even spacing.**Programmatic Use****Block Parameter:** BreakpointsNumPoints**Type:** character vector**Values:** real-valued, positive scalar**Default:** '11'**Name** — Name of a Simulink.Breakpoint object

no default | Simulink.Breakpoint

Specify the name of a Simulink.Breakpoint object. A breakpoint object references Simulink

breakpoint objects. If a Simulink.Breakpoint object does not exist, click the action button  and select **Create**. The corresponding parameters of the new breakpoint object are automatically populated with the block information.

Dependencies

To enable this parameter, set **Specification** to Breakpoint object.

Programmatic Use

Block Parameter: BreakpointObject

Type: character vector

Values: Simulink.Breakpoint object

Default: ''

Algorithm

Output selection — Specify the signals the block outputs

Index and fraction (default) | Index and fraction as bus | Index only

If you want the block to output the index and interval fraction, you can specify whether the block outputs individual signals or a bus signal that includes both the index and fraction signals.

- Index only outputs just the index, without the fraction. Typical applications for this option include:
 - Feeding a Direct Lookup Table (n-D) block, with no interpolation on the interval
 - Feeding selection ports of a subtable selection for an Interpolation Using Prelookup block
 - Performing nonlinear quantizations
- Index and fraction outputs the index and fraction as individual signals.
- Index and fraction as bus outputs a bus signal that includes the index and fraction signals. Using a bus for these signals:
 - Simplifies the model by tying these two related signals together
 - Creates a testpoint DpResult structure for the AUTOSAR 4.0 library
 - For the AUTOSAR 4.0 library, avoids the creation of extra copies during code generation when the Prelookup and Interpolation Using Prelookup blocks are in separate models

Note Selecting Index and fraction as bus displays the **Output** parameter in the **Data Types** pane and sets the **Output** parameter to `Inherit: auto`. Change this default value to specify a user-defined bus object. For details about defining the bus object, see the **Output** parameter description.

Programmatic Use

Block Parameter: OutputSelection

Type: character vector

Values: 'Index and fraction' | 'Index and fraction as bus' | 'Index only'

Default: 'Index and fraction'

Index search method — Method for searching breakpoint data

Binary search (default) | Linear search | Evenly spaced points

Each search method has speed advantages in different situations:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices. This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.
- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input values for `u` do not vary significantly between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input values for `u` jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Programmatic Use

Block Parameter: `IndexSearchMethod`

Type: character vector

Values: `'Evenly spaced points' | 'Linear search' | 'Binary search'`

Default: `'Binary search'`

Begin index search using previous index result — Start search using the index found at the previous time step

`off (default) | on`

For input values of `u` that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Programmatic Use

Block Parameter: `BeginIndexSearchUsingPreviousIndexResult`

Type: character vector

Values: `'off' | 'on'`

Default: `'off'`

Extrapolation method — Method for handling out-of-range input values

`Clip (default) | Linear`

Options include:

- `Clip`

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction of 0
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction of 1

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is 0. If u is 3.5, the index is 1 and the interval fraction is 1.

- Linear

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction that represents the linear distance from u to the first breakpoint
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction that represents the linear distance from the next-to-last breakpoint to u

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is -0.5. If u is 3.5, the index is 1 and the interval fraction is 1.5.

Note The Prelookup block supports linear extrapolation only when all of the following conditions are true:

- The input u , breakpoint data, and fraction output use floating-point data types.
 - The index uses a built-in integer data type.
-

Programmatic Use

Block Parameter: ExtrapMethod

Type: character vector

Values: 'Clip' | 'Linear'

Default: 'Clip'

Use last breakpoint for input at or above upper limit — Method of handling inputs at or above upper limit

off (default) | on

Specify how to index input values of u that are greater than or equal to the last breakpoint. The index value is zero based. When input equals the last breakpoint, block outputs differ as follows.

Check Box	Block Outputs
Selected (on)	<ul style="list-style-type: none"> • Index of the last element in the breakpoint data set • Interval fraction of 0
Cleared (off)	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction of 1

Tip When you select **Use last breakpoint for input at or above upper limit** for a Prelookup block, you must also select **Valid index input may reach last index** for the Interpolation Using Prelookup block to which it connects. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Dependencies

This check box is visible only when:

- **Output only the index** is cleared
- **Extrapolation method** is Clip

However, when **Output only the index** is selected and **Extrapolation method** is Clip, the block behaves as if this check box is selected, even though it is invisible.

Programmatic Use

Block Parameter: UseLastBreakpoint

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for out-of-range input — Block action when input is out of range

None (default) | Warning | Error

Options include:

- None — Produce no response.
- Warning — Display a warning and continue the simulation.
- Error — Terminate the simulation and display an error.

Programmatic Use

Block Parameter: DiagnosticForOutOfRangeInput

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range breakpoint inputs

Off (default) | On

Check Box	Result	When to Use
On	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code.	For code efficiency
Off	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to Error.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input is out-of-range, the behavior is undefined for generated code

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

Additionally, to determine if it is safe to select this check box, if you have a Simulink Design Verifier license, consider using the “Detect Block Input Range Violations” (Simulink Design Verifier) check.

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Advisor Checks”.

Programmatic Use

Block Parameter: RemoveProtectionInput

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Data Types

Breakpoint — Breakpoint data type

Inherit: Same as input (default) | Inherit: Inherit from 'Breakpoint data' | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the breakpoint data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Tip

- Specify a breakpoint data type different from the data type of input `u` for these cases:
 - Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal `u`
 - Sharing of prescaled breakpoint data between two Prelookup blocks with different data types for input `u`
 - Sharing of custom storage breakpoint data in the generated code for blocks with different data types for input `u`
- Specify the same slope and bias for a breakpoint data type and its corresponding input data type if either of them has a fixed-point data type.
- Enumerated data:
 - Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.

- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- Because the fraction is 1 or 0, select **Output selection > Index only**.

If you are using the index only output selection setting with the Interpolation Using Prelookup block, consider using the **Number of sub-table selection dimensions** parameter.

These are limitations for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.
- When breakpoints data source is set to `Inport port`, the enumeration data type must have 0 as the default value. For example, for this enumeration class, the default value of `GEAR1` must be 0.

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(32),
        NEUTRAL(0)
    end
end
```

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog`.

Note When you set **Source** to `Input port`, the block inherits all breakpoint attributes (data type, minimum, and maximum) from the `bp` input port.

Programmatic Use

Block Parameter: `BreakpointDataTypeStr`

Type: character vector

Values: `'Inherit: Same as input'` | `'Inherit: Inherit from 'Breakpoint data''` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as input'`

Index — Index data type

`uint32 (default)` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `fixdt(1,16)` | `<data type expression>`

Specify a data type that can index all elements in the breakpoint data set. You can:

- Select a built-in integer data type from the list.
- Specify an integer data type using a fixed-point representation.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: IndexDataTypeStr

Type: character vector

Values:

'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | '<data type expression>'

Default: 'uint32'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the data type of the interval fraction. You can:

- Select a built-in data type from the list.
- Specify data type inheritance through an internal rule.
- Specify a fixed-point data type using the [Slope Bias] or binary-point-only scaling representation.
 - If you use the [Slope Bias] representation, the scaling must be trivial — that is, the slope is 1 and the bias is 0.
 - If you use the binary-point-only representation, the fixed power-of-two exponent must be less than or equal to zero.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to **Index** and **fraction**.

Programmatic Use

Block Parameter: FractionDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

Inherit: auto (default) | bus: <object name>

To output a virtual bus, use the **Inherit:** auto setting. The resulting virtual bus contains two elements, the index and the fraction signals.

To output and specify a nonvirtual bus, use the `Bus: <object name>` template. Replace `<object name>` with the name of a bus object that contains the index and fraction signals.

- The bus object must contain two elements. The first element corresponds to the index signal and the second to the fraction signal.
- The index and fraction bus element signals cannot be bus signals.
- The data type and the complexity of the bus elements must meet the same constraints that apply to the index and fraction signals if you set **Output selection** to `Index` and `fraction`.

To create the bus object with the index and fraction bus elements, use MATLAB code similar to this, customizing the bus object name and the names and data types of the bus elements.

```
% Bus object: kfBus
elems(1) = Simulink.BusElement;
elems(1).Name = 'Index';
elems(1).DataType = 'int8';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Fraction';
elems(2).DataType = 'double';

kfBus = Simulink.Bus;
kfBus.Elements = elems;
clear elems;
```

Alternatively, you can use the Type Editor to create or modify the bus object to use with the Prelookup block.

If you feed the bus output signal from this block to an Interpolation Using Prelookup block, select the **Require index and fraction as bus** check box in that block.

Note Use the Fixed-Point Tool data type override option to override bus objects with new bus objects that replace fixed-point data types with floating-point data types.

Overridden bus objects used with the Prelookup block can cause an error because the block does not accept floating-point data types for the first element in the bus.

If you encounter this issue, use the **Fix** button to redefine the original bus object and protect it from being overridden. For example, suppose you define the first element of the bus object to be an `int32`.

```
myBus.Elements(1).DataType
int32
```

Clicking the **Fix** button redefines the first bus element:

```
myBus.Elements(1).DataType = 'fixdt('int32','DataTypeOverride','Off')
```

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to **Index** and **fraction as bus**.

Programmatic Use

Block Parameter: OutputBusDataTypeStr

Type: character vector

Values: 'Inherit: auto' | 'Bus: <object name>' | '<data type expression>'

Default: 'Inherit: auto'

Breakpoint Minimum — Minimum value breakpoint data can have

[] (default) | scalar

Specify the minimum value that the breakpoint data can have. The default value is [] (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to **Dialog** on the **Main** tab.

Programmatic Use

Block Parameter: BreakpointMin

Type: character vector

Value: scalar

Default: '[]'

Breakpoint Maximum — Maximum value breakpoint data can have

[] (default) | scalar

Specify the maximum value that the breakpoint data can have. The default value is [] (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to **Dialog** on the **Main** tab.

Programmatic Use

Block Parameter: BreakpointMax

Type: character vector

Value: scalar

Default: '[]'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Block Characteristics

Data Types	double enumerated fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Enumerated Values in Prelookup

Simulate a Prelookup block with enumerated values.

Suppose that you have a Prelookup block with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

Prelookup block has these settings:

- **Breakpoints data** value is enumeration('Gears').

- **Output selection** is Index only.
- For an unordered search, set **Index search method** to Linear search and clear the **Begin index search using previous index result** check box.
- **Extrapolation method** is Clip.

Interpolation using Prelookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is [5 10 20 40 80 -5 0].
- **Interpolation method** is Flat.
- **Number of sub-table selection dimensions** is 1.

Simulation produces a vector [10 -5 80], which correspond to GEAR2, REVERSE, and SPORTS.

Version History

Introduced in R2006b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
----------------------------------	--

InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

Required Block Settings

- **Breakpoint data:** For **Source**, select Dialog.
- **Specification:** You can select either Explicit values or Even spacing.
- **Index search method:** Select Evenly spaced points.
- **Extrapolation method:** Select Clip.
- **Diagnostic for out-of-range input:** Select Error.
- **Use last breakpoint for input at or above upper limit:** Select this check box.
- **Breakpoint:** For **Data Type**, select Inherit: Same as input.
- **Integer rounding mode:** Select Zero, Floor, or Simplest.

Table Data Typing and Sizing

- It is good practice to structure your table such that the spacing between breakpoints is a power of two. If the breakpoint spacing does not meet this condition, HDL Coder issues a warning. When the breakpoint spacing is a power of two, you can replace division operations in the prelookup step with right-shift operations.
- All ports on the block require scalar values.
- The coder permits floating-point data for breakpoints.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Probe

Output signal attributes, including width, dimensionality, sample time, and complex signal flag

Libraries:

Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Probe block outputs selected information about the signal on its input. The block can output the following attributes of the input signal: width, dimensionality, sample time, and a flag indicating whether the input is a complex-valued signal. The block has one input port. The number of output ports depends on the information that you select for probing, that is, signal dimensionality, sample time, and/or complex signal flag. Each probed value is output as a separate signal on a separate output port, with an independent data type control. During simulation, the block icon displays the probed data.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal to probe, specified as a scalar, vector, matrix, or N-D array. The block accepts real or complex-valued signals of any built-in data type.

You can use an array of buses as an input signal to a Probe block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Output

Port_1 (W) — Signal width

scalar

Width, or number of elements, in the input signal, specified as a scalar. The width is also displayed on the block icon with the notation W:.

Dependencies

To enable this port, select **Probe width**.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 (Ts) — Sample time

vector

Sample time of the input signal, as a two-element vector that specifies the period and offset of the sample time, respectively. The sample time is also displayed on the block icon with the notation T_s :. See “Specify Sample Time” for more information.

Dependencies

To enable this port, select **Probe sample time**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_3 (C) — Signal complexity
scalar

Indication of input signal complexity:

- When the input signal is complex, the block outputs 1.
- When the input signal is real-valued, the block outputs 0.

The indication of signal complexity is also displayed on the block icon with the notation C :.

Dependencies

To enable this port, select **Detect complex signal**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Port_4 (D) — Signal dimensions
scalar | vector

Dimensions of the input signal, output as a scalar or vector. The signal dimensions are also displayed on the block icon with the notation D :.

Dependencies

To enable this port, select **Probe signal dimensions**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters**Main**

Probe width — Output width of the input signal

`on` (default) | `off`

Select to output the width, or number of elements, of the probed signal.

Programmatic Use

Block Parameter: `ProbWidth`

Type: character vector

Values: `'off'` | `'on'`

Default: `'on'`

Probe sample time — Output sample time of input signal

on (default) | off

Select to output the sample time of the probed signal. The output is a two-element vector that specifies the period and offset of the sample time, respectively. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: ProbeSampleTime

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Detect complex signal — Indicate the complexity of input signal

on (default) | off

Select to output 1 if the probed signal is complex; otherwise, 0.

Programmatic Use

Block Parameter: ProbeComplexSignal

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Probe signal dimensions — Output dimensions of input signal

on (default) | off

Select to output the dimensions of the probed signal.

Programmatic Use

Block Parameter: ProbeSignalDimensions

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Signal Attributes

Data type for width — Data type of signal width output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the signal width.

Programmatic Use

Block Parameter: ProbeWidthDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Data type for sample time — Data type of sample time output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the sample time information.

Programmatic Use

Block Parameter: ProbeSampleTimeDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Data type for signal complexity — Data type of complexity output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | Same as input

Select the output data type for the complexity information.

Programmatic Use

Block Parameter: ProbeComplexityDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Data type for signal dimensions — Data type for signal dimension output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the signal dimension output.

Programmatic Use

Block Parameter: ProbeDimensionsDataType

Type: character vector

Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'

Default: 'double'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Product, Matrix Multiply

Multiply and divide scalars and nonscalars or multiply and invert matrices

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Math Operations
 Simulink / Matrix Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Product block outputs the result of multiplying two inputs: two scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The default parameter values that specify this behavior are:

- **Multiplication:** Element-wise (`.*`)
- **Number of inputs:** 2

This table shows the output of the Product block for “Multiply Inputs of Different Dimensions with the Product Block” on page 12-67 using default block parameter values.

Inputs and Behavior	Example
Scalar X Scalar Output the product of the two inputs.	
Scalar X Nonscalar Output a nonscalar having the same dimensions as the input nonscalar. Each element of the output nonscalar is the product of the input scalar and the corresponding element of the input nonscalar.	
Nonscalar X Nonscalar Output a nonscalar having the same dimensions as the inputs. Each element of the output is the product of corresponding elements of the inputs.	

The Divide and Product of Elements blocks are variants of the Product block.

- For information on the Divide block, see Divide.
- For information on the Product of Elements block, see Product of Elements.

The Product block (or the Divide block or Product of Elements block, if appropriately configured) can:

- Numerically multiply and divide any number of scalar, vector, or matrix inputs
- Perform matrix multiplication and division on any number of matrix inputs

The Product block performs scalar or matrix multiplication, depending on the value of the **Multiplication** parameter. The block accepts one or more inputs, depending on the **Number of inputs** parameter. The **Number of inputs** parameter also specifies the operation to perform on each input.

The Product block can input any combination of scalars, vectors, and matrices for which the operation to perform has a mathematically defined result. The block performs the specified operations on the inputs, then outputs the result.

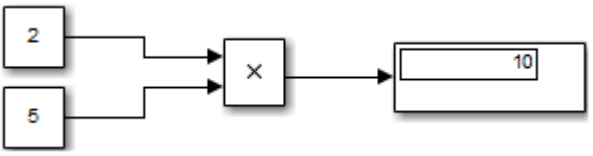

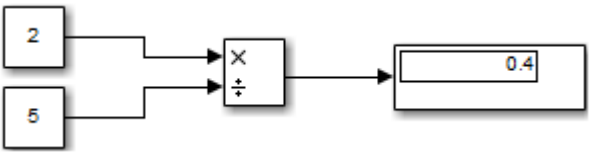

The Product block has two modes: *Element-wise mode*, which processes nonscalar inputs element by element, and *Matrix mode*, which processes nonscalar inputs as matrices.

Element-Wise Mode

When you set **Multiplication** to *Element-wise (.*)*, the Product block is in *Element-wise mode*, in which it operates on the individual numeric elements of any nonscalar inputs. The MATLAB equivalent is the `.*` operator. In element-wise mode, the Product block can perform a variety of multiplication, division, and arithmetic inversion operations.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each is multiplied or divided to form the output. When the Product block is in element-wise mode and has only one input, it is functionally equivalent to a Product of Elements block. When the block has multiple inputs, any nonscalar inputs must have identical dimensions, and the block outputs a nonscalar with those dimensions. To calculate the output, the block first expands any scalar input to a nonscalar that has the same dimensions as the nonscalar inputs.

This table shows the output of the Product block for “Multiply Inputs of Different Dimensions with the Product Block” on page 12-67, using the indicated values for the **Number of inputs** parameter.

Parameter Values	Examples
Number of inputs: 2	
Number of inputs: */	

Parameter Values	Examples
Number of inputs: /**/	
Number of inputs:**	
Number of inputs: */*	

Matrix Mode

When the value of the **Multiplication** parameter is `Matrix(*)`, the Product block is in *Matrix mode*, in which it processes nonscalar inputs as matrices. The MATLAB equivalent is the `*` operator. In Matrix mode, the Product block can invert a single square matrix, or multiply and divide any number of matrices that have dimensions for which the result is mathematically defined.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each input matrix is multiplied or divided to form the output. The syntax of **Number of inputs** is the same as in element-wise mode. The difference between the modes is in the type of multiplication and division that occur.

Interactions Between Block Inputs and Modes

The interactions between the Product block inputs and its **Multiplication** modes are:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is `1` or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a `*` character is multiplied into the output. Each input that corresponds to a `/`

character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

Expected Differences Between Simulation and Code Generation

For element-wise operations on complex floating-point inputs, simulation and code generation results might differ in near-overflow cases. Although **complex numbers** is selected and **non-finite numbers** is not selected on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, the code generator does not emit special case code for intermediate overflows. This method improves the efficiency of embedded operations for the general case that does not include extreme values. If the inputs could include extreme values, you must manage these cases explicitly.

The generated code might not produce the same pattern of NaN and inf values as simulation when these values are mathematically meaningless. For example, if the simulation output contains a NaN, output from the generated code also contains a NaN, but not necessarily in the same place.

Ports

Input

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter and set the **Multiplication** parameter to **Element-wise(.*)**.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more \div ports, specify one or more / characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Element-wise(.*)`.

Data Types: `half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point`

***** — Input signal to multiply
scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more ***** ports, specify one or more * characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Matrix(*)`.

Data Types: `half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point`

Inv — Input signal to divide or invert
scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more **Inv** ports, specify one or more / characters for the **Number of inputs** parameter and set the **Multiplication** parameter to `Matrix(*)`.

Data Types: `half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point`

Output

Port_1 — Output computed by multiplying, dividing, or inverting inputs
scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point`

Parameters**Main**

Number of inputs — Control number of inputs and type of operation

2 (default) | scalar | * or / for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '2' | '**' | '*/' | '*/*' | ...

Default: '2'

Multiplication — Element-wise (.*) or Matrix (*) multiplication

Element-wise (.*) (default) | Matrix (*)

Specify whether the block performs Element-wise (.*) or Matrix (*) multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: 'Element-wise (.*)' | 'Matrix (*)'

Default: 'Element-wise (.*)'

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as All dimensions, or Specified dimension. When you select Specified dimension, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to Element-wise (.*).

Programmatic Use

Block Parameter: CollapseMode

Type: character vector

Values: 'All dimensions' | 'Specified dimension'
Default: 'All dimensions'

Dimension — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to Element-wise (.*)
- **Multiply over** to Specified dimension

Programmatic Use

Block Parameter: CollapseDim

Type: character vector

Values: '1' | '2' | ...

Default: '1'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

Require all inputs to have the same data type — Require that all inputs have the same data type

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type** — Specify the output data type

Inherit: Inherit via internal rule (default) | Inherit: Keep MSB | Inherit: Match scaling | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Data Types of Signals”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.
- **Inherit: Keep MSB**— Simulink chooses a data type that maintains the full range of the operation, then reduces the precision of the output to a size appropriate for the embedded target hardware.

Tip For more efficient generated code, deselect the **Saturate on integer overflow** parameter.

This rule never produces overflows.

- **Inherit: Match scaling**— Simulink chooses a data type whose scaling matches the scaling of the input types. If the full range of the type does not fit on the embedded target hardware, the range is reduced yielding a type appropriate for the embedded target hardware. This rule can produce overflows. This rule does not support multiplication between complex signals

The **Inherit: Keep MSB** and **Inherit: Match scaling** rules do not support multiplication between complex signals or signals with non-zero bias. The rules support only multiplication and division ('**', '*/', '/*') between two inputs, matrix multiplication of two inputs, and collapsing product of two elements of a vector.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.

- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal` rule output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Keep MSB'` | `'Inherit: Match scaling'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'uint64'` | `'int64'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Mode — Select data type mode

Inherit (default) | Built in | Fixed Point

Select the category of data to specify.

- **Inherit** — Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right where you can select the inheritance mode.
- **Built in** — Built-in data types. Selecting **Built in** enables a second menu/text box to the right where you can select a built-in data type.
- **Fixed point** — Fixed-point data types. Selecting **Fixed point** enables additional parameters that you can use to specify a fixed-point data type.
- **Expression** — Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, click the **Show data type assistant** button.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- When you select **Inherit**, Simulink inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.
- When you select **Off**, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, set **Mode** to **Built in** or **Fixed point**.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Signedness — Specify signed or unsigned

Signed (default) | Unsigned

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only.

- **Signed**, specifies the fixed-point data as signed.
- **Unsigned**, specifies the fixed-point data as unsigned.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Mode** to **Fixed point**.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to **Fixed point**.

Fraction length — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to **Binary point**.

Scaling — Method for scaling fixed-point data

Best precision (default) | Binary point | Slope and bias

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to Fixed point.

Slope — Specify slope for the fixed-point data type2⁰ (default) | positive, real-valued scalar

Specify slope for the fixed-point data type. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to Slope and bias.

Bias — Specify bias for the fixed-point data type

0 (default) | real-valued scalar

Specify bias for the fixed-point data type as any real number. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to Slope and bias.

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

The default Linear implementation generates a chain of N operations (multipliers) for N inputs.

Architecture	Parameters	Description
Lineardefault	None	Generate a product operator * in the generated code.
ShiftAdd	LatencyStrategy	<p>Perform product operations on fixed-point types by using multiple shift and add operations. The block has pipelined implementation that introduces additional latency in the generated code. ShiftAdd architecture maps to efficient circuits in ASIC applications. This architecture is useful in applications on FPGA target boards that do not have DSP units.</p> <p>The MAX latency for different word lengths is calculated by using this formula: $\text{ceil}(\log_2(\min(\text{in1WL}, \text{in2WL})))$. in1WL is the first input word length and in2WL is the second input word length. For example, if both inputs are of word length four the MAX latency is two.</p> <p>When you use fixed-point data types, the word length of the inputs must be less than 63.</p>

HDL Block Properties

If you use the block in matrix multiplication mode, you can specify the **DotProductStrategy**. This setting determines whether you want to implement the matrix multiplication by using a tree of adders and multipliers, or use the Multiply-Accumulate block implementation. The default is Fully Parallel.

Note The **DotProductStrategy** must be set to Fully Parallel when you use the Native Floating Point mode.

For more information, see “DotProductStrategy” (HDL Coder).

See also “Design Considerations for Matrices and Vectors” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
LatencyStrategy	To enable this property, set HDL architecture to ShiftAdd. Specify whether to map the blocks in your design to MAX, CUSTOM, or ZERO latency for fixed-point and floating-point types. The default is MAX. See also “LatencyStrategy” (HDL Coder).
CustomLatency	To enable this property, set HDL architecture to ShiftAdd. When LatencyStrategy is set to CUSTOM, use this property to specify a custom latency value between ZERO and MAX for fixed-point types. See also “LatencyStrategy” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is inherit. See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to inherit, Max, Min, Zero, or Custom for the floating-point operator. The default is inherit. See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to Custom. HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is inherit. See also “MantissaMultiplyStrategy” (HDL Coder).

Complex Data Support

The default (linear) implementation supports complex data.

Complex division is not supported. For block implementations of the Product block in divide mode or reciprocal mode, see “HDL Code Generation” on page 1-604 on the Divide block reference page.

Restrictions

- HDL code generation does not support more than two inputs at the ports of the block when you use the block in matrix multiplication mode.
- Product block with /* for **Number of inputs** block parameter performs a division where the second input is divided by the first input. This mode has the same restrictions that apply to the Divide block. See “HDL Code Generation” on page 1-604.
- The Product block does not support the sharing optimization in ShiftAdd architecture. To apply the sharing optimization on the Product block, consider using Linear architecture. To view sharing optimization results for your subsystem, generate the **Streaming and Sharing Report**.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Divide | Dot Product | Product of Elements

Product of Elements

Copy or invert one scalar input, or collapse one nonscalar input

Libraries:

Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Product of Elements block inputs one scalar, vector, or matrix. You can use the block to:

- Copy a scalar input unchanged
- Invert a scalar input (divide 1 by it)
- Collapse a vector or matrix to a scalar by multiplying together all elements or taking successive inverses of the elements
- Collapse a matrix to a vector using one of these options:
 - Multiply together the elements of each row or column
 - Take successive inverses of the elements of each row or column

The Product of Elements block is functionally a Product block that has two preset parameter values:

- **Multiplication:** Element-wise (.*)
- **Number of inputs:** *

Setting nondefault values for either of those parameters can change a Product of Elements block to be functionally equivalent to a Product block or a Divide block.

Ports

Input

Port_1 — First input to multiply or divide
 scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Port_N — Nth input to multiply or divide
 scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

X — Input signal to multiply
scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

÷ — Input signal to divide or invert
scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more **÷** ports, specify one or more / characters for the **Number of inputs** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output computed by multiplying, dividing, or inverting inputs
scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Number of inputs — Control number of inputs and type of operation

* (default) | positive integer scalar | * or / for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a

degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Integer value > 1**

The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

- **Unquoted string of two or more * and / characters**

The block has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1611 and “Matrix Mode” on page 1-1612 for more information.

Programmatic Use

Block Parameter: Inputs

Type: character vector

Values: '2' | '*' | '**' | '*/' | '*/*' | ...

Default: '*'

Multiplication — Element-wise (.*) or Matrix (*) multiplication

Element-wise (.*) (default) | Matrix (*)

Specify whether the block performs Element-wise (.*) or Matrix (*) multiplication.

Programmatic Use

Block Parameter: Multiplication

Type: character vector

Values: 'Element-wise (.*)' | 'Matrix (*)'

Default: 'Element-wise (.*)'

Multiply over — All dimensions or specified dimension

All dimensions (default) | Specified dimension

Specify the dimension to multiply over as All dimensions, or Specified dimension.

When you select All dimensions and select configuration parameter **Use algorithms optimized for row-major array layout**, Simulink enables row-major algorithms for simulation. To generate row-major code, set configuration parameter **Array layout** (Simulink Coder) to Row-major in addition to selecting **Use algorithms optimized for row-major array layout**. The column-major and row-major algorithms differ only in the multiplication order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms.

When you select Specified dimension, you can specify the **Dimension** as 1 or 2.

Dependencies

To enable this parameter, set **Number of inputs** to * and **Multiplication** to Element-wise (.*).

Programmatic Use**Block Parameter:** CollapseMode**Type:** character vector**Values:** 'All dimensions' | 'Specified dimension'**Default:** 'All dimensions'**Dimension** — Dimension to multiply over

1 (default) | 2 | ... | N

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to *
- **Multiplication** to Element-wise (.*)
- **Multiply over** to Specified dimension

Programmatic Use**Block Parameter:** CollapseDim**Type:** character vector**Values:** '1' | '2' | ...**Default:** '1'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Signal Attributes****Require all inputs to have the same data type** — Require that all inputs have the same data type

off (default) | on

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use**Block Parameter:** InputSameDT**Type:** character vector

Values: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type** — Specify the output data type

```
Inherit: Inherit via internal rule (default) | Inherit: Inherit via back
propagation | Inherit: Same as first input | double | single | int8 | uint8 | int16 |
uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) |
fixdt(1,16,2^0,0) | <data type expression>
```

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Data Types of Signals”.

When you select an inherited option, the block behaves as follows:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of **Inherit: Same as input**.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use **Inherit: Inherit via back propagation** and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.
- **Inherit: Same as first input** — Use data type of first input signal.

Dependencies

When input is a floating-point data type smaller than single precision, the **Inherit: Inherit via internal rule** output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Same as first input' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use**Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (<code>on</code>).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (<code>off</code>).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Mode — Select data type mode

Inherit (default) | Built in | Fixed Point

Select the category of data to specify.

- **Inherit** — Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right where you can select the inheritance mode.
- **Built in** — Built-in data types. Selecting **Built in** enables a second menu/text box to the right where you can select a built-in data type.
- **Fixed point** — Fixed-point data types. Selecting **Fixed point** enables additional parameters that you can use to specify a fixed-point data type.
- **Expression** — Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, click the **Show data type assistant** button.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- When you select **Inherit**, Simulink inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.
- When you select **Off**, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, set **Mode** to **Built in** or **Fixed point**.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to

ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Signedness — Specify signed or unsigned

Signed (default) | Unsigned

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only.

- Signed, specifies the fixed-point data as signed.
- Unsigned, specifies the fixed-point data as unsigned.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Mode** to Fixed point.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to Fixed point.

Fraction length — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to Binary point.

Scaling — Method for scaling fixed-point data

Best precision (default) | Binary point | Slope and bias

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to Fixed point.

Slope — Specify slope for the fixed-point data type

2⁰ (default) | positive, real-valued scalar

Specify slope for the fixed-point data type. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to Slope and bias.

Bias — Specify bias for the fixed-point data type

0 (default) | real-valued scalar

Specify bias for the fixed-point data type as any real number. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to Slope and bias.

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms

The Product of Elements block uses these algorithms to perform element-wise operations on inputs of floating-point, built-in integer, and fixed-point types.

Input	Element-Wise Operation	Algorithm
Real scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Real vector or matrix with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$
Complex scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Complex vector or matrix with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1)/u_2)/u_3) \dots /u_N$

If the specified dimension for element-wise multiplication or division is a row or column of a matrix, the algorithm applies to that row or column. Consider the “Complex Division Using the Product of Elements Block” on page 12-70 example.

The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- $y = (((1/2+i)/3)/4-i)/5$

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- $y(1) = ((1/2+i)/3)$
- $y(2) = ((1/4-i)/5)$

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

HDL Coder supports Tree architectures for Product or Product of Elements blocks that have a single vector input with multiple elements.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Additional cycles of latency	Description
Linear (default)	0	Generates a linear chain of adders to compute the sum of products.
Tree	0	Generates a tree structure of adders to compute the sum of products.

Note The Product of Element block does not support HDL code generation with double data types in the Native Floating Point mode.

HDL Block Properties

If you use the block in matrix multiplication mode, you can specify the **DotProductStrategy**. This setting determines whether you want to implement the matrix multiplication by using a tree of adders and multipliers, or use the Multiply-Accumulate block implementation. The default is Fully Parallel.

Note The **DotProductStrategy** must be set to Fully Parallel when you use the Native Floating Point mode.

For more information, see “DotProductStrategy” (HDL Coder).

See also “Design Considerations for Matrices and Vectors” (HDL Coder).

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also “DSPStyle” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Native Floating Point	
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Native Floating Point	
MantissaMultiplyStrategy	Specify how to implement the mantissa multiplication operation during code generation. By using different settings, you can control the DSP usage on the target FPGA device. The default is <code>inherit</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

Complex Data Support

The default (linear) implementation supports complex data.

Complex division is not supported. For block implementations of the Product block in divide mode or reciprocal mode, see “HDL Code Generation” on page 1-604 on the Divide block reference page.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Propagation Delay

Model loop delay, latency, pulse delay

Libraries:
Simulink / Discrete

Description

The Propagation Delay block delays the current value for a signal into the future by an amount specified by a delay signal. The Propagation Delay block is well suited for implementing time delay in a discrete system.

On each simulation step k , the block samples the signal input U_k and the delay input D_k . The block output value becomes the signal value after the delay time D_k has elapsed from the current simulation time T_k .

$$y(t) = U_k \text{ when } t = T_k + D_k$$

At the start of the simulation, the block output value is the **Initial output** block parameter value Y_0 . The first sample of the delay signal D_0 determines when the block output changes from the **Initial output** value to the delayed input signal values.

$$y(t) = Y_0 \text{ when } t < T_0 + D_0$$

When the simulation reaches the time $T_0 + D_0$, the block output is determined by the signal and delay samples.

$$y(t) = U_k \text{ when } T_k + D_k \leq t \leq T_{k+1} + D_{k+1},$$

where:

- U_k is the sample of the input signal taken at $t = T_k$.
- D_k is the sample of the delay signal taken at $t = T_k$.
- T_{k+1} is the simulation time at which the next signal and delay samples were taken.
- D_{k+1} is the delay sample taken at time T_{k+1} .

Ports

Input

u — Signal to delay
scalar

The Propagation Delay block supports real, scalar input signals with continuous or discrete sample time. The input signal data type can be any built-in type besides `int64` and `uint64`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

dt — Delay signal
scalar

The delay signal specifies the amount of delay to apply at each time step in the simulation. You can use the Propagation Delay block to implement a constant or variable delay.

The delay signal values must satisfy these constraints:

- The delay signal must contain scalar, real, finite, positive values larger than $128 \cdot \text{eps}$, which is the smallest time resolution the software supports.
- The output times for delayed input signal samples must increase monotonically.

For example, suppose the delay signal value is 0.6 at simulation time 0 and the next simulation step occurs at time 0.5 . The delay signal at time 0.5 must be greater than 0.1 so that the delayed output time for the input signal sample $U_{0.5}$ is greater than the output time for input signal sample U_0 (0.6).

- When you select **Run at fixed time intervals**, the delay signal values must be greater than the value you specify for the **Sample time** parameter.

Data Types: `double`

Output

y — Delayed signal
scalar

The output signal has the same data type as the input signal. By default, the output signal has fixed-in-minor-step sample time. When you select **Run at fixed time intervals**, the output signal has the discrete sample time you specify for the **Sample time** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

Initial output — Initial value for output signal

0 (default) | scalar

Specify the initial output signal value Y_0 . The first sample of the delay signal D_0 determines when the block output changes from the **Initial output** value to the delayed input signal values.

$$y(t) = Y_0 \text{ when } t < T_0 + D_0$$

Programmatic Use

Block Parameter: `InitialOutput`

Type: `string` | character vector

Values: numeric scalar

Default: 0

Run at fixed time intervals — Option to execute block at fixed rate

`off` (default) | `on`

This parameter specifies how the block executes and the sample time for the output signal.

- **off** — Block executes each time the delay for an input sample elapses. Output signal has fixed-in-minor sample time.
- **on** — Block executes at a fixed rate that you specify using the **Sample time** parameter. Output signal has the sample time you specify using the **Sample time** parameter.

When you select **Run at fixed time intervals**:

- The delay signal values must be greater than the value you specify for the **Sample time** parameter.
- Delay signal values that are not integer multiples of the specified sample time are rounded down to the nearest integer multiple of the sample time. For example, if the sample time is 0.1 and the delay signal value is 0.68, the software rounds the delay to 0.6.

Programmatic Use

Block Parameter: RunAtFixedTimeIntervals

Type: string | character vector

Values: 'on' | 'off'

Default: 'off'

Sample time — Output sample time

0.1 (default) | scalar

Specify the sample time for the block output signal. The delay signal values must be greater than the specified sample time.

When the delay signal value is not an integer multiple of the specified sample time, the software rounds the delay value down to the closest value that is an integer multiple of the sample time. For example, if the sample time is 0.1 and the delay value is 0.68, the software rounds the delay to 0.6.

Dependencies

To enable this parameter, select **Run at fixed time intervals**.

Programmatic Use

Block Parameter: SampleTime

Type: string | character vector

Values: numeric scalar

Default: 0.1

Block Characteristics

Data Types	Boolean double integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2022b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

To generate code from a model that uses the Propagation Delay block, you must configure the Propagation Delay block to produce an output with discrete sample time. Select **Run at fixed sample intervals** and specify a discrete rate for the **Sample time** parameter.

The Propagation Delay block dynamically allocates memory to store input signal and delay signal samples. The target for code generation must support dynamic memory allocation.

Pulse Generator

Generate square wave pulses at regular intervals

Libraries:
Simulink / Sources

Description

The Pulse Generator block generates square wave pulses at regular intervals. The block waveform parameters, **Amplitude**, **Pulse Width**, **Period**, and **Phase delay**, determine the shape of the output waveform. The following diagram shows how each parameter affects the waveform.

The Pulse Generator block can emit scalar, vector, or matrix signals of any real data type. To emit a scalar signal, use scalars to specify the waveform parameters. To emit a vector or matrix signal, use vectors or matrices, respectively, to specify the waveform parameters. Each element of the waveform parameters affects the corresponding element of the output signal. For example, the first element of a vector amplitude parameter determines the amplitude of the first element of a vector output pulse. All the waveform parameters must have the same dimensions after scalar expansion. The data type of the output is the same as the data type of the **Amplitude** parameter.

The block output can be generated in time-based or sample-based modes, determined by the **Pulse type** parameter.

Time-Based Mode

In time-based mode, Simulink computes the block output only at times when the output actually changes. This approach results in fewer computations for the block output over the simulation time period. Activate this mode by setting the **Pulse type** parameter to `Time based`.

The block does not support a time-based configuration that results in a constant output signal. Simulink returns an error if the parameters **Pulse Width** and **Period** satisfy either of these conditions:

$$Period * \frac{PulseWidth}{100} = 0$$

$$Period * \frac{PulseWidth}{100} = Period$$

Depending on the pulse waveform characteristics, the intervals between changes in the block output can vary. For this reason, a time-based Pulse Generator block has a variable sample time. The sample time color of such blocks is brown (see “View Sample Time Information” for more information).

Simulink cannot use a fixed-step solver to compute the output of a time-based pulse generator. If you specify a fixed-step solver for models that contain time-based pulse generators, Simulink computes a fixed sample time for the time-based pulse generators. Then the time-based pulse generators simulate as sample based.

If you use a fixed-step solver and the **Pulse type** is `Time based`, choose the step size such that the period, phase delay, and pulse width (in seconds) are integer multiples of the solver step size. For example, suppose that the period is 4 seconds, the pulse width is 75% (that is, 3 s), and the phase delay is 1 s. In this case, the computed sample time is 1 s. Therefore, choose a fixed-step size of 1 or a number that divides 1 exactly (for example, 0.25). To ensure this setting, select `auto` on the **Solver** pane of the Configuration Parameters dialog box.

Sample-Based Mode

In sample-based mode, the block computes its outputs at fixed intervals that you specify. Activate this mode by setting the **Pulse type** parameter to `Sample based`.

An important difference between the time-based and sample-based modes is that in time-based mode, the block output is based on simulation time, and in sample-based mode, the block output depends only on the simulation start, regardless of elapsed simulation time.

This block supports reset semantics in sample-based mode. For example, if a Pulse Generator block is in a resettable subsystem that hits a reset trigger, the block output resets to its initial condition.

Ports

Output

Port_1 — Output signal

scalar | vector | matrix

Generated square wave pulse signal specified by the parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Pulse type — Computational technique

Time based (default) | Sample based

Computational technique to generate the type of square wave that this block generates, either time- or sample-based. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Programmatic Use**Block Parameter:** PulseType**Type:** character vector**Values:** 'Time based' | 'Sample based'**Default:** 'Time based'**Time (t)** — Source of time variable

Use simulation time (default) | Use external signal

Specifies whether to use simulation time or an external signal as the source of values for the output pulse's time variable. If you specify an external source, the block displays an input port for connecting the source. The output pulse differs as follows:

- **Use simulation time:** The block generates an output pulse where the time variable equals the simulation time.
- **Use external signal:** The block generates an output pulse where the time variable equals the value from the input port, which can differ from the simulation time.

Programmatic Use**Block Parameter:** TimeSource**Type:** character vector**Values:** 'Use simulation time' | 'Use external signal'**Default:** 'Use simulation time'**Amplitude** — Signal amplitude

1 (default) | scalar

Specify the amplitude of the signal.

Programmatic Use**Block Parameter:** Amplitude**Type:** character vector**Value:** scalar**Default:** '1'**Period (secs)** — Pulse period

10 (default) | scalar

Pulse period specified in seconds if the pulse type is time-based. If the pulse type is sample-based, then the period is specified as the number of sample times.

Programmatic Use**Block Parameter:** Period**Type:** character vector**Value:** scalar**Default:** '10'**Pulse width** — Duty cycle

5 (default) | scalar in the range [0,100]

Duty cycle specified as the percentage of the pulse period that the signal is on if time-based or as number of sample times if sample-based.

Programmatic Use**Block Parameter:** PulseWidth**Type:** character vector**Value:** scalar**Default:** '5'**Phase delay (secs)** — Delay before pulse`0 (default) | scalar`

Delay before the pulse is generated, specified in seconds, if the pulse type is time-based or as number of sample times if the pulse type is sample-based.

Programmatic Use**Block Parameter:** PhaseDelay**Type:** character vector**Value:** scalar**Default:** '0'**Sample time** — Length of sample time`0 (default) | scalar | vector`

Length of the sample time for this block in seconds. This parameter appears only if the block's pulse type is sample-based. See “Specify Sample Time”.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Value:** scalar**Default:** '0'**Interpret vector parameters as 1-D** — Treat vectors as 1-D`on (default) | off`

Select this check box to output a vector of length **N** if the **Amplitude**, **Period**, **Pulse width**, or **Phase delay** parameter evaluates to an **N**-element row or column vector.

- When you select this check box, the block outputs a vector of length **N** if any of the value parameters evaluate to an **N**-element row or column vector. For example, the block outputs a matrix of dimension 1-by-**N** or **N**-by-1.
- When you clear this check box, the block does not output a vector of length **N** if any of the value parameters evaluate to an **N**-element row or column vector.

For more information on how this parameter is used, see “Determine the Output Dimensions of Source Blocks”.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

These blocks do not reference absolute time when configured for sample-based operation. In time-based operation, they depend on absolute time.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Push Button

Change parameter or variable value using button with customizable appearance

**Libraries:**

Simulink / Dashboard / Customizable Blocks

Description

Use the Push Button block to change the value of the connected variable or parameter before or during simulation. You can configure the button to change the value only while you press the button or to latch the value change until you click the button again. When you use the Push Button block in the Customizable Blocks library, you can modify the appearance of the block so it looks like a button in your real system. Use the Push Button block with other Dashboard blocks to create an interactive dashboard to control your model.

To push the virtual button, click the Push Button block. While you press down your pointer, the button is pushed. When you release your pointer, you release the button.

You can use callback functions to specify what you want the button to do:

- **PressFcns** functions run while the button is pushed. You can configure the button to run the **PressFcn** function only once while the button is pushed, or you can specify a repeat interval.
- **ClickFcns** functions run when you release the button.

You can configure the button to stay pushed when you release your pointer by setting the **Button Type** to **Latched**. When you choose the latched button type:

- To latch the button, click the button.
- To unlatch the button, click the button again.

The **PressFcn** function runs while the button is latched. The **ClickFcn** function runs once when you latch the button, and once when you unlatch the button.

You can use states to specify how the appearance of the Push Button block changes when you interact with the button:

- While you push the button, the block is in the **Pressed** state.
- When the button is latched and you are not pushing it, the block is in the **Latched** state.
- When the button is latched and you are pushing it, the block is in the **Latched and Pressed** state.
- When the block is not in any of these three states, it is in the **Default** state.

A state pairs pointer actions with:

- A State Label
- A state icon
- A state image

The Pressed, Latched, and Latched and Pressed states also pair pointer actions with the **On Value** of the Push Button block. When you enter one of these states from the default state, the **On Value** is assigned to the Simulink component to which the Push Button block connects.

Note Double-clicking the Push Button block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the **Property Inspector** or open the block dialog box by:

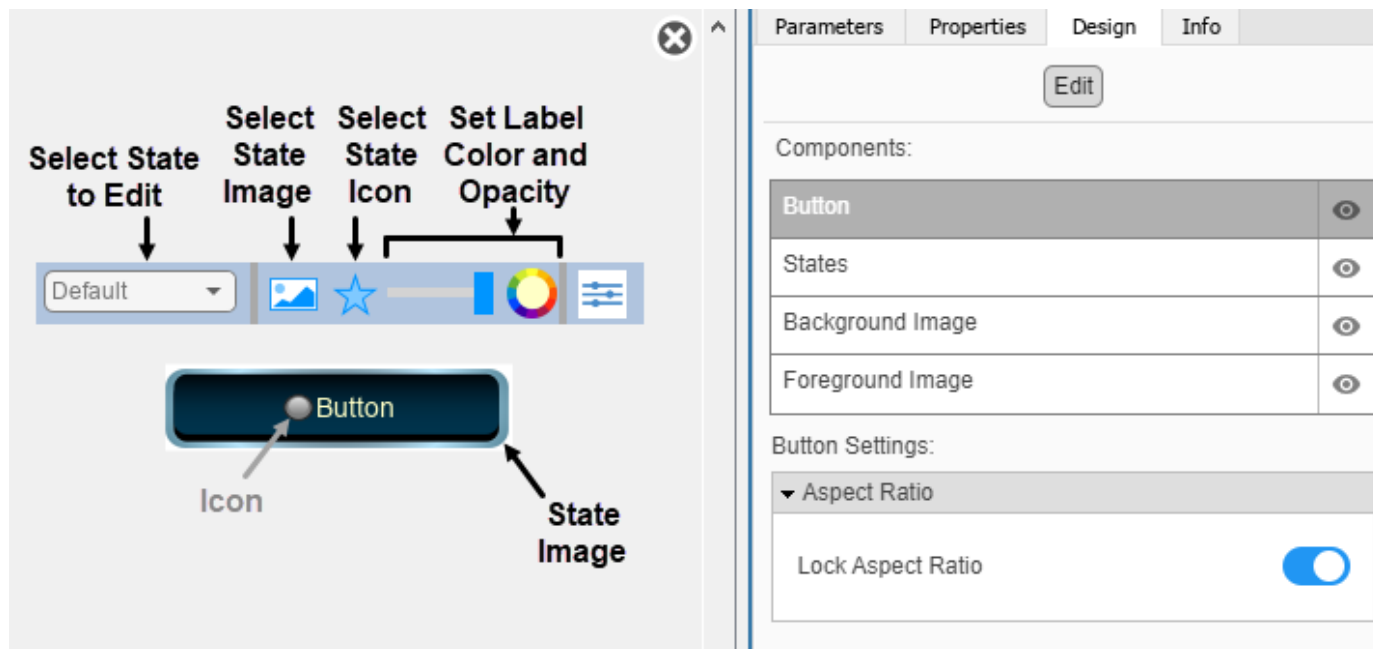

- Double-clicking the block when the block is not selected and the model is not simulating
- Right-clicking the block and selecting **Block Parameters** from the context menu

Customize Push Button Blocks

When you add a Push Button block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

When you design a Push Button block, you configure the block appearance for each possible state. When you configure the **Block Type** as Momentary, the block has two states. When you configure the **Block Type** as Latch, the block has four.

You can use the toolbar above the block to switch states. For each state, you can:

- Upload a state image.
- Upload a state icon and specify the position of the icon relative to the state label.
- Specify the State Label text, color, opacity, and position.

For the Pressed, Latched, and Latched and Pressed states, you can specify the **On Value**.

You can also upload a foreground or a background image, or set a solid background color. The foreground and background apply to all states.

Use the toolbar above the block to configure the image, the icon, and the State Label color and opacity.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the **On Value**.
- Specify the State Label text and position.
- Specify the icon position.
- Upload a foreground image.
- Upload a background image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

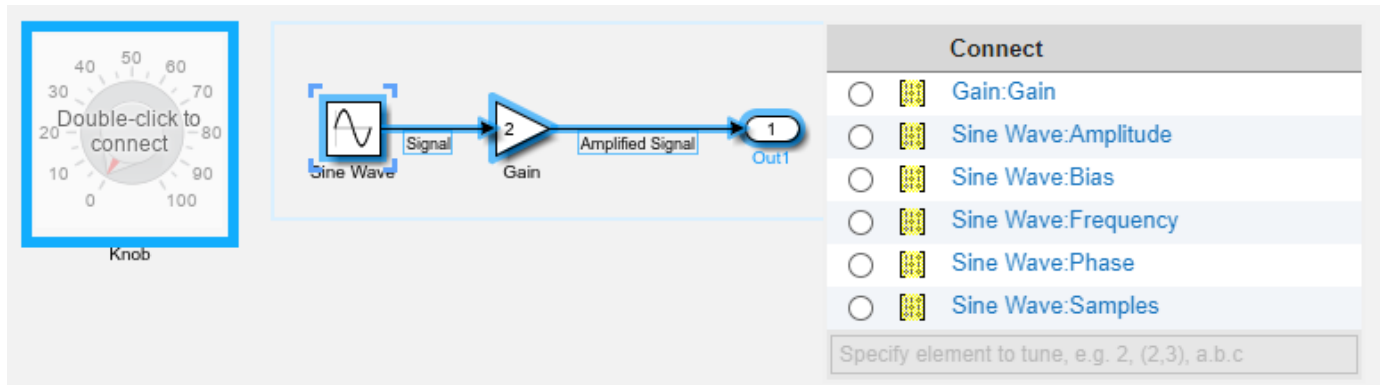

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block.

To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.

- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify **a.b** to connect to scalar element **b** of the structure or bus **a** nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect** and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.
 - To exit bind mode, click **Done Connecting** over the dashboard block.
-

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Button Type — Button response to click

Momentary (default) | Latch

Specify how the block responds to a click.

- **Momentary** — The button changes state only while pressed. When you release the click, the button returns to its default state.

- **Latch** — The button latches the state change when clicked. The button remains in the pressed state until you click it again.

When you configure **Button Type** as **Momentary**, the block has these states:

- **Default** — Default state for the block when it is not pressed
- **Pressed** — Block state when the block is pressed

When you configure **Button Type** as **Latch**, the block has these states:

- **Default** — Default state for the block when it is not pressed.
- **Pressed** — Transitional state when you press the button while it is in the **Default** state. The block transitions to the **Latched** state when you release the click.
- **Latched** — Latched state for the block when it is not pressed.
- **Latched and Pressed** — Transitional state when you press the button while it is in the **Latched** state. The block transitions to the **Default** state when you release the click.

Programmatic Use

Block Parameter: ButtonType

Type: string or character array

Value: 'Momentary' | 'Latch'

Button Text — Button label text

'Button' (default) | string | character array

Specify the text for the button label. The label is applied to the button for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Programmatic Use

Specify the **ButtonText** parameter for the block as a string or a character vector.

Block Parameter: ButtonText

Type: character vector | string

On value — Value assigned to connected parameter when button is pressed or latched

1 (default) | scalar

The value assigned to the connected block parameter when the button is pressed or latched.

Tip Use the **Block Type** parameter to configure how the block responds to a click:

- **Momentary** — The button applies the **On Value** only while you press it.
 - **Latch** — The button latches the state change when you click it and applies the **On value** until you click it again.
-

Programmatic Use

Specify the **OnValue** parameter for the block as a scalar value that is formatted as a string or a character vector.

Block Parameter: OnValue**Type:** string or character array**Values:** scalar**Default:** '1'**Label** — Position of label displaying name of connected element

Hide (default) | Bottom | Top

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify Hide.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**Lock Aspect Ratio** — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Callbacks**ClickFcn** — MATLAB code that executes in response to click

MATLAB code

MATLAB code that executes in response to a click of the button.

Every time you click the button, the ClickFcn code executes once, at the point in time when you release the click.

To specify code for the ClickFcn, select ClickFcn from the drop-down menu. Enter the code in the text box below the menu.

Programmatic Use

Specify the `ClickFcn` parameter for the block as MATLAB code that is formatted as a string or a character vector.

Block Parameter: `ClickFcn`

Type: character vector | string

Values: MATLAB code

PressFcn — MATLAB code that executes in response to press
MATLAB code

MATLAB code that executes in response to a press of the button.

While the button is in the pressed state, the `PressFcn` code executes once when the **Press Delay** time has elapsed and periodically at every **Repeat Interval**.

To specify code for the `PressFcn`, select `PressFcn` from the drop-down menu. Enter the code in the text box below the menu.

How you press the button to execute the `PressFcn` code depends on the **Button Type**.

- If the **Button Type** is `Momentary`, hold down your click for the duration that you want to press the button.
- If the **Button Type** is `Latch`, click to press the button, but do not hold down your click. The button remains pressed until you click it again.

Note Every time that you click on the button, even when you do so as part of the process for pressing the button, the `ClickFcn` code executes once, at the point in time when you release the click.

Programmatic Use

Specify the `PressFcn` parameter for the block as MATLAB code that is formatted as a string or a character vector.

Block Parameter: `PressFcn`

Type: character vector | string

Values: MATLAB code

Press Delay (ms) — Time to hold button for press

500 (default) | scalar

Amount of time required to cause the `PressFcn` code to execute.

Dependencies

Press Delay (ms) is visible only when `PressFcn` is selected as the callback.

Programmatic Use

Specify the `PressDelay` parameter for the block as a positive scalar value.

Block Parameter: `PressDelay`

Type: scalar

Repeat Interval (ms) — Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the PressFcn code executes again if the Callback Button block is still pressed.

Dependencies

Repeat Interval (ms) is visible only when PressFcn is selected as the callback.

Programmatic Use

Specify the RepeatInterval parameter for the block as a positive scalar value.

Block Parameter: RepeatInterval

Type: scalar

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Button

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States

Select State — Selection of state to configure

Default (default) | Pressed | Latched | Latched and Pressed

Select a state that you want to configure from the drop-down menu in the **Select State** section of the **States** component. When the **Button Type** is **Momentary**, you can select these states:

- **Default** — Default state for the block when it is not pressed
- **Pressed** — Block state when the block is pressed

When the **Button Type** is **Latch**, you can select these states:

- **Default** — Default state for the block when it is not pressed.
- **Pressed** — Transitional state when you press the button while it is in the **Default** state. The block transitions to the **Latched** state when you release the click.

- **Latched** — Latched state for the block when it is not pressed.
- **Latched and Pressed** — Transitional state when you press the button while it is in the Latched state. The block transitions to the **Default** state when you release the click.

Note You can configure all of the parameters in the **States** component of the **Design** tab for a state. For example, you can select an icon that will appear on the button when it is in the state. When you configure any of the parameters in the **States** component, the changes are applied to the state that is selected in the **Select State** section of the **States** component.

Example: Pressed

Button Text — Button label text

'Button' (default) | string | character array

Specify the text for the button label. The label is applied to the button for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Programmatic Use

Specify the `ButtonText` parameter for the block as a string or a character vector.

Block Parameter: `ButtonText`

Type: character vector | string

Label Color — Button label font color

[r g b] vector

Choose a font color for the button label from the palette of standard colors, or specify a custom color. The color is applied to the button label for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Horizontal Alignment — Horizontal button text alignment

Center (default) | Left | Right

Set the alignment of the button text.

- **Center:** Midway between left and right edges of block
- **Left:** Left edge of block
- **Right:** Right edge of block

Vertical Alignment — Vertical button text alignment

Center (default) | Bottom | Top

Set the alignment of the button text.

- **Center:** Midway between top and bottom edges of block
- **Bottom:** Bottom edge of block
- **Top:** Top edge of block

Label X Offset — Horizontal offset of button text center from default position for selected horizontal alignment setting

0 (default) | scalar

Specify the horizontal offset of the center of the **Button Text** from the default position for the selected **Horizontal Alignment** setting as a ratio of the block width. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text left, and an offset with a positive value moves the text right.

Label Y Offset — Vertical offset of button text center from default position for selected horizontal alignment setting

0 (default) | scalar

Specify the vertical offset of the center of the **Button Text** from the default position for the selected **Vertical Alignment** setting as a ratio of the block height. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text up, and an offset with a positive value moves the text down.

Icon Placement — Placement of icon relative to button text

Left (default) | Top | Right | Bottom

Specify the placement of the icon relative to the button text.

Note Changing the placement of the icon moves the button text, but does not change the specified **X Offset**, **Y Offset**, **Horizontal Alignment**, or **Vertical Alignment** of the text.

Width — Width of state image or icon

scalar

Specify the width of the state image or the state icon as a ratio of the block width.

Example: 0.5

Height — Height of state image or icon

scalar

Specify the height of the state image or the state icon as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Image X Offset — Horizontal offset of left edge of image from left edge of block

scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block
scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width
scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height
scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio
on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2021b

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Push Button

Change parameter or variable value using button

Libraries:
Simulink / Dashboard

Description

Use the Push Button block to change the value of the connected variable or parameter before or during simulation. You can configure the button to change the value only while you press the button or to latch the value change until you click the button again. Use the Push Button block with other Dashboard blocks to create an interactive dashboard to control your model.

Double-clicking the Push Button block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the **Property Inspector** or open the block dialog box by:

- Double-clicking the block when the block is not selected and the model is not simulating.
- Right-clicking the block and selecting **Block Parameters** from the context menu.

Push Button Icons

You can add an icon to the Push Button block that is displayed alongside the button text. You can choose an icon from a predefined set that includes basic shapes, automotive indicators, and wireless icons, or you can upload your own custom icon. For more information, including a complete list of the built-in icons, see "Icon" on page 1-0 .

When you add an icon to the Push Button block, you can configure an on color and an off color for the icon so its color changes with the state of the block and specify the alignment of the icon relative to the button text. For example, this Push Button block is configured to use a circle icon with the on color specified as bright green, aligned to the left of the button text.

The icon settings for the Push Button block allow you to configure the appearance of the block in your model. When you want to customize the appearance of the block further, consider using the Push Button block in the Customizable Blocks library. The Push Button block in the Customizable Blocks library supports adding a custom icon but does not include any built-in icons.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of

connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

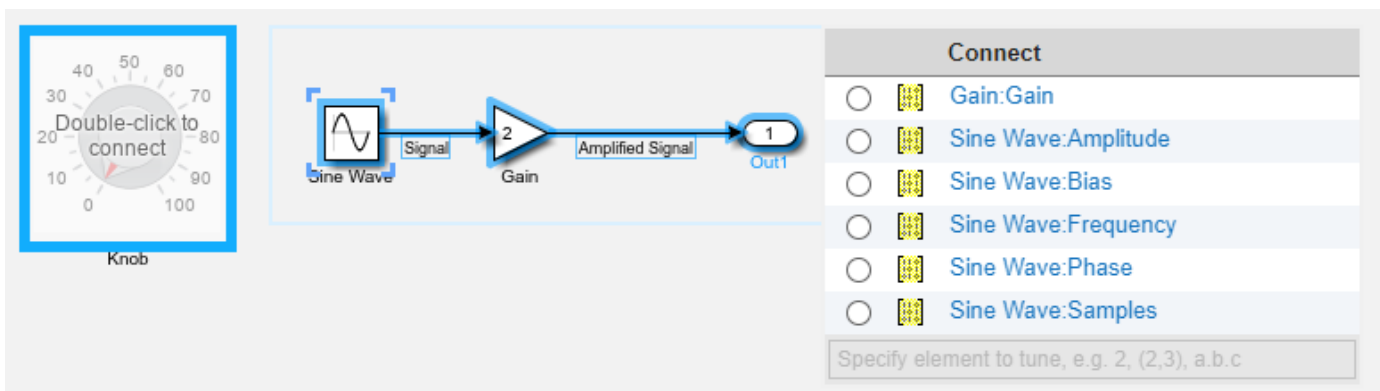

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection

Connection — Select a variable or block parameter to connect
[variable and parameter connection options](#)

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the

context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Button Text — Text label for button

Button (default) | string | character vector

The text displayed on the Push Button block in your model.

Tips

To design a button that displays different text depending on the state of the block, use the Push Button block in the Customizable Blocks library.

Programmatic Use

Block Parameter: `ButtonText`

Type: string or character array

Default: `'Button'`

On Value — Value assigned to connected parameter when button is pressed or latched

1 (default) | scalar

The value assigned to the connected block parameter when the button is pressed or latched.

Tips

Use the **Block Type** parameter to configure how the block responds to a click:

- **Momentary** — The button applies the **On Value** only while you press it.
- **Latch** — The button latches the state change when you click it and applies the **On value** until you click it again.

Programmatic Use**Block Parameter:** OnValue**Type:** string or character array**Default:** '1'**Button Type** — Button response to click

Momentary (default) | Latch

Specify how the button responds to a click.

- **Momentary** — The button applies the **On Value** only while you press it.
- **Latch** — The button latches the state change when you click it and applies the **On value** until you click it again.

Programmatic Use**Block Parameter:** ButtonType**Type:** string or character array**Value:** 'Momentary' | 'Latch'**Label** — Block label position

Hide (default) | Bottom | Top

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use**Block Parameter:** LabelPosition**Type:** character vector**Values:** 'Hide' | 'Bottom' | 'Top'**Default:** 'Hide'**Format****Opacity** — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use**Block Parameter:** Opacity**Type:** scalar**Default:** 1**Foreground Color** — Block foreground color

[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: `[r g b]` vector

Background Color — Block background color

`[r g b]` vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: `[r g b]` vector

Icon

Icon — Icon to display on button

[SVG file](#) | [PNG file](#) | [JPEG file](#)

You can add an icon to the Push Button block to display alongside or instead of the button text. You can choose from built-in shape, automotive, and wireless icons, or you can upload your own custom SVG, PNG, or JPEG file to use as the icon.

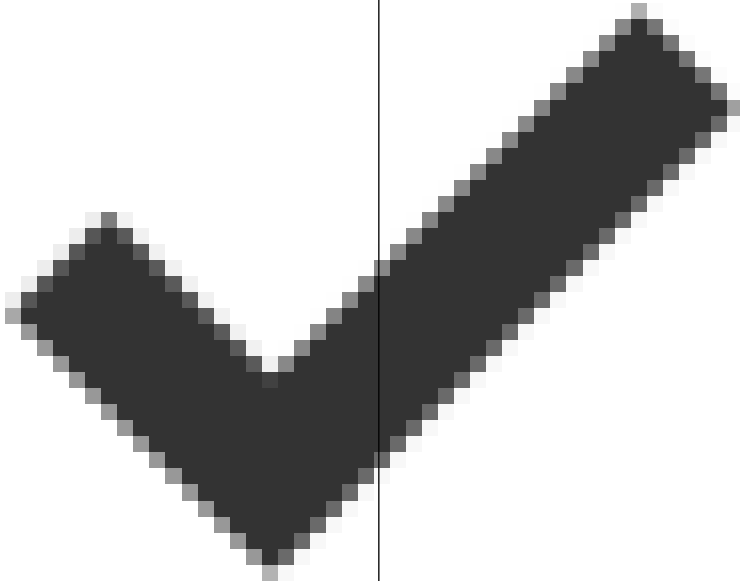

To view icon options, on the **Icon** tab of the block dialog box, select an **Icon Type**. To use your own custom icon, select **Custom** as the **Icon Type** and upload the image file.

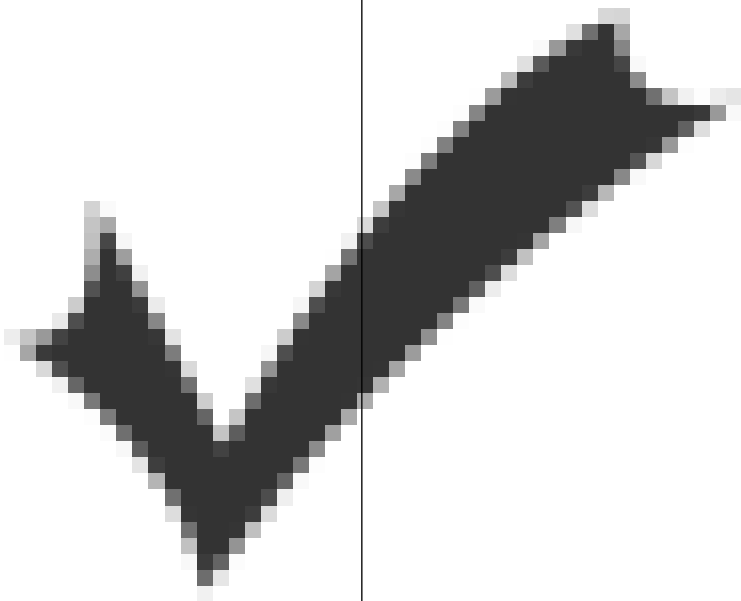

When you add an icon, you can configure the icon appearance using these parameters:

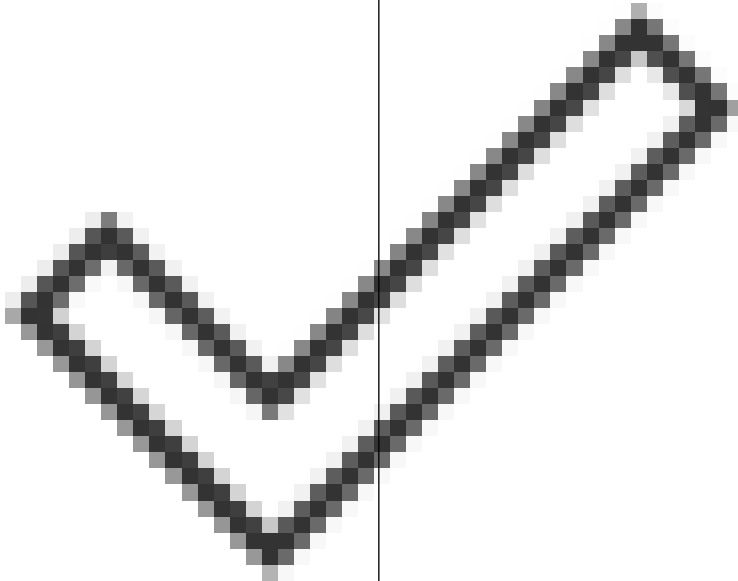

- **Icon Alignment** — Alignment of icon relative to button text
- **On Color** — Icon color when block is pressed or latched and applying the **On value** to the connected parameter
- **Off Color** — Icon color when the block is not pressed or latched and is not applying the **On value** to the connected parameter

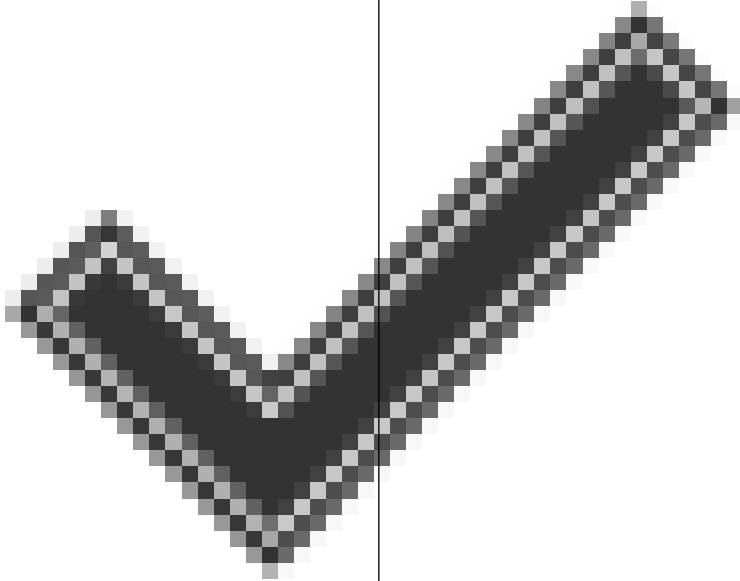

To specify an **On Color** and **Off Color** for the icon, you must select **Customize Icon Color**.

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
 A pixelated icon representing low beams, showing a series of horizontal lines on the left and a large, rounded 'D' shape on the right.	Low Beams	LowBeams

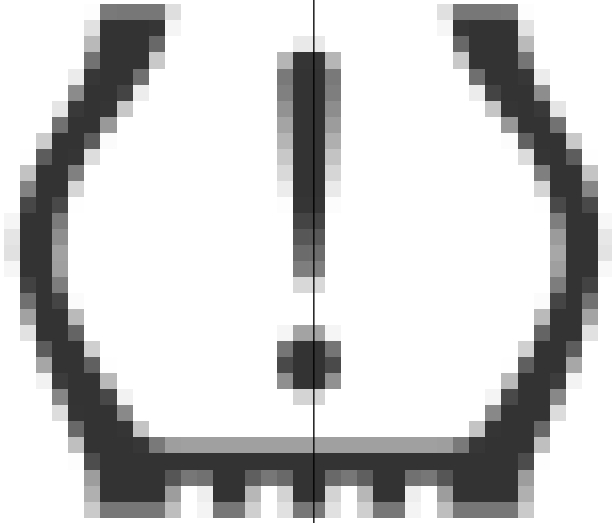

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Parking Assistance	ParkingAssistance

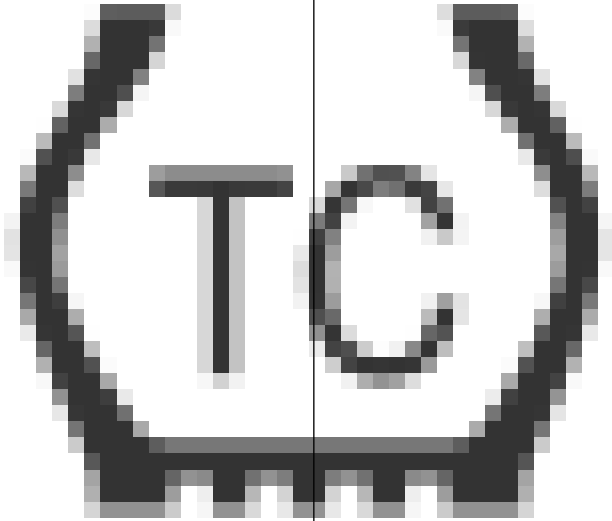

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
 A pixelated icon of a rear fog light, consisting of a large, vertically-oriented oval shape with a thick, dark border.	Rear Fog Light	RearFogLight

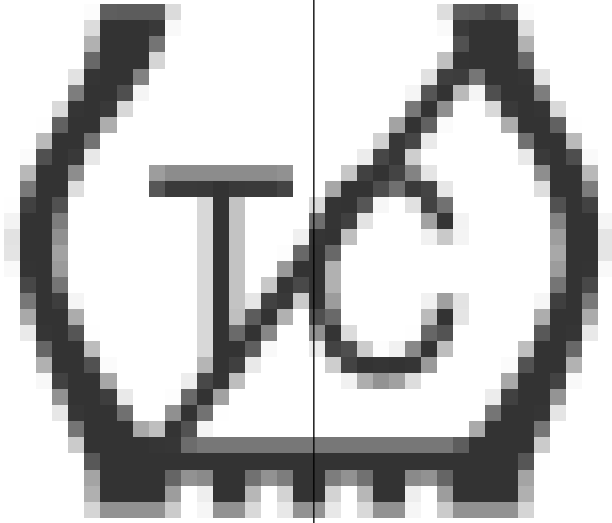

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Side Lights	SideLights

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Stability Control	StabilityControl

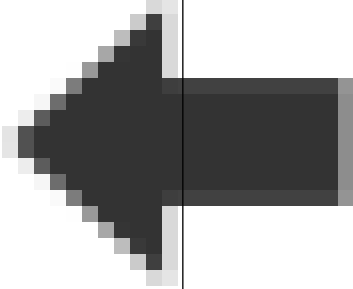

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
 A pixelated icon showing a car from a top-down perspective. Below the car, the letters 'SC' are written in a stylized font, and below that, the word 'OFF' is written in a larger, bold, sans-serif font.	Stability Control Off	StabilityControlOff

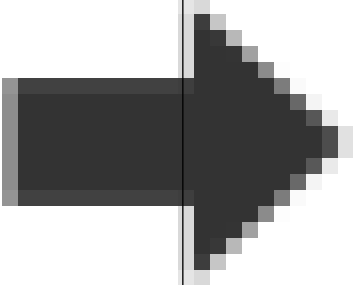

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Tire Monitor	TireMonitor

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Traction Control	TractionControl

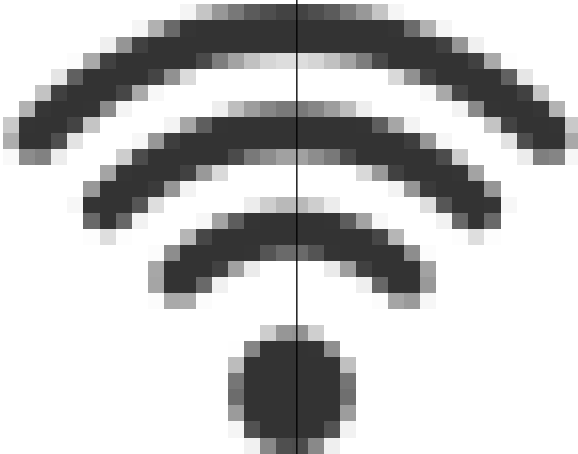

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
 A pixelated black and white icon showing a gear with the letters 'TC' inside it, representing a traction control system.	Traction Control Off	TractionControlOff

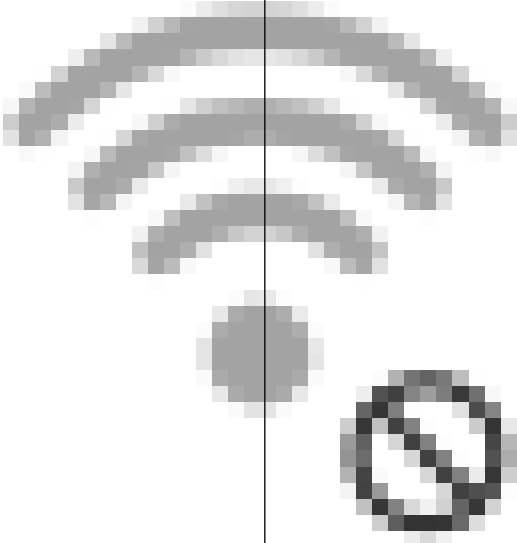

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Traction Control Failure	TractionControlFailure

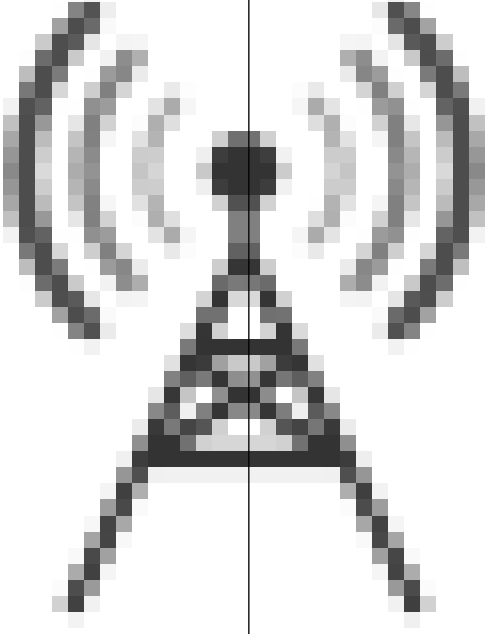

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
 A black arrow pointing to the left, representing a left turn signal.	Turn Signal Left	TurnSignalLeft

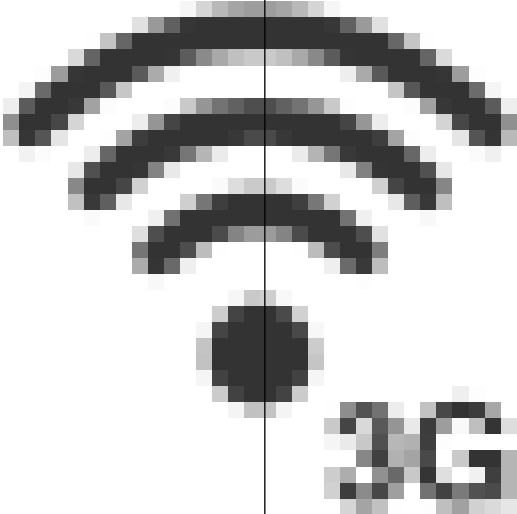

Icon	Automotive Indicator Lamps Library Block Name	Programmatic Use Value
	Turn Signal Right	TurnSignalRight

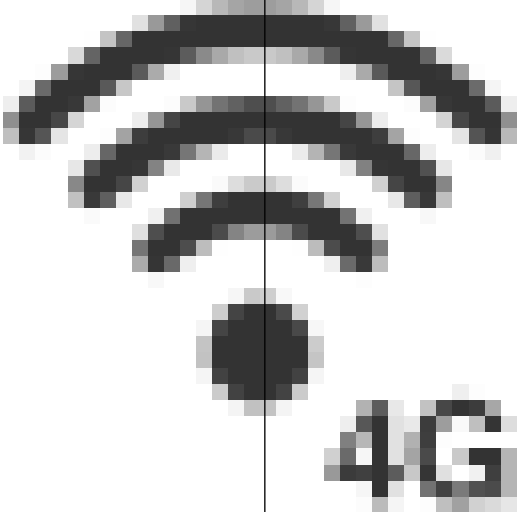

Wireless Icons

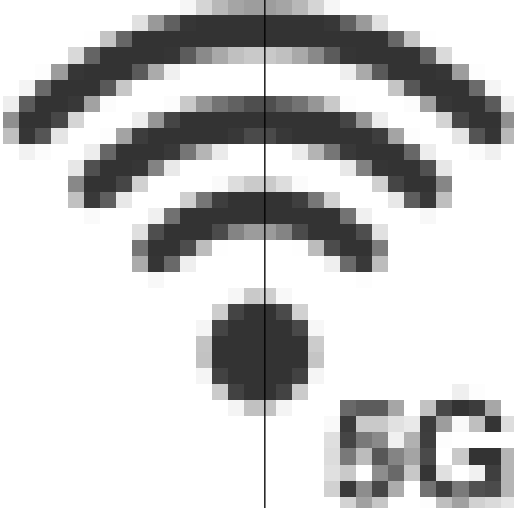

Icon	Icon Name	Programmatic Use Value
 A black and white icon representing a wireless network. It consists of a solid black circle at the bottom, with three curved lines of increasing length extending upwards and outwards from the circle, resembling a signal or broadcast pattern.	Network	Network

Icon	Icon Name	Programmatic Use Value
 The icon depicts a standard Wi-Fi signal symbol consisting of three curved lines of decreasing length from top to bottom. Below these lines is a solid circle, and to the right of the circle is a square with a diagonal slash through it, indicating a lack of signal.	Network No Signal	NetworkNoSignal

Icon	Icon Name	Programmatic Use Value
 A pixelated icon of a radio tower with two large curved lines above it, representing signal waves.	Network Transmission	NetworkTransmission

Icon	Icon Name	Programmatic Use Value
	Network3G	Network3G

Icon	Icon Name	Programmatic Use Value
 A black and white icon representing a 4G network. It features three curved lines of varying lengths, resembling a signal strength indicator, with a solid black circle at the bottom center. To the right of the circle, the letters "4G" are displayed in a bold, sans-serif font.	Network4G	Network4G

Icon	Icon Name	Programmatic Use Value
 A pixelated icon representing 5G connectivity. It features three curved lines of varying lengths, a solid black circle below them, and the letters '5G' to the right of the circle.	Network5G	Network5G

Tips

- You can change the icon for a Push Button block using the **Button** tab in the toolbar.
- If you want to customize the appearance of the Push Button block further, consider designing your own button using the Push Button block in the Customizable Blocks library.

The Push Button block in the Customizable Blocks library supports adding a custom icon but does not include any built-in icons.

- The on and off colors for the icon can apply to these SVG elements:
 - altGlyph
 - circle
 - ellipse
 - path
 - polygon
 - rect
 - text
 - textPath
 - tref
 - tspan

Programmatic Use**Block Parameter:** Icon**Type:** string | character vector**Default:** 'Default'**Icon Alignment** — Icon alignment relative to button text

Left (default) | Right | Top | Bottom | Center

Alignment of the icon relative to the button text. When you do not specify button text, the icon is always in the center of the block.

Programmatic Use**Block Parameter:** IconAlignment**Type:** string | character vector**Value:** 'Left' | 'Right' | 'Top' | 'Bottom' | 'Center'**Default:** 'Left'**Customize Icon Color** — Whether to use icon on and off colors

Off (default) | On

When you add an icon to the Push Button block, you can specify on and off colors so the icon color changes to reflect the state of the block. To use and specify the **On Color** and **Off Color** for an icon, select **Customize Icon Color**.

Programmatic Use**Block Parameter:** IconColor**Type:** string | character vector**Value:** 'On' | 'Off'**Default:** 'Off'**On Color** — Icon color when block is pressed or latched

[r g b] vector

When you add an icon to the Push Button block, you can specify on and off colors so the icon color changes to reflect the state of the block. The **On Color** specifies the color of the icon when the block is pressed or latched and is applying the **On value** to the connected parameter. You can select a color from a palette of standard colors or specify a custom color.

Dependencies

To enable the **On Color** parameter, select **Customize Icon Color**.

Programmatic Use

Specify the IconOnColor parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: IconOnColor**Type:** [r g b] vector**Off Color** — Icon color when block is not pressed or latched

[r g b] vector

When you add an icon to the Push Button block, you can specify on and off colors so the icon color changes to reflect the state of the block. The **Off Color** specifies the color of the icon when the block

is not pressed or latched and is not applying the **On value** to the connected parameter. You can select a color from a palette of standard colors or specify a custom color.

Dependencies

To enable the **On Color** parameter, select **Customize Icon Color**.

Programmatic Use

Specify the `IconOffColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `IconOffColor`

Type: [r g b] vector

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015a

R2021b: Push Button Block Can Apply Value After You Release Click

Starting in R2021b, you can configure the behavior of the Push Button block to latch or momentarily apply the **On Value** when you click the block.

R2021b: Push Button Block Can Display Icons

Starting in R2021b, you can add an icon to display on the Push Button block alongside or instead of the button text. Choose an icon for the block from a predefined set or upload your own custom icon using the block dialog box or the **Button** tab of the toolbar.

You can also specify an on color and an off color so the icon color changes with the state of the block and specify the alignment of the icon relative to the button text.

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Background Color, Foreground Color, and Opacity properties added for several dashboard blocks

Starting in R2020b, you can specify a background color, a foreground color, and opacity for these blocks from the Dashboard library:

- Check Box
- Combo Box
- Edit
- Push Button
- Radio Button

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

PWM

Generate ideal pulse width modulated signal corresponding to input duty cycle

Libraries:
Simulink / Discontinuities

Description

Use the PWM block to generate an ideal pulse width modulated signal.

Pulse-width modulation (PWM) is a technique for encoding an analog signal using square pulses. This encoding is achieved by controlling the fraction of one period of the square wave that is set to high. This fraction is the duty cycle of the signal. The relationship between the modulated signal and the input duty cycle can be simply described as:

$$\bar{y} = Dy_{max} + (1 - D)y_{min}$$

where y_{max} and y_{min} are the upper and lower bounds of the output signal, respectively. For the PWM block, the duty cycle is constrained to $[0, 1]$. The ideal PWM signal is proportional to the duty cycle D .

Ports

Input

D — Duty Cycle
scalar

Desired duty cycle of the pulse P , specified as scalar within the range $[0,1]$.

Data Types: double

Output

Port 1 — Output pulse
scalar

PWM signal corresponding to the input duty cycle.

Data Types: double

Parameters

Period (s) — Pulse width

1 (default) | real scalar

Time between rising edges of consecutive pulses of the output signal. A small value represents a high-frequency pulse.

Programmatic Use**Block Parameter:** Period**Type:** string | character vector**Values:** real scalar**Default:** '1'**Initial Delay** — Initial delay

0 (default) | real scalar

Specify an initial delay or phase delay for the generated PWM signal, in seconds.

Programmatic Use**Block Parameter:** InitialDelay**Type:** string | character vector**Values:** numeric scalar**Default:** 0**Disallow zero duty cycle** — Avoid algebraic loops

off | on

Enable this parameter to break algebraic loops containing the PWM block.

Note Enabling this parameter causes a signal value of 0 or below, which causes the duty cycle input to throw an error.

Programmatic Use**Block Parameter:** DisallowZeroDutyCycle**Type:** string | character vector**Values:** 'on' | 'off'**Default:** 'off'**Run at fixed time intervals** — Select for discrete time behavior

on (default) | off

Specify when the block executes and the sample time for the output signal.

- **off** — Block executes each time the delay for an input sample elapses. Output signal has fixed-in-minor sample time.
- **on** — Block executes at a fixed rate you specify using the **Sample time** parameter. Output signal has the sample time you specify using the **Sample time** parameter.

When you select **Run at fixed time intervals**:

- The delay signal values must be greater than the value you specify for the **Sample time** parameter.
- Delay signal values that are not integer multiples of the specified sample time are rounded down to the nearest integer multiple of the sample time. For example, if the sample time is 0.1 and the delay signal value is 0.68, the software rounds the delay to 0.6.

Programmatic Use**Block Parameter:** RunAtFixedTimeIntervals**Type:** string | character vector**Values:** 'on' | 'off'**Default:** 'off'**Sample Time** — Set pulse resolution

0.1 (default) | scalar

Block execution rate and output signal sample time. The delay signal values must be greater than the specified sample time.

When the delay signal value is not an integer multiple of the specified sample time, the software rounds the delay value down to the closest value that is an integer multiple of the sample time. For example, if the sample time is 0.1 and the delay value is 0.68, the software rounds the delay to 0.6.

Dependencies

To enable this parameter, select **Run at fixed time intervals**.

Programmatic Use**Block Parameter:** SampleTime**Type:** string | character vector**Values:** numeric scalar**Default:** 0.1**Block Characteristics**

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Continuous Sampling Mode

For a pulse starting at time t_k

$$y(t) = \begin{cases} 1 & t_k < t < t_k + pw \\ 0 & t_{k+1} < t < t_k + pw \end{cases}$$

where pw is the pulse width. For a given period P , pw is proportional to the duty cycle D

$$pw = D(t_k) * P(t_k)$$

Discrete Sampling Mode

In Discrete sampling mode, the input duty cycle signal is sampled at the rate specified by the **Run at fixed time intervals** parameter.

For a specified sampling rate t_s , the number of samples needed for a pulse of width pw can be expressed as follows

$$n_{pw} = \left\lceil \frac{D_k \cdot P_k}{T_S} \right\rceil \quad 0 < n_{pw} < n_P$$

$$n_P = \left\lceil \frac{P}{T_S} \right\rceil$$

where n_P is the number of samples needed to simulate a pulse of period P .

Consider a nominal pulse of period P with the sampling rate of the block set to be $t_s = 0.25 P$. The number of samples needed for one period of the pulse, $n_p = 4$. Thus, for the input duty cycle $D = 0.47$, the number of samples n_{pw} is floored to $\left\lfloor \frac{0.47P}{0.25} \right\rfloor = 1$. Therefore, the pulse is high for 1 of the 4 samples in the period.

Version History

Introduced in R2020b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Variable Pulse Generator

Quantizer

Discretize input at given interval

Libraries:
Simulink / Discontinuities

Description

The Quantizer block discretizes the input signal using a quantization algorithm. The block uses a round-to-nearest method to map signal values to quantized values at the output that are defined by the **Quantization interval**. A smooth input signal can take on a stair-step shape after quantization.

This equation mathematically describes the round-to-nearest method:

$$y = q * \text{round}(u/q)$$

where y is the quantized output, u is the input, and q is the **Quantization interval**.

Ports

Input

Port_1 — Input signal to quantize
scalar | vector

Input signal to the quantization algorithm.

Data Types: single | double

Output

Port_1 — Quantized output signal
scalar | vector

Output signal composed of discrete values, quantized with a round-to-nearest approach:

$$y = q * \text{round}(u/q)$$

where y is the output, u is the input, and q is the **Quantization interval**.

Data Types: single | double

Parameters

Quantization interval — Interval that defines quantization levels for the output signal

0.5 (default) | scalar | vector

Specify the quantization interval used in the algorithm. Quantization levels for the Quantizer block output are integer multiples of the **Quantization interval**.

Programmatic Use**Block Parameter:** QuantizationInterval**Type:** character vector**Value:** Any real or complex value**Default:** '0.5'**Treat as gain when linearizing** — Specify the gain value

On (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use**Block Parameter:** LinearizeAsGain**Type:** character vector**Value:** 'off' | 'on'**Default:** 'on'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Block Characteristics**

Data Types	double single

Quarter Gauge

Display input value on quadrant scale

Libraries:
Simulink / Dashboard

Description

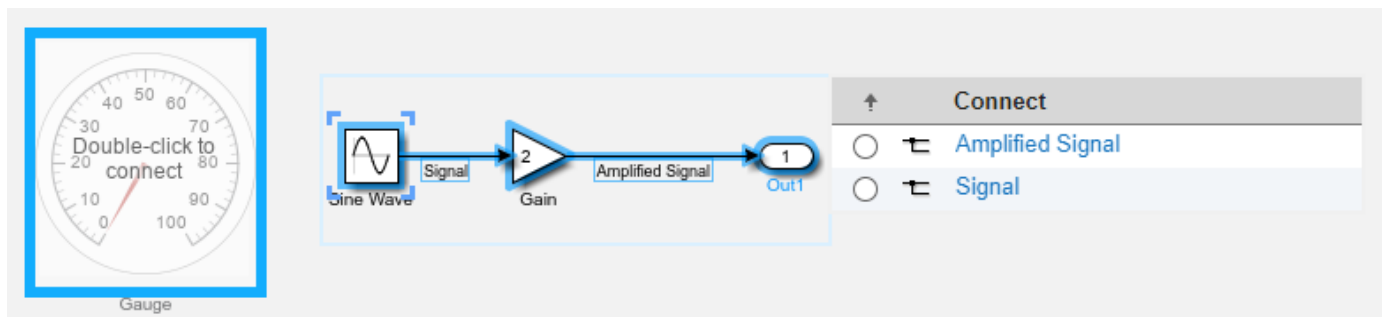

The Quarter Gauge block displays the connected signal on a quadrant scale during simulation. You can use the Quarter Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Quarter Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Quarter Gauge block to fit your data. You can also customize the appearance of the Quarter Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.
- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Signal

Connection — Signal to connect and display
signal connection options

Use the connection table to select the signal to connect to the block. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more signals.
- 2 In the table, select the signal you want to connect.
- 3 Click **Apply**.

Tip You can connect dashboard blocks to signals in the model during simulation.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Main

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the **Minimum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the `auto` value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the `auto` value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the `auto` value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Scale Colors — Color indications on gauge scale

colors for scale ranges

Color specifications for value ranges on the scale. Press the + button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with the fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of `double` values between 0 and 1 that specify the color for the range in the form `[r g b]`

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Scale Direction — Gauge scale direction

Clockwise (default) | Counterclockwise

Gauge scale direction.

Programmatic Use

Block Parameter: ScaleDirection

Type: character vector

Values: 'Clockwise' | 'Counterclockwise'

Default: 'Clockwise'

Format

Opacity — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, excluding the text. The **Foreground Color** applies to the scale and the block name. You can select a color from a palette of standard colors or specify a custom color. To specify the color for the block text, use the **Font Color**.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: [r g b] vector

Background Color — Block background color

[r g b] vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Font Color — Block font color

[r g b] vector

Block font color. The **Font Color** applies to the tick labels on the scale. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `FontColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `FontColor`

Type: [r g b] vector

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no

Queue, Entity Queue

Enqueue messages and entities

Description

This block stores entities or messages in a queue, based on the order of arrival or priority. Each element at the head of the queue departs when the downstream block is ready to accept it. The Queue block and the Entity Queue block are the same blocks with different default values for the **Overwrite the oldest element if queue is full** check box.

You can specify the capacity of the queue, and the policy when the queue is full. The block supports three different message or queue sorting policies, first-in-first out (FIFO), last-in-first out (LIFO), and priority. The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

Ports

Input

Port_1 — Input entity or message

scalar | vector | matrix

Input entity or message that carries scalar, bus, or vector data to enter the queue.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Output

Port_1 — Output entity or message

scalar | vector | matrix

Output port that allows entities or messages at the head of the queue to depart when a downstream block is ready to accept them.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | enumerated | bus | fixed point

Port_d — Number of entities that have departed the block

scalar

Number of entities that have departed the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities departed, d**.

Data Types: double

Port_n — Number of entities that have not yet departed the block
scalar

Number of entities that have not yet departed the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities in block, n**.

Data Types: double

Port_w — Average wait time for entities in the block
scalar

Average wait time for entities in the block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Average wait, w**.

Data Types: double

Port_l — Average length of the entity queue
scalar

Port_l outputs the average length of the entity queue.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Average queue length, l**.

Data Types: double

Port_ex — Number of entities extracted
scalar

Number of entities that are pulled out of this block.

Dependencies

To enable this port, select **Overwrite the oldest element if queue is full** check box, and click the **Statistics** tab and select the box labeled **Number of entities extracted, ex**.

Data Types: double

Parameters

Overwrite the oldest element if queue is full — Specify queue overwriting policy
on (default for Simulink) | off (default for SimEvents)

Select this check box to choose between two queue overwriting policies.

- If you select the check box, an incoming message overwrites the oldest if the queue is full.

This mode represents a simple message buffer that you can use to generate asynchronous communication between Simulink components and production code.

- If you clear the check box, the block does not accept new messages if the queue is full.

In this mode, you can manipulate entity data using event actions and visualize statistics.

To customize actions when entities or messages enter, exit, or are blocked, enter MATLAB code in the **Entry action**, **Exit action**, or **Blocked action** field of the **Event actions** tab. For more information, see “Events and Event Actions” (SimEvents).

For an example, see “Manage Entities Using Event Actions” (SimEvents).

Programmatic Use**Block Parameter:** QueueOverwriting**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on' (for Simulink) and 'off' (for SimEvents)**Capacity** — Specify the capacity of the queue

25 (default) | scalar

Specify the capacity of the queue.

Programmatic Use**Block Parameter:** Capacity**Type:** character vector**Values:** '25' | scalar**Default:** '25'**Queue type** — Choose the queue type

FIFO (default) | LIFO | Priority

Choose the queue type.

- FIFO — first-in-first-out
- LIFO — last-in-first-out
- Priority — store elements in order of priority, see “Serve High-Priority Customers by Sorting Entities Based on Priority” (SimEvents). Priority can be selected when you clear the **Overwrite the oldest element if queue is full** check box.

Note Priority queue does not support fixed point data type.

Programmatic Use**Block Parameter:** QueueType**Type:** character vector**Values:** 'FIFO' | 'LIFO' | 'Priority'**Default:** 'FIFO'**Multicast tag** — Specify the tag when accepting entities broadcast via multicast sources

A (default) | character vector

Specify the tag when accepting entities broadcast via multicast sources. The Entity Multicast block requires SimEvents license.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Entity arrival source** to Multicast.

Programmatic Use

Block Parameter: MulticastTag

Type: character vector

Values: 'A' | character vector

Default: 'A'

Priority source — Specify which attribute of the entity determines its priority

PriorityAttribute (default) | character vector

Specify which attribute of the entity determines its priority.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to Priority.

Programmatic Use

Block Parameter: PrioritySource

Type: character vector

Values: 'PriorityAttribute' | character vector

Default: 'PriorityAttribute'

Sorting direction — Choose the direction of sorting based on priority

Ascending (default) | Descending

Choose the direction of sorting based on priority.

- Ascending — Elements with smaller priority values appear in front of the queue.
- Descending — Elements with greater priority values appear in front of the queue.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to Priority.

Programmatic Use

Block Parameter: SortingDirection

Type: character vector

Values: 'Ascending' | 'Descending'

Default: 'Ascending'

Entity arrival source — Choose the source of arrival for the entities

Input port (default) | Multicast

Choose the source of arrival for the entities.

- `Input port` — Input port is source of messages or entities.
- `Multicast` — Entity Multicast block is source of entities. The Entity Multicast block requires SimEvents license.

Dependencies

This parameter is visible when you clear the **Overwrite the oldest element if queue is full** check box, and set **Queue type** to `Priority`.

Programmatic Use

Block Parameter: `EntityArrivalSource`

Type: character vector

Values: `'Input port' | 'Multicast'`

Default: `'Input port'`

Event action — Specify the behavior of the entity in certain events

`Entry (default) | Exit | Blocked`

Specify the behavior of the entity in certain events. Define the behavior in the **Event action** parameter. The **Entry** and the **Exit** actions are called just after the entity entry and just before entity exit. The **Blocked** action is called after an entity is blocked. For more information, see “Events and Event Actions” (SimEvents).

Note If an event action changes an entity, related block behavior such as resorting a priority queue, and rescheduling of any events, will occur after the event action has fully finished and returned.

Note Event actions do not support `fixed point` data type.

Dependencies

Event actions are visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: `EntryAction, ExitAction, BlockedAction`

Type: character vector

Values: MATLAB code

Default: `''`

Number of entities departed, d — Outputs the number of entities that have departed the block
`off (default) | on`

Number of entities that have departed the block.

Dependencies

Number of entities departed, d is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use**Block Parameter:** NumberEntitiesDeparted**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'

Number of entities in block, n — Outputs the number of entities present in the block, that are yet to depart

off (default) | on

Number of entities present in the block, but which are yet to depart.

Dependencies

Number of entities in block, n is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use**Block Parameter:** NumberEntitiesInBlock**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'

Average wait, w — Outputs the average wait time

off (default) | on

Sum of the wait times for entities departing the block divided by their total number. Wait time is the duration between the Entity Queue block entry and exit of an entity. For more information, see “Interpret SimEvents Models Using Statistical Analysis” (SimEvents).

Dependencies

Average wait, w is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use**Block Parameter:** AverageWait**Type:** character vector**Values:** 'on' | 'off'**Default:** 'off'

Average queue length, l — Outputs the average length of the entity queue

off (default) | on

Accumulated time-weighted average queue size. The block computes this value by:

- 1 Multiplying the size of the queue by its duration to calculate time-weighted queue size
- 2 Summing up all time-weighted queue sizes and averaging them over total time

For more information, see “Interpret SimEvents Models Using Statistical Analysis” (SimEvents).

Dependencies

Average queue length, l is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: AverageQueueLength

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Number of entities extracted, ex — Number of entities extracted from this block

off (default) | on

Outputs the number of extracted entities which are pulled out from this block by the Entity Find block. The Entity Find block requires a SimEvents license. If the extracted entity is the first entity in the queue, the next entity is set as the pending entity to leave the block. If an entity attribute defines the priority in a priority queue and it is modified by the Entity Find block, the queue is sorted again. When an entity is extracted, **Number of entities departed, d**, **Number of entities in block, n**, **Average wait, w**, and **Average queue length, l** statistics are updated accordingly. For more information about finding and extracting entities, see “Find and Extract Entities in SimEvents Models” (SimEvents).

Dependencies

Number of entities extracted, ex is visible when you clear the **Overwrite the oldest element if queue is full** check box.

Programmatic Use

Block Parameter: NumEntitiesExtracted

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

“Overview of Queues and Servers in Discrete-Event Simulation” (SimEvents)

Radio Button

Select parameter value

Libraries:
Simulink / Dashboard

Description

The Radio Button block lets you change the value of the connected parameter during simulation. You can specify a list of values and labels and then select the value for the parameter from that list. Use the Radio Button block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Radio Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

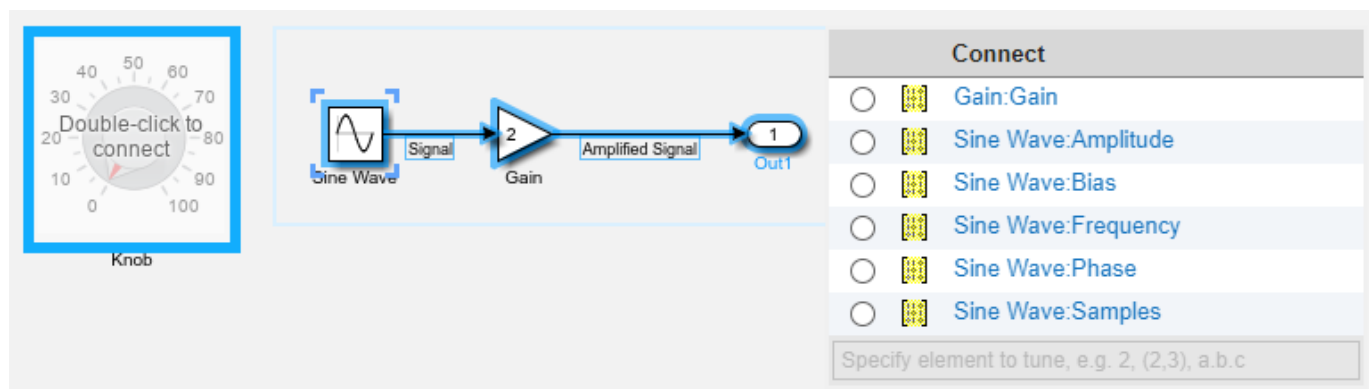

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus

or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection

Connection — Select a variable or block parameter to connect
[variable and parameter connection options](#)

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Enumerated Data Type — Specify state values and labels using an enumerated data type

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. To specify the states for the block using an enumerated data type, first select the **Enumerated Data Type** option. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Example: myEnumType

Programmatic Use

To programmatically specify the state labels and values for the block using an enumerated data type, specify 'on' for the UseEnumeratedDataType parameter and the name of the enumerated data type for the EnumeratedDataType parameter.

Block Parameter: UseEnumeratedDataType

Type: string or character array

Values: 'on' | 'off'

Default: 'off'

Block Parameter: EnumeratedDataType

Type: string or character array

Default: ''

Group Name — Radio Button group name

RadioButtonGroup (default) | character vector

Name for the group of values displayed on the Radio Button block. Unlike the **Block Name** and **Label**, the **Group Name** always shows on the Radio Button block.

Example: Input Amplitude

Programmatic Use

Block Parameter: ButtonGroupName

Type: string or character array

Default: 'Group'

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

States — Set of states to select for connected parameter
scalar and character vector

Set of states from which to select a value for the connected parameter. Each **State** consists of a **State Value** and a **State Label**.

- **State Value** — Value assigned to the connected variable or parameter when you select the state with the corresponding **Label**.
- **State Label** — Label for each state. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a descriptive text label.

Click the **+** button to add additional **States**.

The default configuration for the block includes these **States**.

States

State Value	State Label
0	Label1
1	Label2
2	Label3

Programmatic Use

To programmatically configure the **States** for a block, use an array of structures containing the fields **Value** and **Label**. Include a structure in the array for each state you want to configure on the block.

```
state1.Value = 1;
state1.Label = 'State 1';
state2.Value = 2;
state2.Label = 'State 2';
radioStates = [state1 state2];
```

Block Parameter: States

Type: structure

Default: 3x1 structure array

Format

Opacity — Block background opacity

1 (default) | scalar

Block background opacity, specified as a scalar value between 0 and 1.

Example: 0.5

Programmatic Use

Block Parameter: Opacity

Type: scalar

Default: 1

Foreground Color — Block foreground color

[r g b] vector

Block foreground color, including the text. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: `[r g b]` vector

Background Color — Block background color

`[r g b]` vector

Block background color. You can select a color from a palette of standard colors or specify a custom color.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 `[r g b]` vector with values between 0 and 1.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: `[r g b]` vector

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2017b

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Background Color, Foreground Color, and Opacity properties added for several dashboard blocks

Starting in R2020b, you can specify a background color, a foreground color, and opacity for these blocks from the Dashboard library:

- Check Box
- Combo Box
- Edit
- Push Button
- Radio Button

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

R2019a: Enhanced enumerated data type support for the Radio Button block

Starting in R2019a, you can use an enumeration class to configure the values and labels for the states of a Radio Button block. To configure the states of a Radio Button block with an enumerated data type, select the **Enumerated Data Type** parameter. In the text box, enter the name of the enumeration class you want to use.

When you use an enumeration class to configure the states of the block, you cannot manually edit, add, or remove states from the **States** table.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Ramp

Generate constantly increasing or decreasing signal

Libraries:
Simulink / Sources

Description

The Ramp block generates a signal that starts at a specified time and value and changes by a specified rate. The block's **Slope**, **Start time**, and **Initial output** parameters determine the characteristics of the output signal. All must have the same dimensions after scalar expansion.

Ports

Output

Port_1 — Output signal
scalar | vector | matrix

Generated output ramp signal characterized by the **Slope**, **Start time**, and **Initial output** parameters.

Data Types: double

Parameters

Slope — Slope of signal

1 (default) | scalar | vector | matrix

Specify the rate of change of the generated signal.

Programmatic Use

Block Parameter: slope

Type: character vector

Values: scalar

Default: '1'

Start time — Time output begins

0 (default) | scalar

Specify the time at which the block begins generating the signal.

Programmatic Use

Block Parameter: start

Type: character vector

Values: scalar

Default: '0'

Initial output — Initial value of output signal

0 (default) | scalar | vector | matrix

Specify the initial value of the output signal.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector

Values: scalar

Default: '0'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Repeating Sequence | Pulse Generator

Random Number

Generate normally distributed random numbers

Libraries:
Simulink / Sources

Description

The Random Number block generates normally distributed random numbers. To generate uniformly distributed random numbers, use the Uniform Random Number block. Both blocks use the Normal (Gaussian) random number generator ('v4': legacy MATLAB 4.0 generator of the `rng` function).

You can generate a repeatable sequence using any Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts. By default, the block produces a sequence that has a mean of 0 and a variance of 1. To generate a vector of random numbers with the same mean and variance, specify the **Seed** parameter as a vector.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box, and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

Ports

Output

Port_1 — Output signal
scalar | vector | matrix

Output signal that is the generated random numbers falling within a normal Gaussian distribution. The output is repeatable for a given seed.

Data Types: double

Parameters

Mean — Mean of random numbers

0 (default) | scalar | array

Specify the mean of the random numbers generated.

Programmatic Use**Block Parameter:** Mean**Type:** character vector**Values:** scalar | array**Default:** '0'**Variance** — Variance of random numbers

1 (default) | scalar | array

Specify the variance of the random numbers.

Programmatic Use**Block Parameter:** Variance**Type:** character vector**Values:** scalar | array**Default:** '1'**Seed** — Starting seed

0 (default) | positive integer | scalar | array

Specify the starting seed for the random number generator.

The output of number generated is repeatable for a given seed.

Programmatic Use**Block Parameter:** Seed**Type:** character vector**Values:** scalar | array**Default:** '0'**Sample time** — Time between intervals

0.1 (default) | integer

Specify the time interval between samples. The default is 0.1, which matches the default sample time of the Band-Limited White Noise block. See “Specify Sample Time” for more information.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Values:** scalar**Default:** '0.1'**Interpret vector parameters as 1-D** — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Mean**, **Variance**, and **Seed** parameters evaluate to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Mean**, **Variance**, and **Seed** parameters evaluate to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.

- When you clear this check box, the block does not output a vector of length N if the **Mean**, **Variance**, and **Seed** parameters evaluate to an N-element row or column vector.

Rate Limiter

Limit rate of change of signal

Libraries:
Simulink / Discontinuities

Description

The Rate Limiter block limits the first derivative of the signal passing through it. The output changes no faster than the specified limit. The derivative is calculated using this equation:

$$rate = \frac{u(i) - y(i-1)}{t(i) - t(i-1)}$$

where $u(i)$ and $t(i)$ are the current block input and time, and $y(i-1)$ and $t(i-1)$ are the output and time at the previous step. The output is determined by comparing $rate$ to the **Rising slew rate** and **Falling slew rate** parameters:

- If $rate$ is greater than the **Rising slew rate** parameter (R), the output is calculated as

$$y(i) = \Delta t \cdot R + y(i-1).$$

- If $rate$ is less than the **Falling slew rate** parameter (F), the output is calculated as

$$y(i) = \Delta t \cdot F + y(i-1).$$

- If $rate$ is between the bounds of R and F , the change in output is equal to the change in input:

$$y(i) = u(i)$$

When the block is running in continuous mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is zero), the **Initial condition** is ignored. The block output at $t = 0$ is equal to the initial input:

$$y(0) = u(0)$$

When the block is running in discrete mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is nonzero), the **Initial condition** is preserved:

$$y(-1) = Ic$$

where Ic is the initial condition. The block output at $t = 0$ is calculated as if $rate$ is outside the bounds of R and F . For $t = 0$, $rate$ is calculated as follows:

$$rate = \frac{u(0) - y(-1)}{sample\ time}$$

Limitations

- You cannot use a Rate Limiter block inside a Triggered Subsystem. Use the Rate Limiter Dynamic block instead.

Ports

Input

Port_1 — Input signal
scalar

The input signal to the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Output signal
scalar

Output signal from the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Rising slew rate — Limit of derivative for increasing input

1 (default) | real number

Specify the limit of the rising rate of the input signal. This parameter is tunable for fixed-point inputs.

Programmatic Use

Block Parameter: `RisingSlewLimit`

Type: character vector

Values: real number

Default: `'1'`

Falling slew rate — Limit of derivative for decreasing input

-1 (default) | real number

Specify the lower limit on the falling rate of the input signal. This parameter is tunable for fixed-point inputs.

Programmatic Use

Block Parameter: `FallingSlewLimit`

Type: character vector

Values: real number

Default: `'-1'`

Sample time mode — Sample time mode

`inherited` (default) | `continuous`

Specify the sample time mode, `continuous` or `inherited` from the driving block.

Programmatic Use**Block Parameter:** SampleTimeMode**Type:** character vector**Values:** 'inherited' | 'continuous' |**Default:** 'inherited'**Initial condition** — Initial output

0 (default) | scalar

Set the initial output of the simulation. Simulink does not allow you to set the initial condition of this block to `inf` or `NaN`.

Programmatic Use**Block Parameter:** InitialCondition**Type:** character vector**Values:** scalar**Default:** '0'**Treat as gain when linearizing** — Specify the gain value

On (default) | Boolean

Select this check box to cause the commands to treat the gain as 1. The linearization commands in Simulink software treat this block as a gain in state space. Clear the box to have the commands treat the gain as 0.

Programmatic Use**Block Parameter:** LinearizeAsGain**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Block Characteristics**

Data Types	double fixed point integer single

Rate Limiter Dynamic | Saturation

Rate Limiter Dynamic

Limit rate of change of signal

Libraries:
Simulink / Discontinuities

Description

The Rate Limiter Dynamic block limits the rising and falling rates of the signal.

- The external signal **up** sets the upper limit on the rising rate of the signal.
- The external signal **lo** sets the lower limit on the falling rate of the signal.

Follow these guidelines when using the Rate Limiter Dynamic block:

- Ensure that the data types of **up** and **lo** are the same as the data type of the input signal **u**.

When the lower limit uses a signed type and the input signal uses an unsigned type, the output signal keeps increasing regardless of the input and the limits.

- Use a fixed-step solver to simulate models that contain this block.

Because the Rate Limiter Dynamic block supports only discrete sample time.

Ports

Input

u — Input signal
scalar

Input signal to the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

lo — Limit of derivative for decreasing input
scalar

Dynamic value providing the limit of the falling rate of the input signal. Make the signal data type of **lo** the same data type of the input signal **u**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

up — Limit of derivative for increasing input
scalar

Dynamic value providing the limit of the rising rate of the input signal. Make the signal data type of **up** the same data type of the input signal **u**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Y — Output signal
scalar

Output signal from the rate limiter algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | enumerated | bus

Block Characteristics

Rate Limiter

Rate Transition

Handle transfer of data between blocks operating at different rates

Libraries:

Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Rate Transition block transfers data from the output of a block operating at one rate to the input of a block operating at a different rate. Use the block parameters to trade data integrity and deterministic transfer for faster response or lower memory requirements. To learn about data integrity and deterministic data transfer, see “Data Transfer Problems” (Simulink Coder).

Transition Handling Options

Transition Handling Options	Block Parameter Settings
<ul style="list-style-type: none"> Data integrity Deterministic data transfer Maximum latency 	Select: <ul style="list-style-type: none"> Ensure data integrity during data transfer Ensure deterministic data transfer
<ul style="list-style-type: none"> Data integrity Nondeterministic data transfer Minimum latency Higher memory requirements 	Select: <ul style="list-style-type: none"> Ensure data integrity during data transfer Clear: <ul style="list-style-type: none"> Ensure deterministic data transfer
<ul style="list-style-type: none"> Potential loss of data integrity Nondeterministic data transfer Minimum latency Lower memory requirements 	Clear: <ul style="list-style-type: none"> Ensure data integrity during data transfer Ensure deterministic data transfer

Dependencies

The behavior of the Rate Transition block depends on:

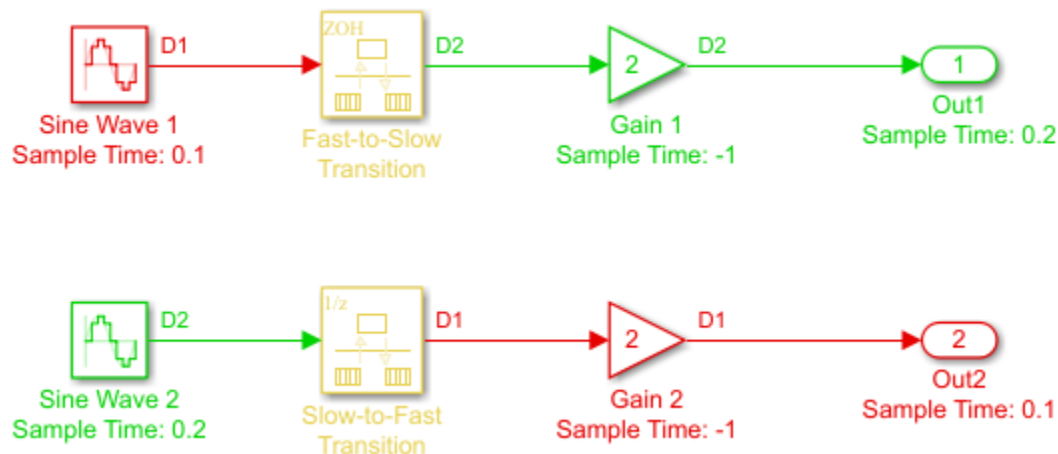

- Sample times of the ports to which the block connects (see “Effects of Synchronous Sample Times” on page 1-1783 and “Effects of Asynchronous Sample Times” on page 1-1784)
- Priorities of the tasks for the source and destination sample times (see Sample time properties in the Simulink documentation)
- Whether the model specifies a fixed- or variable-step solver (see “Compare Solvers” in the Simulink documentation)
- Setting of model configuration parameters **Device vendor** and **Device type** (see “Effects of Device Configuration” on page 1-1784)

Block Labels

When you update your diagram, a label appears on the Rate Transition block to indicate simulation behavior.

Label	Block Behavior
ZOH	Acts as a zero-order hold
1/z	Acts as a unit delay
Buf	Copies input to output under semaphore control
Db_buf	Copies input to output using double buffers
3buf	Copies input to output using triple buffers
Copy	Unprotected copy of input to output
NoOp	Does nothing
Mixed	Expands to multiple blocks with different behaviors
RT	Indicates data transfer between partitions when using the Schedule Editor. For more information on using the Schedule Editor, see “Using the Schedule Editor”.
Memory	Indicates memory mode. The block is in memory mode when Ensure deterministic data transfer (maximum delay) is off.

The block behavior label shows the method that ensures safe transfer of data between tasks operating at different rates. You can use the sample-time colors feature (see “View Sample Time Information”) to display the relative rates that the block bridges. Consider, for example, the following model:

Sample-time colors and the block behavior label show:

- The Rate Transition block at the top of the diagram acts as a zero-order hold in a fast-to-slow transition.
- The Rate Transition block at the bottom of the diagram acts as a unit delay in a slow-to-fast transition.

For more information, see “Handle Rate Transitions” (Simulink Coder).

Effects of Synchronous Sample Times

The following table summarizes how each label appears when the sample times of the input and output ports ($inTs$ and $outTs$) are periodic, or synchronous.

Block Settings		Block Label		
Rate Transition	Conditions for Rate Transition Block	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
(Equal)	$inTsOffset < outTsOffset$	None (error)	Buf	Copy or NoOp (see note that follows the table)
	$inTsOffset = outTsOffset$	Copy or NoOp (see note that follows the table)	Copy or NoOp (see note that follows the table)	
	$inTsOffset > outTsOffset$	None (error)	Db_buf	
(Fast to slow)	$inTs = outTs / N$ $inTsOffset, outTsOffset = 0$	ZOH	Buf	
	$inTs = outTs / N$ $inTsOffset \leq outTsOffset$	None (error)		
	$inTs = outTs / N$ $inTsOffset > outTsOffset$	None (error)	Db_buf	
	$inTs \neq outTs / N$	None (error)		
(Slow to fast)	$inTs = outTs * N$ $inTsOffset, outTsOffset = 0$	1/z	Db_buf	
	$inTs = outTs * N$ $inTsOffset \leq outTsOffset$	None (error)		
	$inTs = outTs * N$ $inTsOffset > outTsOffset$	None (error)		
	$inTs \neq outTs * N$	None (error)		

KEY

- $inTs$, $outTs$: Sample times of input and output ports, respectively
- $inTsOffset$, $outTsOffset$: Sample time offsets of input and output ports, respectively
- N : Integer value > 1

When you select the **Block reduction** parameter on the Configuration Parameters dialog box, Copy reduces to NoOp. No code generation occurs for a Rate Transition block with a NoOp label. To prevent a block from being reduced when block reduction is on, add a test point to the block output (see “Configure Signals as Test Points” in the Simulink documentation).

Effects of Asynchronous Sample Times

The following table summarizes how each label appears when the sample time of the input or output port (inTs or outTs) is not periodic, or asynchronous.

Block Settings	Block Label		
	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
inTs = outTs	Copy	Copy	Copy
inTs ≠ outTs	None (error)	Db_buf	
KEY			
<ul style="list-style-type: none"> • inTs, outTs: Sample times of input and output ports, respectively 			

Effects of Device Configuration

If the settings of model configuration parameters **Device vendor** and **Device type** specify hardware that supports atomic data load and store operations, the code generator optimizes the generated rate transition code when the target hardware supports atomic load and store operations for the data type of the signal being transferred. The code generator takes advantage of the hardware data load and store capability by replacing double-buffering code between asynchronous tasks with code that performs a single memory copy.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal to transition to a new sample rate, specified as a scalar, vector, matrix, or N-D array. To learn about the block parameters that enable you to trade data integrity and deterministic transfer for faster response or lower memory requirements, see “Transition Handling Options” on page 1-1781.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector | matrix | N-D array

Output signal is the input signal converted to the sample rate you specify. The default configuration ensures safe and deterministic data transfer. To learn about the block parameters that enable you to trade data integrity and deterministic transfer for faster response or lower memory requirements, see “Transition Handling Options” on page 1-1781.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Ensure data integrity during data transfer — Ensure data integrity

on (default) | off

Selecting this check box results in generated code that ensures data integrity when the block transfers data. If you select this check box and the transfer is nondeterministic (see **Ensure deterministic data transfer**), depending on the priority of input rate and output rate, the generated code uses a proper algorithm using single or multiple buffers to protect data integrity during data transfer.

Otherwise, the Rate Transition block is either reduced or generates code using a copy operation to affect the data transfer. This unprotected mode consumes less memory. But the copy operation is also interruptible, which can lead to loss of data integrity during data transfers. Select this check box if you want the generated code to operate with maximum responsiveness (that is, nondeterministically) and data integrity. For more information, see “Rate Transition Block Options” (Simulink Coder).

Programmatic Use

Block Parameter: Integrity

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Ensure deterministic data transfer (maximum delay) — Ensure deterministic data transfer

on (default) | off

Selecting this check box results in generated code that transfers data at the sample rate of the slower block, that is, deterministically. If you do not select this check box, data transfers occur when new data is available from the source block and the receiving block is ready to receive the data. You avoid transfer delays, thus ensuring that the system operates with maximum responsiveness. However, transfers can occur unpredictably, which is undesirable in some applications. For more information, see “Rate Transition Block Options” (Simulink Coder).

Programmatic Use

Block Parameter: Deterministic

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Initial conditions — Initial conditions

0 (default) | scalar | vector | matrix | N-D array

This parameter applies only to slow-to-fast transitions. It specifies the initial output of the Rate Transition block at the beginning of a transition, when there is no output signal due to the absence of input signal coming from the slow block connected to the input of the Rate Transition block. Simulink does not allow the initial output of this block to be Inf or NaN. The value you specify must be a scalar, or have the same dimensions as the input signal.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Values: finite scalar

Default: '0'

Output port sample time options — Mode for specifying output port sample time

Specify (default) | Inherit | Multiple of input port sample time

Specifies a mode for setting the output port sample time. The options are:

- **Specify** — Allows you to use the **Output port sample time** parameter to specify the output rate to which the Rate Transition block converts its input rate.
- **Inherit** — Specifies that the Rate Transition block inherits an output rate from the block to which the output port is connected.
- **Multiple of input port sample time** — Allows you to use the **Sample time multiple (>0)** parameter to specify the Rate Transition block output rate as a multiple of its input rate.

If you select **Inherit** and all blocks connected to the output port also inherit sample time, the fastest sample time in the model applies.

Programmatic Use

Block Parameter: OutPortSampleTimeOpt

Type: character vector

Values: 'Specify' | 'Inherit' | 'Multiple of input port sample time'

Default: 'Specify'

Output port sample time — Output rate

-1 (default) | scalar | vector

Enter a value that specifies the output rate to which the block converts its input rate. The default value (-1) specifies that the Rate Transition block inherits the output rate from the block to which the output port is connected. See “Specify Sample Time” for information on how to specify the output rate.

Dependencies

To enable this parameter, set **Output port sample time options** to **Specify**.

Programmatic Use

Block Parameter: OutPortSampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Sample time multiple(>0) — Sample time multiple

1 (default) | positive scalar

Enter a positive value that specifies the output rate as a multiple of the input port sample time. The default value (1) specifies that the output rate is the same as the input rate. A value of 0.5 specifies that the output rate is half of the input rate. A value of 2 specifies that the output rate is twice the input rate.

Dependencies

To enable this parameter, set **Output port sample time options** to Multiple of input port sample time.

Programmatic Use

Block Parameter: OutPortSampleTimeMultiple

Type: character vector

Values: scalar

Default: '1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

- Generated code relies on memcpy or memset functions (string.h) under certain conditions.
- Cannot use inside a triggered subsystem hierarchy.
- Generated code for concurrent programs is platform specific and assumes deployment platform and host platform are the same.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides configuration options that affect HDL implementation and synthesized logic.

Best Practices

- When the Rate Transition block is operating at a fast input rate and slow output rate, it is good practice to follow the Rate Transition block with a unit delay. Doing so prevents the code generator from inserting an extra bypass register in the HDL code. See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).
- To upsample the input signal without incurring a unit delay, in the Block Parameters dialog box of the Rate Transition block:

- Clear the **Ensure data integrity during data transfer** check box.

Clearing this check box hides the **Ensure deterministic data transfer (maximum delay)** check box.

- Configure the output port sample time of the block to be an integer multiple of the input port sample time. Specify a fractional value of $1/n$ for **Sample time multiple**, where n is an integer. If **Sample time multiple** uses a value $1/n$, you can choose any value for the block parameter **Output port sample time** options.

Note When downsampling the input signal, leave the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** check boxes selected. This mode generates an additional bypass register in the HDL code.

See also “Usage of Rate Change and Constant Blocks” (HDL Coder).

Restrictions

- The sample rate cannot be 0 or Inf for block input or output ports.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

AsyncRTAsWire	<p>Map Asynchronous Rate Transition as Wire.</p> <p>When Output port sample time has noninteger values, it is considered as an asynchronous rate. Enable the AsyncRTAsWire option to generate a wire when such asynchronous rates are present for the Rate Transition block.</p> <p>Dependencies: This option is available only when the Ensure data integrity during data transfer and Ensure deterministic data transfer parameters are turned off.</p> <p>When using asynchronous rate transition as wire, set Clock inputs option to Multiple.</p>
----------------------	---

Note While mapping the asynchronous rate transition as wire, you may see the numerical mismatches between Simulink and Code Generation results.

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Real-Imag to Complex

Convert real and/or imaginary inputs to complex signal

**Libraries:**

Simulink / Math Operations

HDL Coder / Math Operations

Description

The Real-Imag to Complex block converts real and/or imaginary inputs to a complex-valued output signal.

The inputs can both be arrays (vectors or matrices) of equal dimensions, or one input can be an array and the other a scalar. If the block has an array input, the output is a complex array of the same dimensions. The elements of the real input map to the real parts of the corresponding complex output elements. The imaginary input similarly maps to the imaginary parts of the complex output signals. If one input is a scalar, it maps to the corresponding component (real or imaginary) of all the complex output signals.

Ports

Input

Re — Real part of complex output

scalar | vector | matrix

Real value to be converted to complex-valued output signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

Im — Imaginary part of complex output

scalar | vector | matrix

Imaginary value to be converted to complex-valued output signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

Port 1 — Real or imaginary part of complex output

scalar | vector | matrix

Real or imaginary value to convert to complex output signal, specified as a finite scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

Output

Port 1 — Complex signal

scalar | vector | matrix

Complex signal, formed from real and imaginary values.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Input — Real, imaginary, or both

Real (default) | Imag | Real and imag

Specify the type of input: a real input, an imaginary input, or both.

Programmatic Use

Block Parameter: Input

Type: character vector

Values: 'Real and imag' | 'Real' | 'Imag'

Default: 'Real and imag'

Imag part — Imaginary part of complex output

0 (default) | finite scalar, vector, or matrix

Specify the imaginary value to use when converting the input to a complex-valued output signal.

Dependencies

To enable this parameter, set **Input** to Real.

Programmatic Use

Block Parameter: ConstantPart

Type: character vector

Values: imaginary value

Default: '0'

Real part — Real part of complex output

0 (default) | finite scalar, vector, or matrix

Specify the constant real value to use when converting the input to a complex-valued output signal.

Dependencies

To enable this parameter, set **Input** to Imag.

Programmatic Use

Block Parameter: ConstantPart

Type: character vector

Values: finite, real-valued scalar, vector, or matrix

Default: '0'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Record, XY Graph

Log data to the workspace, to a file, or both

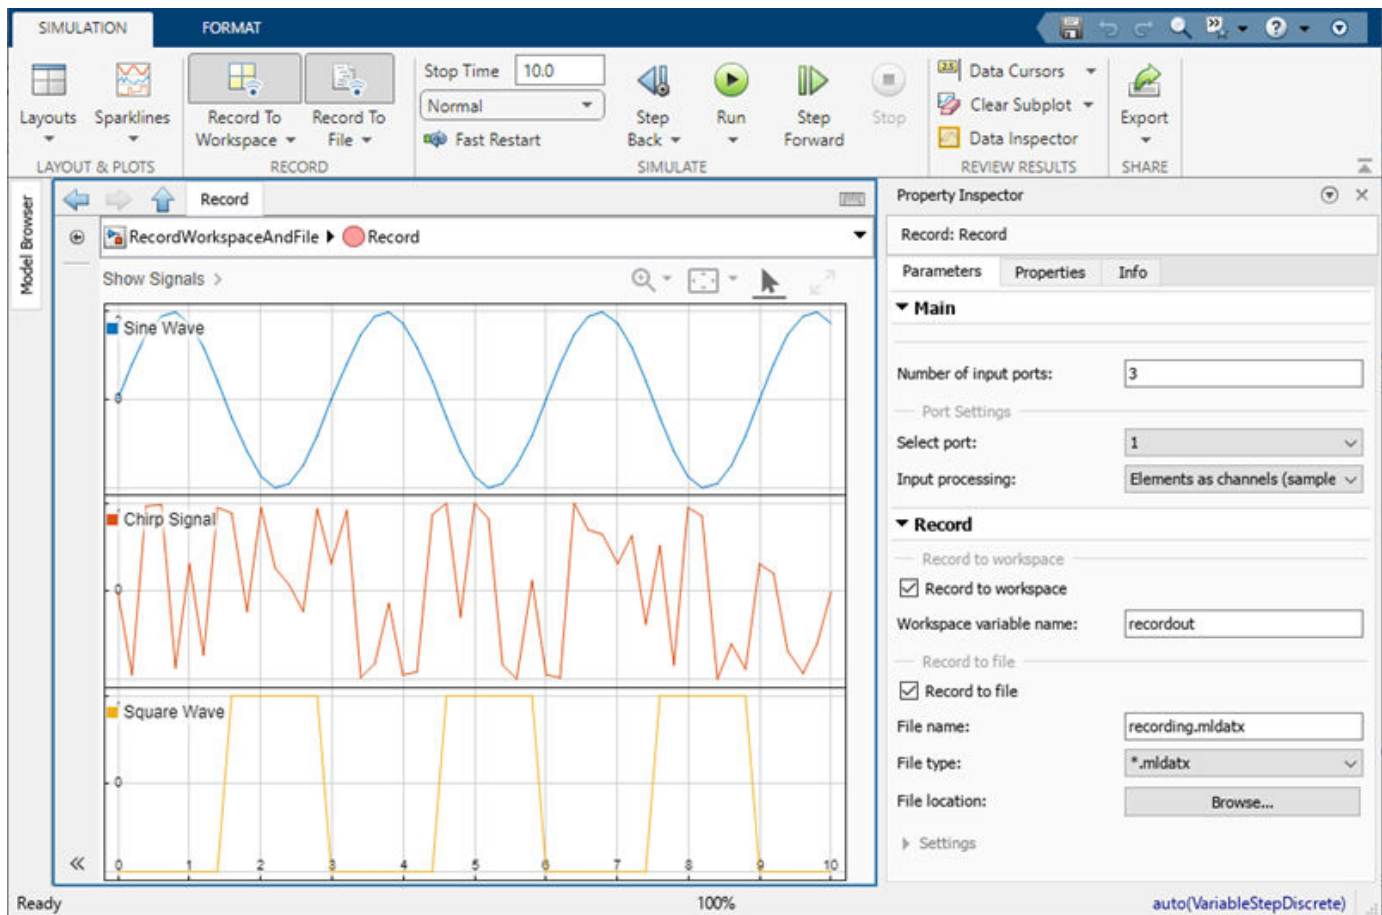

Libraries:
Simulink / Sinks

Description

You can use the Record block or the XY Graph block to record data to the workspace, to a file, or to both the workspace and a file. When you log data to a file, you can choose to log to a MAT file, an MLDATX file, or an Excel file. Signals connected to a Record block always log to the Simulation Data Inspector. If you decide that you need to save data after simulation, you can export data from the Record block to the workspace or to any supported file type.

You can also use the Record block to visualize connected signals. To view data for signals connected to the Record block, double-click the block. You have access to simulation controls, such as the **Run** button, while viewing data in the Record block.

By default, the Record block displays all connected signals on a sparklines plot. A sparkline is added for each connected signal. After sparklines fill the visible space, a scrollbar allows you to continue plotting signals.

Build Visualizations

The Record block supports most visualizations available in the Simulation Data Inspector. When a different visualization makes sense for your data, you can modify the plot layout and plot types using the **Layouts** option and the plot types selector, labeled **Sparklines** by default. Use the **Layouts** list to select a layout of subplots. To change the plot type of a subplot, select the subplot then select the desired plot type from the plot types selector.

For more information, see “Log Data to the Workspace and a File Using the Record Block”. For examples that show how to use each visualization type, see:

- Sparklines — “View Many Signals Together Using Sparklines”
- XY — “Visualize Simulation Data on an XY Plot” and “Analyze Data Using the XY Plot”
- Map — “View and Replay Map Data”
- Time plot and text editor — “Create Plots Using the Simulation Data Inspector”

The Record block does not support the array visualization available in the Simulation Data Inspector. The Record block supports logging multidimensional signal data, including variable-size signals, but does not support visualizing multidimensional data. To visualize the data for a multidimensional signal using the Record block, convert the signal with multidimensional sample values to a set of signals, called channels, that each have scalar sample values. For more information, see “Analyze Multidimensional Signal Data”.

XY Graph Block

The XY Graph block in the Simulink Sinks library is an alternative configuration of the Record block that visualizes two input signals on an XY plot. The first input port provides the x data for the XY plot, and the second input port provides the y data.

The XY Graph block supports logging and visualizing data for nonscalar inputs. However, the XY visualization does not support multidimensional data. When you connect nonscalar signals to the XY Graph block, you must manually configure which channels or elements of the nonscalar signal provide the x and y data for the XY plot.

Ports

Input

Port_1 — Signal to record

scalar | vector | matrix | array | bus

Signal to record. You can add ports to the Record block by dragging lines to the edge of the block or by using the **Ports** parameter.

The Record block supports logging variable-size signals but does not support visualizing variable-size signals.

The XY Graph block is an alternative configuration of the Record block that visualizes data connected to two input ports on an XY plot. The first input port provides the x data for the XY plot, and the second input port provides the y data.

Tips

- To log frame-based data, specify the **Input Processing** parameter for each port that receives a frame-based signal.
- When you connect a nonscalar signal to an input port of the XY Graph block, you must manually configure which channels or elements of the nonscalar signal provide the x and y data for the XY plot.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

To modify Record block parameters, use the Property Inspector.

Main

Number of input ports — Number of input ports

1 (default) | integer in the range [1, 100]

Number of input ports, specified as an integer between 1 and 100, inclusive.

The XY Graph block is an alternative configuration of the Record block that visualizes data connected to two input ports on an XY plot. The first input port provides the x data for the XY plot, and the second input port provides the y data.

Programmatic Use**Block Parameter:** 'NumPorts'**Type:** integer | character vector**Values:** integer in the range [1,100]**Default:** 1**Port** — Port for which to specify input processing mode

1 (default) | integer

Use the **Port** and **Input Processing** parameters together to specify the input processing mode for a port. The input processing mode determines how the Record block interprets matrix data:

- Sample-based — Each element in the matrix is a separate channel.
- Frame-based — Each column in the matrix is a separate channel.

To use frame-based input processing, the signal must have a discrete sample rate, and the sample values must be nonscalar with fixed dimensions.

By default, each port processes the input signal as sample-based.

To change the input processing mode for a port:

- 1 Select the port number using the **Port** parameter.
- 2 Select the input processing mode using the **Input Processing** parameter.

Programmatic Use

Programmatically specify the input processing mode for each port by specifying the `FrameSettings` parameter as a row vector with as many elements as block ports. The element index corresponds to the port number on the block. Specify 1 to use frame-based input processing for the port and 0 to use sample-based processing.

Block Parameter: 'FrameSettings'**Type:** logical array**Values:** 1-by-n row vector, where n is equal to the number of ports**Default:** 0**Input Processing** — Input processing mode for selected port

Elements as channels (sample-based) (default) | Columns as channels (frame-based)

Use the **Port** and **Input Processing** parameters together to specify the input processing mode for a port. The input processing mode determines how the Record block interprets matrix data:

- Sample-based — Each element in the matrix is a separate channel.
- Frame-based — Each column in the matrix is a separate channel.

To use frame-based input processing, the signal must have a discrete sample rate, and the sample values must be nonscalar with fixed dimensions.

By default, each port processes the input signal as sample-based.

To change the input processing mode for a port:

- 1 Select the port number using the **Port** parameter.
- 2 Select the input processing mode using the **Input Processing** parameter.

Programmatic Use

Programmatically specify the input processing mode for each port by specifying the `FrameSettings` parameter as a row vector with as many elements as block ports. The element index corresponds to the port number on the block. Specify 1 to use frame-based input processing for the port and 0 to use sample-based processing.

Block Parameter: 'FrameSettings'

Type: logical array

Values: 1-by-n row vector, where n is equal to the number of ports

Default: 0

Record

Record to Workspace — Workspace logging option

off (default) | on

Workspace logging option. By default, the Record block logs data to the Simulation Data Inspector only. Select **Record to Workspace** to log data for signals connected to the Record block to the MATLAB workspace in a `Simulink.SimulationData.Dataset` object.

Use the **Workspace Variable Name** parameter to specify the name of the Dataset object that contains the logged Record block data.

Tips

- When you log data to the workspace, the way you access the data depends on your model configuration. By default, models provide all logged data in a single output variable as a `Simulink.SimulationOutput` object. You can access the Record block data using the `get` function or a dot with the Record block workspace variable name. When the **Single simulation output** option is disabled, logging data appears in separate variables in the workspace, and you access the Record block data directly.
- Logging intervals specified using the **Logging intervals** configuration parameter apply to data logged to the workspace using the Record block.
- You can use a single Record block to log data to the Simulation Data Inspector, to the workspace, and to a file.

Programmatic Use

Block Parameter: 'RecordToWorkspace'

Type: character vector | boolean | numeric

Values: 'on' | 'off' | true or 1 | false or 0

Default: 'off'

Workspace Variable Name — Name for workspace variable that contains logged block data

recordout (default) | character vector | string

Name for the workspace variable that contains the logged block data.

Dependencies

To enable this parameter, select the **Record to Workspace** parameter.

Programmatic Use

Block Parameter: 'VariableName'

Type: character vector | string

Default: 'recordout'

Record to File — Log to file option

off (default) | on

Log to file option. By default, the Record block logs data to the Simulation Data Inspector only. Select **Record to File** to log data for signals connected to the Record block to a file.

Tips

- Use the **File Name** parameter to specify a name for the file.
- Use the **File Type** parameter to specify whether to log data to an MLDATX file, a MAT file, or an Excel file.
- Use the **File Location** parameter to specify the path to the file.
- Logging intervals specified using the **Logging intervals** configuration parameter do not apply to data logged to a file using the Record block.

Programmatic Use**Block Parameter:** 'RecordToFile'**Type:** character vector | boolean | numeric**Values:** 'on' | 'off' | true or 1 | false or 0**Default:** 'off'**File Name** — Name of file with logged data

recording.mldatx (default) | character vector | string

Name of the file that contains the logged data. The name does not need to include the file extension. If you do include the file extension in the name, ensure the name uses a valid extension for the specified **File Type**.

Tips

- If you do not change the name or location of the file you log to from one run to the next, the Record block overwrites prior data in the file.
- When you want to save the file in a location other than your working directory, use the **File Location** parameter to specify the path to the directory where you want to save the file.

Dependencies

To enable this parameter, select the **Record to File** parameter.

Programmatic Use

Use the FileName parameter to specify the **File Name**, **File Type**, and **File Location** parameters. Include the extension for the desired file type in the name you pass to set_param. When you want to save the file somewhere other than the current working directory, specify the path with the file name and extension.

Block Parameter: 'FileName'**Type:** character vector | string**Default:** 'recording.mldatx'**File Type** — Type of file for logged data

*.mldatx (default) | *.mat | *.xlsx

Use the **File Type** parameter to specify whether you want to log data to an MLDATX file, a MAT file, or an Excel file.

Tips

- When you log data to an Excel file, the data is formatted as described in “Microsoft Excel Import, Export, and Logging Format”.
- When you log data to an Excel file, you can specify whether to share time columns using the **Time** parameter and which signal attributes to log using the **Attributes** parameter.

Dependencies

To enable this parameter, select **Record to File**.

Programmatic Use

Use the `FileName` parameter to specify the **File Name**, **File Type**, and **File Location** parameters. Include the extension for the desired file type in the name you pass to `set_param`. When you want to save the file somewhere other than the current working directory, specify the path with the file name and extension.

Block Parameter: 'FileName'

Type: character vector | string

Default: 'recording.mldatx'

File Location — Path to file with logged data

working directory (default) | character vector | string

Use the **File Location** parameter to specify the location where you want to save the file with the logged data when you want to save the file somewhere other than the working directory. Ensure you have write permissions in the directory you specify.

Dependencies

To enable this parameter, select **Record to File**.

Programmatic Use

Use the `FileName` parameter to specify the **File Name**, **File Type**, and **File Location** parameters. Include the extension for the desired file type in the name you pass to `set_param`. When you want to save the file somewhere other than the current working directory, specify the path with the file name and extension.

Block Parameter: 'FileName'

Type: character vector | string

Default: 'recording.mldatx'

Time — Options for exporting time data to Excel file

Shared Time Columns (default) | Individual Time Columns

Use the **Time** parameter to specify how to log signal time data when you log the Record block data to an Excel file.

- **Shared Time Columns** — When time data is identical for multiple signals, the signals share a single time column in the logging file. The logging file may still include multiple time columns if the Record block logs data for signals with unique time data.
- **Individual Time Columns** — Each logged signal always has its own time column in the logging file.

Dependencies

To enable this parameter, select **Record to File** and specify **File Type** as `*.xlsx`.

Attributes — Signal attributes to export to Excel file

Data Type | Units | Port Index | Block Path | Interpolation

Select one or more signal attribute options to include in the logging file when you log data to an Excel file. Selected signal attributes appear in the signal column above the first data point according to the format described in “Microsoft Excel Import, Export, and Logging Format”.

Dependencies

To enable this parameter, select **Record to File** and specify **File Type** as `*.xlsx`.

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

- To open the Record block in a new window, right-click the block, then select **Open In New Window**.
- To open the Record block in a new tab, right-click the block, then select **Open In New Tab**.

Model Settings

Single simulation output

Reinitialize Function

Execute subsystem on model or subsystem reinitialize event

Libraries:
Simulink / User-Defined Functions

Description

The Reinitialize Function block is a preconfigured Subsystem block that executes on a model or subsystem reinitialize event. By default, the Reinitialize Function block includes:

- An Event Listener block with the **Event type** set to `Reinitialize` and the **Event name** set to `reinit`
- A Constant block with the **Constant value** set to `0`
- A State Writer block with no **State owner block** set

Customize the Reinitialize Function block by, for example, replacing the Constant block with source blocks that generate the state value for the State Writer block and specifying a **State owner block** for the State Writer block.

To generate a model reinitialize event, send a function-call signal to a reinitialize port of a Model block that references a model that contains a Reinitialize Function block. To generate a subsystem reinitialize event, send a function-call signal to a reinitialize port of a Subsystem block that contains a Reinitialize Function block. The reinitialize event has these effects:

- 1 The state of each block in the model or subsystem reverts back to its initial condition, including blocks within subsystems or referenced models inside the model or subsystem receiving the reinitialize event.
- 2 The contents of the Reinitialize Function block corresponding to the reinitialize port are executed.
- 3 If any subsystems or referenced models inside the model or subsystem receiving the reinitialize event contain a Reinitialize Function block, and the **Event name** of that block matches the **Event name** of the Reinitialize Function block corresponding to the reinitialize port, then the contents of those Reinitialize Function blocks are executed.

If a Simulink based state in a Stateflow chart contains a Reinitialize Function block, to generate a subsystem reinitialize event for the state, use a transition event with this syntax:

```
{StateName.ReinitializeEventName()}
```

Conditionally executed subsystems with output ports are fully supported within Reinitialize Function blocks.

A model or subsystem can have multiple Reinitialize Function blocks with each block having a different **Event name**. Each of these reinitialize events appears in the generated code as a different function. Set the **Event name** in the block dialog of the Event Listener block. The **Event Name** appears on the Reinitialize Function block icon, and as the port label for the reinitialize port corresponding to the reinitialize event.

You can select an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select

Related Blocks  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Limitations

- If a referenced model or subsystem contains more than one Reinitialize Function block, the function-call signals driving all reinitialize ports of the Model or Subsystem block must have a common source.
- Only these blocks can have reinitialize ports:
 - Model
 - Atomic Subsystem
 - Enabled Subsystem
 - Triggered Subsystem
 - Enabled and Triggered Subsystem
 - Message Triggered Subsystem
 - Message Polling Subsystem
 - Function-Call Subsystem
 - If Action Subsystem
 - Switch Case Action Subsystem
 - For Iterator Subsystem
 - While Iterator Subsystem
- For a list of unsupported blocks and features, see “Initialize, Reinitialize, Reset, and Terminate Function Limitations”.

Relational Operator

Perform specified relational operation on inputs

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Logic and Bit Operations
 HDL Coder / Commonly Used Blocks
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Logic and Bit Operations

Description

The Relational Operator block performs the specified relational operation on the input. The value you choose for the **Relational operator** parameter determines whether the block accepts one or two input signals.

Two-Input Mode

By default, the Relational Operator block compares two inputs using the **Relational operator** parameter that you specify. The first input corresponds to the top input port and the second input to the bottom input port. (See “Identify Port Location on Rotated or Flipped Block” for a description of the port order for various block orientations.)

You can specify one of the following operations in two-input mode:

Operation	Description
==	True if the first input is equal to the second input
~=	True if the first input is not equal to the second input
<	True if the first input is less than the second input
<=	True if the first input is less than or equal to the second input
>=	True if the first input is greater than or equal to the second input
>	True if the first input is greater than the second input

You can specify inputs as scalars, arrays, or a combination of a scalar and an array.

For...	The output is...
Scalar inputs	A scalar
Array inputs	An array of the same dimensions, where each element is the result of an element-by-element comparison of the input arrays
Mixed scalar and array inputs	An array, where each element is the result of a comparison between the scalar and the corresponding array element

If the relational operation can be efficiently and accurately represented on the hardware board, this efficient representation is used. Otherwise, both operands are cast to a common type using overflow saturation and the specified rounding mode.

You can specify the output data type using the **Output data type** parameter. The output equals 1 for true and 0 for false.

Tip Select an output data type that represents zero exactly. Data types that satisfy this condition include signed and unsigned integers and any floating-point data type.

One-Input Mode

When you select one of the following operations for **Relational operator**, the block switches to one-input mode.

Operation	Description
isInf	True if the input is Inf
isNaN	True if the input is NaN
isFinite	True if the input is finite

For an input that is not floating point, the block produces the following output.

Data Type	Operation	Block Output
<ul style="list-style-type: none"> • Fixed point • Boolean • Built-in integer 	isInf	False
	isNaN	False
	isFinite	True

Rules for Data Type Propagation

The following rules apply for data type propagation when your block has one or more input ports with unspecified data types.

When the block is in...	And...	The block uses...
Two-input mode	Both input ports have unspecified data types	double as the default data type for both inputs
	One input port has an unspecified data type	The data type from the specified input port as the default data type of the other port
One-input mode	The input port has an unspecified data type	double as the default data type for the input

Ports

Input

Port_1 — First input signal
scalar | vector | matrix

First input signal, specified as a scalar, vector, or matrix.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Port_2 — Second input signal

scalar | vector | matrix

Second input signal, specified as a scalar, vector, or matrix.

DependenciesTo enable this port, set the **Relational operator** to ==, ~=, <, <=, >=, or >.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output**Port_1** — Output signal

scalar | vector | matrix

Output signal, consisting of zeros and ones, with the same dimensions as the input. You control the output data type with the **Output data type** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters**Main****Relational operator** — Relational operator

<= (default) | ~= | == | < | >= | > | isInf | isNaN | isFinite

Specify the operation for comparing two inputs or determining the signal type of one input.

- == — True if the first input is equal to the second input
- ~= — True if the first input is not equal to the second input
- < — True if the first input is less than the second input
- <= — True if the first input is less than or equal to the second input
- >= — True if the first input is greater than or equal to the second input
- > — True if the first input is greater than the second input
- isInf — True if the input is Inf
- isNaN — True if the input is NaN
- isFinite — True if the input is finite

Programmatic Use**Block Parameter:** Operator**Type:** character vector**Values:** '==' | '~=' | '<' | '<=' | '>=' | '>' | 'isInf' | 'isNaN' | 'isFinite'**Default:** '<='**Enable zero-crossing detection** — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Parameter: ZeroCross

Type: character vector, string

Values: 'on' | 'off'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Data Type

Require all inputs to have the same data type — Require all inputs to have same data type

off (default) | on

To require that all block inputs have the same data type, select this check box. When you clear this check box, the inputs can have different data types.

Dependencies

This check box is not available when you set **Relational operator** to `isInf`, `isNaN`, or `isFinite` because, in those modes, the block only has one input port.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output data type — Output data type

boolean (default) | Inherit: Logical (see Configuration Parameters: Optimization) | fixdt(1,16) | <data type expression>

Specify the output data type. When you select:

- `boolean` — The block output has data type `boolean`.
- `Inherit: Logical (see Configuration Parameters: Optimization)` — The block uses the **Implement logic signals as Boolean data** configuration parameter to specify the output data type (see “Implement logic signals as Boolean data (vs. double)”).

Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

- `fixdt(1,16)` — The block output has the specified fixed-point data type `fixdt(1,16)`.

Tip The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show data type assistant** . For more information, see “Specify Data Types Using Data Type Assistant”.

- `<data type expression>` — The block output has the data type you specify as a data type expression, for example, `Simulink.NumericType`.

Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Logical (see Configuration Parameters: Optimization)'` | `'boolean'` | `'fixdt(1,16)'` | `'<data type expression>'`

Default: `'boolean'`

Integer rounding mode — Rounding mode for fixed-point operations

`Simplest (default)` | `Convergent` | `Floor` | `Nearest` | `Round` | `Ceiling` | `Zero`

Specify the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Simplest'

Mode — Category of data to specify

`Built in` (default) | `Inherit` | `Fixed point` | `Expression`

Select the category of data to specify.

- `Built in` — Specifies built-in data types. Selecting `Built in` enables `boolean`.
- `Inherit` — Specifies inheritance rules for data types. Selecting `Inherit` enables `Logical` (see `Configuration Parameters: Optimization`).
- `Fixed point` — Specifies fixed-point data types.
- `Expression` — Specifies expressions that evaluate to data types.

Dependencies

To enable this parameter, click the **Show data type assistant** button.

Data type override — Specify data type override mode for this signal

`Inherit` | `Off`

Select the data type override mode for this signal.

- When you select `Inherit`, Simulink inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.
- When you select `Off`, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, set **Mode** to `Built in` or `Fixed point`.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Signedness — Signedness of fixed-point data

Signed (default) | Unsigned

Specify whether you want the fixed-point data as signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to Fixed point.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to Fixed point.

Scaling — Method of scaling

Integer (default)

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. Specifying Integer has the same result as specifying a binary point location and setting the fraction length to 0.

Dependencies

To enable this parameter, click the **Show data type assistant** button and set **Mode** to Fixed point.

Block Characteristics

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , <code>Zero</code> , or <code>Custom</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to <code>Custom</code> . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Complex Data Support

The `~=` and `==` operators are supported for code generation.

Logical Operator

Relay

Switch output between two constants

Libraries:

Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The output for the Relay block switches between two specified values. When the relay is on, it remains on until the input drops below the value of the **Switch off point** parameter. When the relay is off, it remains off until the input exceeds the value of the **Switch on point** parameter. The block accepts one input and generates one output.

Note When the initial input falls *between* the **Switch off point** and **Switch on point** values, the initial output is the value when the relay is off.

Ports

Input

Port_1 — Input signal
scalar

The input signal that switches the relay on or off.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output signal
scalar

The output signal switches between two values determined by the parameters **Output when on** and **Output when off**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Switch on point — Input value which switches the relay on

'eps' (default) | scalar

When the input crosses this threshold, the relay switches on. The **Switch on point** value must be greater than or equal to the **Switch off point**. Specifying a **Switch on point** value greater than the

Switch off point models hysteresis, whereas specifying equal values models a switch with a threshold at that value.

The **Switch on point** parameter is converted to the input data type offline using round-to-nearest and saturation methods.

Programmatic Use

Block Parameter: OnSwitchValue

Type: character vector

Values: scalar

Default: 'eps'

Switch off point — Input value which switches the relay off

'eps' (default) | scalar

When the input crosses this threshold the relay switches off. The value of **Switch off point** must be less than or equal to **Switch on point**. The **Switch off point** parameter is converted to the input data type offline using round-to-nearest and saturation.

Programmatic Use

Block Parameter: OffSwitchValue

Type: character vector

Values: scalar

Default: 'eps'

Output when on — Output value when the relay is on

1 (default) | scalar

The output value when the relay is on.

Programmatic Use

Block Parameter: OnOutputValue

Type: character vector

Values: scalar

Default: '1'

Output when off — Output value when the relay is off

0 (default) | scalar

The output value when the relay is off.

Programmatic Use

Block Parameter: OffOutputValue

Type: character vector

Values: scalar

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector | string

Values: 'off' | 'on'

Default: 'on'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMin**Type:** character vector**Values:** ' [] ' | scalar**Default:** ' [] '**Output maximum** — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** ' [] ' | scalar**Default:** ' [] '**Output data type** — Data type of output signal

Inherit: All ports same datatype (default) | Inherit: Inherit via back propagation | double | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” in *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Same as input', 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'fixdt(1,16,0)', 'fixdt(1,16,2^0,0)', 'fixdt(1,16,2^0,0)'. '<data type expression>'

Default: 'Inherit: Same as input'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Saturation | Backlash

Repeating Sequence

Generate arbitrarily shaped periodic signal

Libraries:
Simulink / Sources

Description

The Repeating Sequence block outputs a periodic scalar signal having a waveform that you specify using the **Time values** and **Output values** parameters. The **Time values** parameter specifies a vector of output times. The **Output values** parameter specifies a vector of signal amplitudes at the corresponding output times. Together, the two parameters specify a sampling of the output waveform at points measured from the beginning of the interval over which the waveform repeats (the period of the signal).

By default, both parameters are [0 2]. These default settings specify a sawtooth waveform that repeats every 2 seconds from the start of the simulation and has a maximum amplitude of 2.

Ports

Output

Port_1 — Periodic output signal
scalar

Output signal specified by the **Time values** and **Output values** parameters to create a periodic scalar signal.

Data Types: double

Parameters

Time values — Vector of output times

[0 2] (default) | vector

Vector of strictly monotonically increasing time values. The period of the generated waveform is the difference of the last and first values of this parameter.

Programmatic Use

Block Parameter: rep_seq_t

Type: character vector

Values: vector

Default: [0 2]

Output values — Vector of output values

[0 2] (default) | vector

Vector of output values that specify the output waveform. Each element corresponds to the time value in the **Time values** parameter.

Programmatic Use

Block Parameter: rep_seq_y

Type: character vector

Values: vector

Default: [0 2]

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The block sets the input period as the difference between the first and last value of the **Time values** parameter. The output at any time t is the output at time $t = t - n \cdot \text{period}$, where n is an integer. The sequence repeats at $t = n \cdot \text{period}$. The block uses linear interpolation to compute the value of the waveform between the output times that you specify.

Repeating Sequence Stair | Repeating Sequence Interpolated

Repeating Sequence Interpolated

Output discrete-time sequence and repeat, interpolating between data points

Libraries:
Simulink / Sources

Description

The Repeating Sequence Interpolated block outputs a periodic discrete-time sequence based on the values in **Vector of time values** and **Vector of output values** parameters. Between data points, the block uses the method you specify for the **Lookup Method** parameter to determine the output.

Ports

Output

Port_1 — Periodic output signal
scalar

Output signal generated based on the values in the **Vector of time values** and **Vector of output values** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Main

Vector of output values — Vector of output values

[3 1 4 2 1]. ' (default) | vector

Vector of output values that specify the output waveform. Each element corresponds to the time value in the **Vector of time values** parameter.

Programmatic Use

Block Parameter: OutValues

Type: character vector

Values: vector

Default: [3 1 4 2 1]. '

Vector of time values — Vector of time values

[0 0.1 0.5 0.6 1]. ' (default) | vector

Specify the column vector containing time values. The time values must be strictly increasing, and the vector must have the same size as the vector of output values.

Programmatic Use**Block Parameter:** TimeValues**Type:** character vector**Values:** vector**Default:** [0 0.1 0.5 0.6 1].'**Lookup Method** — Lookup method for output

Interpolation-Use End Values (default) | Use Input Nearest | Use Input Below | Use Input Above

Specify the lookup method to determine the output between data points.

Programmatic Use**Block Parameter:** LookUpMeth**Type:** character vector**Values:** 'Interpolation-Use End Values' | 'Use Input Nearest' | Use Input Below | Use Input Above**Default:** 'Interpolation-Use End Values'**Sample time** — Time interval between samples

0.01 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Programmatic Use**Block Parameter:** tsamp**Type:** character vector**Values:** scalar**Default:** '0.01'**Signal Attributes****Output minimum** — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

double (default) | Inherit: Inherit via back propagation | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'fixdt(1,16,0)', 'fixdt(1,16,2^0,0)', 'fixdt(1,16,2^0,0)', '<data type expression>'

Default: 'Double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Repeating Sequence | Repeating Sequence Stair

Repeating Sequence Stair

Output and repeat discrete time sequence

Libraries:
Simulink / Sources

Description

The Repeating Sequence Stair block outputs and repeats a stair sequence that you specify with the **Vector of output values** parameter. For example, you can specify the vector as $[3 \ 1 \ 2 \ 4 \ 1]'$. A value in **Vector of output values** is output at each time interval, and then the sequence repeats.

Ports

Output

Port_1 — Repeating discrete output signal
scalar

Output signal generated based on the values in the **Vector of time values** and **Sample time** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

Vector of output values — Vector of output values

`[3 1 4 2 1].'` (default) | vector

Specify the vector containing values of the repeating stair sequence.

Programmatic Use

Block Parameter: `OutValues`

Type: character vector

Values: vector

Default: `[3 1 4 2 1].'`

Sample time — Time interval between samples

`-1` (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: `tsamp`

Type: character vector

Values: scalar

Default: `'-1'`

Signal Attributes

Output minimum — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

double (default) | Inherit: Inherit via back propagation | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via back propagation' | 'single' | 'int8' | 'uint8' | int16 | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | fixdt(1,16,0) | fixdt(1,16,2^0,0) | fixdt(1,16,2^0,0) | '<data type expression>'

Default: 'Double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Reset

Control block for resettable subsystem

Description

A Reset block placed at the root level of a Subsystem block adds a control port to the block. When a reset trigger signal occurs on the signal connected to the port, the block states of the subsystem are reset to their initial condition. See Resettable Subsystem.

Parameters

Reset trigger type — Select the type of trigger event

`level (default) | rising | falling | either | level hold`

Select the type of trigger signal that resets the subsystem block states.

`level`

Reset the block states when the trigger signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

`rising`

Reset the block states when the trigger signal rises from a zero to a positive value or from a negative to a positive value.

`falling`

Reset the block states when the trigger signal falls from a positive value to zero or from a positive to a negative value.

`either`

Reset the block states when the trigger signal changes from a zero to a nonzero value or changes sign.

`level hold`

Reset the block states when the trigger signal is nonzero at the current time step.

Programmatic Use

Block Parameter: ResetTriggerType

Type: character vector

Value: 'level' | 'rising' | 'falling' | 'either' | 'level hold'

Default: 'level'

Propagate sizes of variable-size signals — Select when to propagate a variable-size signal

`During execution (default) | Only when enabling`

Select when to propagate a variable-size signal.

`During execution`

Propagate variable-size signals at each time step.

Only when resetting

Propagate variable-size signals when resetting a Subsystem block containing a Reset port block. When you select this option, sample time must be periodic.

Programmatic Use

Block Parameter: PropagateVarSize

Type: character vector

Value: 'During execution' | 'Only when resetting'

Default: 'During execution'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Version History

Introduced in R2015a

Extended Capabilities

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

“Using Resettable Subsystems”

“Simulink Block Support for Variable-Size Signals”

Reset Function

Execute subsystem on model reset event

Libraries:
Simulink / User-Defined Functions

Description

The Reset Function block is a preconfigured Subsystem block that executes on a model reset event. By default, the Reset Function block includes:

- An Event Listener block with the **Event type** set to **Reset** and the **Event name** set to **reset**
- A Constant block with the **Constant value** set to **0**
- A State Writer block with no **State owner block** set

Customize the contents of the Reset Function block by, for example, replacing the Constant block with source blocks that generate the state value for the State Writer block and specifying a **State owner block** for the State Writer block.

Conditionally executed subsystems with output ports are fully supported within Reset Function blocks.

For a list of unsupported blocks and features, see “Initialize, Reinitialize, Reset, and Terminate Function Limitations”.

A model can potentially have multiple Reset Function blocks with each block having a different **Event name**. Each of these reset events appear in the generated code as a different function.

You can select an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select

Related Blocks  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no

Resettable Delay

Delay input signal by variable sample period and reset with external signal

Libraries:
 Simulink / Discrete
 HDL Coder / Discrete

Description

The Resettable Delay block is a variant of the Delay block that has the source of the initial condition set to Input port and the external reset algorithm set to **Rising**, by default.

Ports

Input

u — Data input signal
 scalar | vector

Input data signal delayed according to parameters settings.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

d — Delay length
 scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as Input port.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Enable — External enable signal
 scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

External reset — External reset signal
 scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

x0 — Initial condition
scalar | vector

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as `Input port`.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Output signal
scalar | vector

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-338.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Delay length — Delay length
`Dialog (default)` | `Input port`

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the `d` input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A non-integer value from an input port (variable delay) truncates it to the integer.

Programmatic Use

Block Parameter: `DelayLengthSource`

Type: character vector

Values: `'Dialog'` | `'Input port'` |

Default: `'Dialog'`

Block Parameter: `DelayLength`

Type: character vector

Values: scalar

Default: `'2'`

Block Parameter: `DelayLengthUpperLimit`

Type: character vector

Values: scalar

Default: `'100'`

Initial condition — Initial condition

Input port (default) | Dialog

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to Dialog, enter the initial condition in the edit field under **Value**.
- If you set **Source** to Input port, verify that an upstream signal supplies an initial condition for the x0 input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal u using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is Input port, the block ignores the initial value of the signal object.

Programmatic Use**Block Parameter:** InitialConditionSource**Type:** character vector**Values:** 'Dialog' | 'Input port' |**Default:** 'Input Port'**Block Parameter:** InitialCondition**Type:** character vector**Values:** scalar**Default:** ''**Input processing** — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use**Block Parameter:** InputProcessing**Type:** character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Use circular buffer for state — Circular buffer for storing state

off (default) | on

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed:

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: UseCircularBuffer

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Prevent direct feedthrough — Prevent direct feedthrough

off (default) | on

Select to increase the delay length from zero to the lower limit for the **Input processing** mode:

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, u , to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, x_0 , to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: PreventDirectFeedthrough

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Remove delay length check in generated code — Remove delay length out-of-range check

off (default) | on

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: RemoveDelayLengthCheckInGeneratedCode

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Diagnostic for delay length — Diagnostic checks for delay length

None (default) | Warning | Error

Specify whether to produce a warning or error when the input d is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use

Block Parameter: DiagnosticForDelayLength

Type: character vector

Values: 'None' | 'Warning' | 'Error'

Default: 'None'

Show enable port — Create enable port

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

External reset — External state reset

Rising (default) | None | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> when the reset signal is nonzero at the current time step when the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type single, double, boolean, or integer. Fixed point data types, except for ufix1, are not supported.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector

Values: 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'

Default: 'Rising'

Sample time (-1 for inherited) — Discrete interval between sample time hits

-1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. This block supports discrete sample time, but not continuous sample time.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Value: real scalar

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ' '

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced in R2012b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Consider using the Model Discretizer to map these continuous blocks into discrete equivalents that support code generation. From a model, in the **Apps** tab, under **Control Systems**, click **Model Discretizer**.
- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For information about HDL code generation, see the “HDL Code Generation” on page 1-347 section on the Delay page.

Fixed-Point Conversion

“Using Enabled Subsystems”

Resettable Subsystem

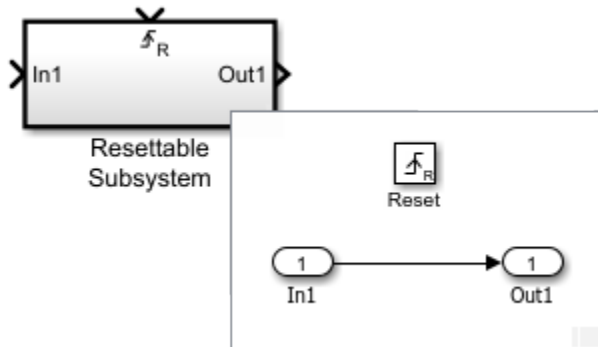

Subsystem whose block states reset with external trigger

Libraries:
Simulink / Ports & Subsystems

Description

The Resettable Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that resets the block states each time the control port receives a trigger signal. The behavior of the subsystem is controlled by a Reset block placed inside the subsystem.

Ports

Input

In — Signal input to a subsystem block
scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the Subsystem block. The port label matches the name of the Inport block.

Use Inport blocks to receive signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Reset — Control signal input to a subsystem block
scalar | vector | matrix

Placing a Reset block in a subsystem adds an external input port to the Subsystem block and changes the block to a Resettable Subsystem block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Out — Signal output from a subsystem
 scalar | vector | matrix

Placing an Outputport block in a subsystem adds an output port from the Subsystem block. The port label on the Subsystem block is the name of the Outputport block.

Use Outputport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed_point | enumerated | bus | image

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed_point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Topics

“Using Resettable Subsystems”

Reshape

Change dimensionality of signal

**Libraries:**

Simulink / Math Operations

HDL Coder / Math Operations

Description

The Reshape block changes the dimensionality of the input signal to a dimensionality that you specify, using the **Output dimensionality** parameter. For example, you can use the block to change an N -element vector to a 1-by- N or N -by-1 matrix signal.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal whose dimensions are changed based on the **Output dimensionality** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector | matrix

Output signal created with the dimensions specified in the **Output dimensionality** parameter.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Output dimensionality — Dimensions of output signal

1-D array (default) | Column vector (2-D) | Row vector (2-D) | Customize | Derive from reference input port

Specify the dimensionality of the output signal.

Output Dimensionality	Description
1-D array	Converts a multidimensional array to a vector (1-D array) array signal. The output vector consists of the first column of the input matrix followed by the second column, and so on. (This option leaves a vector input unchanged.)
Column vector	Converts a vector, matrix, or multidimensional input signal to a column matrix, a M -by-1 matrix, where M is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Row vector	Converts a vector, matrix, or multidimensional input signal to a row matrix, a 1-by- N matrix where N is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Customize	Converts the input signal to an output signal whose dimensions you specify, using the Output dimensions parameter.
Derive from reference input port	Creates a second input port, Ref , on the block. Derives the dimensions of the output signal from the dimensions of the signal input to the Ref input port. Selecting this option disables the Output dimensions parameter. When you select this parameter, the input signals for both inport ports, U and Ref , must have the same sampling mode (sample-based or frame-based).

Programmatic Use**Block Parameter:** OutputDimensionality**Type:** character vector**Value:** '1-D array' | 'Column vector (2-D)' | 'Row vector (2-D)' | 'Customize' | 'Derive from reference input port'**Default:** '1-D array'**Output dimensions** — Custom dimensions of output signal

[1,1] (default) | [integer] | [integer, integer]

Specify the dimensions for the output signal. The value can be a one- or multi-element vector. A value of [N] outputs a vector of size N. A value of [M N] outputs an M-by-N matrix. The number of elements of the input signal must match the number of elements specified by the **Output dimensions** parameter. For multidimensional arrays, the conversion is done along the first dimension.

DependencyTo enable this parameter, set **Output dimensionality** to Customize.**Programmatic Use****Block Parameter:** OutputDimensions**Type:** character vector**Value:** '[integer, integer]' |**Default:** '[1,1]'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

FOR-GENERATE Loop Support

For this block, HDL Coder generates code using FOR-GENERATE loop when you set the target language to VHDL.

The loop unrolled code is generated when target language is Verilog. For more information, see “Unroll For-Generate Loops in VHDL Code” (HDL Coder)

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Rocker Switch

Change parameter or variable value using switch with customizable appearance

**Libraries:**

Simulink / Dashboard / Customizable Blocks

Description

Use the Rocker Switch block to change the value of the connected variable or parameter before or during simulation. When you use the Rocker Switch block in the Customizable Blocks library, you can customize the appearance of the block to look like a real switch in your system. You can configure the switch with any number of states to customize the behavior. For example, you could design a three-way toggle switch or a gearbox. Use the Rocker Switch block with other dashboard blocks to create an interactive dashboard for your model.

A real rocker switch has multiple settings. The Rocker Switch block treats these settings as different states. A state pairs a State Value with an image, a click area, and a State Label that is displayed on the click area.

You can activate a state by clicking its click area. When you activate the state, the State Value is assigned to the Simulink block diagram element to which the Rocker Switch block connects.

Note Double-clicking the Rocker Switch block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the Property Inspector or open the block dialog box by:

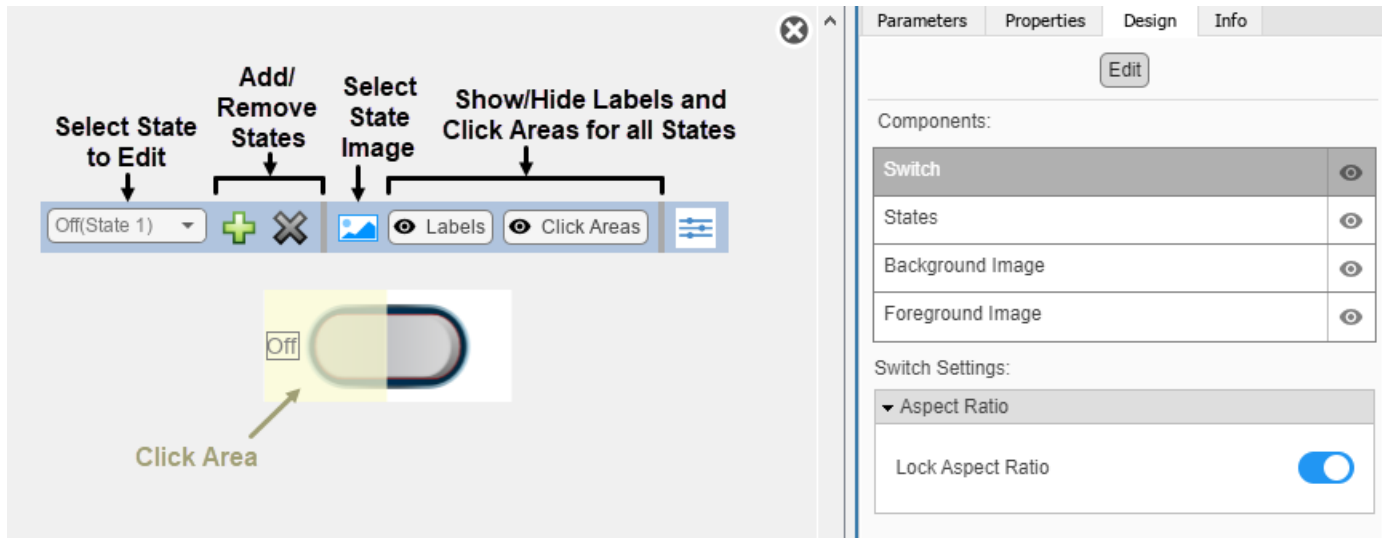

- Double-clicking the block when the block is not selected and the model is not simulating
 - Right-clicking the block and selecting **Block Parameters** from the context menu
-

Customize Rocker Switch Blocks

When you add a Rocker Switch block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can add any number of states to the block. To add or delete states, use the toolbar above the block.

For each state, you can:

- Upload an image that defines the appearance of the block in the state.
- Configure the size and position of the click area for the state.
- Specify the State Value.
- Specify the State Label text, color, and position.

To upload an image for a state, use the toolbar above the block.

To resize the click area of a state, in the toolbar above the block, select the state from the drop-down menu. Then, click and drag the grab points of the yellow click area in the canvas. To reposition the click area, click and drag it in the canvas.

You can use the **Design** tab in the Property Inspector for fine control over the block design, and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the State Value.
- Specify the State Label.
- Upload a foreground image.
- Upload a background image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at

once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

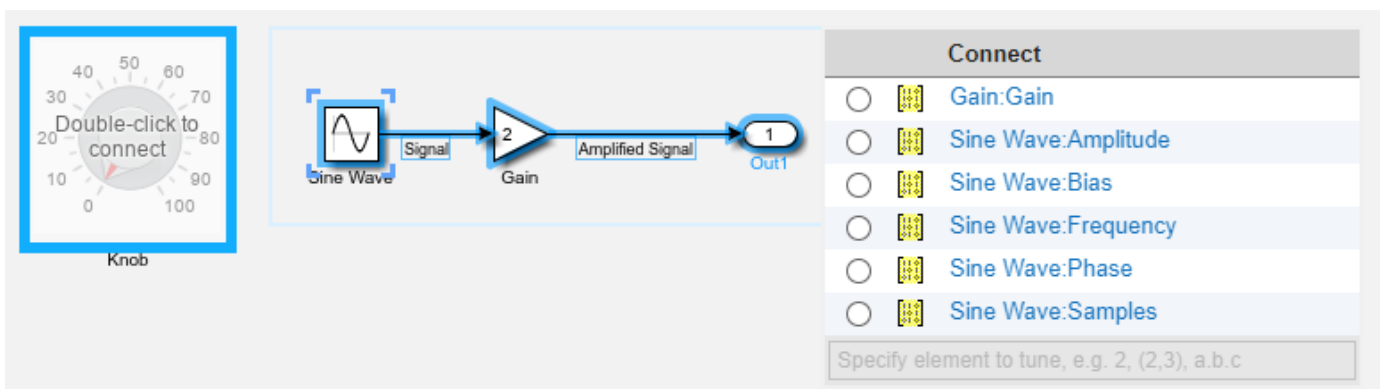

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect** and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.

- To exit bind mode, click **Done Connecting**  over the dashboard block.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Label — Position of label displaying name of connected element

Hide (default) | Bottom | Top

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify `Hide`.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: `'Hide'` | `'Bottom'` | `'Top'`

Default: `'Hide'`

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States — Pairings of value with label
scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of 0.
- In the **On** state, the block assigns the connected variable or parameter a value of 1.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the + button. To delete the current state, click the - button.

Tip You can configure a variety of other parameters for a state besides the value and label in design mode. For example, you can select an image that will appear on the switch when it is in the state. To configure parameters in design mode:

- 1 Enter design mode. In the Property Inspector, on the **Design** tab, click the **Edit** button.
 - 2 On the **Design** tab, open the **States** component, expand the **Select State** section, and select the state that you want to configure from the drop-down menu.
 - 3 Configure the parameter values for the selected state, either using the toolbar above the block, or in the **States** component on the **Design** tab in the Property Inspector.
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;  
leftState.Label = 'Off';  
rightState.Value = 1;  
rightState.Label = 'On';  
switchStates = [leftState rightState];
```

Block Parameter: States

Type: two element array of structures

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Switch

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States**Select State** — Management and configuration of states

scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of **0**.
- In the **On** state, the block assigns the connected variable or parameter a value of **1**.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the **+** button. To delete the current state, click the **X** button.

To configure a state, in the **States** component, expand the **Select State** section and select the state.

You can configure the value, label text, and a variety of other parameters for the selected state in the **States** component on the **Design** tab in the Property Inspector. For example, you can select an image that will appear on the switch when it is in the state.

All changes that you make to parameter values in the **States** component are applied only to the selected state. To configure a different state, in the **Select State** section, select the state in the drop-down menu. Then, configure the parameter values of that state in the **States** component.

Tip Alternatively, you can:

- Configure the parameters for the selected state using the toolbar that appears above the switch block in design mode
 - Configure the values and label text of the states for the block using the **Parameters** tab in the Property Inspector
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.

- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;
leftState.Label = 'Off';
rightState.Value = 1;
rightState.Label = 'On';
switchStates = [leftState rightState];
```

Block Parameter: States**Type:** two element array of structures**Value** — State value

scalar

Each state pairs a **State Value** with a **State Label**. Specify the **State Value** that activates the state selected in the **Design** tab.

Text — State label text

string | character array

Each state pairs a **State Value** with a **State Label**. Specify the text for the **State Label** of the state selected in the **Design** tab.

Label Color — Button label font color

[r g b] vector

Choose a font color for the button label from the palette of standard colors, or specify a custom color. The color is applied to the button label for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Label X Offset — Horizontal offset of text center from left edge of block

scalar

Specify the horizontal offset of the center of the **State Label** from the left edge of the block as a ratio of the block width. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text left, and an offset with a positive value moves the text right.

Label Y Offset — Vertical offset of text center from top edge of block

scalar

Specify the vertical offset of the center of the **State Label** from the top edge of the block as a ratio of the block height. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text up, and an offset with a positive value moves the text down.

Image X Offset — Horizontal offset of left edge of image from left edge of block

scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width

scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Click Area X Offset — Horizontal offset of left edge of click area from left edge of block

scalar

Specify the horizontal offset of the left edge of the click area from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Click Area Y Offset — Vertical offset of top edge of click area from top edge of block

scalar

Specify the vertical offset of the top edge of the click area from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Click area width

scalar

Specify the click area width as a ratio of the block width.

Example: 0.5

Height — Click area height

scalar

Specify the click area height as a ratio of the block height.

Example: 0.5

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block
scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width
scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height
scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio
on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Tips

- When you want to design a circular switch that distributes the state labels and the click areas that cause state transitions on an arc, consider using the Rotary Switch block.
- To design a control that applies values to a connected variable or parameter from a continuous range, use the Knob, Horizontal Slider, or Vertical Slider blocks.

Version History

Introduced in R2021b

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

“Getting Started with Panels”

Rocker Switch

Toggle parameter between two values

Libraries:
Simulink / Dashboard

Description

The Rocker Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Rocker Switch block to a Switch block in your model and change its state during simulation. Use the Rocker Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Rocker Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

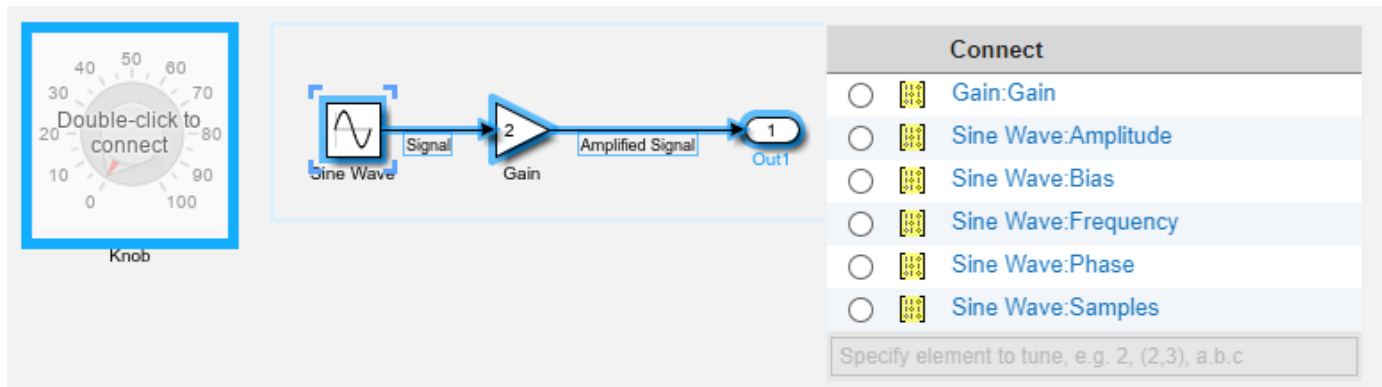

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus

or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.

- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

States — Pair values and labels
scalar and character vector

Pairs of values to assign to the connected variable or parameter and text to display on the block. Switches have two states — **Top** and **Bottom** — one corresponding to each switch position. Each state contains a **Value** and a **Label**.

- **Value** — Value to assign to the connected variable or parameter when the switch is in the corresponding position.
- **Label** — Text to display on the block for the corresponding position.

This table describes the default configuration for the block.

States

Position	State Value	State Label
Top	0	on
Bottom	1	off

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
topState.Value = 0;
topState.Label = 'Off';
bottomState.Value = 1;
bottomState.Label = 'On';
switchStates = [topState bottomState];
```

Block Parameter: States

Type: two element array of structures

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015a

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Rotary Switch

Change parameter or variable value using rotary switch with customizable appearance

Libraries:

Simulink / Dashboard / Customizable Blocks

Description

Use the Rotary Switch block to change the value of the connected variable or parameter before or during simulation. When you use the Rotary Switch block in the Customizable Blocks library, you can customize the appearance of the block to look like a real rotary switch in your system. Use the Rotary Switch block with other dashboard blocks to create an interactive dashboard for your model.

A real rotary switch has multiple settings. The Rotary Switch block treats these settings as different states. A state pairs a State Value with a handle orientation, a click area, and a State Label that is displayed on the click area.

You can activate a state by clicking its click area or by dragging the handle and releasing it over the click area. When you activate the state, the State Value is assigned to the Simulink block diagram element to which the Rotary Switch block connects.

Collectively, the state click areas cover the area of the block within the angular range that the handle traverses when it moves from the first state to the last state. The state labels are evenly spaced over the range, with the first label at the start of the range, and the last label at the end of the range. The range is subdivided into click areas such that the borders of adjacent click areas bisect the angular distance between labels.

Note Double-clicking the Rotary Switch block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the Property Inspector or open the block dialog box by:

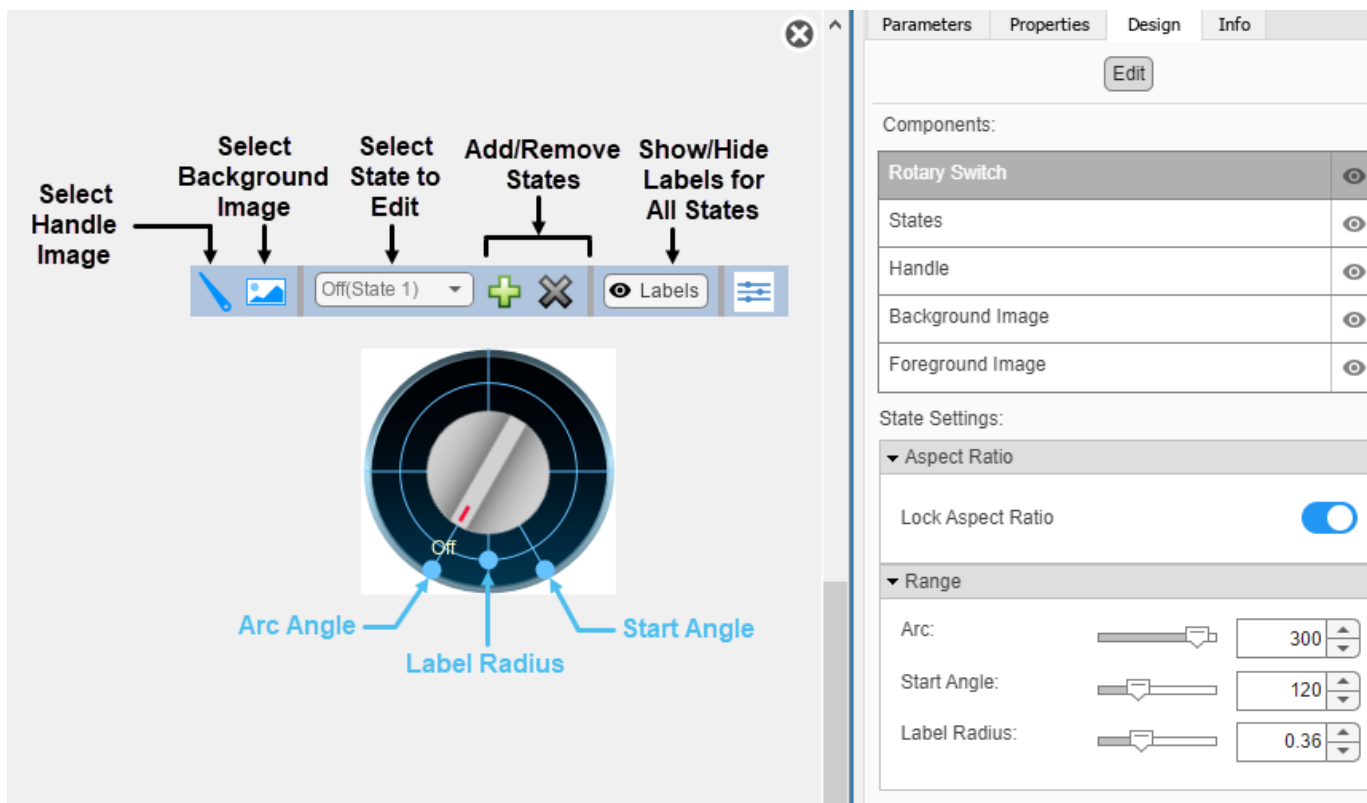

- Double-clicking the block when the block is not selected and the model is not simulating
- Right-clicking the block and selecting **Block Parameters** from the context menu

Customize Rotary Switch Blocks

When you add a Rotary Switch block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can specify the arc the handle traverses when it moves from the first state to the last state.

- To change the arc length, on the **Design** tab, in the **Rotary Switch** component, specify the **Arc**.
- To change the orientation of the arc, in the **Rotary Switch** component, specify the **Start Angle**.

You can replace the handle image and background image using the toolbar above the block.

To resize the handle, select the handle in the canvas. Then, click and drag the grab points that define its dimensions. To reposition the handle, click and drag it in the canvas.

You can add any number of states to the block. To add or delete states, use the toolbar above the block.

For each state, you can:

- Specify the State Label text and color.
- Specify the State Value.

To change the color of the State Labels, on the **Format** tab, under **Style**, click the arrow on the **Foreground** button and select a color. You can select from a palette of standard colors or click

Custom Colors  to specify a custom color.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the State Value.
- Configure the State Label.
- Upload a foreground image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

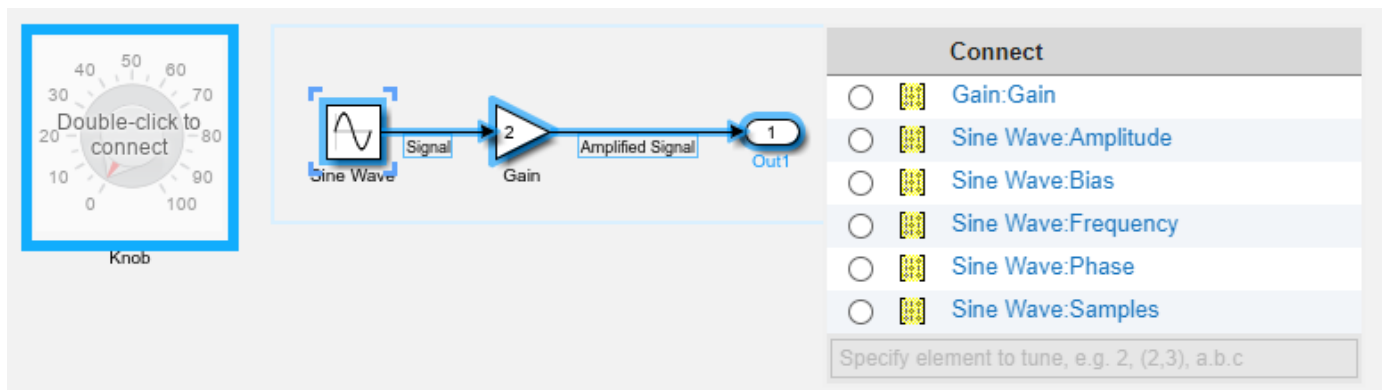

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to

the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.

- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect**  and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.
- To exit bind mode, click **Done Connecting**  over the dashboard block.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Label — Position of label displaying name of connected element

Hide (default) | Bottom | Top

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify `Hide`.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: 'Hide' | 'Bottom' | 'Top'

Default: 'Hide'

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
- When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.

Enumerated Data Type — Specify state values and labels using enumerated data type

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. First, select **Enumerated Data Type**. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Note You can define an enumerated data type using the `Simulink.findIntEnumType` function. For example, to define a set of Roman numerals from one to five, in the MATLAB command line, enter this command:

```
Simulink.defineIntEnumType('myEnumType', {'I', 'II', 'III', 'IV', 'V'}, [1 2 3 4 5]);
```

Then, in the Property Inspector, on the **Parameters** tab, in the **Enumerated Data Type** text box, enter `myEnumType`.

States — Pairings of value with label

scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has five states, one corresponding to each switch position.

States

State Value	State Label
0	Off
1	Low
2	Medium
3	High
4	On

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the + button. To delete the current state, click the - button.

Note When **Enumerated Data Type** is enabled, you cannot add or delete states.

Tip You can also configure the parameters for a state in design mode:

- 1 Enter design mode. In the Property Inspector, on the **Design** tab, click **Edit**.
 - 2 On the **Design** tab, open the **States** component, expand the **Select State** section, and select the state that you want to configure from the drop-down menu.
 - 3 Configure the parameter values for the selected state either using the toolbar above the block or in the Property Inspector.
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with these fields:

- **Value** — Scalar double value for the state
- **Label** — String or character array to use as the label for the switch position

```
firstState.Value = 0;
firstState.Label = 'Off';
secondState.Value = 1;
secondState.Label = 'On';
switchStates = [firstState secondState];
```

Block Parameter: States

Type: two element array of structures

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Rotary Switch

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Arc — Arc length spanned by state labels

300 (default) | scalar

Specify the arc length spanned by the center points of the state labels as a scalar value, measured in degrees.

Example: 90

Start Angle — Angular location of State 1

120 (default) | scalar

Specify the angular location of the first state as a scalar value, measured in degrees clockwise from the horizontal axis pointing right.

Example: 0

Label Radius — Distance of labels from block center

scalar

Specify the distance of the labels from the center of the block as a ratio of the smaller of the two block dimensions, width or height.

Example: 0.5

States**Select State** — Management and configuration of states

scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has five states, one corresponding to each switch position.

State

State Value	State Label
0	Off
1	Low
2	Medium
3	High
4	On

You can use a customizable Lamp block to design a lamp with any number of states greater than or equal to 1. To add a new state, click the **+** button. To delete the current state, click the **X** button.

Note When **Enumerated Data Type** is enabled, you cannot add or delete states. You can disable this option in the **Parameters** tab of the Property Inspector.

To configure a state, in the **States** component, expand the **Select State** section and select the state.

Configure the value and the label text for the selected state in the **States** component on the **Design** tab of the Property Inspector.

All changes that you make to parameter values in the **States** component are applied only to the selected state. To configure a different state, expand the **Select State** section and select the state. Then, configure the parameter values of that state in the **States** component.

Tip You can also configure the states for the block using the **Parameters** tab in the Property Inspector.

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with two fields:

- **Value** — Scalar double value for the state
- **Label** — String or character array to use as the label for the switch position

```
firstState.Value = 0;
firstState.Label = 'Off';
secondState.Value = 1;
secondState.Label = 'On';
switchStates = [firstState secondState];
```

Block Parameter: States

Type: two element array of structures

Value — State value
scalar

Each state pairs a **State Value** with a **State Label**. Specify the **State Value** that activates the state selected in the **Design** tab.

Note When **Enumerated Data Type** is enabled, you cannot change the value.

Text — State label text
string | character array

Each state pairs a **State Value** with a **State Label**. Specify the text for the **State Label** of the state selected in the **Design** tab.

Note When **Enumerated Data Type** is enabled, you cannot change the text.

Handle

Width — Handle image width
scalar

Specify the width of the handle image as a ratio of the smaller of the two block dimensions, width or height.

Example: 1

Height — Handle image height
scalar

Specify the height of the handle image as a ratio of the smaller of the two block dimensions, width or height.

Example: 1

Lock Aspect Ratio — Option to maintain image aspect ratio
on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Rotate Image — Rotation of handle image
0 (default) | scalar

Rotate the handle image about its center in 90 degree increments.

Example: 90

Offset from Center — Offset of handle image center from block center
0 (default) | scalar

Specify the distance from the center of the handle image to the center of the block as a ratio of the smaller of the two block dimensions, width or height.

Example: 1

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, select the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, in the **Format** tab of the Simulink Toolstrip, specify the **Foreground Color**.

Programmatic Use

Specify the **BackgroundColor** parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: BackgroundColor

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Offset from Scale — Offset of outer edge of area with block background color from label radius
scalar

Set the offset of the outer edge of the area covered by the block background color from the label radius, specified as a scalar value from 0 to 1.

Example: 0.1

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block
scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width
scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height
scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Tips

- The Rotary Switch block allows you to design a circular control, with the state labels and the click areas that cause state transitions distributed along an arc. For more flexibility in the design of a control block with several states, use one of the customizable switch blocks. Each block is preconfigured with two states, but you can add and configure any number of states as required by your design.
 - Rocker Switch
 - Slider Switch
 - Toggle Switch
- To design a control that applies values to a connected variable or parameter from a continuous range, use the Knob, Horizontal Slider, or Vertical Slider blocks.

Version History

Introduced in R2021b

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.

- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch

- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Topics

“Tune and Visualize Your Model with Dashboard Blocks”
“Simulation Pacing”

“Getting Started with Panels”

Rotary Switch

Switch parameter to set values on dial

Libraries:
Simulink / Dashboard

Description

The Rotary Switch changes the value of the connected block parameter to several specified values during simulation. For example, you can connect the Rotary Switch block to the amplitude or frequency of an input signal in your model and change its characteristics during simulation. Use the Rotary Switch block with other Dashboard blocks to create an interactive dashboard to control your model.

Double-clicking the Rotary Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

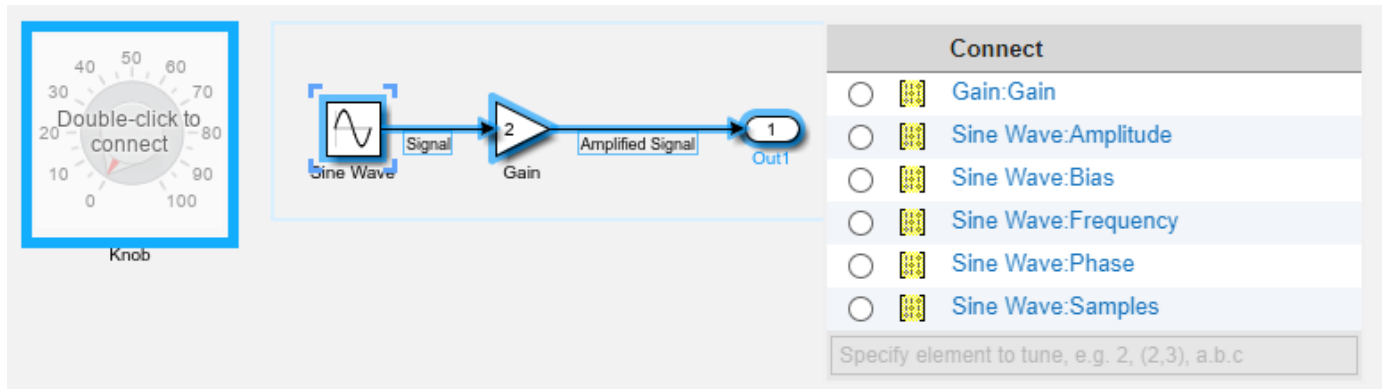

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or

(1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.

- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

States — Position labels and values
scalar and character vector

Pairs of numeric values to assign to the connected variable or parameter with labels for the block. A State consists of a **State Value** and a **State Label**.

- **State Value** — Value assigned to the connected variable or parameter when the Rotary Switch block is positioned at the corresponding **State Label**.
- **State Label** — Label for the switch position. You can use the **State Label** to display the value the connected variable or parameter takes when the Rotary Switch block points to the **State Label**, or you can use a descriptive text label.

Click the + button to add **States**.

The default configuration for the block includes these **States**:

States

State Value	State Label
0	Off
1	Low
2	Medium
3	High

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

Include a structure element in the array for each state you want to specify for the block.

```
state1.Value = 1;
state1.Label = 'State 1';
state2.Value = 2;
state2.Label = 'State 2';
states = [state1 state2];
```

Block Parameter: States

Type: structure array

Enumerated Data Type — Specify state values and labels using an enumerated data type

off (default) | on

You can use an enumerated data type that pairs a numeric value with each enumeration to configure the state values and labels for the block. To specify the states for the block using an enumerated data type, first select the **Enumerated Data Type** option. Then, specify the name of the enumerated data type in the text box. The definition for the specified enumerated data type must be saved on the MATLAB path or in the base workspace.

Example: myEnumType

Programmatic Use

To programmatically specify the state labels and values for the block using an enumerated data type, specify 'on' for the `UseEnumeratedDataType` parameter and the name of the enumerated data type for the `EnumeratedDataType` parameter.

Block Parameter: `UseEnumeratedDataType`

Type: string or character array

Values: 'on' | 'off'

Default: 'off'

Block Parameter: `EnumeratedDataType`

Type: string or character array

Default: ''

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015a

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019b: Enhanced enumerated data type support for the Rotary Switch block and Combo Box block

Starting in R2019b, you can use an enumeration class to configure the values and labels for the states of a Rotary Switch block and a Combo Box block.

To configure the **States** for a Rotary Switch or Combo Box block with an enumerated data type, select **Enumerated Data Type**. In the text box, enter the name of the enumeration class you want to use.

When you use an enumeration class to configure the states of the block, you cannot manually edit, add, or remove states from the **States** table.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Rounding Function

Apply rounding function to signal

Libraries:
Simulink / Math Operations

Description

The Rounding Function block rounds each element of the input signal to produce the output signal.

You select the type of rounding from the **Function** parameter list. The name of the selected function appears on the block.

Tip Use the Rounding Function block when you want vector or matrix output.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal to which the rounding function is applied.

Data Types: single | double

Output

Port_1 — Output signal
scalar | vector | matrix

Output signal after the rounding function is applied to the input signal. The output signal has the same dimensions and data type as the input. Each element of the output signal is the result of applying the selected rounding function to the corresponding element of the input signal.

Data Types: single | double

Parameters

Function — Rounding function

floor (default) | ceil | round | fix

Choose the rounding function applied to the input signal.

Rounding function	Rounds each element of the input signal
floor	To the nearest integer value towards minus infinity
ceil	To the nearest integer towards positive infinity
round	To the nearest integer
fix	To the nearest integer towards zero

Programmatic Use**Block Parameter:** Operator**Type:** character vector**Values:** 'floor' | 'ceil' | 'round' | 'fix'**Default:** 'floor'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Block Characteristics**

Data Types	double single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Code Generation Requirements

HDL code generation for the block requires that you use single data types as inputs to the block, and enable the native floating point mode. In the Configuration Parameters dialog box, on the **HDL Code Generation > Floating Point** pane, for **Library**, select **Native Floating Point**. To learn more about using the native floating-point mode, see “Getting Started with HDL Coder Native Floating-Point Support” (HDL Coder) and “Generate Target-Independent HDL Code with Native Floating-Point” (HDL Coder).

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to inherit , Max , Min , Zero , or Custom for the floating-point operator. The default is inherit . See also “LatencyStrategy” (HDL Coder).
NFPCustomLatency	To specify a value, set LatencyStrategy to Custom . HDL Coder adds latency equal to the value that you specify for the NFPCustomLatency setting. See also “NFPCustomLatency” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Saturation

Limit input signal to the upper and lower saturation values

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Discontinuities
 HDL Coder / Discontinuities

Description

The Saturation block produces an output signal that is the value of the input signal bounded to the upper and lower saturation values. The upper and lower limits are specified by the parameters **Upper limit** and **Lower limit**.

Input	Output
Lower limit \leq Input value \leq Upper limit	Input value
Input value < Lower limit	Lower limit
Input value > Upper limit	Upper limit

Ports

Input

Port_1 — Input signal
 scalar | vector

The input signal to the saturation algorithm.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal
 scalar | vector

Output signal that is the value of the input signal, upper saturation limit, or lower saturation limit.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main

Upper limit — Upper saturation boundary for the input signal

0.5 (default) | scalar | vector

Specify the upper bound on the input signal. If the input signal is greater than this boundary, then the output signal is set to this saturation value. The **Upper limit** parameter is converted to the output data type using round-to-nearest and saturation. **Upper limit** must be greater than the **Output minimum** parameter and less than the **Output maximum** parameter.

Programmatic Use**Block Parameter:** UpperLimit**Type:** character vector**Value:** real scalar or vector**Default:** '0.5'**Lower limit** — Lower saturation boundary for the input signal

-0.5 (default) | scalar | vector

Specify the lower bound on the input signal. If the input signal is less than this boundary, then the output signal is set to this saturation value. The **Lower limit** parameter is converted to the output data type using round-to-nearest and saturation. **Lower limit** must be greater than the **Output minimum** parameter and less than the **Output maximum** parameter.

Programmatic Use**Block Parameter:** LowerLimit**Type:** character vector**Value:** real scalar or vector**Default:** '-0.5'**Treat as gain when linearizing** — Specify the gain value

On (default) | Boolean

Select this check box to cause the commands to treat the gain as 1. The linearization commands in Simulink software treat this block as a gain in state space. Clear the box to have the commands treat the gain as 0.

Programmatic Use**Block Parameter:** LinearizeAsGain**Type:** character vector**Values:** 'off' | 'on'**Default:** 'on'**Enable zero-crossing detection** — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use**Block Parameter:** ZeroCross**Type:** character vector | string**Values:** 'off' | 'on'**Default:** 'on'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Signal Attributes

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output data type — Specify the output data type

Inherit: Same as input (default) | Inherit: Inherit via back propagation | double | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType. For more information, see “Control Data Types of Signals”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as input', 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'fixdt(1,16,0)', 'fixdt(1,16,2^0,0)', 'fixdt(1,16,2^0,0)'. '<data type expression>'

Default: 'Inherit: Same as input'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturation Dynamic | Backlash

Saturation Dynamic

Limit input signal to dynamic upper and lower saturation values

Libraries:

Simulink / Discontinuities
HDL Coder / Discontinuities

Description

The Saturation Dynamic block produces an output signal that is the value of the input signal bounded to the saturation values from the input ports **up** and **lo**.

Input	Output
$lo \leq \text{Input value} \leq up$	Input value
Input value < lo	Lower limit
Input value > up	Upper limit

Ports

Input

u — Input signal
scalar | vector

The input signal to the saturation algorithm.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

up — Signal that provides the upper saturation limit
scalar | vector

Dynamic value providing the upper saturation limit. When the input is greater than **up** then the output value is bound to **up**.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

lo — Signal that provides the lower saturation limit
scalar | vector

Dynamic value providing the lower saturation limit. When the input is less than **lo** then the output value is bound to **lo**.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

y — Output signal
scalar | vector

Output signal that is the value of the input signal, upper saturation limit, or lower saturation limit.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

To edit the parameters for the Saturation Dynamic block, double-click the block icon.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | scalar

Default: '[]'

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' []' | scalar

Default: ' []'

Output data type — Specify the output data type

Inherit: Same as input (default) | Inherit: Inherit via back propagation | double | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Data Types of Signals”.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Same as input', 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', 'fixdt(1,16,0)', 'fixdt(1,16,2^0,0)', 'fixdt(1,16,2^0,0)'. '<data type expression>'

Default: 'Inherit: Same as input'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

Saturate on integer overflow — Choose the behavior when integer overflow occurs

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean ^a double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

a This block is not recommended for use with Boolean signals.

Saturation

Scan String

Scan input string and convert to signals per specified format

Libraries:
Simulink / String

Description

The Scan String block scans an input string and converts it to signals per the format specified by the **Format** parameter. The block converts values to their decimal (base 10) representation and outputs the results as numeric or string signals. Use this block when you want to deconstruct a string, for example a sentence, into its individual components. For example, if the **Format** parameter is set to "%s is %f.", the block outputs two parts, a string signal and a single signal. If the input is the string "Pi is 3.14", the two outputs are "Pi" and "3.14".

Note If you specify a numeric display format that is not large enough to display all the digits of a value, the displayed values may lose precision. The result depends on your computer hardware and operating system.

The Scan String, String to Double, and String to Single blocks are identical blocks. When configured for String to Double, the block converts the input string signal to a double numerical output. When configured for String to Single, the block converts the input string signal to a single numerical output.

For code generation, configure models that contain this block for non-finite number support by selecting the **Configuration Parameters > Code Generation > Interface > Support non-finite numbers** check box.

Ports

Input

Port_1 — Input string
scalar

Input string, specified as a scalar.

Data Types: `string`

Output

d — Output data whose format matches %d format
scalar

Output data whose format matches the specified format, defined as a scalar. Total maximum number of outputs is 128.

If the block cannot match an input string to a format operator specified in **Format**, it returns a warning and outputs an appropriate value (0 or "") for each unmatched format operator.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

f — Output data whose format matches %f format
scalar

Output data whose format matches the %f format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Port_N — Output data whose format matches N format
scalar

Output data whose format matches N format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Format — Format operator for input
"%d %f" (default) | format string | character vector

Format operator for input, specified as a scalar. If the block cannot match the input string with the specified format, it returns 0. The return of 0 differs from the `sscanf` function return, which is an empty matrix if the function cannot match the input with the specified format.

- For the String to Double block, this parameter has a default value of %lf.
- For the String to Single block, this parameter has a default value of %f.

For more information about acceptable format operators, see the Algorithms section.

Programmatic Use

Block Parameter: Format

Type: character vector

Values: '<filename>'

Default: '"%d %f"'

Block Characteristics

Data Types	<code>double</code> <code>integer</code> <code>single</code> <code>string</code>
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no

Zero-Crossing Detection	no
--------------------------------	----

Algorithms

The Scan String block uses this format specifier prototype:

`%[width][length]specifier`

Numeric Fields

This table lists available conversion specifiers to convert text to numeric outputs. The block converts values to their decimal (base 10) representation.

Output Port Data Type	Conversion Specifier	Description
Integer, signed	%d	Base 10
Integer, unsigned	%u	Base 10
Floating-point number	%f, %e, or %g	Floating-point values. Input fields can contain NaN (case sensitive). Input fields that represents floating-point numbers can include leading + or - symbols and exponential notation using e or E. The conversion specifiers %f, %e, and %g all treat input fields the same way.

Character Fields

This table lists available conversion specifiers to convert text so that the output is a string.

Character Field Type	Conversion Specifier	Description
String scalar	%s	Read the text until the block encounters white space.
	%c	Read any single character, including white space. To read multiple characters at a time, specify field width. For example, %10c reads 10 characters at a time.
Pattern-matching	%[. . .]	Read only the characters in the brackets up to the first nonmatching character or white space. Example: %[mus] reads 'summer' as 'summ'.
	%[^ . . .]	Read any characters not in the brackets up to the first matching character or white space. Example: %[^m] reads 'summer' as 'su'.

Optional Operators

- **Field Width** — To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, `%10s` reads up to 10 characters at a time, including white space. `%4f` reads up to four digits at a time, including the decimal point.
- **Literal Text to Ignore** — This block must match the specified text immediately before or after the conversion specifier.

Example: `Hell%s` reads "Hello!" as "o!".

Length Specifiers

The Scan String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings.

Length	i	u	f e g	s c [...] [^...]
No length specifier	int	unsigned int	single	string
h	short	unsigned short	—	—
l	long	unsigned long	double	—

Notes for Specifiers that Specify Integer Data Types (d, u)

- Target `int`, `long`, and `short` type sizes are controlled by settings in the **Configuration Parameters > Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. For this example, the Scan String block requires that the output type be exactly `int32`. It cannot be any other data type.

Scope

Display signals generated during simulation

Libraries:

- Simulink / Commonly Used Blocks
- Simulink / Sinks
- HDL Coder / Commonly Used Blocks
- HDL Coder / Sinks

Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope”.

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same y-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple y-axes. All the y-axes have a common time range on the x-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — Scope data is saved during a simulation. If a scope is closed at the start of a simulation, when you open the scope after a simulation, the scope displays simulation results for attached input signals.

Note If you have a high sample rate or long simulation time, you may run into issues with memory or system performance because the scope saves data internally. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically”.

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- If you step through a model, the scope only updates when the scope block runs. This means that the time shown in the status bar may not match the model time.
- When connected to a constant signal, a scope block may plot a single point.
- The scope shows gaps in the display when the signal value is NaN.

- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.
- Scope displays have limitations in Rapid Accelerator mode. See “Behavior of Scopes and Viewers with Rapid Accelerator Mode”
- When the Scope is in a ForEach subsystem, the scope only displays the last index.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Signal Dimensions”.

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to Dataset. You can use any **Save format** to log virtual bus signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main

Open at simulation start — Specify when scope window opens

off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

Number of input ports — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

Programmatic Use

See `NumInputPorts`.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of m-by-n axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See `LayoutDimensions`.

Sample time — Simulation interval between scope updates

-1 (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers. For a more detailed explanation of sample time with the scope, see “Sample Time with Scope Blocks”

Programmatic Use

See `SampleTime`.

Input processing — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 1-0 and “Y-label” on page 1-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time**Time span** — Length of x-axis to display

`Auto` (default) | `User defined` | `One frame period`

- `Auto` — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 1-0 and “Time span” on page 1-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- **User defined** — Enter any value less than the total simulation time.
- **One frame period** — Use the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to **Columns as channels (frame based)**.

Programmatic Use

See `TimeSpan`.

Time span overrun action — Display data beyond visible x-axis

Wrap (default) | Scroll

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- **Wrap** — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- **Scroll** — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

Time units — x-axis units

None (default for Scope) | Metric (default for Time Scope) | Seconds

- **Metric** — Display time units based on the length of “Time span” on page 1-0 .
- **Seconds** — Display time in seconds.
- **None** — Do not display time units.

Programmatic Use

See `TimeUnits`.

Time display offset — x-axis offset

0 (default) | scalar | vector

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- **Scalar** — Offset all channels of an input signal by the same time value.
- **Vector** — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

Time-axis labels — Display of x-axis labels

Bottom Displays Only (default for Scope) | All (default for Time Scope) | None

Specify how x-axis (time) labels display:

- All — Display x-axis labels on all y-axes.
- None — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only — Display x-axis label on the bottom y-axis.

Dependencies

To enable this property, set:

- “Show time-axis label” on page 1-0 to on.
- “Maximize axes” on page 1-0 to off.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See TimeAxisLabels.

Show time-axis label — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

Dependencies

To enable this property, set “Time-axis labels” on page 1-0 to All or Bottom Displays Only.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowTimeAxisLabel.

Display

Active display — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See ActiveDisplay.

Title — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

Show legend — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.

- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `PlotAsMagnitudePhase`.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLimits`.

Y-label — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter Velocity (%<SignalUnits>).

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See `YLabel`.

Logging**Limit data points to last** — Limit buffered data values

off and 5000 (default) | on | positive integer

Limit data saved by the scope internally. By default all data points are saved so that you can view the scope visualization after the simulation finishes. For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Note If you do not select **Limit data points to last** and you have a high sample rate or long simulation time, you may run into issues with memory or system performance.

When you select this property, the scope saves the latest n data points, where n the specified number of data points.

- Off — Save and plot all data values.
- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

In some cases, selecting this property can have the effect of plotting signals for less than the entire time range of a simulation (for example if your sample time is small). If the scope plots a portion of your signals, consider increasing the number of data points to save.

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every N th data point, where N is the decimation factor entered in the text box. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log data to workspace — Save data to MATLAB workspace

off (default) | on

Select this check box to enable logging and enable the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Scope Block”.

Programmatic Use

See `DataLogging`.

Variable name — Name of saved data variable

`ScopeData` (default) | string

Specify a variable name for saving scope data in the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

Programmatic Use

See `DataLoggingVariableName`.

Save format — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a `Dataset` object, by default a `timeseries` object.
- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

Programmatic Use

See `DataLoggingSaveFormat`.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- **Auto** — Scale the y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to Auto and clear the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Scale y-axis after the number of time steps specified in the **Number of updates** text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

Do not allow Y-axis limits to shrink — When y-axis limits can change

on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set **Axes scaling** to Auto.

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set **Axes scaling** to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale axes limits at stop — When y-axis limits can change

on (default) | off

- **On** — Scale axes when simulation stops.
- **Off** — Scale axes continually.

Dependency

To use this property, set **Axes scaling** to Auto.

Y-axis Data range (%) — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the y-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the y-axis range.

Autoscale X-axis limits — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

X-axis Align — Alignment along x-axis

Center (default) | Left | Right

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- Right — Align signals with the maximum values of the x-axis range.
- Center — Center signals between the minimum and maximum values.
- Left — Align signals with the minimum values of the x-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope.

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select **Auto**, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line — Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Line — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Marker — Data point marker style

None (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Block Characteristics

Data Types	Boolean bus ^a double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format.

Version History

Introduced in R2015b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Second-Order Integrator

Second-order integration of input signal

Libraries:

Simulink / Continuous

Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\begin{aligned}\frac{d^2x}{dt^2} &= u, \\ \frac{dx}{dt}\Big|_{t=0} &= dx_0, \\ x\Big|_{t=0} &= x_0,\end{aligned}$$

where u is the input to the system. The block is therefore a dynamic system with two continuous states: x and dx/dt .

Note These two states have a mathematical relationship, namely, that dx/dt is the derivative of x . To satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1930.

Simulink software can use several different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “Solver Selection Criteria”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states

- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize dx/dt when x reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state x as a block parameter, use the **Initial condition source x** drop-down menu to select **internal** and enter the value in the **Initial condition x** field.
- To provide the initial conditions from an external source for state x , specify the **Initial condition source x** parameter as **external**. An additional input port appears on the block.
- To define the initial conditions of state dx/dt as a block parameter, use the **Initial condition source dx/dt** drop-down menu to select **internal** and enter the value in the **Initial condition dx/dt** field.
- To provide the initial conditions from an external source for state dx/dt , specify **Initial condition source dx/dt** as **external**. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.

Note

- Simulink does not allow initial condition values of **inf** or **NaN**.
- If you limit state x or state dx/dt by specifying saturation limits (see “Limiting the States” on page 1-1930) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.

Limiting the States

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position (x). With the Second-Order Integrator block, you can limit the states x and dx/dt independent of each other. You can even change the limits during simulation; however, you cannot

change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

The block appearance changes when you limit one or both states. With both states limited, the block appears as follows.

For each state, you can use the block parameter dialog box to set appropriate saturation limits.

Limiting x Only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state x on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.

The block then determines the values of the states as follows:

- When x is less than or equal to its lower limit, the value of x is held at its lower limit and dx/dt is set to zero.
- When x is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When x is greater than or equal to its upper limit, the value of x is held at its upper limit and dx/dt is set to zero.

You can choose to reinitialize dx/dt to a new value at the time when x reaches saturation. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1935.

Limiting dx/dt Only

As with state x , state dx/dt is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited block dialog box. You can manually set this parameter, **Limit dx/dt**, on the Second-Order Integrator block. In either case, you must enter the appropriate limits for dx/dt .

If you limit only the state dx/dt , then the block determines the values of dx/dt as follows:

- When dx/dt is less than or equal to its lower limit, the value of dx/dt is held at its lower limit.
- When dx/dt is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When dx/dt is greater than or equal to its upper limit, the value of dx/dt is held at its upper limit.

When state dx/dt is held at its upper or lower limit, the value of x is governed by the first-order initial value problem:

$$\begin{aligned}\frac{dx}{dt} &= L, \\ x(t_L) &= x_L,\end{aligned}$$

where L is the dx/dt limit (upper or lower), t_L is the time when dx/dt reaches this limit, and x_L is the value of state x at that time.

Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for dx/dt . Such limitations are necessary to satisfy the following constraints:

- When x is at its saturation limits, the value of dx/dt must be zero.
- In order for x to leave the upper limit, the value of dx/dt must be strictly negative.
- In order for x to leave its lower limit, the value of dx/dt must be strictly positive.

For such cases, the upper limit of dx/dt must be strictly positive and the lower limit of dx/dt must be strictly negative.

When both states are limited, the block determines the states as follows:

- Whenever x reaches its limits, the resulting behavior is the same as that described in “Limiting x only”.
- Whenever dx/dt reaches one of its limits, the resulting behavior is the same as that described in “Limiting dx/dt only” — including the computation of x using a first-order ODE when dx/dt is held at one of its limits. In such cases, when x reaches one of its limits, it is held at that limit and dx/dt is set to zero.
- Whenever both reach their respective limits simultaneously, the state x behavior overrides dx/dt behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize dx/dt at the time when state x reaches saturation. If the reinitialized value is outside specified limits on dx/dt , then dx/dt is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1935

Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.

- Select **rising** to reset the states when the reset signal rises from zero to a positive value, from a negative to a positive value, or a negative value to zero.
- Select **falling** to reset the states when the reset signal falls from a positive value to zero, from a positive to a negative value, or from zero to negative.
- Select **either** to reset the states when the reset signal changes from zero to a nonzero value or changes sign.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loop Concepts”).

Enabling Zero-Crossing Detection

This parameter controls whether zero-crossing detection is enabled for this block. By default, the **Enable zero-crossing detection** parameter is selected on the **Attributes** pane. However, this parameter is only in affect if the **Zero-crossing control**, on the **Solver** pane of the Configuration Parameters dialog box, is set to Use local settings. For more information, see “Zero-Crossing Detection”.

Reinitializing dx/dt When x Reaches Saturation

For certain modeling applications, dx/dt must be reinitialized when state x reaches its limits in order to pull x out of saturation immediately. You can achieve this by selecting **Reinitialize dx/dt when x reaches saturation** on the **Attributes** pane.

If this option is on, then at the instant when x reaches saturation, Simulink checks whether the current value of the dx/dt initial condition (parameter or signal) allows the state x to leave saturation immediately. If so, Simulink reinitializes state dx/dt with the value of the initial condition (parameter or signal) at that instant. If not, Simulink ignores this parameter at the current instant and sets dx/dt to zero to make the block states consistent.

This parameter only applies at the time when x actually reaches saturation limit. It does not apply at any future time when x is being held at saturation.

Refer to the sections on limiting the states for more information. For an example, see “Simulation of Bouncing Ball” on page 13-6.

Disregarding State Limits and External Reset for Linearization

For cases where you simplify your model by linearizing it, you can have Simulink disregard the limits of the states and the external reset by selecting **Ignore state limits and the reset for linearization**.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the integrator blocks. If this value does not provide sufficient error control, specify a more appropriate value for state x in the **Absolute tolerance x** field and for state dx/dt in the **Absolute tolerance dx/dt** field of the parameter dialog box. Simulink uses the values that you specify to compute the state values of the block.

Specifying the Display of the Output Ports

You can control whether to display the x or the dx/dt output port using the ShowOutput parameter. You can display one output port or both; however, you must select at least one.

Specifying the State Names

You can specify the name of x states and dx/dt states using the StateNameX and StateNameDXDT parameters. However, you must specify names for both or neither; you cannot specify names for just x

or just dx/dt . Both state names must have identical type and length. Furthermore, the number of names must evenly divide the number of states.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

Input

u — Input signal u
scalar | vector | matrix

Input signal u to the integrator system, specified as a scalar, vector, or matrix.

Data Types: double

x0 — Initial condition x_0
scalar | vector | matrix

External signal specifying the initial condition x_0 to the integrator system. You can specify the initial condition as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source x** parameter to external.

Data Types: double

dx0 — Initial condition dx_0
scalar | vector | matrix

External signal specifying the initial condition dx_0 to the integrator system. You can specify the initial condition dx_0 as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source dx/dt** parameter to external.

Data Types: double

Output

x — Output signal x
 scalar | vector | matrix

x state output signal, provided as a scalar, vector, or matrix.

Data Types: double

dx — Output signal dx
 scalar | vector | matrix

dx state output signal, specified as a scalar, vector, or matrix.

Data Types: double

Parameters

x

Initial condition source x — Source of initial condition for state x

internal (default) | external

Specify the source of the initial conditions for state x .

- `internal` — Get the initial conditions of state x from the **Initial condition x** parameter.
- `external` — Get the initial conditions of state x from an external block connected to the \mathbf{X}_0 input port.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Selecting `internal` enables the **Initial condition x** parameter and removes the \mathbf{X}_0 input port.

Selecting `external` disables the **Initial condition x** parameter and enables the \mathbf{X}_0 input port.

Programmatic Use

Block Parameter: `ICSourceX`

Type: character vector, string

Values: `'internal'` | `'external'`

Default: `'internal'`

Initial condition x — Initial condition of state x

0.0 (default) | scalar | vector | matrix

Specify the initial condition of state x .

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set **Initial condition source x** to `internal`.

Setting **Initial condition source x** to `external` disables this parameter and enables the X_0 input port.

Programmatic Use

Block Parameter: ICX

Type: character vector, string

Values: scalar | vector | matrix

Default: `'0.0'`

Limit x — Limit values of state x

`off` | `on`

Limit state x of the block to a value between the **Lower limit x** and **Upper limit x** parameters. The default value of the Second-Order Integrator block is `off`. The default value of the Second-Order Integrator Limited is `on`.

- To limit state x to a value between the **Lower limit x** and **Upper limit x** parameters, select this check box.
- To remove range limitations on state x , clear this check box.

Dependencies

Selecting this check box enables the **Upper limit x** and **Lower limit x** parameters.

Programmatic Use

Block Parameter: LimitX

Type: character vector, string

Values: `'off'` | `'on'`

Default: `'off'` (Second-Order Integrator) | `'on'` (Second-Order Integrator Limited)

Upper limit x — Upper limit of state x

`1` | `inf` | scalar | vector | matrix

Specify the upper limit of state x . The default value for the Second-Order Integrator block is `inf`. The default value for the Second-Order Integrator Limited block is `1`.

Tips

The upper saturation limit for state x must be strictly greater than the lower saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use

Block Parameter: UpperLimitX

Type: character vector, string

Values: `'1'` | `'inf'` | scalar | vector | matrix

Default: `'1'` (Second-Order Integrator Limited) | `'inf'` (Second-Order Integrator)

Lower limit x — Lower limit of state x

0 (default) | $-\infty$ | scalar | vector | matrix

Specify the lower limit of state x . The default value for the Second-Order Integrator block is $-\infty$. The default value for the Second-Order Integrator Limited block is 0.

Tip

The lower saturation limit for state x must be strictly less than the upper saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use

Block Parameter: LowerLimitX

Type: character vector, string

Values: '0' | $-\infty$ | scalar | vector | matrix

Default: '0' (Second-Order Integrator Limited) | $-\infty$ (Second-Order Integrator)

Wrap x — Enable wrapping of x

off (default) | on

Enable wrapping of x between the **Wrapped upper value x** and **Wrapped lower value x** parameters. Enabling wrapping of x eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped upper value x** as ∞ and **Wrapped lower value x** as $-\infty$, wrapping will never occur.

Dependencies

Selecting this check box enables **Wrapped upper value x** and **Wrapped lower value x**.

Programmatic Use

Block Parameter: WrapX

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Wrapped upper value x — Upper value for wrapping x

π (default) | scalar | vector | matrix

Specify the upper value for wrapping x .

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: WrappedUpperValueX

Type: character vector, string

Values: scalar | vector | matrix

Default: 'pi'

Wrapped lower value x — Lower value for wrapping x

-pi (default) | scalar | vector | matrix

Specify the lower value for wrapping x.

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: WrappedLowerValueX

Type: character vector, string

Values: scalar | vector | matrix

Default: '-pi'

Absolute tolerance x — Absolute tolerance for computing state x

auto (default) | -1 | scalar | vector

Specify the absolute tolerance for computing state x.

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute state x.
- If you enter a real scalar value, that value overrides the absolute tolerance in the Configuration Parameters dialog box and is used for computing all x states.
- If you enter a real vector, the dimension of that vector must match the dimension of state x. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: AbsoluteToleranceX

Type: character vector, string

Values: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

State name x — Name for state x

' ' (default) | character vector | string

Assign a unique name to state x.

Tips

- To assign a name to a single state, enter the name between quotes, for example, `position'`.
- To assign names to multiple x states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for x, you must also specify a state name for dx/dt .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than x states, but you cannot specify more names than x states. For example, you can

specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for dx/dt .

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string or a cell array.

Programmatic Use

Block Parameter: StateNameX

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

dx/dt

Initial condition source dx/dt — Source of initial condition for state dx/dt

`internal` (default) | `external`

Specify the source of initial conditions for state dx/dt as `internal` or `external`.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Selecting `internal` enables the **Initial condition dx/dt** parameter and removes the dx_0 input port.
- Selecting `external` disables the **Initial condition dx/dt** parameter and enables the dx_0 input port.

Programmatic Use

Block Parameter: ICSourceDXDT

Type: character vector

Values: 'internal' | 'external'

Default: 'internal'

Initial condition dx/dt — Initial condition of state dx/dt

`0.0` (default) | scalar | vector | matrix

Specify the initial condition of state dx/dt .

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Setting **Initial condition source dx/dt** to `internal` enables this parameter.
- Setting **Initial condition source dx/dt** to `external` disables this parameter.

Programmatic Use

Block Parameter: ICDXDT

Type: character vector

Values: scalar | vector | matrix

Default: '0.0'

Limit dx/dt — Limit values of state dx/dt

off | on

Limit the dx/dt state of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters. The default value of the Second-Order Integrator block is off. The default value of the Second-Order Integrator Limited is on.

Tip

If you set saturation limits for x , then the interval defined by the **Upper limit dx/dt** and **Lower limit dx/dt** must contain zero.

Dependencies

Selecting this check box enables the **Upper limit dx/dt** and **Lower limit dx/dt** parameters.

Programmatic Use

Parameter: LimitDXDT

Type: character vector

Values: 'off' | 'on'

Default: 'off' (Second-Order Integrator) | 'on' (Second-Order Integrator Limited)

Upper limit dx/dt — Upper limit of state dx/dt

inf (default) | scalar | vector | matrix

Specify the upper limit for state dx/dt .

Dependencies

If you limit x , then this parameter must have a strictly positive value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use

Block Parameter: UpperLimitDXDT

Type: character vector

Values: scalar | vector | matrix

Default: 'inf'

Lower limit dx/dt — Lower limit of state dx/dt

-inf (default) | scalar | vector | matrix

Specify the lower limit for state dx/dt .

Dependencies

If you limit x , then this parameter must have a strictly negative value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use**Block Parameter:** LowerLimitDXDT**Type:** character vector**Values:** scalar | vector | matrix**Default:** '-inf'**Absolute tolerance dx/dt** — Absolute tolerance for computing state dx/dt

auto (default) | -1 | scalar | vector

Specify the absolute tolerance for computing state dx/dt .

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the dx/dt output of the block.
- If you enter a numeric value, that value overrides the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use**Block Parameter:** AbsoluteToleranceDXDT**Type:** character vector, string, scalar, or vector**Values:** 'auto' | '-1' | any positive real scalar or vector**Default:** 'auto'**State name dx/dt** — Name for state dx/dt

' ' (default) | character vector | string

Assign a unique name to state dx/dt .**Tips**

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple dx/dt states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for dx/dt , you must also specify a state name for x .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than dx/dt states, but you cannot specify more names than dx/dt states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for x .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, or a cell array.

Programmatic Use**Block Parameter:** StateNameDXDT**Type:** character vector, string**Values:** ' ' | user-defined**Default:** ' '

Attributes

External reset — Reset states to their initial conditions

`none` (default) | `rising` | `falling` | `either`

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.
- `falling` — Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.
- `either` — Reset the state when the reset signal changes from zero to a nonzero value or changes sign.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector, string

Values: 'none' | 'rising' | 'falling' | 'either'

Default: 'none'

Enable zero-crossing detection — Enable zero-crossing detection

`on` (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Parameter: ZeroCross

Type: character vector, string

Values: 'on' | 'off'

Default: 'on'

Reinitialize dx/dt when x reaches saturation — Reset dx/dt when x reaches saturation

`off` (default) | `on`

At the instant when state x reaches saturation, reset dx/dt to its current initial conditions.

Tip

The dx/dt initial condition must have a value that enables x to leave saturation immediately. Otherwise, Simulink ignores the initial conditions for dx/dt to preserve mathematical consistency of block states.

Programmatic Use

Block Parameter: ReinitDXDTwhenXreachesSaturation

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Ignore state limits and the reset for linearization — Ignore state limits and external reset for linearization

off (default) | on

For linearization purposes, have Simulink ignore the specified state limits and the external reset.

Programmatic Use

Block Parameter: IgnoreStateLimitsAndResetForLinearization

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Show output — Output ports to display

both (default) | x | dxdt

Specify the output ports on the block.

- both — Show both x and dx/dt output ports.
- x — Show only the x output port.
- dx/dt — Show only the dx/dt output port.

Programmatic Use

Block Parameter: ShowOutput

Type: character vector, string

Values: 'both' | 'x' | 'dxdt'

Default: 'both'

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Version History

Introduced in R2010a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Second-Order Integrator Limited

Second-order integration of input signal

Libraries:

Simulink / Continuous

Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\frac{d^2x}{dt^2} = u,$$

$$\left. \frac{dx}{dt} \right|_{t=0} = dx_0,$$

$$x|_{t=0} = x_0,$$

where u is the input to the system. The block is therefore a dynamic system with two continuous states: x and dx/dt .

Note These two states have a mathematical relationship, namely, that dx/dt is the derivative of x . To satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1948.

Simulink software can use several different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “Solver Selection Criteria”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states

- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize dx/dt when x reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state x as a block parameter, use the **Initial condition source x** drop-down menu to select **internal** and enter the value in the **Initial condition x** field.
- To provide the initial conditions from an external source for state x , specify the **Initial condition source x** parameter as **external**. An additional input port appears on the block.
- To define the initial conditions of state dx/dt as a block parameter, use the **Initial condition source dx/dt** drop-down menu to select **internal** and enter the value in the **Initial condition dx/dt** field.
- To provide the initial conditions from an external source for state dx/dt , specify **Initial condition source dx/dt** as **external**. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.

Note

- Simulink does not allow initial condition values of **inf** or **NaN**.
- If you limit state x or state dx/dt by specifying saturation limits (see “Limiting the States” on page 1-1948) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.

Limiting the States

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position (x). With the Second-Order Integrator block, you can limit the states x and dx/dt independent of each other. You can even change the limits during simulation; however, you cannot

change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

The block appearance changes when you limit one or both states. With both states limited, the block appears as follows.

For each state, you can use the block parameter dialog box to set appropriate saturation limits.

Limiting x Only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state x on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.

The block then determines the values of the states as follows:

- When x is less than or equal to its lower limit, the value of x is held at its lower limit and dx/dt is set to zero.
- When x is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When x is greater than or equal to its upper limit, the value of x is held at its upper limit and dx/dt is set to zero.

You can choose to reinitialize dx/dt to a new value at the time when x reaches saturation. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1953.

Limiting dx/dt Only

As with state x , state dx/dt is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited block dialog box. You can manually set this parameter, **Limit dx/dt**, on the Second-Order Integrator block. In either case, you must enter the appropriate limits for dx/dt .

If you limit only the state dx/dt , then the block determines the values of dx/dt as follows:

- When dx/dt is less than or equal to its lower limit, the value of dx/dt is held at its lower limit.
- When dx/dt is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.
- When dx/dt is greater than or equal to its upper limit, the value of dx/dt is held at its upper limit.

When state dx/dt is held at its upper or lower limit, the value of x is governed by the first-order initial value problem:

$$\frac{dx}{dt} = L,$$

$$x(t_L) = x_L,$$

where L is the dx/dt limit (upper or lower), t_L is the time when dx/dt reaches this limit, and x_L is the value of state x at that time.

Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for dx/dt . Such limitations are necessary to satisfy the following constraints:

- When x is at its saturation limits, the value of dx/dt must be zero.
- In order for x to leave the upper limit, the value of dx/dt must be strictly negative.
- In order for x to leave its lower limit, the value of dx/dt must be strictly positive.

For such cases, the upper limit of dx/dt must be strictly positive and the lower limit of dx/dt must be strictly negative.

When both states are limited, the block determines the states as follows:

- Whenever x reaches its limits, the resulting behavior is the same as that described in “Limiting x only”.
- Whenever dx/dt reaches one of its limits, the resulting behavior is the same as that described in “Limiting dx/dt only” — including the computation of x using a first-order ODE when dx/dt is held at one of its limits. In such cases, when x reaches one of its limits, it is held at that limit and dx/dt is set to zero.
- Whenever both reach their respective limits simultaneously, the state x behavior overrides dx/dt behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize dx/dt at the time when state x reaches saturation. If the reinitialized value is outside specified limits on dx/dt , then dx/dt is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1953

Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.

- Select **rising** to reset the states when the reset signal rises from zero to a positive value, from a negative to a positive value, or a negative value to zero.
- Select **falling** to reset the states when the reset signal falls from a positive value to zero, from a positive to a negative value, or from zero to negative.
- Select **either** to reset the states when the reset signal changes from zero to a nonzero value or changes sign.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loop Concepts”).

Enabling Zero-Crossing Detection

This parameter controls whether zero-crossing detection is enabled for this block. By default, the **Enable zero-crossing detection** parameter is selected on the **Attributes** pane. However, this parameter is only in affect if the **Zero-crossing control**, on the **Solver** pane of the Configuration Parameters dialog box, is set to Use local settings. For more information, see “Zero-Crossing Detection”.

Reinitializing dx/dt When x Reaches Saturation

For certain modeling applications, dx/dt must be reinitialized when state x reaches its limits in order to pull x out of saturation immediately. You can achieve this by selecting **Reinitialize dx/dt when x reaches saturation** on the **Attributes** pane.

If this option is on, then at the instant when x reaches saturation, Simulink checks whether the current value of the dx/dt initial condition (parameter or signal) allows the state x to leave saturation immediately. If so, Simulink reinitializes state dx/dt with the value of the initial condition (parameter or signal) at that instant. If not, Simulink ignores this parameter at the current instant and sets dx/dt to zero to make the block states consistent.

This parameter only applies at the time when x actually reaches saturation limit. It does not apply at any future time when x is being held at saturation.

Refer to the sections on limiting the states for more information. For an example, see “Simulation of Bouncing Ball” on page 13-6.

Disregarding State Limits and External Reset for Linearization

For cases where you simplify your model by linearizing it, you can have Simulink disregard the limits of the states and the external reset by selecting **Ignore state limits and the reset for linearization**.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the integrator blocks. If this value does not provide sufficient error control, specify a more appropriate value for state x in the **Absolute tolerance x** field and for state dx/dt in the **Absolute tolerance dx/dt** field of the parameter dialog box. Simulink uses the values that you specify to compute the state values of the block.

Specifying the Display of the Output Ports

You can control whether to display the x or the dx/dt output port using the ShowOutput parameter. You can display one output port or both; however, you must select at least one.

Specifying the State Names

You can specify the name of x states and dx/dt states using the StateNameX and StateNameDXDT parameters. However, you must specify names for both or neither; you cannot specify names for just x

or just dx/dt . Both state names must have identical type and length. Furthermore, the number of names must evenly divide the number of states.

Selecting All Options

When you select all options, the block icon looks like this.

Ports

Input

u — Input signal u
scalar | vector | matrix

Input signal u to the integrator system, specified as a scalar, vector, or matrix.

Data Types: double

x0 — Initial condition x_0
scalar | vector | matrix

External signal specifying the initial condition x_0 to the integrator system. You can specify the initial condition as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source x** parameter to external.

Data Types: double

dx0 — Initial condition dx_0
scalar | vector | matrix

External signal specifying the initial condition dx_0 to the integrator system. You can specify the initial condition dx_0 as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source dx/dt** parameter to external.

Data Types: double

Output

x — Output signal x
 scalar | vector | matrix

x state output signal, provided as a scalar, vector, or matrix.

Data Types: double

dx — Output signal dx
 scalar | vector | matrix

dx state output signal, specified as a scalar, vector, or matrix.

Data Types: double

Parameters

x

Initial condition source x — Source of initial condition for state x

internal (default) | external

Specify the source of the initial conditions for state x .

- `internal` — Get the initial conditions of state x from the **Initial condition x** parameter.
- `external` — Get the initial conditions of state x from an external block connected to the \mathbf{X}_0 input port.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Selecting `internal` enables the **Initial condition x** parameter and removes the \mathbf{X}_0 input port.

Selecting `external` disables the **Initial condition x** parameter and enables the \mathbf{X}_0 input port.

Programmatic Use

Block Parameter: `ICSourceX`

Type: character vector, string

Values: `'internal'` | `'external'`

Default: `'internal'`

Initial condition x — Initial condition of state x

0.0 (default) | scalar | vector | matrix

Specify the initial condition of state x .

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set **Initial condition source x** to `internal`.

Setting **Initial condition source x** to `external` disables this parameter and enables the \mathbf{X}_0 input port.

Programmatic Use

Block Parameter: ICX

Type: character vector, string

Values: scalar | vector | matrix

Default: `'0.0'`

Limit x — Limit values of state x

`off` | `on`

Limit state x of the block to a value between the **Lower limit x** and **Upper limit x** parameters. The default value of the Second-Order Integrator block is `off`. The default value of the Second-Order Integrator Limited is `on`.

- To limit state x to a value between the **Lower limit x** and **Upper limit x** parameters, select this check box.
- To remove range limitations on state x , clear this check box.

Dependencies

Selecting this check box enables the **Upper limit x** and **Lower limit x** parameters.

Programmatic Use

Block Parameter: LimitX

Type: character vector, string

Values: `'off'` | `'on'`

Default: `'off'` (Second-Order Integrator) | `'on'` (Second-Order Integrator Limited)

Upper limit x — Upper limit of state x

`1` | `inf` | scalar | vector | matrix

Specify the upper limit of state x . The default value for the Second-Order Integrator block is `inf`. The default value for the Second-Order Integrator Limited block is `1`.

Tips

The upper saturation limit for state x must be strictly greater than the lower saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use

Block Parameter: UpperLimitX

Type: character vector, string

Values: `'1'` | `'inf'` | scalar | vector | matrix

Default: `'1'` (Second-Order Integrator Limited) | `'inf'` (Second-Order Integrator)

Lower limit x — Lower limit of state x

0 (default) | $-\infty$ | scalar | vector | matrix

Specify the lower limit of state x . The default value for the Second-Order Integrator block is $-\infty$. The default value for the Second-Order Integrator Limited block is 0.

Tip

The lower saturation limit for state x must be strictly less than the upper saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use

Block Parameter: LowerLimitX

Type: character vector, string

Values: '0' | ' $-\infty$ ' | scalar | vector | matrix

Default: '0' (Second-Order Integrator Limited) | ' $-\infty$ ' (Second-Order Integrator)

Wrap x — Enable wrapping of x

off (default) | on

Enable wrapping of x between the **Wrapped upper value x** and **Wrapped lower value x** parameters. Enabling wrapping of x eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped upper value x** as ∞ and **Wrapped lower value x** as $-\infty$, wrapping will never occur.

Dependencies

Selecting this check box enables **Wrapped upper value x** and **Wrapped lower value x**.

Programmatic Use

Block Parameter: WrapX

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Wrapped upper value x — Upper value for wrapping x

π (default) | scalar | vector | matrix

Specify the upper value for wrapping x .

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: WrappedUpperValueX

Type: character vector, string

Values: scalar | vector | matrix

Default: 'pi'

Wrapped lower value x — Lower value for wrapping x

-pi (default) | scalar | vector | matrix

Specify the lower value for wrapping x.

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: WrappedLowerValueX

Type: character vector, string

Values: scalar | vector | matrix

Default: '-pi'

Absolute tolerance x — Absolute tolerance for computing state x

auto (default) | -1 | scalar | vector

Specify the absolute tolerance for computing state x.

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute state x.
- If you enter a real scalar value, that value overrides the absolute tolerance in the Configuration Parameters dialog box and is used for computing all x states.
- If you enter a real vector, the dimension of that vector must match the dimension of state x. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: AbsoluteToleranceX

Type: character vector, string

Values: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

State name x — Name for state x

' ' (default) | character vector | string

Assign a unique name to state x.

Tips

- To assign a name to a single state, enter the name between quotes, for example, `position'`.
- To assign names to multiple x states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for x, you must also specify a state name for dx/dt .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than x states, but you cannot specify more names than x states. For example, you can

specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for dx/dt .

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string or a cell array.

Programmatic Use

Block Parameter: StateNameX

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

dx/dt

Initial condition source dx/dt — Source of initial condition for state dx/dt

internal (default) | external

Specify the source of initial conditions for state dx/dt as `internal` or `external`.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Selecting `internal` enables the **Initial condition dx/dt** parameter and removes the dx_0 input port.
- Selecting `external` disables the **Initial condition dx/dt** parameter and enables the dx_0 input port.

Programmatic Use

Block Parameter: ICSourceDXDT

Type: character vector

Values: 'internal' | 'external'

Default: 'internal'

Initial condition dx/dt — Initial condition of state dx/dt

0.0 (default) | scalar | vector | matrix

Specify the initial condition of state dx/dt .

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Setting **Initial condition source dx/dt** to `internal` enables this parameter.
- Setting **Initial condition source dx/dt** to `external` disables this parameter.

Programmatic Use

Block Parameter: ICDXDT

Type: character vector

Values: scalar | vector | matrix

Default: '0.0'

Limit dx/dt — Limit values of state dx/dt

off | on

Limit the dx/dt state of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters. The default value of the Second-Order Integrator block is off. The default value of the Second-Order Integrator Limited is on.

Tip

If you set saturation limits for x , then the interval defined by the **Upper limit dx/dt** and **Lower limit dx/dt** must contain zero.

Dependencies

Selecting this check box enables the **Upper limit dx/dt** and **Lower limit dx/dt** parameters.

Programmatic Use

Parameter: LimitDXDT

Type: character vector

Values: 'off' | 'on'

Default: 'off' (Second-Order Integrator) | 'on' (Second-Order Integrator Limited)

Upper limit dx/dt — Upper limit of state dx/dt

inf (default) | scalar | vector | matrix

Specify the upper limit for state dx/dt .

Dependencies

If you limit x , then this parameter must have a strictly positive value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use

Block Parameter: UpperLimitDXDT

Type: character vector

Values: scalar | vector | matrix

Default: 'inf'

Lower limit dx/dt — Lower limit of state dx/dt

-inf (default) | scalar | vector | matrix

Specify the lower limit for state dx/dt .

Dependencies

If you limit x , then this parameter must have a strictly negative value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use**Block Parameter:** LowerLimitDXDT**Type:** character vector**Values:** scalar | vector | matrix**Default:** '-inf'**Absolute tolerance dx/dt** — Absolute tolerance for computing state dx/dt

auto (default) | -1 | scalar | vector

Specify the absolute tolerance for computing state dx/dt .

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the dx/dt output of the block.
- If you enter a numeric value, that value overrides the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use**Block Parameter:** AbsoluteToleranceDXDT**Type:** character vector, string, scalar, or vector**Values:** 'auto' | '-1' | any positive real scalar or vector**Default:** 'auto'**State name dx/dt** — Name for state dx/dt

' ' (default) | character vector | string

Assign a unique name to state dx/dt .**Tips**

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple dx/dt states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for dx/dt , you must also specify a state name for x .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than dx/dt states, but you cannot specify more names than dx/dt states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for x .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, or a cell array.

Programmatic Use**Block Parameter:** StateNameDXDT**Type:** character vector, string**Values:** ' ' | user-defined**Default:** ' '

Attributes

External reset — Reset states to their initial conditions

`none` (default) | `rising` | `falling` | `either`

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.
- `falling` — Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.
- `either` — Reset the state when the reset signal changes from zero to a nonzero value or changes sign.

Programmatic Use

Block Parameter: ExternalReset

Type: character vector, string

Values: 'none' | 'rising' | 'falling' | 'either'

Default: 'none'

Enable zero-crossing detection — Enable zero-crossing detection

`on` (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Parameter: ZeroCross

Type: character vector, string

Values: 'on' | 'off'

Default: 'on'

Reinitialize dx/dt when x reaches saturation — Reset dx/dt when x reaches saturation

`off` (default) | `on`

At the instant when state x reaches saturation, reset dx/dt to its current initial conditions.

Tip

The dx/dt initial condition must have a value that enables x to leave saturation immediately. Otherwise, Simulink ignores the initial conditions for dx/dt to preserve mathematical consistency of block states.

Programmatic Use

Block Parameter: ReinitDXDTwhenXreachesSaturation

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Ignore state limits and the reset for linearization — Ignore state limits and external reset for linearization

off (default) | on

For linearization purposes, have Simulink ignore the specified state limits and the external reset.

Programmatic Use

Block Parameter: IgnoreStateLimitsAndResetForLinearization

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Show output — Output ports to display

both (default) | x | dxdt

Specify the output ports on the block.

- both — Show both x and dx/dt output ports.
- x — Show only the x output port.
- dx/dt — Show only the dx/dt output port.

Programmatic Use

Block Parameter: ShowOutput

Type: character vector, string

Values: 'both' | 'x' | 'dxdt'

Default: 'both'

Block Characteristics

Data Types	double
Multidimensional Signals	No
Variable-Size Signals	No

Version History

Introduced in R2010a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One

exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Selector

Select input elements from vector, matrix, or multidimensional signal

Libraries:

Simulink / Signal Routing
HDL Coder / Signal Routing

Description

The Selector block extracts selected elements of an input vector, matrix, or multidimensional signal based on specified indices. The extracted signals can be grouped differently than the input signals.

Based on the value you enter for the **Number of input dimensions** parameter, a table of indexing settings is displayed. Each row of the table corresponds to one of the input dimensions in **Number of input dimensions**. For each dimension, you define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. When you configure the Selector block for multidimensional signal operations, the block icon changes.

For example, assume a 6-D signal with a one-based index mode. The table of the Selector block dialog changes to include one row for each dimension. If you define dimensions as shown in the next table, the output is $Y = U(1:\text{end}, 2:6, [1\ 3\ 5], \text{Idx}4:\text{Idx}4+7, \text{Idx}5, \text{Idx}6(1):\text{Idx}6(2))$, where $\text{Idx}4$, $\text{Idx}5$, and $\text{Idx}6$ are the index ports for dimensions 4, 5, and 6.

Row	Index Option	Index	Output Size
1	Select all		
2	Starting index (dialog)	2	5
3	Index vector (dialog)	[1 3 5]	
4	Starting index (port)		8
5	Index vector (port)		
6	Starting and ending indices (port)		

You can use an array of buses as an input signal to a Selector block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Limitations

- The **Index** parameter is not tunable during simulation. If the **Index Option** for a dimension is set to **Index vector (dialog)** or **Starting index (dialog)** and you specify a symbolic value,

including a `Simulink.Parameter` object, for the corresponding **Index** in the block dialog, then the instantaneous value at the start of simulation will be used throughout the simulation, and the parameter will appear as an inlined value in the generated code. See “Tune and Experiment with Block Parameter Values”. You can adjust the selection index dynamically by using index ports.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | multidimensional

Input signal and source of elements to output signal.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

IndxN — Nth index signal

scalar | vector | matrix

External port specifying an index for the selection of the corresponding output element.

You can specify integer of custom width (for example, a 15-bit integer or 23-bit integer) as an index signal value. When you configure the width of the integer, you must specify the **Mode** as **Fixed point**, with **Word length** less than or equal to 128, **Slope** equal to 1, and **Bias** equal to 0. For more information on specifying a fixed-point data type, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable an external index port, in the corresponding row of the **Index Option** table, set **Index Option** to **Index vector (port)**, **Starting index (port)**, or **Starting and ending indices (port)**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

Port_1 — Output signal

scalar | vector | matrix | multidimensional

Output signal generated from selected or reordered elements of input signal.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Number of input dimensions — Number of dimensions of input signal

1 (default) | integer

Specifies the number of dimensions of the input signal.

Programmatic Use**Block Parameter:** NumberOfDimensions**Type:** character vector**Values:** integer**Default:** '1'**Index mode** — Index mode

One-based (default) | Zero-based

Specifies the indexing mode. If **One-based** is selected, an index of 1 specifies the first element of the input vector. If **Zero-based** is selected, an index of 0 specifies the first element of the input vector.

Programmatic Use**Block Parameter:** IndexMode**Type:** character vector**Values:** 'One-based' | 'Zero-based'**Default:** 'One-based'**Index Option** — Index method for elements

Index vector (dialog) (default) | Select all | Index vector (port) | Starting index (dialog) | Starting index (port) | Starting and ending indices (port)

Defines, by dimension, how the elements of the signal are to be indexed. From the list, select:

- Select all

No further configuration is required. All elements are selected.

- Index vector (dialog)

Enables the **Index** column. Enter the vector of indices of the elements.

- Index vector (port)

No further configuration is required.

- Starting index (dialog)

Enables the **Index** and **Output Size** columns. Enter the starting index of the range of elements to select in the **Index** column and the number of elements to select in the **Output Size** column.

- Starting index (port)

Enables the **Output Size** column. Enter the number of elements to be selected in the **Output Size** column.

- Starting and ending indices (port)

No further configuration is required.

Using this option results in a variable-size output signal. When you update, the output dimension is set to be the same as the input signal dimension. During execution, the output dimension is updated based on the signal feeding the index.

When logging output signal data, signals not selected are padded with NaN values.

The **Index** and **Output Size** columns appear as needed.

Programmatic Use**Block Parameter:** IndexOptionArray**Type:** character vector**Values:** 'Select all' | 'Index vector (dialog)' | 'Index option (port)' | 'Starting index (dialog)' | 'Starting index (port)' | 'Starting and ending indices (port)'**Default:** 'Index vector (dialog)'**Index** — Index of elements

1 (default) | integer

If the **Index Option** is `Index vector (dialog)`, enter the index of each element you are interested in.

If the **Index Option** is `Starting index (dialog)`, enter the starting index of the range of elements to be selected.

Programmatic Use**Block Parameter:** IndexParamArray**Type:** character vector**Values:** cell array**Default:** '{ }'**Output Size** — Width of block output signal

1 (default) | integer

Specifies the width of the block output signal.

Programmatic Use**Block Parameter:** OutputSizeArray**Type:** character vector**Values:** cell array**Default:** '{ }'**Input port size** — Width of input signal

3 (default) | integer

Specify the width of the block input signal for 1-D signals. Enter -1 to inherit from the driving block.

Programmatic Use**Block Parameter:** InputPortWidth**Type:** character vector**Values:** integer**Default:** '3'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"

Check for out-of-range index in accelerated simulation — Option to check for out-of-range index values in accelerator and rapid accelerator simulation modes

off (default) | on

Select this check box to have Simulink check during simulation in accelerator or rapid accelerator mode whether any index values are outside the range of valid indices for the relevant dimension of the input signal. If an index is out of range, Simulink stops the simulation and displays an error message.

Note If you do not select this check box, out-of-range index values could lead to undefined behavior during accelerator or rapid accelerator mode simulation.

Simulink performs this check during normal mode simulation regardless of whether you select this check box.

Programmatic Use**Parameter:** RuntimeRangeChecks**Type:** character vector**Values:** 'Off' | 'On'**Default:** 'Off'**Block Characteristics**

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History**Introduced before R2006a****R2023a: Index signal supports integer of custom width**

Starting in R2023a, you can customize the width of the integer that you use to specify the index signal value for the Selector block.

R2023a: Variable size signal support for Index vector (dialog) and Starting index (dialog) as Index Option

Starting in R2023a, a Selector block that is configured to accept a 1-D variable-size input signal, supports Index vector (dialog) and Starting index (dialog) as the **Index Option**.

This enhancement allows you to choose from all the available **Index Option** settings when you configure the Selector block to accept a 1-D variable-size input signal.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
Native Floating Point	
LatencyStrategy	Specify whether to map the blocks in your design to inherit, Max, Min, or Zero for the floating-point operator. The default is inherit. See also “LatencyStrategy” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Sequence Viewer

Display messages, events, states, transitions, and functions between blocks during simulation

Libraries:

Simulink / Messages & Events
 Simulink Test
 SimEvents
 Stateflow

Description

The Sequence Viewer block displays messages, events, states, transitions, and functions between certain blocks during simulation. The blocks that you can display are called lifeline blocks and include:

- Subsystems
- Referenced models
- Blocks that contain messages, such as Stateflow charts
- Blocks that call functions or generate events, such as Function Caller, Function-Call Generator, and MATLAB Function blocks
- Blocks that contain functions, such as Function-Call Subsystem and Simulink Function blocks

To see states, transitions, and events for lifeline blocks in a referenced model, you must have a Sequence Viewer block in the referenced model. Without a Sequence Viewer block in the referenced model, you can see only messages and functions for lifeline blocks in the referenced model.

Note The Sequence Viewer block does not display function calls generated by MATLAB Function blocks and S-functions.

Parameters

Time Precision for Variable Step — Digits for time increment precision

3 (default) | scalar

Number of digits for time increment precision. When using a variable step solver, change this parameter to adjust the time precision for the sequence viewer. By default the block supports 3 digits of precision.

Suppose the block displays two events that occur at times 0.1215 and 0.1219. Displaying these two events precisely requires 4 digits of precision. If the precision is 3, then the block displays two events at time 0.121.

Programmatic Use

Block Parameter: VariableStepTimePrecision

Type: string scalar or character vector

Values: "3" | scalar

Default: "3"

History — Maximum number of previous events to display
5000 (default) | scalar

Total number of events before the last event to display.

For example, if **History** is 5 and there are 10 events in your simulation, then the block displays 6 events, including the last event and the five events prior the last event. Earlier events are not displayed. The time ruler is greyed to indicate the time between the beginning of the simulation and the time of the first displayed event.

Each send, receive, drop, or function call event is counted as one event, even if they occur at the same simulation time.

Programmatic Use

Block Parameter: History

Type: string scalar or character vector

Values: "1000" | scalar

Default: "1000"

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for visualizing message transitions during simulation, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block displays messages during simulation when used in subsystems that generate HDL code, but it is not included in the hardware implementation.

S-Function

Include S-function in model

Libraries:

Simulink / User-Defined Functions

Description

The S-Function block provides access to S-functions from a block diagram. The S-function named as the **S-function name** parameter can be a Level-1 or Level-2 C MEX S-function (see “MATLAB S-Function Basics” for information on how to create S-functions).

Note Use the Level-2 MATLAB S-Function block to include a Level-2 MATLAB S-function in a block diagram.

The S-Function block displays the name of the specified S-function and the number of input and output ports specified by the S-function. Signals connected to the inputs must have the dimensions specified by the S-function for the inputs.

Parameters

S-function name — Name of the S-function

character array (default)

Use this parameter to specify the name of your S-function.

Programmatic Use

Block Parameter: FunctionName

Type: character vector

Value: name of the S-function

Default: 'system'

S-function parameters — Additional S-function parameters

cell array (default)

Specify the additional S-function parameters.

The function parameters can be specified as MATLAB expressions or as variables separated by commas. For example,

```
A, B, C, D, [eye(2,2);zeros(2,2)]
```

Note that although individual parameters can be enclosed in brackets, the list of parameters must not be enclosed in brackets.

Programmatic Use**Block Parameter:** Parameters**Type:** character vector**Value:** S-function parameters**Default:** ' '**S-function modules** — List additional files for code generation

cell array (default)

This parameter applies only if this block represents a C MEX S-function and you intend to use the Simulink Coder software to generate code from the model containing the block. If you use it, when you are ready to generate code, you must force the coder to rebuild the top model as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

For more information on using this parameter, see “Specify Additional Source Files for an S-Function” (Simulink Coder).

Programmatic Use**Block Parameter:** SFunctionModules**Type:** character vector**Value:** character vector of file names**Default:** ' '**Block Characteristics**

Data Types	Boolean ^a bus ^a double ^a fixed point ^{ba} half ^a integer ^a single ^a string ^a
Direct Feedthrough	yes ^a
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	yes ^a

^a Actual data type or capability support depends on block implementation.

^b See Writing Fixed-Point S-Functions for details on using fixed-point data types in S-functions.

Version History**Introduced before R2006a****Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

- Actual code generation support depends on block implementation.
- S-functions that call into MATLAB are not supported for code generation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

- Actual data type support depends on block implementation.
- See “Integrate External Code” (Fixed-Point Designer) for details on using fixed-point data types in S-functions.

Topics

“Implementing S-Functions”

“Create a Basic C MEX S-Function”

“Write Level-2 MATLAB S-Functions”

S-Function Builder

Integrate C or C++ code to create S-functions

Libraries:

Simulink / User-Defined Functions

Description

The S-function Builder block integrates new or existing C or C++ code and creates a C MEX S-function from specifications you provide. See “Use a Bus with S-Function Builder to Create an S-Function” for detailed instructions on using the S-Function Builder block to generate an S-function.

Instances of the S-Function Builder block also serve as wrappers for generated S-functions in Simulink models. When simulating a model that contains instances of an S-Function Builder block, Simulink software invokes the generated S-function in order to call your C or C++ code in the instance `mdlStart`, `mdlOutputs`, `mdlDerivatives`, `mdlUpdate` and `mdlTerminate` methods. To learn how Simulink engine interacts with S-functions, see “Simulink Engine Interaction with C S-Functions”.

Note The S-Function Builder block does not support masking. However, you can mask a Subsystem block that contains an S-Function Builder block. For more information, see “Dynamic Masked Subsystem”.

Ports

Input

Port 1 — S-function input

scalar | vector | matrix

The S-Function Builder block can accept real and complex, 1-D, or 2-D signals and nonvirtual buses. For each of these cases, the signals must have a data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

Output

Out — S-function output

scalar | vector | matrix

The S-Function Builder can produce real and complex, 1-D, or 2-D signals and nonvirtual buses. For each of these cases, the signals must have a data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `bus`

Parameters

See “Build S-Functions Automatically Using S-Function Builder” for information about configuring the S-Function Builder block using the S-Function Builder editor.

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>fixed point</code> <code>integer</code> <code>single</code>
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

S-functions that call into MATLAB are not supported for code generation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Shift Arithmetic

Shift bits or binary point of signal

Libraries:
 Simulink / Logic and Bit Operations
 HDL Coder / Logic and Bit Operations

Description

The Shift Arithmetic block can shift the bits or the binary point of an input signal, or both.

For example, shifting the binary point on an input of data type `sfixed(8)` by two places to the right and left gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Binary point shift right by two places	1100101.1	-26.5
Binary point shift left by two places	110.01011	-1.65625

This block performs arithmetic bit shifts on signed numbers. Therefore, the block recycles the most significant bit for each bit shift. Shifting the bits on an input of data type `sfixed(8)` by two places to the right and left gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Bit shift right by two places	11110.010	-1.75
Bit shift left by two places	00101.100	5.5

Ports

Input

u — Number to be operated on
 scalar | vector | array

Number to be operated on, specified as a scalar, vector, or array.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

s — Number of bits to shift
 scalar

Number of bits to shift, specified as a scalar.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Result of operation

scalar | vector | array

Result of operation, returned as a scalar, vector, or array.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Bits to shift: Source — Source of bits to shift

Dialog (default) | Input port

Specify whether to enter the bits to shift on the dialog box or to inherit the values from an input port.

Tunable: No

Programmatic Use

Block Parameter: BitShiftNumberSource

Type: character vector, string

Values: 'Dialog' | 'Input port'

Default: 'Dialog'

Bits to shift: Number — Bits to shift

8 (default) | scalar

Specify a scalar, vector, or array of bit shift values. This parameter is available when **Bits to shift: Source** is Dialog.

If the direction is...	Then...
Left or Right	Use positive integers to specify bit shifts.
Bidirectional	Use positive integers for right shifts and negative integers for left shifts.

Tunable: No

Programmatic Use

Block Parameter: BitShiftNumber

Type: character vector, string

Values: scalar

Default: '9'

Bits to shift: Direction — Direction in which to shift bits

Left (default) | Right | Bidirectional

Specify the direction in which to shift bits: left, right, or bidirectional.

Tunable: No

Programmatic Use**Block Parameter:** BitShiftDirection**Type:** character vector, string**Values:** 'Left' | 'Right' | 'Bidirectional'**Default:** 'Bidirectional'**Binary points to shift: Number** — Number of places to shift binary point

0 (default) | scalar

Specify an integer number of places to shift the binary point of the input signal. A positive value indicates a right shift, while a negative value indicates a left shift.

Tunable: No**Programmatic Use****Block Parameter:** BinPtShiftNumber**Type:** character vector, string**Values:** 'Dialog' | 'Input port'**Default:** 'Dialog'**Diagnostic for out of range shift value** — Diagnostic action

None (default) | Warning | Error

Specify whether to produce a warning or error during simulation when the block contains an out-of-range shift value. Options include:

- **None** — Simulink takes no action.
- **Warning** — Simulink displays a warning and continues the simulation.
- **Error** — Simulink terminates the simulation and displays an error.

For more information, see “Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values” on page 1-1986.

Programmatic Use**Block Parameter:** DiagnosticForOORShift**Type:** character vector, string**Values:** 'None' | 'Warning' | 'Error'**Default:** 'None'**Check for out-of-range 'Bits to shift' in generated code** — Check for out-of-range bits to shift in generated code

off (default) | on

Select this check box to include conditional statements in the generated code that protect against out-of-range bit shift values. This check box is available when **Bits to shift: Source** is **Input port**.

For more information, see “Code Generation for Out-of-Range Bit Shift Values” on page 1-1987.

Programmatic Use**Block Parameter:** CheckOORBitShift**Type:** character vector, string

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

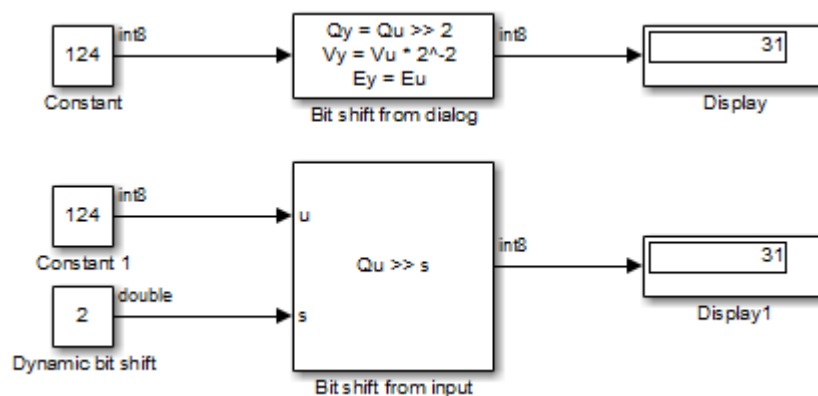

Block Icon Variables

The Shift Arithmetic block icon shows the block behavior using these variables:

- Q — Stored integer value
- V — Real world value
- E — Exponent
- Qy — Stored integer value of output
- Qu — Stored integer value of input
- Vy — Value of output
- Vu — Value of input
- Ey — Exponent of output
- Eu — Exponent of input

Block Output for Right Bit Shifts

The “Effect of Binary Point Shifts” on page 12-244 example compares the behavior of right bit shifts using the dialog box versus the block input port.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8
Dynamic bit shift	Constant value	2
	Output data type	Inherit: Inherit from 'Constant value'

The key block parameter settings of the Shift Arithmetic blocks are:

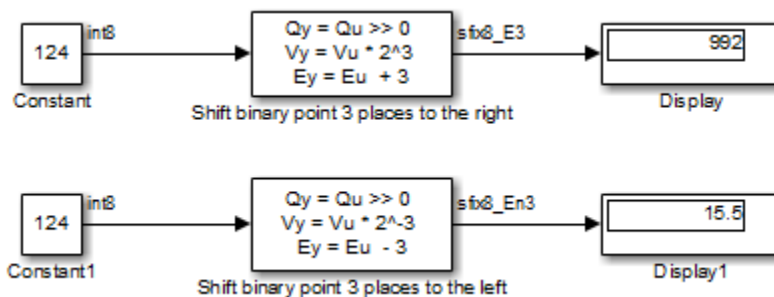

Block	Parameter	Setting
Bit shift from dialog	Bits to shift: Source	Dialog
	Bits to shift: Direction	Right
	Bits to shift: Number	2
Bit shift from input	Bits to shift: Source	Input port
	Bits to shift: Direction	Right

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the number of bits two places to the right produces 00011111 in binary format. Therefore, the block outputs 31.

The bottom Shift Arithmetic block performs the same operation as the top block. However, the bottom block receives the bit shift value through an input port instead of the dialog box. By supplying this value as an input signal, you can change the number of bits to shift during simulation.

Block Output for Binary Point Shifts

The “Effect of Binary Point Shifts” on page 12-244 example shows the effect of binary point shifts.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8

The key block parameter settings of the Shift Arithmetic blocks are:

Block	Parameter	Setting
Shift binary point 3 places to the right	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0
	Binary points to shift: Number	3
Shift binary point 3 places to the left	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0
	Binary points to shift: Number	- 3

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the binary point three places to the right produces 01111100000 in binary format. Therefore, the top block outputs 995.

The bottom Shift Arithmetic block also takes an input of 124. Shifting the binary point three places to the left produces 01111.100 in binary format. Therefore, the bottom block outputs 15.5.

Algorithms

Out-of-Range Bit Shift

Suppose that WL is the input word length. The shaded regions in the following diagram show out-of-range bit shift values for left and right shifts.

Similarly, the shaded regions in the following diagram show out-of-range bit shift values for bidirectional shifts.

The diagnostic for out-of-range bit shifts responds as follows, depending on the mode of operation:

Mode	Diagnostic for out-of-range shift value		
	None	Warning	Error
Simulation modes	Do not report any warning or error.	Report a warning but continue simulation.	Report an error and stop simulation.
Code generation	Has no effect.		

Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values

Suppose that U is the input, WL is the input word length, and Y is the output. The output for an out-of-range bit shift value for left shifts is as follows:

Similarly, the output for an out-of-range bit shift value for right shifts is as follows:

For bidirectional shifts, the output for an out-of-range bit shift value is as follows:

Code Generation for Out-of-Range Bit Shift Values

For generated code, the method for handling out-of-range bit shifts depends on the setting of **Check for out-of-range 'Bits to shift' in generated code**.

Check Box Setting	Generated Code	Simulation Results Compared to Generated Code
Selected	Includes conditional statements to protect against out-of-range bit shift values.	Simulation and Accelerator mode results match those of code generation.

Check Box Setting	Generated Code	Simulation Results Compared to Generated Code
Cleared	Does not protect against out-of-range bit shift values.	<ul style="list-style-type: none"> For in-range values, simulation and Accelerator mode results match those of code generation. For out-of-range values, the code generation results are compiler specific.

For right shifts on signed negative inputs, most C compilers use an arithmetic shift instead of a logical shift. Generated code for the Shift Arithmetic block depends on this compiler behavior.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

You can generate HDL code when **Bits to shift: Source** is **Dialog** or **Input port**.

HDL Architecture

The generated VHDL code uses the `shift_right` function and `sll` operator.

The generated Verilog code uses the `>>>` and `<<<` shift operators.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Restrictions

When **Bits to shift: Source** is **Input port**, binary point shifting is not supported.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Sign

Indicate sign of input

Libraries:

Simulink / Math Operations
HDL Coder / HDL Floating Point Operations
HDL Coder / Math Operations

Description

Block Behavior for Real Inputs

For real inputs, the Sign block outputs the sign of the input:

Input	Output
Greater than zero	1
Equal to zero	0
Less than zero	-1

The “Sign Block Behavior for Real Inputs” on page 12-245 example shows that, for vector and matrix inputs, the block outputs a vector or matrix where each element is the sign of the corresponding input element.

Block Behavior for Complex Inputs

When the input u is a complex scalar, the block output matches the MATLAB result for:

$$\text{sign}(u) = u ./ \text{abs}(u)$$

The “Sign Block Behavior for Complex Issues” on page 12-246 example shows that when an element of a vector or matrix input is complex, the block uses the same formula that applies to scalar input.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal whose sign will determine the output.

The block supports complex input signals only for floating-point data types, `double` and `single`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

Port_1 — Output signal
scalar | vector | matrix

Output signal that is the sign of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean`

Parameters

Enable zero-crossing detection — Enable zero-crossing detection

`on` (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: `ZeroCross`

Type: character vector | string

Values: `'off'` | `'on'`

Default: `'on'`

Sample time — Sample time value other than -1

`-1` (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`

Type: string scalar or character vector

Default: `"-1"`

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

Signal Conversion

Convert signal to new type without altering signal values

Libraries:

Simulink / Signal Attributes
HDL Coder / Signal Attributes

Alternative Configurations of Signal Conversion Block:

Signal Copy | To Virtual Bus | To Nonvirtual Bus

Description

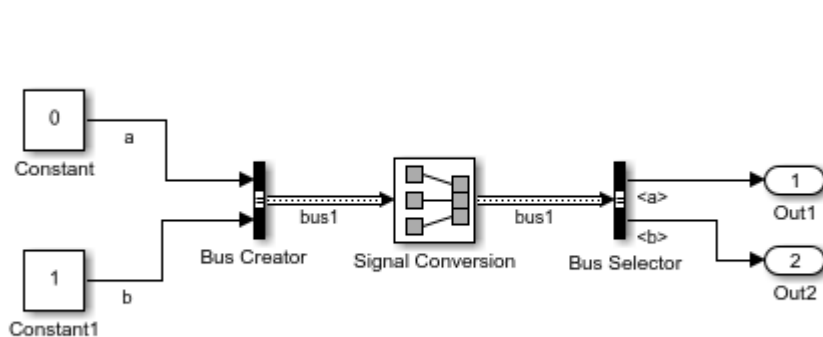

The Signal Conversion block converts a signal from one type to another. To select the type of conversion to perform, use the **Output** parameter or one of the preconfigured Signal Conversion blocks:

- Signal Copy block
- To Virtual Bus block
- To Nonvirtual Bus block

Examples

Create Contiguous Copy of Bus

Use the Signal Conversion block to create a contiguous copy of a bus.

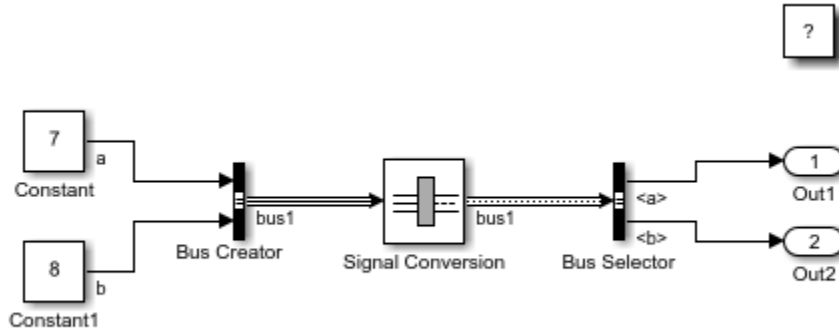

Copyright 2011 The MathWorks, Inc.

The Bus Creator block creates a nonvirtual bus that is input to the Signal Conversion block. With the **Output** parameter set to **Signal copy**, the Signal Conversion block creates another contiguous copy of that input bus.

Convert Virtual Bus to Nonvirtual Bus

Use the Signal Conversion block to convert a virtual bus to a nonvirtual bus.

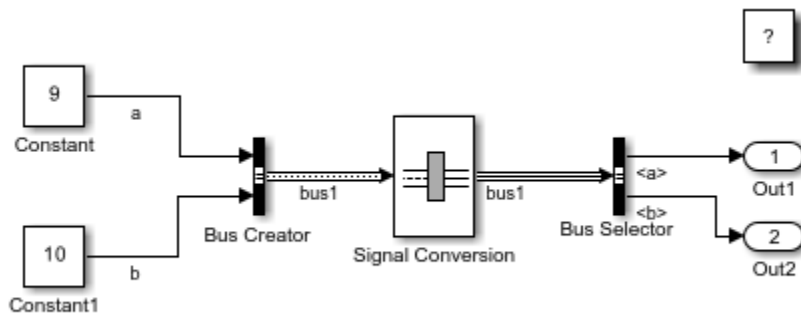

Copyright 2011-2021 The MathWorks, Inc.

The Bus Creator block creates a virtual bus that is input to the Signal Conversion block. To convert the virtual bus to a nonvirtual bus, the Signal Conversion block has its **Output** parameter set to **Nonvirtual bus** and its **Data type** parameter set to a **Simulink.Bus** object. The specified Bus object matches the bus hierarchy of the bus from the Bus Creator block. The nonvirtual bus output from the Signal Conversion block is input to the Bus Selector block.

Convert Nonvirtual Bus to Virtual Bus

Use the Signal Conversion block to convert a nonvirtual bus to a virtual bus.

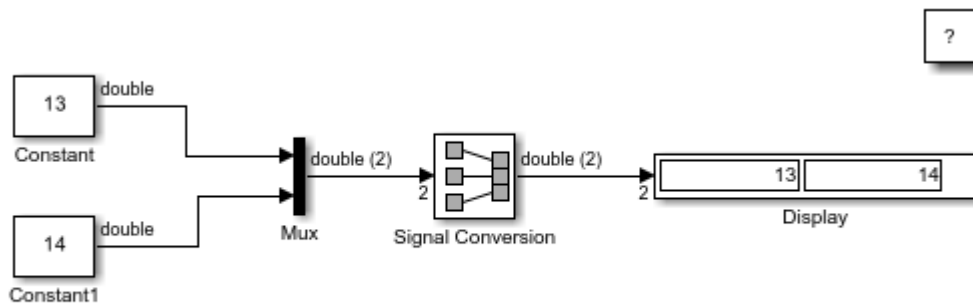

Copyright 2011 The MathWorks, Inc.

The Bus Creator block creates a nonvirtual bus that is input to the Signal Conversion block. To convert the nonvirtual bus to a virtual bus, the **Output** parameter of the Signal Conversion block is set to **Virtual bus**. The virtual bus output from the Signal Conversion block is input to the Bus Selector block.

Convert Mux Signal to Vector

Use the Signal Conversion block to convert a mux signal to a vector.

Copyright 2011 The MathWorks, Inc.

The Mux block creates a mux signal that is input to the Signal Conversion block. To convert the mux signal to a vector, the **Output** parameter of the Signal Conversion block is set to `Signal copy`. The vector output from the Signal Conversion block is input to the Display block.

Ports

Input

Port_1 — Input signal to convert

scalar | vector | matrix | array | bus

The input signal is a scalar, vector, matrix, array, or bus that this block converts to another type.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus | image

Output

Port_1 — Converted signal

scalar | vector | matrix | array | bus

The output signal is the input signal converted to the specified type.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

To edit block parameters interactively, use the **Property Inspector**. From the Simulink Toolstrip, on the **Simulation** tab, in the **Prepare** gallery, select **Property Inspector**.

Output — Type of conversion

Signal copy | Virtual bus | Nonvirtual bus

Specify the type of conversion to perform.

- `Signal copy` — Create a contiguous copy of the input signal. This value is the default value for the Signal Conversion and Signal Copy blocks.

- `Virtual bus` — Convert a nonvirtual bus to a virtual bus. This value is the default value for the To Virtual Bus block.
- `Nonvirtual bus` — Convert a virtual bus to a nonvirtual bus. This value is the default value for the To Nonvirtual Bus block.

For the `Signal copy` option, the type of input determines how the block makes the copy.

For example, suppose the block receives a mux signal, which has elements that occupy discontinuous areas of memory. The conversion allocates a contiguous area of memory for the elements of the mux signal and copies the values from the discontinuous areas represented by the block input to the contiguous areas represented by the block output at each time step. The output is a vector with elements that occupy contiguous areas of memory.

The type of conversion that you use depends on your modeling goal.

Modeling Goal	Option
Reduce generated code for a muxed signal. For an example involving Simulink Coder software, see “Generate Reentrant Code from Subsystems” (Simulink Coder).	<code>Signal copy</code>
Connect a block with a constant sample time to an output port of an enabled subsystem.	<code>Signal copy</code>
Save memory by converting a nonvirtual bus to a virtual bus.	<code>Virtual bus</code>
Pass a virtual bus to a modeling construct that requires a nonvirtual bus.	<code>Nonvirtual bus</code>
Create a copy of an array of buses. The block cannot convert an array of buses to a nonvirtual or virtual bus. To extract a bus from an array of buses, use a Selector block.	<code>Signal copy</code>

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	<code>ConversionOutput</code>
Values:	<code>'Signal copy'</code> (default) <code>'Virtual bus'</code> <code>'Nonvirtual bus'</code>

Example: `set_param(gcb,'ConversionOutput','Virtual bus')`

Data type — Nonvirtual bus data type

Inherit: `auto` (default) | Bus: `<object name>` | `<data type expression>`

Specify the output data type of the nonvirtual bus that this block produces.

- `Inherit: auto` — Inherit the data type from an upstream block. For example, inherit the `Simulink.Bus` object data type from an upstream Bus Creator block.
- `Bus: <object name>` or `<data type expression>` — Specify a `Simulink.Bus` object that matches the hierarchy of the input bus. If an upstream Bus Creator block specifies a bus object, specify the same bus object.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show data type assistant** . For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set **Output** to `Nonvirtual bus`.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	<code>OutDataTypeStr</code>
Values:	<code>'Inherit: auto' (default) 'Bus: <object name>' '<data type expression>'</code>

Example: `set_param(gcf, 'OutDataTypeStr', 'Bus: myBusObj')`

Exclude this block from 'Block reduction' optimization — Option to exclude block from block reduction optimization

`off (default) | on`

When the elements of the input signal occupy contiguous areas of memory, by default, the software eliminates this block from the compiled model as an optimization. For more information, see “Block reduction”.

To prevent this block from being eliminated from the compiled model, select this parameter.

Changes to this parameter take effect the next time you compile the model.

Dependencies

To enable this parameter, set **Output** to `Signal copy`.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	<code>OverrideOpt</code>
Values:	<code>'off' (default) 'on'</code>

Example: `set_param(gcf, 'OverrideOpt', 'on')`

Block Characteristics

Data Types	<code>Boolean bus double enumerated fixed point half image integer single string</code>
Direct Feedthrough	<code>yes</code>
Multidimensional Signals	<code>yes</code>
Variable-Size Signals	<code>yes</code>

Zero-Crossing Detection	no
--------------------------------	----

Signal Copy — Duplicate input signal

The Signal Copy block differs from the Signal Conversion block in name only.

Libraries:

Simulink / Quick Insert / Signal Attributes

To Virtual Bus — Convert nonvirtual bus to virtual bus

The To Virtual Bus block sets **Output** to **Virtual bus**.

Libraries:

Simulink / Quick Insert / Signal Attributes

To Nonvirtual Bus — Convert virtual bus to nonvirtual bus

The To Nonvirtual Bus block sets **Output** to **Nonvirtual bus**.

Libraries:

Simulink / Quick Insert / Signal Attributes

Signal Editor

Display, create, edit, and switch interchangeable scenarios

Libraries:
Simulink / Sources

Description

The Signal Editor block displays, creates, and edits interchangeable scenarios, which contain signals. Signals can be:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A two-dimensional matrix

The block creates one port for each signal.

To create and edit scenarios and the signals contained in the scenarios, click **Launch Signal Editor** (). You can also use the Signal Editor block to switch scenarios in and out of models.

The Signal Editor block supports MAT files that contain signals as one or more scalar `Simulink.SimulationData.Dataset` objects.

Create and Edit Scenarios and Signals

To create and edit scenarios and the signals contained in them, start the Signal Editor tool by clicking . The Signal Editor tool enables you to easily manipulate signals in these ways:

- Create and edit multiple signals in multiple data sets. By default, Signal Editor creates `timeseries` format data.
- Use signal notations to create more complicated signals using MATLAB® expressions. You can use the Author and Insert dialog box or manually enter simple MATLAB expressions in the tabular area.
- Use existing scenarios to get existing data sets for which you can edit and create signals.
- Create and edit multidimensional signals.

For more information on the Signal Editor tool, see “Create and Edit Signal Data”.

Programmatic Interactions

To programmatically get the total number of scenarios and signals in the Signal Editor block, use the `get_param` `NumberOfScenarios` and `NumberOfSignals` properties. These properties contain the values as character vectors. To convert these values to doubles, use the `str2double` function.

To programmatically enable the Signal Editor block to label output signal lines, set the `set_param` `PreserveSignalName` to 'on' (default). For example:

```
set_param(gcb, 'PreserveSignalName', 'on')
```

For more information on programmatic interactions, see “Replace Programmatic Use of signalbuilder”.

Import and Export

The Signal Editor supports custom file types, such as Microsoft Excel, by letting you:

- Edit signals imported from registered custom file types. For more information, see “Import Custom File Type”.
- Export signals from Signal Editor to your registered custom file types. For more information, see “Export Signals to Custom Registered File Types”.

Migrating from Signal Builder Blocks

You can port Signal Builder block configurations to the Signal Editor block using the `signalBuilderToSignalEditor` function. For more information, see “Replace Signal Builder Block with Signal Editor Block” and “Migrate from Signal Builder Block to Signal Editor Block”.

Fast Restart

The Signal Editor block supports fast restart. With fast restart enabled, you can still:

- Change the active scenario.
- Change the active signal.

While you can change the active signal, you cannot edit the signal properties in the block.

- Start the Signal Editor user interface and edit data.

Limitations

The Signal Editor block does not support:

- Function-calls
- Ground signals

The Signal Editor block supports dynamic strings. It does not support strings with maximum length. In addition, strings in the Signal Editor block cannot output:

- Non-scalar MATLAB strings.
- String data that contains missing values.
- String data that contains non-ASCII characters.

Ports

Output Arguments

Signal1 — Signals in scenario
scalar | vector | matrix | array

One or more signals, returned as a scalar, vector, matrix, or array. The block creates one port per signal.

The port label depends on the associated variable in the data set MAT file.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To create and edit scenarios, launch Signal Editor user interface — Start Signal Editor button click

To start Signal Editor user interface, click .

File name — Data set file
`untitled.mat` (default) | character vector

Data set file, specified as character vector, containing one or more scalar `Simulink.SimulationData.Dataset` objects. Do not use a file name from one locale in a different locale. When using the block on multiple platforms, consider specifying just the MAT file name and having the MAT file be on the MATLAB path.

Dependencies

- If `untitled.mat` does not exist in the current folder, these parameters are disabled:
 - **Active scenario**
 - **Signals**
 - **Output a bus signal**
 - **Unit**
 - **Sample time**
 - **Interpolate data**
 - **Enable zero-crossing detection**
 - **Form output after final data value by**
- To create a MAT file, click . This button starts the Signal Editor user interface, which lets you create and edit scenario MAT files.

Programmatic Use

Block Parameter: Filename

Type: character vector

Values: character vector

Default: `'untitled.mat'`

Active scenario — Active scenario
 Scenario (default) | character vector

Active scenario, specified as a character vector. The specified MAT file must exist. You can switch the active scenario as necessary.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: ActiveScenario

Type: character vector | numeric

Values: character vector | index value

Default: 'Scenario'

Active signal — Signal to configure

Signal 1 (default) | character vector

Signal to configure, specified as a signal name. This signal is considered the active signal. The MAT file must exist before you can configure signals.

To enable this parameter, ensure that the specified MAT file exists.

Tip Do not use the `set_param` function to set the active signal property name-value argument ('ActiveSignal') in combination with another Name-Value pair argument for the Signal Editor block.

Programmatic Use

Block Parameter: ActiveSignal

Type: character vector | numeric

Values: character vector | index vector

Default: 'Signal 1'

Apply properties to active signal in all scenarios — Apply specified signal properties to active signal

on (default) | off

Apply the specified signal properties:

On

Apply the specified signal properties to the active signal with the same name in all scenarios.

Off

Apply signal property only to the active signal in the current active scenario.

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: ApplySigPropsToAllScenarios

Type: character vector | numeric

Values: 'off' | 'on'

Default: 'on'

Output a bus signal — Configure signal as bus

off (default) | on

Configure signal as a bus:

On

Configure signal as a bus.

Off

Do not configure signal as a bus.

The specified MAT file must exist.

Tip Select this check box only if the active signal is a MATLAB structure whose fields are the same as an existing bus object, or create a new matching bus object. If you select this check box for an active signal that is not a MATLAB structure, simulation returns an error.

Dependencies

- Selecting **Output a bus signal** enables the **Select bus object** parameter.
- To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: IsBus

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Select bus object — Bus object

Bus: BusObject (default) | bus object name

Select or enter the bus object name. To edit the bus object or create a bus object using the Data Type Assistant, click >>. The active signal must be a MATLAB structure whose fields are the same as this bus object. The specified MAT file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: OutputBusObjectStr

Type: character vector

Values: bus object name

Default: 'Bus: BusObject'

Mode — Bus object mode

Bus Object (default) | bus object data type

Select the bus object name. If you do not have a bus object, create one by clicking **Edit**, which starts the Type Editor. For more information, see “Create and Specify Simulink.Bus Objects”.

Unit — Physical unit

inherit (default) | supported physical unit

Physical unit of the signal, specified as an allowed unit. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For more information, see “Unit Specification in Simulink Models”. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

The specified MAT file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | supported physical unit

Default: 'inherit'

Sample time — Time interval between samples

0 (default) | -1 | sample time in seconds

Time interval between samples, specified in seconds. The specified MAT file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: -1 | sample time in seconds

Default: '0'

Interpolate data — Linearly interpolate data

off (default) | on

Linearly interpolate data at time hits for which no corresponding workspace data exist. The specified MAT file must exist.

The Signal Editor block linearly interpolates:

On

Linearly interpolate at time hits for which no corresponding workspace data exist, select this option.

Off

The current output equals the output at the most recent time for which data exists.

The Signal Editor block interpolates by using the two corresponding workspace samples:

- For `double` data, linearly interpolates the value by using the two corresponding samples
- For `Boolean` data, uses `false` for the first half of the time between two time values and `true` for the second half
- For a built-in data type other than `double` or `Boolean`:
 - Upcasts the data to `double`
 - Performs linear interpolation (as described for `double` data)
 - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (`enum`) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: Interpolate

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Enable zero-crossing detection — Detect zero-crossings

off (default) | on

If you select **Enable zero-crossing detection**, the Signal Editor block detects a zero crossing when the input array contains multiple entries for the same time value. For example, suppose that the block loads this input data:

```
time:    0 1 2 2 3
signal:  2 3 4 5 6
```

At time 2, a zero crossing occurs because of the discontinuity in the input data. For more information, see “Zero-Crossing Detection”.

When you load input data for a bus, the Signal Editor block detects zero crossings for all leaf bus elements.

This block supports zero-crossing detection only in simulations that use a variable-step solver. When you use a fixed-step solver for simulation, the software does not detect or locate zero crossings for this block.

The specified MAT file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Form output after final data value by — Block output after the last time hit for which data is available

Setting to zero (default) | Extrapolation | Holding final value

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero
	Off	Zero
Holding final value	On	Final value from workspace
	Off	Final value from workspace

For example, the block uses the last two known data points to extrapolate data points that occur after the last known point if you:

- Select **Interpolate data**.
- Set **Form output after final data value by** to Extrapolation.

The specified MAT file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT file exists.

Programmatic Use

Block Parameter: OutputAfterFinalValue

Type: character vector

Values: 'Setting to zero' | 'Extrapolation' | 'Holding final value'

Default: 'Setting to zero'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

Version History

Introduced in R2017b

R2023a: Signal Editor Block Updates

The Signal Editor block dialog has these updates:

- The **Launch Signal Editor** button has moved to the top of the block parameters dialog box.
- The **Signal properties** section is reorganized.
- In the **Signal properties** section, the new **Apply properties to active signal in all scenarios** check box lets you apply the specified signal properties to the active signal with the same name in all scenarios.

Signal Editor Block

How to Create Freehand Input Signals in the Signal Editor in Simulink

How to Import and Export Excel Files in Signal Editor

Signal Generator

Generate various waveforms

Libraries:
Simulink / Sources

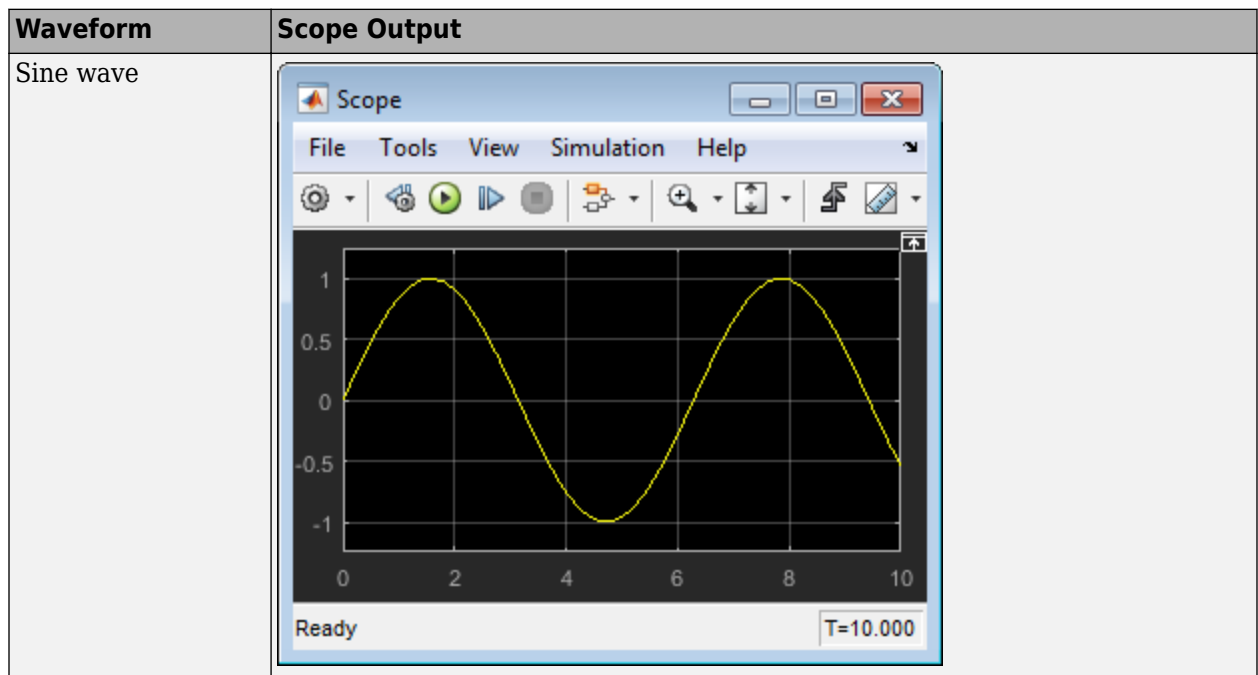

Description

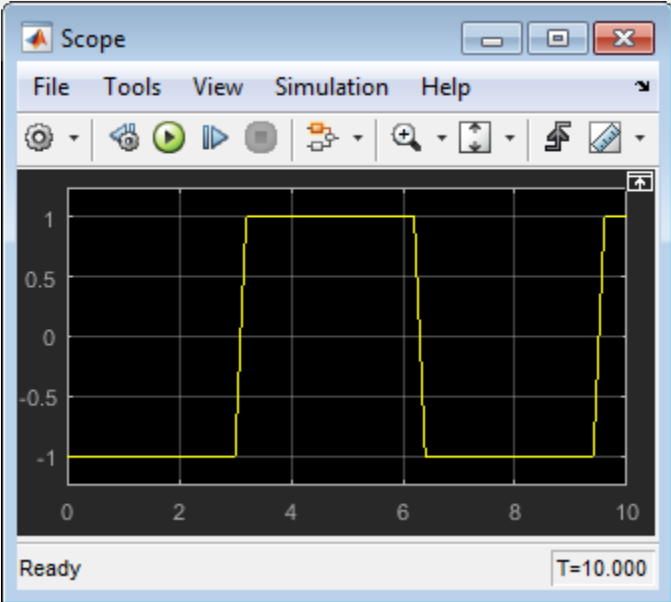

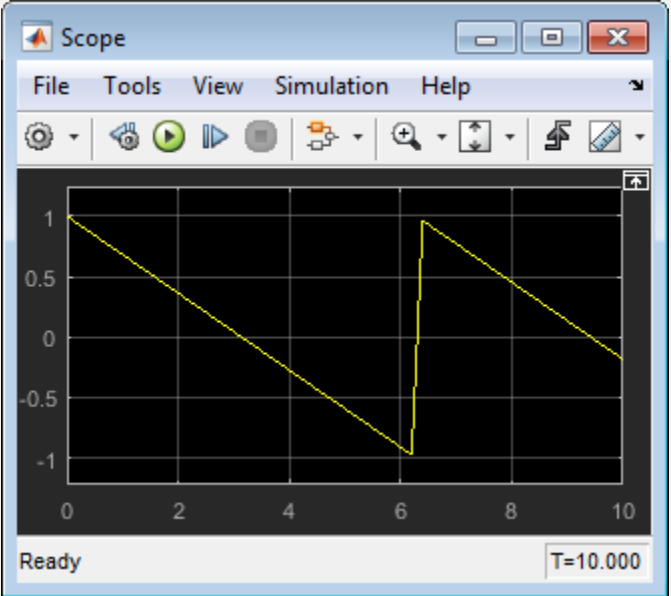

Supported Operations

The Signal Generator block can produce one of four different waveforms:

- sine
- square
- sawtooth
- random

You can express signal parameters in hertz or radians per second. Using default parameter values, you get one of the following waveforms:

Waveform	Scope Output
Square wave	
Sawtooth wave	

A negative **Amplitude** parameter value causes a 180-degree phase shift. You can generate a phase-shifted wave at other than 180 degrees in many ways. For example, you can connect a Clock block signal to a MATLAB Function block and write the equation for the specific wave.

You can vary the output settings of the Signal Generator block while a simulation is in progress to determine quickly the response of a system to different types of inputs.

The **Amplitude** and **Frequency** parameters determine the amplitude and frequency of the output signal. The parameters must be of the same dimensions after scalar expansion. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensions as the **Amplitude** and **Frequency** parameters (after scalar expansion). If you select the **Interpret vector parameters as 1-D** check box, the block outputs a vector (1-D) signal if the **Amplitude** and **Frequency** parameters are row or column vectors, that is, single-row or column 2-D arrays. Otherwise, the block outputs a signal of the same dimensions as the parameters.

Solver Considerations

If your model uses a fixed-step solver, Simulink uses the same step size for the entire simulation. In this case, the Signal Generator block output provides a uniformly sampled representation of the ideal waveform.

If your model uses a variable-step solver, Simulink might use different step sizes during the simulation. In this case, the Signal Generator block output does not always provide a uniformly sampled representation of the ideal waveform. To ensure that the block output is a uniformly sampled representation, add a Hit Crossing block directly downstream of the Signal Generator block. These models show the difference in Signal Generator block output with and without the Hit Crossing block.

Model That Uses a Variable-Step Solver

Signal Generator Block Output

Ports

Output

Port_1 — Generated output signal
scalar | vector | matrix

Output signal specified as one of these waveforms.

- sine
- square
- sawtooth
- random

Data Types: double

Parameters

Wave form — Wave form to generate

sine (default) | square | sawtooth | random

Specify the wave form.

Programmatic Use

Block Parameter: WaveForm

Type: character vector

Values: 'sine' | 'square' | 'sawtooth' | 'random'

Default: 'sine'

Time (t) — Source of time variable

Use simulation time (default) | Use external signal

Specify whether to use simulation time or an external signal as the source of values for the waveform time variable. If you specify an external source, the block displays an input port for connecting the source.

Programmatic Use

Block Parameter: TimeSource

Type: character vector

Values: 'Use simulation time' | 'Use external signal'

Default: 'Use simulation time'

Amplitude — Signal amplitude

1 (default) | scalar | vector | matrix

Specify the amplitude of the generated waveform.

Programmatic Use

Block Parameter: Amplitude

Type: character vector

Values: real scalar

Default: '1'

Frequency — Signal frequency

1 (default) | scalar | vector | matrix

Specify the frequency of the generated waveform.

Programmatic Use

Block Parameter: Frequency

Type: character vector

Values: real scalar

Default: '1'

Units — Signal units

rad/sec (default) | Hertz

Specify the signal units as Hertz or rad/sec.

Programmatic Use

Block Parameter: Units

Type: character vector

Values: 'rad/sec' | 'Hertz'

Default: 'rad/sec'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	yes

Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

These blocks do not reference absolute time when configured for sample-based operation. In time-based operation, they depend on absolute time.

Signal Specification

Specify desired dimensions, sample time, data type, numeric type, and other attributes of signal

Libraries:

Simulink / Signal Attributes
HDL Coder / Signal Attributes

Description

The Signal Specification block allows you to specify the attributes of the signal connected to its input and output ports. If the specified attributes conflict with the attributes specified by the blocks connected to its ports, the software displays an error when it compiles the model. For example, at the beginning of a simulation, if no conflict exists, the software eliminates the Signal Specification block from the compiled model. In other words, the Signal Specification block is a virtual block. It exists only to specify the attributes of a signal and plays no role in the simulation of the model.

You can use the Signal Specification block to ensure that the actual attributes of a signal meet desired attributes. For example, suppose that you and a colleague are working on different parts of the same model. You use Signal Specification blocks to connect your part of the model with your colleague's. If your colleague changes the attributes of a signal without informing you, the attributes entering the corresponding Signal Specification block do not match. When you try to simulate the model, you get an error.

You can also use the Signal Specification block to ensure correct propagation of signal attributes throughout a model. However, if some blocks have unspecified attributes for the signals they accept or output, the model does not have enough information to propagate attributes correctly. In these cases, the Signal Specification block can provide the information the software needs. Using the Signal Specification block also helps speed up model compilation when blocks are missing signal attributes.

The Signal Specification block supports signal label propagation. For more information, see “Signal Label Propagation”.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal whose attributes to check, specified as a scalar, vector, matrix, or N-D array. The block checks the attributes of the input signal against the desired attributes you specify in the block dialog box. If the attributes do not match, the block generates an error.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Output

Port 1 — Output signal

scalar | vector | matrix | N-D array

Output signal is the input signal when all attributes of the signal match those specified in the dialog box. If the attributes do not match, the block generates an error.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

Minimum — Minimum value for range checking

[] (default) | scalar

Specify the minimum value for the block output as a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the minimum values specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Maximum — Maximum value for range checking

[] (default) | scalar

Specify the maximum value for the block output as a finite real double scalar value.

The software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges”)
- Automatic scaling of fixed-point data types

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the maximum values specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** '[]'**Data type** — Output data type

Inherit: auto (default) | double | single | half | int8 | uint8 | int16 | uint16 | ...

Specify the desired output data type. If the data type of the input signal does not match the value you specify, the block generates an error or warning.

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

You can specify any of these options:

- Inherited data type
- Built-in Simulink data type — For example, specify `single` or `uint8`. See “Data Types Supported by Simulink”.
- Fixed-point data type — Use the `fixdt` function. For example, specify `fixdt(1,16,0)`.
- Enumerated data type — Use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.
- Bus data type — Use the name of the `Simulink.Bus` object preceded by `Bus:`. For example, specify `Bus: myBusObject`.
- Simulink image data type — If you have Computer Vision Toolbox, use the constructor for the `Simulink.ImageType` object and specify the properties to describe the image. By default, the data type uses the `Simulink.ImageType(480,640,3)` expression that represents the rows, columns, and channels of the image respectively.
- Value type — Use the name of the `Simulink.ValueType` object preceded by `ValueType:`. For example, specify `ValueType: windVelocity`.
- Custom data type — Use a MATLAB expression that specifies the type. For example, you can specify a `Simulink.NumericType` object whose `DataTypeMode` property is set to a value other than `'Fixed-point: unspecified scaling'`.

When you specify a `Simulink.ValueType` or `Simulink.Bus` object as the data type, some parameters of the Signal Specification block are ignored. For example, the **Min**, **Max**, and **Unit** parameters of the Signal Specification block are ignored. The software uses the corresponding properties of the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead. For example, suppose a block sets **Unit** to ft/s. When the **Data type** of the block specifies a `ValueType` object that has m/s as its unit, the block uses m/s instead of ft/s.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Value:** 'Inherit: auto' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' |

```
'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'string' | 'Enum: <class name>' |
'Bus: <object name>' | 'ValueType: <object name>' | <data type expression> |
Simulink.ImageType(480,640,3)
Default: 'Inherit: auto'
```

Lock output data type setting against changes by the fixed-point tools — Option to prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the output data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` object.

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Require nonvirtual bus — Accept only nonvirtual bus signals

off (default) | on

If you specify a bus object as the data type, use this parameter to specify whether to accept only nonvirtual bus signals.

- off — Specifies that a signal must come from a *virtual* bus.
- on — Specifies that a signal must come from a *nonvirtual* bus.

Dependencies

To enable this parameter, the **Data type** block parameter must resolve to a `Simulink.Bus` object.

Programmatic Use

Block Parameter: BusOutputAsStruct

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Unit (e.g., m, m/s², N*m) — Physical unit of the input signal to the block

inherit (default) | <Enter unit>

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.

- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the units specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use

Block Parameter: Unit

Type: character vector

Values: 'inherit' | '<Enter unit>'

Default: 'inherit'

Dimensions (-1 for inherited) — Dimensions of input and output signals

-1 (default) | n | [m n]

Specify the dimensions of the input and output signals.

- -1 — Specifies that signals inherit dimensions.
- n — Specifies a vector of width n.
- [m n] — Specifies a matrix with m rows and n columns.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` object. The software uses the dimensions specified by the `Simulink.ValueType` object instead.

Programmatic Use

Block Parameter: Dimensions

Type: character vector

Values: '-1' | n | [m n]

Default: '-1'

Variable-size signal — Allow signal to be variable-size, fixed-size, or both

Inherit (default) | No | Yes

Specify the signal to be of variable-size, fixed size, or both.

- Inherit — Allows variable-size and fixed-size signals.
- No — Does not allow variable-size signals.
- Yes — Allows only variable-size signals.

When the signal is a variable-size signal, the **Dimensions** parameter specifies the maximum dimensions of the signal.

Dependencies

- When **Data type** specifies a `Simulink.Bus` object, the simulation allows variable-size signals only with a disabled bus object.

- The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` object. The software uses the dimensions mode specified by the `Simulink.ValueType` object instead.

Programmatic Use**Block Parameter:** `VarSizeSig`**Type:** character vector**Values:** 'Inherit' | 'No' | 'Yes'**Default:** 'Inherit'**Sample time (-1 for inherited)** — Time interval between samples`-1 (default) | scalar | vector`

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” for more information.

Programmatic Use**Parameter:** `SampleTime`**Type:** character vector**Values:** Any valid sample time**Default:** '`-1`'**Signal type** — Complexity of signal`auto (default) | real | complex`

Specify the complexity of the input and output signals.

- `auto` — Accepts either `real` or `complex` as the numeric type.
- `real` — Specifies the numeric type as a real number.
- `complex` — Specifies the numeric type as a complex number.

Dependencies

The software ignores the value of this parameter when **Data type** specifies a `Simulink.ValueType` or `Simulink.Bus` object. The software uses the complexity specified by the `Simulink.ValueType` object or the `Simulink.BusElement` objects in the `Simulink.Bus` object instead.

Programmatic Use**Parameter:** `SignalType`**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Mode** — Data type mode`Inherit (default) | Built in | Fixed Point | Enumerated | Bus object | Expression`

Select the category of data to specify. For more information, see “Specify Data Types Using Data Type Assistant”.

Inherit

Specifies inheritance rules for data types. Selecting `Inherit` enables `auto`.

Built in

Specifies built-in data types. Selecting **Built in** enables a list of possible values:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `int64`
- `uint64`
- `boolean`

Fixed point

Specifies fixed-point data types.

Enumerated

Specifies enumerated data types. Selecting **Enumerated** enables you to enter a class name.

Bus

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Type Editor. For details, see “Create and Specify Simulink.Bus Objects”.

Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Dependencies

To enable this parameter, click the **Show data type assistant** button  .

Signedness — Signed or unsigned**Signed**

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only.

- **Signed**, specifies the fixed-point data as signed.
- **Unsigned**, specifies the fixed-point data as unsigned.

For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Data type override — Specify data type override mode for this signal

`Inherit` | `Off`

Select the data type override mode for this signal.

- When you select `Inherit`, Simulink inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.
- When you select `Off`, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, set **Mode** to `Built in` or `Fixed point`.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Scaling — Method for scaling fixed-point data

`Best precision` (default) | `Binary point` | `Slope and bias`

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Fraction length — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Binary point`.

Slope — Specify slope for the fixed-point data type

2^{θ} (default) | positive, real-valued scalar

Specify slope for the fixed-point data type. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Slope and bias`.

Bias — Specify bias for the fixed-point data type

θ (default) | real-valued scalar

Specify bias for the fixed-point data type as any real number. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Scaling** to `Slope and bias`.

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Simulink Function

Graphically define a function with Simulink blocks

Libraries:
Simulink / User-Defined Functions
SimEvents

Description

The Simulink Function block is a subsystem block preconfigured as a starting point for graphically defining a function with Simulink blocks. The block provides a text interface to function callers. You can call a Simulink Function block from a Function Caller block, a MATLAB Function block, or a Stateflow chart. See “Call a Simulink Function from a Model”.

For a description of the block parameters, see Subsystem.

You can visualize Simulink Function calls in the **Sequence Viewer**. The viewer shows when calls were made with the argument and the return values.

You can select a Simulink Function or Function Caller block to highlight related blocks. If one or more of the related blocks are in a subsystem or referenced model, the related blocks and the Subsystem block or Model block that contains the related blocks are also highlighted.

To show a related block in an open diagram or new tab, pause on the ellipsis that appears after you select a Simulink Function or Function Caller block. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Function Interface

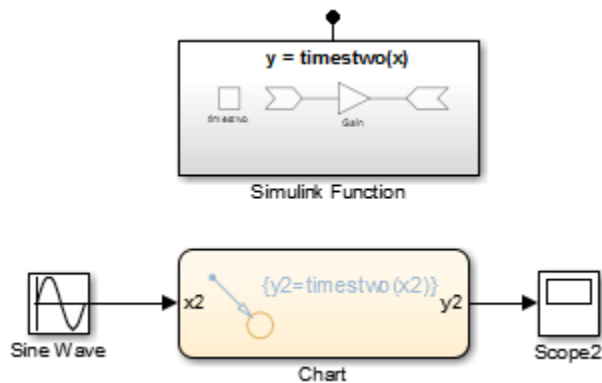

The function interface appears on the face of a Simulink Function block. Editing the block text adds and deletes Argument Inport blocks and Argument Outport blocks from the function definition. Editing also sets the **Function name** parameter in the Trigger block within the Simulink Function block.

For example, entering `y = myfunction(u)` on the face of a Simulink Function block adds one Argument Inport block (`u`) and one Argument Outport block (`y`) within the subsystem.

When calling a function using a Function Caller block, the parameter **Function prototype** in the Function Caller block must match exactly the function interface you specify on the Simulink Function block. This match includes the name of the function and the names of input and output arguments. For example, this Simulink Function block and Function Caller block both use the argument names `u` and `y`.

When calling a function from a Stateflow transition or state label, you can use different argument names. For example, this Simulink Function block uses `x` and `y` arguments while the Stateflow transition uses `x2` and `y2` arguments to call the function.

Function-Call Subsystems Versus Simulink Function Blocks

In general, a Function-Call Subsystem block provides better signal traceability with direct signal connections than a Simulink Function block, whereas a Simulink Function block eliminates the need for routing input and output signal lines through the model hierarchy.

Attribute	Function-Call Subsystem block	Simulink Function block
Method of executing/invoking function	Triggered using a signal line	Called by reference using the function name
Formal input arguments (Argument Inport blocks) and output arguments (Argument Outport blocks)	No	Yes
Local inputs (Inport block) and outputs (Outport block)	Yes	Yes

Ports

Input

In — Signal input to a subsystem block
scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to receive signals from the local environment.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image | struct

ArgIn — Argument input to a subsystem block
scalar | vector | matrix

An Argument Inport block in a subsystem block provides an input port corresponding to an input argument. A port is not displayed on the subsystem block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image | struct

Output

Out — Signal output from a subsystem
scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image | struct

ArgOut — Argument output from a subsystem block
scalar | vector | matrix

An Argument Outport block in a subsystem block provides an output port corresponding to an output argument. A port is not displayed on the subsystem block.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image | struct

Block Characteristics

Sine, Cosine

Implement fixed-point sine or cosine wave using lookup table approach that exploits quarter wave symmetry

Libraries:

Simulink / Lookup Tables

Description

The Sine and Cosine block implements a sine and/or cosine wave in fixed point using a lookup table method that exploits quarter wave symmetry. The block can output the following functions of the input signal, depending upon what you select for the **Output formula** parameter:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(j2\pi u)$
- $\sin(2\pi u)$ and $\cos(2\pi u)$

You define the number of lookup table points in the **Number of data points for lookup table** parameter. The block implementation is most efficient when you specify the lookup table data points to be $(2^n)+1$, where n is an integer.

Use the **Output word length** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

Ports

Input

u — Input signal to implement as fixed-point sine or cosine wave
real-valued signal

Input signal, u , specified as a real-valued scalar, vector, or matrix.

Tip To obtain meaningful block output, the block input values should fall within the range $[0, 1)$. For input values that fall outside this range, the values are cast to an unsigned data type, where overflows wrap. For these out-of-range inputs, the block output might not be meaningful.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

sin(2*pi*u) — Fixed-point sine wave
real-valued fixed-point signal

Fixed-point sine wave, implemented using a lookup table approach.

Dependencies

This port is enabled when the **Output formula** is set to $\sin(2\pi u)$ or $\sin(2\pi u)$ and $\cos(2\pi u)$.

Data Types: fixed point

cos(2*pi*u) — Fixed-point cosine wave
real-valued fixed-point signal

Fixed-point cosine wave, implemented using a lookup table approach.

Dependencies

This port is enabled when the **Output formula** is set to $\cos(2\pi u)$ or $\sin(2\pi u)$ and $\cos(2\pi u)$.

Data Types: fixed point

exp(j*2*pi*u) — $\exp(j*2\pi u)$
complex-valued fixed-point signal

$\exp(j*2\pi u)$, implemented using a lookup table approach.

Dependencies

This port is enabled when the **Output formula** is set to $\exp(j*2\pi u)$.

Data Types: fixed point

Parameters

Output formula — Select the signal(s) to output

$\cos(2\pi u)$ | $\sin(2\pi u)$ | $\exp(j*2\pi u)$ | $\sin(2\pi u)$ and $\cos(2\pi u)$

Programmatic Use

Block Parameter: Formula

Values: ' $\sin(2\pi u)$ ' | ' $\cos(2\pi u)$ ' | ' $\exp(j*2\pi u)$ ' | ' $\sin(2\pi u)$ and $\cos(2\pi u)$ '

Number of data points for lookup table — Specify the number of data points to retrieve from the lookup table

$(2^5)+1$ (default) | integer, greater than or equal to 2

The implementation is most efficient when you specify the lookup table data points to be $(2^n)+1$, where n is an integer. To be compatible with the **Output word length** parameter, the **Number of data points for lookup table** must be less than or equal to $(2^{(\text{Output word length}-2)}+1)$.

Programmatic Use**Block Parameter:** NumDataPoints**Type:** scalar**Value:** integer ≥ 2 **Default:** $(2^5)+1$ **Output word length** — Specify the word length for the fixed-point data type of the output signal

16 (default) | integer from 2 to 53

The fraction length of the output is the output word length minus 2. To be compatible with the **Number of data points for lookup table** parameter, $(2^{(\text{Output word length} - 2)} + 1)$ must be greater than or equal to **Number of data points for lookup table**.

Note The block uses double-precision floating-point values to construct lookup tables. Therefore, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length to values greater than 53 bits does not improve the precision of your output.

Programmatic Use**Block Parameter:** OutputWordLength**Type:** scalar**Value:** integer from 2 to 53**Default:** '16'**Internal rule priority for lookup table** — Specify the internal rule for intermediate calculations

Speed (default) | Precision

Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use**Block Parameter:** InternalRulePriority**Values:** 'Speed' | 'Precision'**Default:** 'Speed'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

The HDL code implements Cosine and Sine blocks by using the quarter-wave lookup table that you specify in the Simulink block parameters.

To avoid generating a division operator (/) in the HDL code, for **Number of data points for lookup table**, enter $(2^n)+1$. n is an integer.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Limitations

If you use Intel MAX 10 device, to map the lookup table to RAM, add this Tcl command when creating the project in the Quartus tool:

```
set_global_assignment -name INTERNAL_FLASH_UPDATE_MODE "SINGLE IMAGE WITH ERAM"
```

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

“About Lookup Table Blocks”

Sine Wave

Generate sine wave, using simulation time as time source

Libraries:
Simulink / Sources

Description

The Sine Wave block outputs a sinusoidal waveform. The block can operate in time-based or sample-based mode.

Note This block is the same as the Sine Wave Function block that appears in the Math Operations library. If you select **Use external signal** for the **Time** parameter in the block dialog box, you get the Sine Wave Function block.

Time-Based Mode

The block calculates the output waveform.

$$y = \text{amplitude} \times \sin(\text{frequency} \times \text{time} + \text{phase}) + \text{bias}.$$

In time-based mode, the value of the **Sample time** parameter determines whether the block operates in continuous mode or discrete mode.

- 0 (the default) causes the block to operate in continuous mode.
- >0 causes the block to operate in discrete mode.

For more information, see “Specify Sample Time”.

Block Behavior in Continuous Mode

When operating in continuous mode, the Sine Wave block can become inaccurate due to loss of precision as time becomes very large.

Block Behavior in Discrete Mode

A **Sample time** parameter value greater than zero causes the block to behave as if it were driving a Zero-Order Hold block whose sample time is set to that value.

This way, you can build models with sine wave sources that are purely discrete, rather than models that are hybrid continuous/discrete systems. Hybrid systems are inherently more complex and as a result take more time to simulate.

In discrete mode, this block uses a differential incremental algorithm instead of one based on absolute time. As a result, the block can be useful in models intended to run for an indefinite length of time, such as in vibration or fatigue testing.

The differential incremental algorithm computes the sine based on the value computed at the previous sample time. This method uses the following trigonometric identities:

$$\begin{aligned}\sin(t + \Delta t) &= \sin(t)\cos(\Delta t) + \sin(\Delta t)\cos(t) \\ \cos(t + \Delta t) &= \cos(t)\cos(\Delta t) - \sin(t)\sin(\Delta t)\end{aligned}$$

In matrix form, these identities are:

$$\begin{bmatrix} \sin(t + \Delta t) \\ \cos(t + \Delta t) \end{bmatrix} = \begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Because Δt is constant, the following expression is a constant:

$$\begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix}$$

Therefore, the problem becomes one of a matrix multiplication of the value of $\sin(t)$ by a constant matrix to obtain $\sin(t + \Delta t)$.

Discrete mode reduces but does not eliminate the accumulation of round-off errors. This accumulation can happen because computation of the block output at each time step depends on the value of the output at the previous time step.

Methods to Handle Round-Off Errors in Discrete Mode

To handle round-off errors when the Sine Wave block operates in time-based discrete mode, use one of these methods.

Method	Rationale
Insert a Saturation block directly downstream of the Sine Wave block.	By setting saturation limits on the Sine Wave block output, you can remove overshoot due to accumulation of round-off errors.
Set up the Sine Wave block to use the <code>sin()</code> math library function to calculate block output. <ol style="list-style-type: none"> On the Sine Wave block dialog box, set Time to Use external signal so that an input port appears on the block icon. Connect a clock signal to this input port using a Digital Clock block. Set the sample time of the clock signal to the sample time of the Sine Wave block. 	The <code>sin()</code> math library function computes block output at each time step <i>independently</i> of output values from other time steps, preventing the accumulation of round-off errors.

Sample-Based Mode

Sample-based mode uses this formula to compute the output of the Sine Wave block.

$$y = A\sin(2\pi(k + o)/p) + b$$

- A is the amplitude of the sine wave.
- p is the number of time samples per sine wave period.
- k is a repeating integer value that ranges from 0 to $p-1$.
- o is the offset (phase shift) of the signal.
- b is the signal bias.

In this mode, Simulink sets k equal to θ at the first time step and computes the block output, using the formula. At the next time step, Simulink increments k and recomputes the output of the block. When k reaches p , Simulink resets k to θ before computing the block output. This process continues until the end of the simulation.

The sample-based method of computing block output at a given time step does not depend on the output of the previous time steps. Therefore, this mode avoids the accumulation of round-off errors. Sample-based mode supports reset semantics in subsystems that offer it. For example, if a Sine Wave block is in a resettable subsystem that receives a reset trigger, the repeating integer k resets and the block output resets to its initial condition.

Ports

Output

Port_1 — Sine wave output signal
scalar | vector

Output sine wave signal created based on the block parameter values.

Data Types: double

Parameters

Sine type — Type of sine wave

Time based (default) | Sample based

Specify the type of sine wave that this block generates. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Programmatic Use

Block Parameter: SineType

Type: character vector

Values: 'Time based' | 'Sample based'

Default: 'Time based'

Time (t) — Source of time variable

Use simulation time (default) | Use external signal

Specify whether to use simulation time as the source of values for the time variable, or an external source. If you specify an external time source, the block creates an input port for the time source. When you select an external time source, the block is the same as the Sine Wave Function block.

Programmatic Use

Block Parameter: TimeSource

Type: character vector

Values: 'Use simulation time' | 'Use external signal'

Default: 'Use simulation time'

Amplitude — Amplitude of the sine wave

1 (default) | scalar | vector

Specify the amplitude of the output sine wave signal.

Programmatic Use

Block Parameter: Amplitude

Type: character vector

Value: scalar

Default: '1'

Bias — Constant added to sine wave

0 (default) | scalar | vector

Specify the constant value added to the sine to produce the output.

Programmatic Use

Block Parameter: Bias

Type: character vector

Value: scalar

Default: '0'

Frequency (rad/sec) — Frequency of sine wave

1 (default) | scalar | vector

Specify the frequency, in rad/sec.

Dependencies

To enable this parameter, set **Sine type** to Time based.

Programmatic Use

Block Parameter: Frequency

Type: character vector

Value: scalar

Default: '1'

Phase (rad) — Phase shift of sine wave

0 (default) | scalar | vector

Specify the phase shift of the sine wave.

You cannot configure this parameter to appear in the generated code as a tunable global variable if you set **Time (t)** to Use simulation time. For example, if you set **Default parameter behavior** to Tunable or apply a storage class to a Simulink.Parameter object, the **Phase** parameter does not appear in the generated code as a tunable global variable.

To generate code so that you can tune the phase during execution, set **Time (t)** to Use external signal. You can provide your own time input signal or use a Digital Clock block to generate the time signal. For an example, see “Tune Phase Parameter of Sine Wave Block During Code Execution” (Simulink Coder).

Dependencies

To enable this parameter, set **Sine type** to Time based.

Programmatic Use**Block Parameter:** Phase**Type:** character vector**Value:** scalar**Default:** '0'**Samples per period** — Samples per period`0 (default) | integer scalar | integer vector`

Specify the number of samples per period.

DependenciesTo enable this parameter, set **Sine type** to `Sample based`.**Programmatic Use****Block Parameter:** Samples**Type:** character vector**Value:** scalar**Default:** '10'**Number of offset samples** — Offset in number of sample times`0 (default) | integer scalar | integer vector`

Specify the offset (discrete phase shift) in number of sample times.

DependenciesTo enable this parameter, set **Sine type** to `Sample based`.**Programmatic Use****Block Parameter:** Offset**Type:** character vector**Value:** scalar**Default:** '0'**Sample time** — Sample period`0 (default) | scalar | vector`

Specify the sample period in seconds. The default is 0. If the sine type is sample-based, the sample time must be greater than 0. See "Specify Sample Time".

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Value:** scalar**Default:** '0'**Interpret vector parameters as 1-D** — Output dimensions for one-row or one-column matrices`off (default) | on`

Specify the output dimensions to be a 1-D vector signal when other parameters are one-row and one-column matrices. If you do not select this box, the block outputs a signal of the same dimensionality

as the numeric parameters. See “Determine the Output Dimensions of Source Blocks”. This parameter is not available when an external signal specifies time. In this case, if numeric parameters are column or row matrix values, the output is a 1-D vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Sine Wave Function

Generate sine wave, using external signal as time source

Libraries:
Simulink / Math Operations

Description

The Sine Wave Function block outputs a sinusoidal waveform. The block can operate in time-based or sample-based mode.

Note This block is the same as the Sine Wave block that appears in the Math Operations library. If you select Use simulation time for the **Time** parameter in the block dialog box, you get the Sine Wave Function block.

Time-Based Mode

The block calculates the output waveform.

$$y = \text{amplitude} \times \sin(\text{frequency} \times \text{time} + \text{phase}) + \text{bias}.$$

In time-based mode, the value of the **Sample time** parameter determines whether the block operates in continuous mode or discrete mode.

- 0 (the default) causes the block to operate in continuous mode.
- >0 causes the block to operate in discrete mode.

For more information, see “Specify Sample Time”.

Block Behavior in Continuous Mode

When operating in continuous mode, the Sine Wave block can become inaccurate due to loss of precision as time becomes very large.

Block Behavior in Discrete Mode

A **Sample time** parameter value greater than zero causes the block to behave as if it were driving a Zero-Order Hold block whose sample time is set to that value.

This way, you can build models with sine wave sources that are purely discrete, rather than models that are hybrid continuous/discrete systems. Hybrid systems are inherently more complex and as a result take more time to simulate.

In discrete mode, this block uses a differential incremental algorithm instead of one based on absolute time. As a result, the block can be useful in models intended to run for an indefinite length of time, such as in vibration or fatigue testing.

The differential incremental algorithm computes the sine based on the value computed at the previous sample time. This method uses the following trigonometric identities:

$$\begin{aligned}\sin(t + \Delta t) &= \sin(t)\cos(\Delta t) + \sin(\Delta t)\cos(t) \\ \cos(t + \Delta t) &= \cos(t)\cos(\Delta t) - \sin(t)\sin(\Delta t)\end{aligned}$$

In matrix form, these identities are:

$$\begin{bmatrix} \sin(t + \Delta t) \\ \cos(t + \Delta t) \end{bmatrix} = \begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Because Δt is constant, the following expression is a constant:

$$\begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix}$$

Therefore, the problem becomes one of a matrix multiplication of the value of $\sin(t)$ by a constant matrix to obtain $\sin(t + \Delta t)$.

Discrete mode reduces but does not eliminate the accumulation of round-off errors, for example, ($4 \cdot \text{eps}$). This accumulation can happen because computation of the block output at each time step depends on the value of the output at the previous time step.

Methods to Handle Round-Off Errors in Discrete Mode

To handle round-off errors when the Sine Wave block operates in time-based discrete mode, use one of these methods.

Method	Rationale
Insert a Saturation block directly downstream of the Sine Wave block.	By setting saturation limits on the Sine Wave block output, you can remove overshoot due to accumulation of round-off errors.
Set up the Sine Wave block to use the <code>sin()</code> math library function to calculate block output. <ol style="list-style-type: none"> On the Sine Wave block dialog box, set Time to Use external signal so that an input port appears on the block icon. Connect a clock signal to this input port using a Digital Clock block. Set the sample time of the clock signal to the sample time of the Sine Wave block. 	The <code>sin()</code> math library function computes block output at each time step <i>independently</i> of output values from other time steps, preventing the accumulation of round-off errors.

Sample-Based Mode

Sample-based mode uses this formula to compute the output of the Sine Wave block.

$$y = A\sin(2\pi(k + o)/p) + b$$

- A is the amplitude of the sine wave.
- p is the number of time samples per sine wave period.
- k is a repeating integer value that ranges from 0 to $p-1$.
- o is the offset (phase shift) of the signal.
- b is the signal bias.

In this mode, Simulink sets k equal to 0 at the first time step and computes the block output, using the formula. At the next time step, Simulink increments k and recomputes the output of the block. When k reaches p , Simulink resets k to 0 before computing the block output. This process continues until the end of the simulation.

The sample-based method of computing block output at a given time step does not depend on the output of the previous time steps. Therefore, this mode avoids the accumulation of round-off errors. Sample-based mode supports reset semantics in subsystems that offer it. For example, if a Sine Wave block is in a resettable subsystem that receives a reset trigger, the repeating integer k resets and the block output resets to its initial condition.

Ports

Input

Port_1 — Time source signal
scalar

Input signal representing the time source in the sine wave calculation.

Data Types: double

Output

Output 1 — Output sine wave signal
scalar

Output signal that is the created sine wave.

Data Types: double

Parameters

Sine type — Type of sine wave
Time based (default) | Sample based

Specify the type of sine wave that this block generates. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Programmatic Use

Block Parameter: SineType

Type: character vector

Values: 'Time based' | 'Sample based'

Default: 'Time based'

Time (t) — Source of time variable
Use external signal (default) | Use simulation time

Specify whether to use simulation time as the source of values for the time variable, or an external source. If you specify an external time source, the block creates an input port for the time source.

Programmatic Use**Block Parameter:** TimeSource**Type:** character vector**Values:** 'Use simulation time' | 'Use external signal'**Default:** 'Use external signal'**Amplitude** — Amplitude of the sine wave

1 (default) | scalar

Specify the amplitude of the output sine wave signal.

Programmatic Use**Block Parameter:** Amplitude**Type:** character vector**Value:** scalar**Default:** '1'**Bias** — Constant added to sine wave

0 (default) | scalar

Specify the constant value added to the sine to produce the output.

Programmatic Use**Block Parameter:** Bias**Type:** character vector**Value:** scalar**Default:** '0'**Frequency (rad/sec)** — Frequency of sine wave

1 (default) | scalar

Specify the frequency, in radians per second.

Dependency

To enable this parameter, set **Sine type** to Time based.

Programmatic Use**Block Parameter:** Frequency**Type:** character vector**Value:** scalar**Default:** '1'**Phase (rad)** — Phase shift of sine wave

0 (default) | scalar

Specify the phase shift of the sine wave.

You cannot configure this parameter to appear in the generated code as a tunable global variable if you set **Time (t)** to Use simulation time. For example, if you set **Default parameter behavior** to Tunable or apply a storage class to a Simulink.Parameter object, the **Phase** parameter does not appear in the generated code as a tunable global variable.

To generate code so that you can tune the phase during execution, set **Time (t)** to `Use external signal`. You can provide your own time input signal or use a `Digital Clock` block to generate the time signal. For an example, see “Tune Phase Parameter of Sine Wave Block During Code Execution” (Simulink Coder).

Dependencies

To enable this parameter, set **Sine type** to `Time based`.

Programmatic Use

Block Parameter: `Phase`

Type: character vector

Value: scalar

Default: `'0'`

Samples per period — Samples per period

`0` (default) | integer

Specify the number of samples per period.

Dependencies

To enable this parameter, set **Sine type** to `Sample based`.

Programmatic Use

Block Parameter: `Samples`

Type: character vector

Value: scalar

Default: `'10'`

Number of offset samples — Offset in number of time samples

`0` (default) | integer

Specify the offset (discrete phase shift) in number of sample times.

Dependencies

To enable this parameter, set **Sine type** to `Sample based`.

Programmatic Use

Block Parameter: `Offset`

Type: character vector

Value: scalar

Default: `'0'`

Sample time — Sample period

`0` (default) | scalar

Specify the sample period in seconds. The default is `0`. If the sine type is sample-based, the sample time must be greater than `0`. See “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Value: scalar

Default: `'0'`

Interpret vector parameters as 1-D — Output dimensions for one-row or one-column matrices
off (default) | on

Specify the output dimensions to be a 1-D vector signal when other parameters are one-row and one-column matrices. If you do not select this box, the block outputs a signal of the same dimensionality as the numeric parameters. See “Determine the Output Dimensions of Source Blocks”. This parameter is not available when an external signal specifies time. In this case, if numeric parameters are column or row matrix values, the output is a 1-D vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Simulink / Dashboard

Description

The Slider block tunes the value of the connected block parameter during simulation. For example, you can connect the Slider block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Slider block's scale to fit your data. Use the Slider block with other Dashboard blocks to create an interactive dashboard to control your model.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

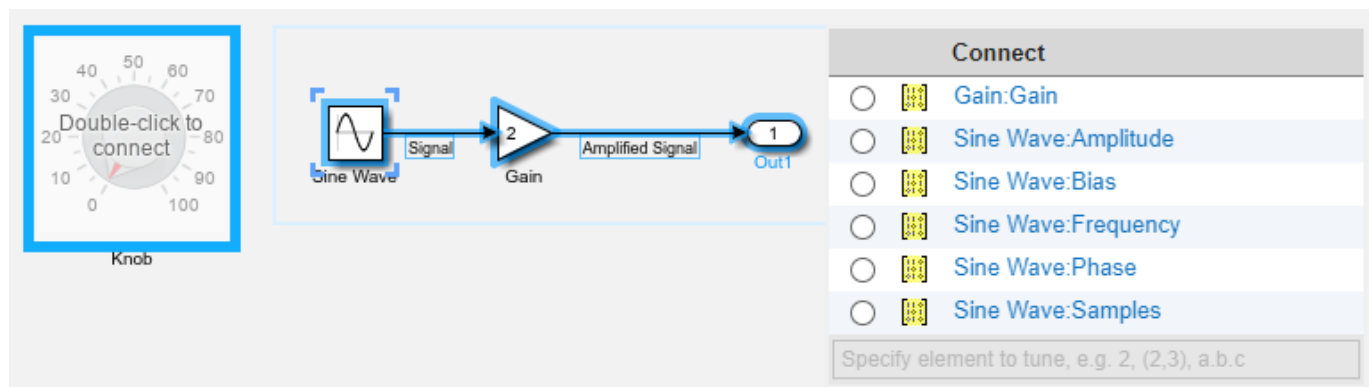

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see "Export Data to the Workspace or a File". The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.

- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

Scale Type — Type of scale

Linear (default) | Log

Type of scale displayed on the block. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

Programmatic Use

Block Parameter: `ScaleType`

Type: string or character vector

Values: 'Linear' | 'Log'

Default: 'Linear'

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the Tick Interval parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the `auto` value for the Tick Interval, leave the Tick Interval position in the vector empty or specify `-1`.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015b

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Slider Gain

Vary scalar gain using slider

Libraries:
Simulink / Math Operations

Description

The Slider Gain block performs a scalar gain that you can modify during simulation. Modify the gain using the slider parameter.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

The Slider Gain block accepts real or complex-valued scalar, vector, or matrix input. The block supports fixed-point data types.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Input multiplied by gain
scalar | vector | matrix

The Slider Gain block outputs the input multiplied by a constant gain value. When the input to the block is real and gain is complex, the output is complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Slider gain — Gain value
0 (default) | real value

Chose the gain value applied to the input.

Programmatic Use

Block Parameter: gain

Type: character vector

Values: real scalar

Default: '1'

Low — Lower limit of slider range

0 (default) | real value

Specify the lower limit of the slider range.

Programmatic Use

Block Parameter: low

Type: character vector

Values: real scalar

Default: '0'

High — Upper limit of slider range

2 (default) | real value

Specify the upper limit of the slider range.

Programmatic Use

Block Parameter: high

Type: character vector

Values: real scalar

Default: '2'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

Gain

Spectrum Analyzer

Display frequency spectrum

Libraries:

DSP System Toolbox / Sinks

DSP System Toolbox HDL Support / Sinks

Description

The Spectrum Analyzer block, referred to here as the scope, displays frequency-domain signals and the frequency spectrum of time-domain signals. The scope shows the spectrum view and the spectrogram view. The block algorithm performs spectral estimation using the filter bank method and Welch's method of averaged modified periodograms. You can customize the spectrum analyzer display to show the data and the measurement information that you need. For more details, see "Algorithms" on page 1-2094.

You can use the Spectrum Analyzer block in models running in `Normal` or `Accelerator` simulation modes. You can also use the Spectrum Analyzer block in models running in `Rapid Accelerator` or `External` simulation modes with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditionally Executed Subsystems Overview” for more information.

Measurements

- “Cursor Measurements” on page 1-2089 — Measure signal values using vertical and horizontal cursors.
- “Peak Finder Measurements” on page 1-2090 — Find maxima and show the x-axis values at which they occur.
- “Channel Measurements” on page 1-2092 — Measure the occupied bandwidth or adjacent channel power ratio (ACPR).
- “Distortion Measurements” on page 1-2090 — Measure harmonic distortion and intermodulation distortion.
- “Spectral Mask” on page 1-2093 — Visualize spectrum limits and compare spectrum values to specification values.

Programmatic Control

You can configure and display the Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

Ports

Input

Signal — Signals to visualize
scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals must have these characteristics:

- **Signal Domain** — Frequency or time signals.
- **Type** — Discrete signals.
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — One dimensional (vector), two dimensional (matrix), or multidimensional (array) signals. Input signal must have a fixed number of channels. See “Signal Dimensions” and “Determine Signal Dimensions”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Frequency — Frequencies in Hz
column vector

Specify the frequencies in Hz. The frequency vector must be a finite, monotonically increasing, column vector with two or more elements. The number of frequency vector points must be equal to

the input frame size. You can also specify the frequencies using the **Frequency (Hz)** parameter on the **Estimation** tab.

Dependency

To enable this port, set the:

- **Input Domain** parameter on the **Estimation** tab to Frequency.
- **Frequency (Hz)** parameter on the **Estimation** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

RBW — RBW Value

positive scalar

Specify the resolution bandwidth in Hz through this port. RBW defines the smallest positive frequency that can be resolved by the scope. You can also specify the RBW value using the **RBW (Hz)** parameter on the **Analyzer** tab.

Dependency

To enable this port, set the **RBW (Hz)** parameter on the **Analyzer** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

VBW — VBW Value

positive scalar

Specify the video bandwidth in Hz through this port. Video bandwidth is the bandwidth of the lowpass filter that the scope uses to average or smooth the noise in the signal before displaying it. You can also specify the VBW value using the **VBW (Hz)** parameter on the **Estimation** tab.

Dependency

To enable this port, set the:

- **Input Domain** parameter on the **Estimation** tab to Time.
- **Averaging Method** parameter on the **Estimation** tab to VBW.
- **VBW (Hz)** parameter on the **Estimation** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Analyzer Tab

Views

Spectrum — Type of spectrum to display

Power (default) | Power Density | RMS

Set the type of spectrum to display as one of these values:

- **Power** — Spectrum Analyzer shows the power spectrum.
- **Power Density** — Spectrum Analyzer shows the power spectral density. The power spectral density is the squared magnitude of the spectrum normalized to a bandwidth of 1 Hz.
- **RMS** — Spectrum Analyzer shows the root mean squared spectrum. Use this option to view the frequency of voltage or current signals.

Tunable: Yes

Dependency

To enable this parameter, set the **Input Domain** parameter on the **Estimation** tab to **Time**.

Programmatic Use

Block Parameter: `SpectrumType`

Type: character vector or string scalar

Bandwidth

Sample Rate (Hz) — Sample rate the scope uses in Hz

Inherited (default) | positive scalar

Specify the sample rate the scope uses in Hz as one of the following:

- **Inherited** -- Use this option to specify the same sample rate as the input signal.
- **Positive scalar** -- The sample rate you specify must be at least twice the sample rate of the input signal. Otherwise, you might see unexpected behavior when visualizing your signal in the scope due to aliasing.

To display this property on the status bar, right-click the status bar at the bottom of the Spectrum Analyzer window and select **Sample Rate**.

Tunable: Yes

Programmatic Use

Block Parameter: `SampleRate`, `SampleRateSource`

Type: double

RBW (Hz) — Resolution bandwidth in Hz

Auto (default) | `Input port` | positive scalar

Specify the resolution bandwidth in Hz. This parameter defines the smallest positive frequency that can be resolved by the scope. By default, this parameter is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span.

If you set this parameter to `Input port`, you can specify the RBW value through an input port on the block.

If you set this parameter to a numeric value, the value must allow at least two RBW intervals over the specified frequency span. In other words, the ratio of the overall frequency span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

To display this property on the status bar, right-click the status bar at the bottom of the Spectrum Analyzer window and select RBW.

Tunable: Yes

Programmatic Use

Block Parameter: RBWSource, RBW

Type: character vector, string scalar, double

Offset (Hz) — Offset to apply to frequency axis

0 (default) | scalar | vector

Specify the offset to apply to the frequency axis (x-axis) in units of Hz as one of the following:

- Scalar — Apply the same frequency offset to all channels.
- Vector — Apply a specific frequency offset for each channel. The vector length must be equal to the number of input channels.

The overall span must fall within the “Nyquist Frequency Interval” on page 1-2100. You can control the overall span in different ways based on how you set the **Span (Hz)** parameter.

Tunable: Yes

Programmatic Use

Block Parameter: FrequencyOffset

Type: double

Configuration > Spectrum Analyzer Settings ()

Num Inputs — Number of input ports

1 (default) | integer between 1 and 96

The number of input ports to the block, specified as an integer between 1 and 96. To change the number of input ports, drag a new input signal line to the block and the block automatically creates new ports.

Programmatic Use

Block Parameter: NumInputPorts

Type: character vector or string scalar

Values: scalar between 1 and 96

Open at Simulation Start — Automatically open scope when simulation starts

on (default) | off

Select this parameter to automatically open the Spectrum Analyzer window when you run the simulation.

Programmatic Use

Block Parameter: OpenAtSimulationStart

Type: logical

Font Size — Font size of labels

Small (default) | Medium | Large | Extra Large

Specify the font size of labels in the display as Small, Medium, Large, and Extra Large.

Tunable: Yes

Programmatic Use

Block Parameter: -

Type: character vector or string scalar

Plot Type — Plot type

Line (default) | Stem

Specify whether to display a Line or Stem plot in the Spectrum display.

Tunable: Yes

Dependency

To enable this parameter:

- Select **Spectrum** in the **Analyzer** tab.
- Select the **Normal Trace** check box in the **Spectrum** tab.

Programmatic Use

Block Parameter: PlotType

Type: character vector or string scalar

Y-Label — y-axis label

character vector | string scalar

Specify the y-axis label in the Spectrum display as a character vector or a string scalar. To display signal units, add (%<SignalUnits>) to the label. When simulation starts, Simulink replaces (%SignalUnits) with the units associated with the signals.

For example, for a velocity signal with units of m/s enter

Velocity (%<SignalUnits>)

Tunable: Yes

Dependency

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

Programmatic Use

Block Parameter: YLabel

Type: character vector or string scalar

Y-Axis Limits — y-axis limits

[-80 20] | [ymin ymax]

Specify the y-axis limits in the Spectrum Analyzer display as a two-element numeric vector of the form [ymin ymax]. The units of the y-axis limits depend on the **Spectrum Unit** in the **Spectrum** tab.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

Programmatic Use

Block Parameter: YLimits

Type: double

Title — Display title

character vector | string

Specify the display title. Enter %<SignalLabel> to use the signal labels in the Simulink model as the axes titles.

Tunable: Yes

Programmatic Use

Block Parameter: Title

Type: character vector or string

Show Grid — Show internal grid lines

on (default) | off

Select this check box to show the grid in the Spectrum Analyzer display.

Tunable: Yes

Programmatic Use

Block Parameter: ShowGrid

Type: logical

Color Map — Spectrogram colormap

jet (default) | hot | bone | cool | copper | gray | parula | three-column matrix

Select a valid colormap name for the spectrogram, or enter a three-column matrix with values in the range [0,1] defining RGB triplets. For more information about colormaps, see `colormap`.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use

Block Parameter: Colormap

Type: character vector or string scalar

Color Limits — Color limits of spectrogram

[-80, 20] (default) | [colorMin colorMax]

Specify the color limits of the spectrogram as a two-element numeric vector of the form [colorMin colorMax]. The units of the color limits directly depend upon the **Spectrum Unit** in the **Spectrogram** tab.

Tunable: Yes

Dependencies

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use

Block Parameter: ColorLimits

Type: double

Preserve colors for copy to clipboard — Preserve colors when copying to clipboard
off (default) | on

When you select this parameter, the scope preserves the colors when you copy the display to the clipboard using the **Copy Display** and the **Print** options in the **Analyzer** tab > **Share** section.

Tunable: Yes

Background — Window background
black (default) | color picker

Specify the background color in the scope figure.

Tunable: Yes

Axes — Axes background color
black (default) | color picker

Specify the background color of the axes.

Tunable: Yes

Labels — Color of labels
gray (default) | color picker

Specify the color of the labels, grid, and the channel names in the legend.

Tunable: Yes

Line — Channel for line property settings
channel names

Specify the channel for which you want to modify the visibility, line color, style, width, and marker properties.

Tunable: Yes

Visible — Channel visibility
on (default) | off

Select this check box to display the channel you have selected. If you clear this check box, the selected channel is no longer visible. You can also click the signal name in the legend to control its visibility. For more details, see .

Tunable: Yes

Style — Line style

- (default) | : | -. | -- | None

Specify the line style for the selected channel.

Tunable: Yes**Width** — Line width

1.5 (default) | 0.5 | 1 | 2 | ...

Specify the line width for the selected channel.

Tunable: Yes**Marker** — Data point markers

None (default) | + | x | ...

Specify a data point marker for the selected channel. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the drop-down list.

Tunable: Yes**Color** — Line color

yellow (default) | color picker

Specify the line color for the selected channel.

Tunable: Yes**Configuration****Legend** — Show or hide signal legend

button

Click the **Legend** button to enable the Spectrum Analyzer to display the signal legend. The legend displays the signal names from the model. For signals with multiple channels, the scope appends a channel index after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

You can control which signals are visible using the legend. To hide a signal, in the scope legend, click the signal name. To display the signal, click the signal name again. Alternatively, you can control

which signal is visible using the **Visible** parameter in the **Spectrum Analyzer Settings** ().

To display only one signal and hide all other signals, right-click the name of the signal you want the scope to display. To show all signals, press **Esc**.

Note The legend displays only the first 20 signals. You cannot view or control any additional signals from the legend.

Tunable: Yes**Dependency**

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

Programmatic Use**Block Parameter:** ShowLegend**Type:** logical**Colorbar** — Show or hide color bar
button

When you select the **Colorbar** button, the Spectrum Analyzer shows the color bar.

Tunable: Yes**Dependencies**

To enable the **Colorbar** button, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use**Block Parameter:** ShowColorbar**Type:** logical**Layout** — Stack axes vertically or horizontally
vertical layout (default) | horizontal layout

Stack axes vertically or horizontally by selecting the appropriate configuration in the layout grid.

Tunable: Yes**Dependencies**

To enable the **Layout**, select **Spectrum** and **Spectrogram** in the **Analyzer** tab.

Programmatic Use**Block Parameter:** AxesLayout**Type:** character vector or string scalar**Share****Copy Display** — Send display to clipboard
button

Click this button to copy the scope display to the clipboard. You can preserve the color in the display by selecting the “Preserve colors for copy to clipboard” on page 1-0 parameter.

Print — Print display
button

Click this button to save the scope display as an image or a PDF or to print the display.

Estimation Tab**Domain****Input Domain** — Domain of the input signal
Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the scope transforms the signal to the frequency spectrum based on the algorithm you specify in the **Method** parameter.

Programmatic Use

Block Parameter: InputDomain

Type: character vector or string scalar

Frequency (Hz) — Frequency vector

Auto (default) | Input port | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display to one of these values:

- Auto — The scope calculates the frequency vector from the length of the input. For more details, see “Frequency Vector” on page 1-2100.
- Input port — You specify the frequency vector at the **Frequency** input port on the block.
- Custom vector — You specify a custom vector as the frequency vector. The length of the custom vector must be equal to the frame size of the input signal.

Tunable: Yes

Dependency

To enable this parameter, set **Input Domain** to Frequency.

Programmatic Use

Block Parameter: FrequencyVectorSource, FrequencyVector

Type: character vector, string scalar, double

Input Unit — Units of frequency input

dBm (default) | dBV | dBW | Vrms | Watts | None

Select the units of the frequency-domain input. This parameter enables the Spectrum Analyzer to scale frequency data when you select a different display unit in the **Spectrum Unit** parameter in the **Estimation** tab.

Tunable: Yes

Dependency

To enable this parameter, set **Input Domain** to Frequency.

Programmatic Use

Block Parameter: InputUnits

Type: character vector or string scalar

Frequency Resolution

Method — Spectrum estimation method

Filter Bank (default) | Welch

Select the spectrum estimation method as one of the following:

- **Filter Bank** -- Use an analysis filter bank to estimate the power spectrum. Compared to Welch's method, this method has a lower noise floor, better frequency resolution, lower spectral leakage, and requires fewer samples per update.
- **Welch** -- Use Welch's method of averaged modified periodograms.

For more details on these methods, see “Algorithms” on page 1-2094.

Tunable: Yes

Dependency

To use this parameter, set **Input Domain** to Time.

Programmatic Use

Block Parameter: Method

Type: character vector or string scalar

Sharpness — Sharpness of lowpass filter

0.5 (default) | nonnegative scalar in the range [0,1]

Specify the sharpness of the prototype lowpass filter as a real nonnegative scalar in the range [0,1].

Increasing the filter sharpness decreases the spectral leakage and gives a more accurate power reading.

Tunable: Yes

Dependencies

To enable this property, set **Method** to Filter bank.

Programmatic Use

Block Parameter: FilterSharpness

Type: double

Averaging

Averaging Method — Smoothing method

VBW (default) | Exponential

Specify the smoothing method as one of the following:

- **VBW** — Video bandwidth method. The block uses a lowpass filter to smooth the trace and decrease the noise. Use the **VBW (Hz)** parameter to specify the video bandwidth (VBW) value.
- **Exponential** — Weighted average of samples. The block computes the average over samples weighted by an exponentially decaying forgetting factor. Use the **Forgetting Factor** parameter to specify the weighted forgetting factor.

For more information on the averaging methods, see “Averaging Method” on page 1-2102.

Tunable: Yes

Dependency

To enable this parameter, set **Input Domain** to Time.

Programmatic Use**Block Parameter:** AveragingMethod**Type:** character vector or string scalar**VBW (Hz)** — Video bandwidth

Auto (default) | Input port | positive scalar

Specify the video bandwidth as one of the following:

- Auto -- The Spectrum Analyzer adjusts the VBW such that the equivalent forgetting factor is 0.9.
- Input port -- You specify the frequency vector at the **VBW** input port on the block.
- Positive scalar -- You specify a positive scalar. The Spectrum Analyzer adjusts the VBW using this value. The value you specify must be less than or equal to **Sample Rate (Hz)/2**.

For more details on the video bandwidth method, see “Averaging Method” on page 1-2102.

The Spectrum Analyzer shows the VBW value in the status bar at the bottom of the display. To display the VBW value, right-click the status bar and select VBW.

Tunable: Yes**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- Averaging Method to VBW.

Programmatic Use**Block Parameter:** VBWSource, VBW**Type:** double**Forgetting Factor** — Forgetting factor of weighted average method

0.9 (default) | scalar in the range [0,1]

Specify the forgetting factor of the exponential weighted averaging method as a scalar in the range [0,1].

Tunable: Yes**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Averaging Method** to Exponential.

Programmatic Use**Block Parameter:** ForgettingFactor**Type:** double

Frequency Options

Frequency Span — Frequency span mode

Full (default) | Span and Center Frequency | Start and Stop Frequencies

Specify the frequency span mode as one of the following:

- **Full** -- The Spectrum Analyzer computes and plots the spectrum over the entire “Nyquist Frequency Interval” on page 1-2100.
- **Span and Center Frequency** -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the **Span (Hz)** and **Center Frequency (Hz)** parameters.
- **Start and Stop Frequencies** -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the **Start Frequency (Hz)** and **Stop Frequency (Hz)** parameters.

Tunable: Yes

Dependency

To enable this parameter, set **Input Domain** to Time.

Programmatic Use

Block Parameter: FrequencySpan

Type: character vector or string scalar

Span (Hz) — Frequency span to compute spectrum in Hz

10e3 (default) | real positive scalar

Specify the frequency span in Hz over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this parameter and the **Center Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 1-2100. This parameter defines the range of the values shown on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Span and Center Frequency.

Programmatic Use

Block Parameter: Span

Type: double

Center Frequency (Hz) — Center of frequency span in Hz

0 (default) | real scalar

Specify the center of the frequency span in Hz over which the Spectrum Analyzer computes and plots the spectrum. Use this parameter with the **Span (Hz)** parameter to define the frequency span around a center frequency. This parameter defines the midpoint of the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Span and Center Frequency.

Programmatic Use

Block Parameter: CenterFrequency

Type: double

Start Frequency (Hz) — Start frequency in Hz

-5e3 (default) | scalar

Specify the starting frequency in Hz of the frequency interval over which the Spectrum Analyzer computes and plots the spectrum. The overall span, which is defined by this parameter and the **Stop Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 1-2100. This parameter defines the leftmost value on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Start and Stop Frequencies.

Programmatic Use

Block Parameter: StartFrequency

Type: double

Stop Frequency (Hz) — Stop frequency in Hz

5e3 (default) | scalar

Specify the stop frequency in Hz of the frequency interval over which the Spectrum Analyzer computes and plots the spectrum. The overall span, which is defined by this parameter and the **Start Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 1-2100. This parameter defines the rightmost value on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Start and Stop Frequencies.

Programmatic Use

Block Parameter: StopFrequency

Type: double

Window Options**Window** — Windowing method

Hann (default) | Blackman-Harris | Chebyshev | Flat Top | Hamming | Kaiser | Rectangular | custom window function name

Specify the windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows” (Signal Processing Toolbox).

You can use your own spectral estimation window by directly specifying a custom window function name in the **Window** parameter.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Method** to Welch.

Programmatic Use

Block Parameter: Window, CustomWindow

Type: character vector or string scalar

Attenuation (dB) — Sidelobe attenuation in dB

60 (default) | scalar greater than or equal to 45

Specify the sidelobe attenuation in dB as a scalar greater than or equal to 45.

Tunable: Yes

Dependency

To enable this parameter, set **Window** to Chebyshev or Kaiser.

Programmatic Use

Block Parameter: SidelobeAttenuation

Type: double

Overlap (%) — Percentage of overlap

0 (default) | scalar in the range [0 100)

Specify the percentage of overlap between the previous and the current buffered data segments as a scalar in the range [0 100). The overlap creates a window segment that the scope uses to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Method** to Welch.

Programmatic Use

Block Parameter: OverlapPercent

Type: double

Measurements Tab

Channel

Channel — Channel for which to obtain measurements
1 (default) | positive integer

The channel for which you need to obtain measurements, specified as a positive integer in the range [1 N], where N is the number of input channels.

Tunable: Yes

Dependency

To enable this parameter, pass some data through the scope.

Programmatic Use

See MeasurementChannel.

Cursors

Data Cursors — Enable cursor measurements
button

Click the **Data Cursors** button to enable data cursor measurements. Each cursor tracks a vertical line along the signal. The scope displays the difference between x - and y -values of the signal at the two cursors in the box between the cursors.

Tunable: Yes

Programmatic Use

See Enabled.

Snap to data — Snap cursors to data
off (default) | on

Select this parameter to position the cursors on the signal data points.

Tunable: Yes

Programmatic Use

See SnapToData.

Lock cursor spacing — Lock cursor spacing
off (default) | on

Select this parameter to lock the frequency difference between the two cursors.

Tunable: Yes

Programmatic Use

See LockSpacing.

Peaks

Peak Finder — Enable peak finder measurements
button

Click the **Peak Finder** button to enable peak finder measurements. An arrow appears on the plot at each maxima and a Peaks panel appears at the bottom of the scope window.

Tunable: Yes

Programmatic Use

See Enabled.

Num Peaks — Maximum number of peaks to show
3 (default) | positive integer less than 100

Specify the maximum number of peaks to show as a positive integer less than 100.

Tunable: Yes

Programmatic Use

See NumPeaks.

Min Height — Level above which scope detects peaks
-Inf (default) | real scalar value

Specify the level above which the scope detects peaks as a real scalar.

Tunable: Yes

Programmatic Use

See MinHeight.

Min Distance — Minimum number of samples between adjacent peaks
1 (default) | positive integer

Specify the minimum number of samples between adjacent peaks as a positive integer.

Tunable: Yes

Programmatic Use

See MinDistance.

Threshold — Minimum difference between height of peak and its neighboring samples
0 (default) | nonnegative scalar

Specify the minimum difference between the height of the peak and its neighboring samples as a nonnegative scalar.

Tunable: Yes

Programmatic Use

See Threshold.

Label Peaks — Label peaks
button

Click the **Label Peaks** button to label the peaks. The scope displays the labels (**P1**, **P2**, ...) above the arrows in the plot.

Tunable: Yes

Programmatic Use

See LabelPeaks.

Distortion

Distortion — Enable distortion measurements
button

Click the **Distortion** button to enable distortion measurements. A Distortion panel appears at the bottom of the scope window when you click this button.

Tunable: Yes

Programmatic Use

See Enabled.

Distortion Type — Type of measurement to display
Harmonic (default) | Intermodulation

Specify the type of measurement data to display as Harmonic or Intermodulation. For more details, see “Distortion Measurements” on page 1-2090.

Tunable: Yes

Programmatic Use

See Type.

Num Harmonics — Number of harmonics to measure
6 (default) | positive integer

Specify the number of harmonics to measure as a positive integer less than or equal to 99.

Tunable: Yes

Dependency

To enable this parameter, set **Distortion Type** to Harmonic.

Programmatic Use

See NumHarmonics.

Label Harmonics — Label harmonics

off (default) | on

When you select this parameter, the Spectrum Analyzer adds numerical labels to harmonics in the spectrum display.

Tunable: Yes**Programmatic Use**

See LabelValues.

Label Frequencies — Label frequencies

off (default) | on

When you select this parameter, the Spectrum Analyzer adds numerical labels to the first-order intermodulation product and third-order frequencies in the Spectrum Analyzer display.

Tunable: Yes**Programmatic Use**

See LabelValues.

Spectrum Tab

Note This tab appears when you select **Spectrum** in the **Analyzer** tab.

Trace Options**Two-Sided Spectrum** — Enable two-sided spectrum view

on (default) | off

Select this check box to enable a two-sided spectrum view. In this view, the Spectrum Analyzer shows both negative and positive frequencies. When the input signal is complex-valued, you must select this parameter. If you clear this check box, the Spectrum Analyzer shows a one-sided spectrum with positive frequencies only. In this case, the input signal data must be real valued.

When you clear this check box, the Spectrum Analyzer uses power folding. The y-axis values are twice the amplitude that they would be if you were to select this parameter, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

Tunable: Yes**Programmatic Use****Block Parameter:** PlotAsTwoSidedSpectrum**Type:** logical**Normal Trace** — Normal trace view

on (default) | off

When you select this check box, the Spectrum Analyzer calculates and plots the power spectral estimates. The Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates and continues its spectral computations even when you clear this parameter.

Tunable: Yes

Dependencies

To clear this check box, first select either the **Max-Hold Trace** or the **Min-Hold Trace** parameters.

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

Programmatic Use

Block Parameter: PlotNormalTrace

Type: logical

Max-Hold Trace — Maximum hold trace view

off (default) | on

Select this check box to enable the Spectrum Analyzer to plot the maximum spectral values of all the estimates. The Spectrum Analyzer computes the maximum-hold spectrum at each frequency bin by keeping the maximum value of all the power spectrum estimates. When you clear this check box, the Spectrum Analyzer resets its maximum-hold computations.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

Programmatic Use

Block Parameter: PlotMaxHoldTrace

Type: logical

Min-Hold Trace — Minimum hold trace view

off (default) | on

Select this check box to enable the Spectrum Analyzer to plot the minimum spectral values of all the estimates. The Spectrum Analyzer computes the minimum-hold spectrum at each frequency bin by keeping the minimum value of all the power spectrum estimates. When you clear this check box, the Spectrum Analyzer resets its minimum-hold computations.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

Programmatic Use

Block Parameter: PlotMinHoldTrace

Type: logical

Scale

Frequency Scale — Scale of frequency axis

Linear (default) | Log

Specify the scale to display frequencies as **Linear** or **Log**. When the frequency span contains negative frequency values, you cannot choose the logarithmic option.

Tunable: Yes

Dependency

To set the **Frequency Scale** to **Log**, clear the **Two-Sided Spectrum** check box in the **Trace Options** section in the **Spectrum** or the **Spectrogram** tab (if enabled). If you select the **Two-Sided Spectrum** check box, then the **Frequency Scale** parameter is set to **Linear**.

Programmatic Use

Block Parameter: FrequencyScale

Type: character vector or string scalar

Reference load (Ω) — Reference load in Ω

1 (default) | positive real scalar

Specify the reference load in ohms that the Spectrum Analyzer uses as a reference to compute the power values.

Tunable: Yes

Dependency

To enable this parameter, set:

- **Spectrum** type to **Power** or **Power Density**.

Programmatic Use

Block Parameter: ReferenceLoad

Type: double

Spectrum Unit — Units of the spectrum

dBm (default) | **dBFS** | **dBV** | **dBW** | **Vrms** | **Watts** | **dBm/Hz** | **dBW/Hz** | **dBFS/Hz** | **Watts/Hz** | **Auto**

Specify the units in which the Spectrum Analyzer displays the power values as one of the following:

- **dBm**
- **dBFS**
- **dBV**
- **dBW**
- **Vrms**
- **Watts**
- **dBm/Hz**
- **dBW/Hz**
- **dBFS/Hz**
- **Watts/Hz**
- **Auto**

Tunable: Yes

Dependency

The units available depend on the value you choose for the **Spectrum** parameter in the **Analyzer** tab.

Estimation tab > Input Domain parameter	Analyzer tab > Spectrum option	Available Units
Time	Power	dBm, dBW, dBFS, Watts
	Power Density	dBm/Hz, dBW/Hz, dBFS/Hz, Watts/Hz
	RMS	dBV, Vrms
Frequency	—	Auto, dBm, dBV, dBW, Vrms, Watts

If you set the **Input Domain** parameter to Frequency and the **Spectrum Unit** parameter to Auto, the Spectrum Analyzer assumes the spectrum units to be equal to input units specified in the **Estimation** tab > **Input Unit** parameter. If you set the **Input Domain** parameter to Time and the **Spectrum Unit** parameter to any option other than Auto, the Spectrum Analyzer converts the units specified in the **Input Unit** parameter to the units specified in the **Spectrum Unit** parameter.

Programmatic Use

Block Parameter: SpectrumUnits

Type: character vector or string scalar

Full Scale — Full scale for dBFS units

Auto (default) | positive real scalar

The full scale used for the decibel full scale (dBFS) units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

Tunable: Yes

Dependencies

To enable this parameter:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

Programmatic Use

Block Parameter: FullScale

Type: double

Spectrogram Tab

Note This tab appears when you select **Spectrogram** in the **Analyzer** tab.

Channel

Channel — Channel for which spectrogram is plotted

1 (default) | character vector of a positive integer | string scalar of a positive integer

Select the signal channel for which the spectrogram settings apply.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use

Block Parameter: SpectrogramChannel

Type: character vector, string scalar, double

Time Options

Time Resolution (s) — Time resolution in seconds

Auto (default) | positive scalar

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current Spectrum Analyzer settings.

When you set **RBW (Hz)** and **Time Resolution (s)** to Auto, then the Spectrum Analyzer adjusts the RBW value such that there are 1024 RBW intervals in one frequency span and sets the time resolution is set to 1/RBW.

When you set **RBW (Hz)** to Auto and **Time Resolution (s)** to a positive scalar, then time resolution becomes the main control and RBW is set to 1/**Time Resolution (s)** Hz.

When you set **RBW (Hz)** to a positive scalar and **Time Resolution (s)** to Auto, then RBW becomes the main control and the time resolution is set 1/**RBW (Hz)** s.

When you set **RBW (Hz)** and **Time Resolution (s)** to a positive value, then time resolution must be equal to or larger than the minimum attainable time resolution defined by 1/**RBW (Hz)**. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/**RBW (Hz)**.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use

Block Parameter: TimeResolutionSource, TimeResolution

Type: character vector, string scalar, double

Time Span (s) — Time span in seconds

Auto (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified as a positive scalar in seconds. The time span is the product of the desired number of spectral lines and the time

resolution. When you set this parameter to **Auto**, the spectrogram displays 100 spectrogram lines at any given time. Otherwise, the spectrogram uses the time duration you specify in this parameter. The time span that you specify must be at least two times larger than the duration of the number of samples required for a spectral update.

Tunable: Yes

Dependency

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

Programmatic Use

Block Parameter: `TimeSpanSource`, `TimeSpan`

Type: character vector, string scalar, double

Trace Options

Two-Sided Spectrum — Enable two-sided spectrum view
on (default) | off

Select this check box to enable a two-sided spectrum view. In this view, the Spectrum Analyzer shows both negative and positive frequencies. When the input signal is complex-valued, you must select this parameter. If you clear this check box, the Spectrum Analyzer shows a one-sided spectrum with positive frequencies only. In this case, the input signal data must be real valued.

When you clear this check box, the Spectrum Analyzer uses power folding. The y-axis values are twice the amplitude that they would be if you were to select this parameter, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

Tunable: Yes

Programmatic Use

Block Parameter: `PlotAsTwoSidedSpectrum`

Type: logical

Spectral Mask Tab

Note This tab appears when you select **Spectrum** in the **Analyzer** tab and set the **Spectrum** type to be **Power** or **Power Density**.

Views

Upper Mask — Enable upper spectral mask
button

Select **Upper Mask** to display the upper mask in the spectrum plot. The **Spectral Mask** panel appears at the bottom of the Spectrum Analyzer window and displays mask details, such as number of times a mask succeeded, number of times a mask failed, channels causing the mask failure, and so on.

Use the **Upper Limits** parameter to specify the upper mask. If the entire spectrum plot is below the upper mask, the upper mask looks green. In all other cases, the upper mask looks red.

Tunable: Yes

Programmatic Use

See EnabledMasks.

Lower Mask — Enable lower spectral mask
button

Select **Lower Mask** to display the lower mask in the spectrum plot. The **Spectral Mask** panel appears at the bottom of the Spectrum Analyzer window and displays mask details, such as number of times a mask succeeded, number of times a mask failed, channels causing the mask failure, and so on.

Use the **Lower Limits** parameter to specify the lower mask. If the entire spectrum plot is above the lower mask, the lower mask looks green. In all other cases, the lower mask looks red.

Tunable: Yes

Programmatic Use

See EnabledMasks.

Configuration

Upper Limits — Limit for upper spectral mask
Inf (default) | scalar | two-column matrix

Specify the limit for the upper spectral mask as a scalar or a two-column matrix.

If UpperMask is a scalar, the upper limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If you specify a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **Reference Level (dBr)** and the **Frequency Offset (Hz)** parameters.

Tunable: Yes

Programmatic Use

See UpperMask.

Lower Limits — Limit for lower spectral mask
-Inf (default) | scalar | two-column matrix

Specify the limit for the lower spectral mask as a scalar or a two-column matrix.

If LowerMask is a scalar, the lower limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If you specify a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **Reference Level (dBr)** and the **Frequency Offset (Hz)** parameters.

Tunable: Yes

Programmatic Use

See LowerMask.

Reference Level (dBr) — Reference level for mask power values
0 (default) | real scalar | Spectrum peak

Specify the reference level for mask power values as a numeric scalar or set it to Spectrum peak.

When you set **Reference Level (dBr)** to a scalar value, the Spectrum Analyzer uses this value as the reference to the power values (in dBr) for the upper mask and the lower mask of the Spectrum Analyzer. The reference level should have the same units as the **Spectrum Unit** parameter in the **Spectrum** tab.

When you set **Reference Level (dBr)** to Spectrum peak, the Spectrum Analyzer uses the peak value of the current spectrum of the **Channel** in the **Spectral Mask** tab as the reference power value.

Tunable: Yes

Programmatic Use

See ReferenceLevel and CustomReferenceLevel.

Channel — Input channel with peak spectrum
1 (default) | integer

Select the input channel which the Spectrum Analyzer uses to determine the mask reference level. The peak value of the spectrum in this channel becomes the mask reference level when you set the **Reference Level (dBr)** parameter to Spectrum peak.

Tunable: Yes

Dependency

To enable this parameter, set **Reference Level (dBr)** to Spectrum peak and display some data on the scope.

Programmatic Use

See SelectedChannel.

Frequency Offset (Hz) — Frequency offset in Hz
0 (default) | finite numeric scalar

Specify the frequency offset in Hz as a finite numeric scalar. Using this value, the Spectrum Analyzer offsets the frequency values in the **Upper Mask** and the **Lower Mask** parameters.

Tunable: Yes

Programmatic Use

See MaskFrequencyOffset.

Channel Measurements Tab

Note This tab appears when you select **Spectrum** in the **Analyzer** tab.

Channel

Channel — Channel for computing occupied bandwidth and adjacent channel power ratio
1 (default) | positive integer

Specify the channel over which the Spectrum Analyzer computes and displays the occupied bandwidth and adjacent channel power ratio as a positive integer in the range [1 N], where N is the number of input channels.

Tunable: Yes

Dependency

To enable this parameter, pass data through the scope.

Programmatic Use

See MeasurementChannel.

Channel Measurements

Channel Measurements — Enable channel measurements
button

Click **Channel Measurements** to enable channel measurements.

Tunable: Yes

Programmatic Use

See Enabled.

Type — Type of measurement data to display
Occupied BW (default) | ACPR

Specify the type of measurement data to display as Occupied BW or ACPR.

Tunable: Yes

Programmatic Use

See Type.

Occupied BW (%) — Percentage of power to compute occupied bandwidth
99 (default) | positive scalar

Specify the percentage of power over which the Spectrum Analyzer computes the occupied bandwidth as a positive scalar.

Tunable: Yes

Dependency

To enable this parameter, set **Type** to Occupied BW.

Programmatic Use

See PercentOccupiedBW.

Frequency Options**Frequency Span** — Frequency span mode

Span and Center Frequency (default) | Start and Stop Frequencies

Specify the frequency span mode as one of the following:

- Span and Center Frequency -- Measure over a frequency range specified in **Span (Hz)** and around the frequency value specified in **Center Frequency (Hz)**.
- Start and Stop Frequencies -- Measure over the frequency range [**Start Frequency (Hz)**, **Stop Frequency (Hz)**].

Tunable: Yes

Programmatic Use

See FrequencySpan.

Span (Hz) — Frequency span in Hz

2000 (default) | positive scalar

Specify the frequency span over which the Spectrum Analyzer computes the channel measurements as a positive scalar in Hz.

Tunable: Yes

Dependency

To enable this parameter, set **Frequency Span** to Span and Center Frequency.

Programmatic Use

See Span.

Center Frequency (Hz) — Center frequency of span in Hz

0 (default) | real scalar

Center frequency of the span over which the object computes the channel measurements, specified as a real scalar in Hz.

Tunable: Yes

Dependency

To enable this parameter, set **Frequency Span** to Span and Center Frequency.

Programmatic Use

See CenterFrequency.

Start Frequency (Hz) — Start frequency in Hz

-1000 (default) | real scalar

Specify the start frequency in Hz over which the Spectrum Analyzer computes the channel measurements.

Tunable: Yes

Dependency

To enable this parameter, set **Frequency Span** to Start and Stop Frequencies.

Programmatic Use

See StartFrequency.

Stop Frequency (Hz) — Stop frequency in Hz

1000 (default) | real scalar

Specify the stop frequency in Hz over which the Spectrum Analyzer computes the channel measurements.

Tunable: Yes

Dependency

To enable this parameter, set **Frequency Span** to Start and Stop Frequencies.

Programmatic Use

See StopFrequency.

Adjacent Channels**Num Pairs** — Number of adjacent channel pairs

2 (default) | positive integer in range [1, 12]

Specify the number of adjacent channel pairs as a positive integer in the range [1, 12].

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR.

Programmatic Use

See NumOffsets.

Offsets (Hz) — ACPR offsets in Hz

[2000 3500] (default) | vector

Specify the frequency of the adjacent channel relative to the center frequency of the main channel as a real vector of length equal to the number of offset pairs specified in **Num Pairs**.

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR.

Programmatic Use

See ACPROffsets.

Adjacent BW (Hz) — Adjacent channel bandwidth in Hz
1000 (default) | positive scalar

Specify the adjacent channel bandwidth in Hz as a positive scalar.

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR.

Programmatic Use

See AdjacentBW.

Filter Shape — Filter shape
None (default) | RRC | Gaussian

Specify the filter shape for the main and adjacent channels as None, RRC, or Gaussian.

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR.

Programmatic Use

See FilterShape.

Roll-off Factor — Roll-off factor
0.5 (default) | real scalar in range [0, 1]

Specify the roll-off factor as a real scalar in the range [0, 1].

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR and **Filter Shape** to RRC.

Programmatic Use

See FilterCoeff.

BT Product — BT product
0.5 (default) | real scalar in range [0, 1]

Specify the BT product as a real scalar in the range [0, 1].

Tunable: Yes

Dependency

To enable this parameter, set **Type** to ACPR and **Filter Shape** to Gaussian.

Programmatic Use

See `FilterCoeff`.

Property Inspector Only**Channel Names** — Input channel names

[] (default) | character vector | string | array of strings or character vectors.

Input channel names, specified as a character vector, string, or array. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify the names, the scope labels the channels as Channel 1, Channel 2, etc.

Example: ["A","B"]

Dependency

To see channel names, select **Legend** in the **Analyzer** tab.

Programmatic Use**Block Parameter:** ChannelNames

Type: cell array of character vectors or string array

Maximize Axes — Maximize size of plots

Auto (default) | Off | On

- Auto — If you have not specified **Title** and **Y-Label**, the scope maximizes all plots.
- On — The scope maximizes all plots and hides all values in **Title** and **Y-label**.
- Off — The scope does not maximize plots.

Hover over the Spectrum Analyzer to see the maximize axes button .

Tunable: Yes

Programmatic Use**Block Parameter:** MaximizeAxes

Type: character vector or string scalar

Axes Scaling — Y-axis scaling mode

OnceAtStop (default) | Manual | Auto | Updates

- OnceAtStop — Scale y-axis after simulation completes.
- Manual — Manually scale y-axis range with the **Scale Y-axis Limits** toolbar button.
- Auto — Scale y-axis range during and after simulation.
- Updates — Scale y-axis after the number of time steps specified in the “Number of Updates” on page 1-0 text box (100 by default). Scaling occurs only once during each run.

Tunable: Yes

Programmatic Use

Block Parameter: AxesScaling

Type: character vector or string scalar

Number of Updates — Number of updates before scaling
100 (default) | integer

Set this property to delay auto scaling the y-axis.

Tunable: Yes

Dependency

To enable this property, set “Axes Scaling” on page 1-0 to Updates.

Programmatic Use

Block Parameter: AxesScalingNumUpdates

Type: character vector or string scalar

Values: scalar

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Cursor Measurements

Measure signal values using vertical waveform cursors that track along the signal.

When you click the **Data Cursors** button in the **Measurements** tab of the Spectrum Analyzer, the spectrum display shows vertical cursors on each signal. Each cursor tracks a vertical line along the signal. The scope displays the difference between x - and y -values of the signal at the two cursors in the box between the cursors.

To enable cursor measurements, click the **Data Cursors** button in the **Measurements** tab. The cursors appear only when the Spectrum Analyzer has at least one signal in its display.

You can use the mouse to move the vertical cursors left and right.

In the **Measurements** tab, click the **Data Cursors** drop-down arrow to select one of these options:

- **Snap to Data** — To position the cursors on the signal data points.
- **Lock Cursor Spacing** — To lock the frequency difference between the two cursors.

For modifying the cursor measurements programmatically, see the `CursorMeasurementsConfiguration` object.

Peak Finder Measurements

Compute and display peak values in the scope display.

When you click on the **Peak Finder** button in the **Measurements** tab of the Spectrum Analyzer, an arrow appears on the plot at each maxima and a **Peaks** panel appears at the bottom of the scope window. The Spectrum Analyzer computes peaks from the portion of the input signal that is currently on display in the scope, and the **Peaks** panel shows the peak values and the frequencies at which they occur.

The **Peaks** section in the **Measurements** tab allows you to specify the number of peaks you want the scope to display, the minimum height above which you want the scope to detect peaks, the minimum distance between peaks, and label the peaks.

The Spectrum Analyzer algorithm defines a peak as a local maximum with lower values present on either side of the peak. It does not consider end points as peaks. For more information on the algorithm, see the `findpeaks` function.

The peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

For modifying the peak finder measurements programmatically, see the `PeakFinderConfiguration` object. For more information on these settings in the UI, see “Peaks” (DSP System Toolbox).

Distortion Measurements

Measure harmonic distortion and intermodulation distortion.

When you click the **Distortion** button in the **Distortion** section of the **Measurements** tab, a distortion panel opens at the bottom of the Spectrum Analyzer window. This panel shows the harmonic and distortion measurement values for the input signal currently on display in the scope. The **Distortion** section in the **Measurements** tab allows you to specify the distortion type, number of harmonics, and even label the harmonics.

Note For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the Spectrum Analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious noise content. In general, you should set the RBW value such that there is at least a 10 dB separation between the peaks of the sinusoids and the noise floor. You also might need to select a different spectral window to obtain a valid measurement.

You can set the **Distortion Type** parameter to one of these values:

- **Harmonic** -- Select **Harmonic** if your input is a single sinusoid.
- **Intermodulation** -- Select **Intermodulation** if your input is two equal-amplitude sinusoids. Intermodulation can help you determine distortion when the scope uses only a small portion of the available bandwidth.

See “Distortion Measurements” (DSP System Toolbox) for information on how distortion measurements are calculated.

Harmonic Distortion

When you set the **Distortion Type** to **Harmonic**, these fields appear in the **Harmonic Distortion** panel at the bottom of the Spectrum Analyzer window.

- **H1** — Fundamental frequency in Hz and its power in decibels of the measured power referenced to 1 milliwatt (dBm).
- **H2, H3, ...** — Harmonics frequencies in Hz and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — Total harmonic distortion. This value represents the ratio of the power in the harmonics D to the power in the fundamental frequency S . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of the power in the fundamental frequency S to the power of all nonharmonic content N , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total nonharmonic content of your signal is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion ratio. This value represents the ratio of the power in the fundamental frequency S to all other content (including noise N and harmonic distortion D) in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N+D}\right)$$

- **SFDR** — Spurious-free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency S to power of the largest spurious signal R regardless of where it falls in the frequency spectrum. The worst spurious signal might or might not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal and ignores any DC component. The measurement does not include any harmonics that are outside the Spectrum Analyzer frequency span. Adjust your frequency span so that it includes all the desired harmonics.

Note To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. The noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

Intermodulation Distortion

When you set the **Distortion Type** to **Intermodulation**, the following fields appear in the **Intermodulation Distortion** panel at the bottom of the Spectrum Analyzer window.

- **F1** — Lower fundamental first-order frequency.
- **F2** — Upper fundamental first-order frequency.
- **2F1 - F2** — Lower intermodulation product from third-order harmonics.
- **2F2 - F1** — Upper intermodulation product from third-order harmonics.
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

The intermodulation distortion measurement automatically locates the fundamental and the first-order frequencies ($F1$ and $F2$). It then computes the frequencies of the third-order intermodulation products ($2F1 - F2$ and $2F2 - F1$).

For modifying the distortion measurements programmatically, see the `DistortionMeasurementsConfiguration` object. For more information on these settings in the UI, see “Distortion” (DSP System Toolbox).

Channel Measurements

Measure the occupied bandwidth or adjacent channel power ratio (ACPR).

When you click the **Channel Measurements** button in the **Channel Measurements** tab, a channel measurements panel opens at the bottom of the Spectrum Analyzer window. This panel displays the occupied bandwidth or the adjacent channel power ratio measurements. In the **Channel Measurements** tab, you can specify the occupied bandwidth or the ACPR settings, frequency span, center frequency, and start and stop frequencies.

You can select the channel measurements **Type** to:

- **Occupied BW** -- Occupied bandwidth
- **ACPR** -- Ratio of the power of the main channel to the power of the adjacent channel

For more details on how the Spectrum Analyzer calculates the occupied bandwidth, see “Occupied BW” on page 1-2100.

Occupied Bandwidth

When you set the **Type** of channel measurement to compute and display to Occupied BW, these fields appear in the measurements panel at the bottom of the scope window.

- **Channel Power** — Total power in the channel
- **Occupied BW** — Bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum.
- **Frequency Error** — Difference between the center of the occupied band and the center frequency (**Center Frequency (Hz)**) of the channel

ACPR

When you set the **Type** of channel measurement to compute and display to ACPR, these fields appear in the measurements panel at the bottom of the scope window.

- **Lower (Rel Power (dBc))** — Ratio of the power of the lower sideband to the power of the main channel
- **Upper (Rel Power (dBc))** — Ratio of the power of the upper sideband to the power of the main channel

To modify the channel measurements programmatically, see the `ChannelMeasurementsConfiguration` object. For more information on these settings in the UI, see “Channel Measurements” on page 1-0 .

Spectral Mask

Visualize spectrum limits and compare spectrum values to specification values.

Add upper and lower masks to the Spectrum Analyzer to visualize spectrum limits and compare spectrum values to specification values. To enable the **Spectral Mask** tab, select **Spectrum** in the **Analyzer** tab. When you click the **Upper Mask** and **Lower Mask** buttons in the **Spectral Mask** tab, a **Spectral Mask** panel opens at the bottom of the Spectrum Analyzer window. This panel provides information on pass-fail statistics of masks, names of masks currently failing or passing, and names of channels causing the failure.

You can modify the mask settings in the **Spectral Mask** tab. For more information on these settings in the UI, see Spectral Mask on page 1-2081. For modifying the channel measurements programmatically, see the `SpectralMaskConfiguration` object.

Check Spectral Masks

You can check the status of the spectral mask using the `getSpectralMaskStatus` function. This function gives details on the number of times a mask succeeded or failed, names of channels causing mask failure, and so on.

You can even use the `MaskTestFailed` event to perform an action every time the mask fails. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger it. For more details about using events, see “Events”.

Customize Visualization

Set configuration and style settings in the Spectrum Analyzer.

To control the settings of the display and labels, color and styling, click on **Settings** () in the **Analyzer** tab of the Spectrum Analyzer toolstrip.

In the dialog box that opens, you can customize the font size, plot type, y-axis properties of the spectrum plot, and color map properties of the spectrogram plot. You can change the color of the spectrum plot, background, axes, and labels and also change the line properties.

When you view the spectrum or the spectrogram, you see only the relevant options. For more details about these options, see Configuration > Spectrum Settings (DSP System Toolbox).

Display Controls

Zoom and pan axes using display controls.

To scale the plot axes, use the mouse to pan around the axes and the scroll button on your mouse to zoom in and out of the plot. Additionally, you can use the buttons that appear when you hover over the plot window.

-  — Maximize the axes, hide all labels and inset the axes values.
-  — Zoom in on the plot.
-  — Pan the plot.
-  — Autoscale the axes to fit the shown data.

Algorithms

Spectrum Estimation — Filter Bank

When you choose the **Filter Bank** method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal $x(n)$, of sample rate fs , into multiple narrow band signals $y_0(m)$, $y_1(m)$, ..., $y_{M-1}(m)$, of sample rate fs/M .

The variable M represents the number of frequency bands in the filter bank. In the Spectrum Analyzer, M is equal to the number of data points needed to achieve the specified RBW value or 1024, whichever is larger. For more information on the analysis filter bank and its implementation, see the “More About” (DSP System Toolbox) and the “Algorithm” (DSP System Toolbox) sections in the `dsp.Channelizer` object.

After the Spectrum Analyzer splits the broadband input signal into multiple narrow bands, it computes the power in each narrow frequency band using the following equation. Each Z_i value is the power estimate over that narrow frequency band.

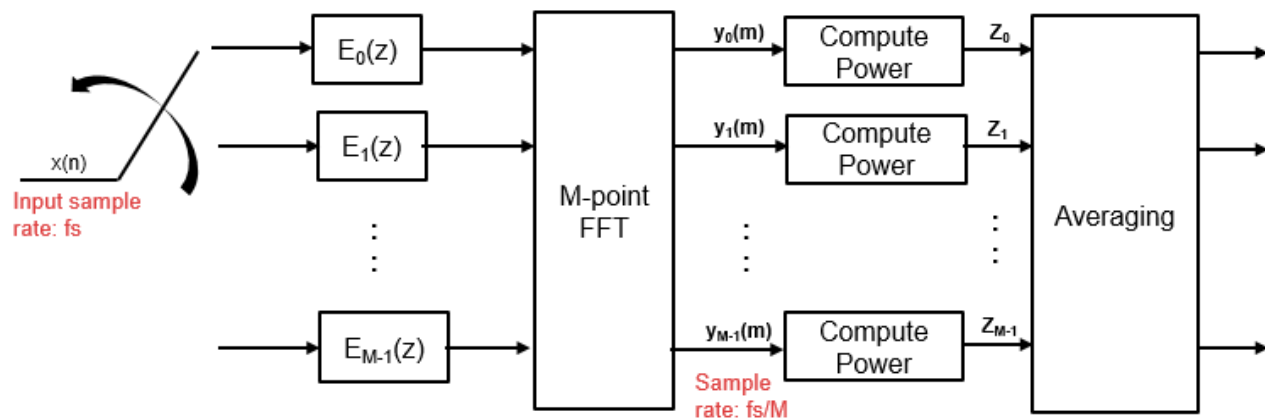

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

L is length of the narrowband signal $y_i(m)$ and $i = 1, 2, \dots, M-1$.

The power values in all the narrow frequency bands (denoted by Z_i) form the Z vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The Spectrum Analyzer averages the current Z vector with the previous Z vectors using one of the two moving average methods: video bandwidth or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 1-2102.

The Spectrum Analyzer uses the value you specify in the **RBW (Hz)** parameter to determine the input frame length. To view the **RBW (Hz)** parameter in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth property **RBW (Hz)**.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to **Auto**, the Spectrum Analyzer calculates RBW using this equation.

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- The Spectrum Analyzer calculates the number of samples $N_{samples}$ using this equation.

$$N_{samples} = \frac{F_s}{RBW}$$

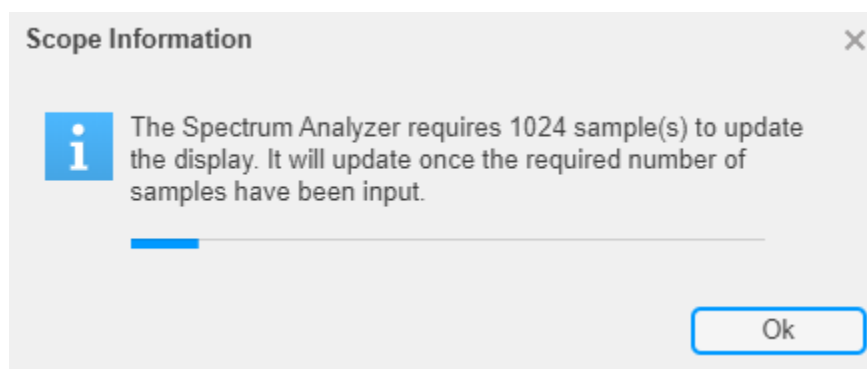

F_s is the sample rate of the input signal as specified in the **Sample Rate (Hz)** property. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you specify a resolution bandwidth using the **RBW (Hz)** parameter, you must specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two.

$$\frac{\text{span}}{\text{RBW}} > 2$$

span is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Frequency Options** section. To enable this property, set **Frequency Span** to Span and Center Frequency.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

Spectrum Estimation — Welch's Method

When you select the Welch method, the power spectrum estimate is the averaged modified periodograms.

The algorithm in the Spectrum Analyzer consists of these steps:

- 1 The block buffers the input into N -point data segments. Each data segment is split into P overlapping data segments, each of length M , overlapping by D points. The data segments can be represented as:

$$x_i(n) = x(n + iD), \quad n = 0, 1, \dots, M - 1$$

$$i = 0, 1, \dots, P - 1$$

- If $D = M/2$, the overlap is 50%.
 - If $D = 0$, the overlap is 0%.
- 2 Apply a window to each of the P overlapping data segments in the time domain.

The Spectrum Analyzer uses **RBW (Hz)** in the **Analyzer** tab to determine the data window length N_{window} internally. Then, it partitions the input signal into a number of windowed data segments.

Most window functions afford more influence to the data at the center of the set than to the data at the edges, which represents a loss of information. To mitigate that loss, the individual data

sets are commonly overlapped in time. For each windowed segment, compute the periodogram by computing the discrete Fourier transform. Then compute the squared magnitude of the result and divide the result by M .

$$P_{xx}^i(f) = \frac{1}{MU} \left| \sum_{n=0}^{M-1} x_i(n)w(n)e^{-j2\pi fn} \right|^2, \quad i = 0, 1, \dots, P-1$$

where U is the normalization factor for the power in the window function and is given by

$$U = \frac{1}{M} \sum_{n=0}^{M-1} w^2(n)$$

You can specify the window using the **Window** parameter in the **Estimation** tab of the Spectrum Analyzer toolstrip.

- 3 The Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS using the modified Periodogram estimator. For more information about the Periodogram method, see [periodogram](#).

To determine the power spectrum estimate for Welch's method, the Spectrum Analyzer averages the result of the periodograms for the last P data segments. The averaging reduces the variance, compared to the original N -point data segment. For more details on the averaging, see "Averaging Method" on page 1-2102.

$$\text{PSD}(f) = \frac{1}{P} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 4 The Spectrum Analyzer computes the power spectral density using:

$$\text{PSD}(f) = \frac{1}{P * F_s} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 5 The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by this equation.

$$P_{\text{spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times \text{NENBW}}{N_{\text{window}}}$$

6

The Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth (RBW).

$$N_{\text{samples}} = \frac{\left(1 - \frac{O_p}{100}\right) \times \text{NENBW} \times F_s}{\text{RBW}}$$

where O_p on page 1-2098 is the overlap percentage, NENBW on page 1-2098 is the normalized effective noise bandwidth, F_s on page 1-2098 is the input sample rate, and RBW on page 1-2099 is the resolution bandwidth.

The Spectrum Analyzer shows the number of samples per update in the Spectrum Analyzer status bar.

You can enable Samples/Update in the status bar only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Overlap Percentage (O_p)

The overlap percentage O_p is the value you specify in the **Overlap %** property. To view the **Overlap %** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Window Options** section.

When you increase the overlap percentage, the Spectrum Analyzer needs fewer new input samples to compute a new spectral update.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

Normalized Effective Noise Bandwidth (NENBW)

The normalized effective noise bandwidth $NENBW$ is a window parameter that measures the noise performance of the window. $NENBW$ is determined using the window length and the window coefficients, and is given by the following equation:

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n) \right]^2}$$

$w(n)$ denotes the vector of window coefficients (calculated internally). N_{window} is the window length the Spectrum Analyzer needs to compute one spectral update, and is directly related to the resolution bandwidth and normalized effective noise bandwidth.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

The rectangular window has the smallest $NENBW$, with a value of 1. All other windows have a larger $NENBW$ value. For example, the Hann window has an $NENBW$ value of approximately 1.5.

The Spectrum Analyzer shows the value of $NENBW$ in the Spectrum Analyzer status bar.

You can enable $NENBW$ only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Input Sample Rate (F_s)

F_s is the sample rate of the input signal. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section. You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **Sample Rate**.

Resolution Bandwidth (RBW)

Resolution bandwidth controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that the scope can resolve. A smaller value gives a higher spectral resolution and lowers the noise floor, that is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

You can set the resolution bandwidth through the **RBW (Hz)** property. To view **RBW (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to Auto, the Spectrum Analyzer calculates using this equation.

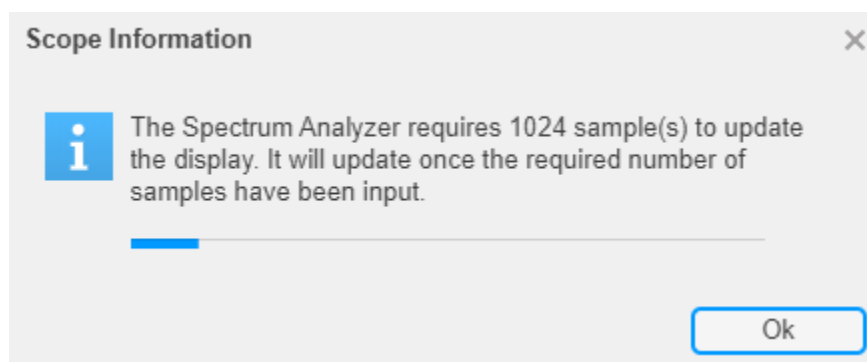

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- Specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

span is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. Spectrum Analyzer shows the span through the **Span (Hz)** property. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip, navigate to the **Frequency Options** section, and set **Frequency Span** to Span and Center Frequency.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **RBW**.

Nyquist Frequency Interval

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** tab, the Nyquist frequency interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ Hz.

When you clear the **Two-Sided Spectrum**, the Nyquist frequency interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ Hz.

Frequency Vector

When you set **Frequency (Hz)** to Auto, the software calculates the frequency vector for the frequency-domain input.

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the frequency vector is:

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right]$$

When you clear the **Two-Sided Spectrum**, the frequency vector is:

$$\left[0, \frac{SampleRate}{2}\right]$$

Occupied BW

The Spectrum Analyzer calculates *Occupied BW* using these steps.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, sum the power distributed in each frequency until the result is

$$\frac{100 - OccupiedBW\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, sum the power distributed in each frequency until the result reaches

$$\frac{100 - OccupiedBW\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The Spectrum Analyzer calculates Distortion Measurements using these steps.

- 1 Estimate spectral content by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values by treating all these values as if they belong to the peak. Using this method, the algorithm removes all spectral

content centered at DC (0 Hz) from the spectrum and records the amount of bandwidth cleared (W_0).

- 2 Determine the fundamental power (P_1) from the remaining maximum value of the displayed spectrum. Create a local estimate (Fe_1) of the fundamental frequency by computing the central moment of the power near the peak. Record the bandwidth of the fundamental power content (W_1). Then remove the power from the fundamental as in step 1.
- 3 Determine the power and width of the higher-order harmonics (P_2, W_2, P_3, W_3 , etc.) in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Remove any spectral content that decreases monotonically about the harmonic frequency from the spectrum before proceeding to the next harmonic.
- 4 After removing the DC, fundamental, and harmonic content from the spectrum, examine the power of the remaining spectrum for its sum ($P_{remaining}$), peak value ($P_{maxspur}$), and median value ($P_{estnoise}$).
- 5 Compute the sum of all the removed bandwidth as $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$.

Compute the sum of powers of the second and higher-order harmonics as $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$.

- 6 Estimate the sum of the noise power as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum})/RBW$$

Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

- 7 Then compute the metrics for SNR, THD, SINAD, and SFDR from the estimates.

$$THD = 10 \cdot \log_{10} \left(\frac{P_{harmonic}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left(\frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left(\frac{P_1}{P_{noise}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left(\frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer might exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 Ignore the DC component.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each

region, the Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.

- 4 N^{th} order intermodulation products occur at $A*F1 + B*F2$,

where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- 5 For intermodulation measurements, compute the third-order intercept (TOI) point as follows.

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = (TOI_{lower} + TOI_{upper})/2$

Where P is power in decibels of the measured power referenced to 1 milliwatt (dBm).

Averaging Method

The Spectrum Analyzer can calculate the moving average using two methods:

- Video bandwidth — The Spectrum Analyzer uses a time-domain lowpass filter to smooth the noise in the signal. The video bandwidth (VBW) filter smoothes the trace and decreases noise, and the Spectrum Analyzer applies the filter to the data before displaying it.

Video bandwidth is the bandwidth of the lowpass filter that Spectrum Analyzer uses to average or smooth the noise in the signal before displaying it in the scope. The Spectrum Analyzer computes the video bandwidth using this equation:

$$VBW = \frac{(1 - \lambda)RBW}{2\pi\lambda NENBW}$$

where,

- λ is the forgetting factor.
- RBW on page 1-2099 is the resolution bandwidth.
- NENBW on page 1-2098 is the normalized effective noise bandwidth.

Video bandwidth does not affect the level of the noise (noise floor), but only increases the signal-to-noise ratio and smoothes the trace of the noise. When you decrease the value of VBW, the signal-to-noise ratio improves.

The cutoff frequency of the video bandwidth filter is given by:

$$\omega_c = \frac{2\pi VBW}{F_s/NFFT}$$

where F_s is the input sample rate and NFFT is the number of FFT points.

The Spectrum Analyzer shows the values of sample rate, VBW, and NFFT in the status bar at the bottom of the display. To enable, right-click the status bar and select **Sample Rate**, **VBW**, and **NFFT**.

- Exponential — The moving average algorithm uses the exponential weighting method to update the weights and compute the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- λ — Forgetting factor
- w_N — Weighting factor applied to the current Z vector
- z_N — Current Z vector
- \bar{z}_{N-1} — Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$ — Effect of the previous Z vectors on the average
- \bar{z}_N — Moving average including the current Z vector

Version History

Introduced in R2014b

R2023a: Spectrum Analyzer with improved responsiveness and toolstrip interface in Simulink

In R2023a, the Spectrum Analyzer block is more responsive and its toolstrip interface is improved to provide you easy access to spectral analysis, estimation, and measurements. You can configure and display Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate PLC code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Slider Switch

Change parameter or variable value using switch with customizable appearance

**Libraries:**

Simulink / Dashboard / Customizable Blocks

Description

Use the Slider Switch block to change the value of the connected variable or parameter before or during simulation. When you use the Slider Switch block in the Customizable Blocks library, you can customize the appearance of the block to look like a real switch in your system. You can configure the switch with any number of states to customize the behavior. For example, you could design a three-way toggle switch or a gearbox. Use the Slider Switch block with other dashboard blocks to create an interactive dashboard for your model.

Note Double-clicking the Slider Switch block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the Property Inspector or open the block dialog box by:

- Double-clicking the block when the block is not selected and the model is not simulating
 - Right-clicking the block and selecting **Block Parameters** from the context menu
-

Customize Slider Switch Blocks

When you add a Slider Switch block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can add any number of states to the block. To add or delete states, use the toolbar above the block.

For each state, you can:

- Upload an image that defines the appearance of the block in the state.
- Configure the size and position of the click area for the state.
- Specify the State Value.
- Specify the State Label text, color, and position.

To upload an image for a state, use the toolbar above the block.

To resize the click area of a state, in the toolbar above the block, select the state from the drop-down menu. Then, click and drag the grab points of the yellow click area in the canvas. To reposition the click area, click and drag it in the canvas.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the State Value.
- Specify the State Label.
- Upload a foreground image.
- Upload a background image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at

once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

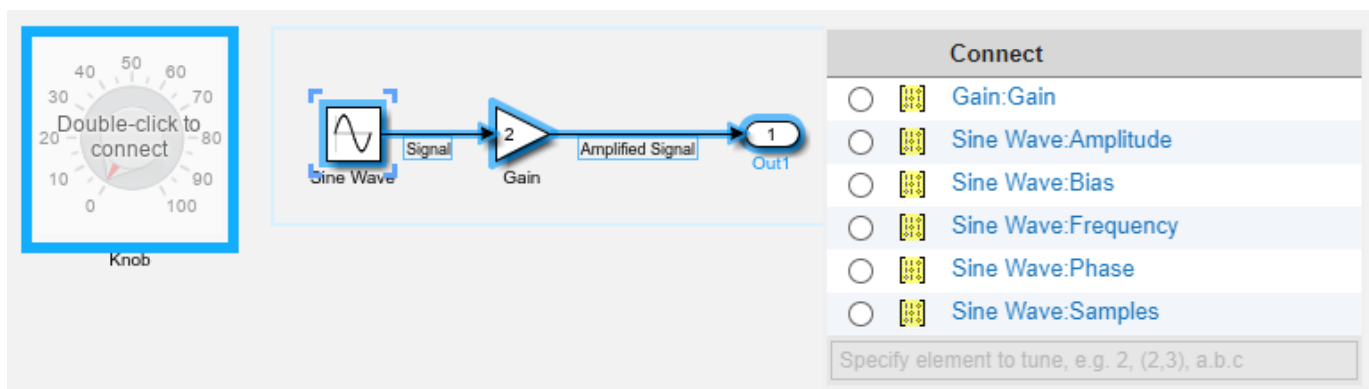

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect** and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.

- To exit bind mode, click **Done Connecting**  over the dashboard block.
-

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Label — Position of label displaying name of connected element

Hide (default) | Bottom | Top

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify `Hide`.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: `'Hide'` | `'Bottom'` | `'Top'`

Default: `'Hide'`

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States — Pairings of value with label
scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of 0.
- In the **On** state, the block assigns the connected variable or parameter a value of 1.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the + button. To delete the current state, click the - button.

Tip You can configure a variety of other parameters for a state besides the value and label in design mode. For example, you can select an image that will appear on the switch when it is in the state. To configure parameters in design mode:

- 1 Enter design mode. In the Property Inspector, on the **Design** tab, click the **Edit** button.
 - 2 On the **Design** tab, open the **States** component, expand the **Select State** section, and select the state that you want to configure from the drop-down menu.
 - 3 Configure the parameter values for the selected state, either using the toolbar above the block, or in the **States** component on the **Design** tab in the Property Inspector.
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;
leftState.Label = 'Off';
rightState.Value = 1;
rightState.Label = 'On';
switchStates = [leftState rightState];
```

Block Parameter: States

Type: two element array of structures

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Switch

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States**Select State** — Management and configuration of states

scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of **0**.
- In the **On** state, the block assigns the connected variable or parameter a value of **1**.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the **+** button. To delete the current state, click the **X** button.

To configure a state, in the **States** component, expand the **Select State** section and select the state.

You can configure the value, label text, and a variety of other parameters for the selected state in the **States** component on the **Design** tab in the Property Inspector. For example, you can select an image that will appear on the switch when it is in the state.

All changes that you make to parameter values in the **States** component are applied only to the selected state. To configure a different state, in the **Select State** section, select the state in the drop-down menu. Then, configure the parameter values of that state in the **States** component.

Tip Alternatively, you can:

- Configure the parameters for the selected state using the toolbar that appears above the switch block in design mode
 - Configure the values and label text of the states for the block using the **Parameters** tab in the Property Inspector
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.

- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;
leftState.Label = 'Off';
rightState.Value = 1;
rightState.Label = 'On';
switchStates = [leftState rightState];
```

Block Parameter: States

Type: two element array of structures

Value — State value

scalar

Each state pairs a **State Value** with a **State Label**. Specify the **State Value** that activates the state selected in the **Design** tab.

Text — State label text

string | character array

Each state pairs a **State Value** with a **State Label**. Specify the text for the **State Label** of the state selected in the **Design** tab.

Label Color — Button label font color

[r g b] vector

Choose a font color for the button label from the palette of standard colors, or specify a custom color. The color is applied to the button label for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Label X Offset — Horizontal offset of text center from left edge of block

scalar

Specify the horizontal offset of the center of the **State Label** from the left edge of the block as a ratio of the block width. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text left, and an offset with a positive value moves the text right.

Label Y Offset — Vertical offset of text center from top edge of block

scalar

Specify the vertical offset of the center of the **State Label** from the top edge of the block as a ratio of the block height. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text up, and an offset with a positive value moves the text down.

Image X Offset — Horizontal offset of left edge of image from left edge of block

scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width

scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Click Area X Offset — Horizontal offset of left edge of click area from left edge of block

scalar

Specify the horizontal offset of the left edge of the click area from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Click Area Y Offset — Vertical offset of top edge of click area from top edge of block

scalar

Specify the vertical offset of the top edge of the click area from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Click area width

scalar

Specify the click area width as a ratio of the block width.

Example: 0.5

Height — Click area height

scalar

Specify the click area height as a ratio of the block height.

Example: 0.5

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width

scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Tips

- When you want to design a circular switch that distributes the state labels and the click areas that cause state transitions on an arc, consider using the Rotary Switch block.
- To design a control that applies values to a connected variable or parameter from a continuous range, use the Knob, Horizontal Slider, or Vertical Slider blocks.

Version History

Introduced in R2021b

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Topics

[“Tune and Visualize Your Model with Dashboard Blocks”](#)

[“Simulation Pacing”](#)

[“Getting Started with Panels”](#)

Slider Switch

Toggle parameter between two values

Libraries:
Simulink / Dashboard

Description

The Slider Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Slider Switch block to a Switch block in your model and change its state during simulation. Use the Slider Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Slider Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus

or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

States — Pair values and labels
scalar and character vector

Pairs of values to assign to the connected variable or parameter and text to display on the block. Switches have two states — **Left** and **Right** — one corresponding to each switch position. Each state contains a **Value** and a **Label**.

- **Value** — Value to assign to the connected variable or parameter when the switch is in the corresponding position.
- **Label** — Text to display on the block for the corresponding position.

This table describes the default configuration for the block.

States

Position	State Value	State Label
Left	0	on
Right	1	off

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;
leftState.Label = 'Off';
rightState.Value = 1;
rightState.Label = 'On';
switchStates = [leftState rightState];
```

Block Parameter: States

Type: two element array of structures

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015a

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

Sqrt

Calculate square root, signed square root, or reciprocal of square root

Libraries:

Simulink / Math Operations
HDL Coder / HDL Floating Point Operations
HDL Coder / Math Operations

Description

The Sqrt block calculates the square root, signed square root, or reciprocal of square root on the input signal. Select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
sqrt	Square root of the input	$u^{0.5}$	sqrt
signedSqrt	Square root of the absolute value of the input, multiplied by the sign of the input	$\text{sign}(u) * u ^{0.5}$	—
rSqrt	Reciprocal of the square root of the input	$u^{-0.5}$	—

The block icon changes to match the function.

Ports

Input

Port 1 — Input signal

scalar | vector | matrix

Input signal to the block to calculate the square root, signed square root, or reciprocal of square root. The `sqrt` function accepts real or complex inputs, except for complex fixed-point signals. `signedSqrt` and `rSqrt` do not accept complex inputs. The input signal must be a floating point number.

This table summarizes the support for complex types and negative values for floating point, integer, and fixed-point data types for `sqrt`, `rSqrt`, and `signedSqrt` functions.

Function	Data Type	Complex		Negative Values
		Input	Output	
sqrt	Floating point	Yes	Yes	Yes
	Integer and fixed-point	No	No	No
rSqrt	Floating point	No	No	Yes

Function	Data Type	Complex		Negative Values
		Input	Output	
	Integer and fixed-point	No	No	No
signedSqrt	Floating point	No	Yes	Yes
	Integer and fixed-point	No	No	No

If the input is negative, set the **Output signal** to complex for all functions except `signedSqrt`.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Output signal

`scalar` | `vector` | `matrix`

Output signal that is the square root, signed square root, or reciprocal of square root of the input signal. When the input is an integer or fixed-point type, the output must be floating point.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

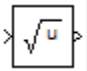

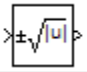

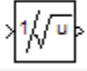

Parameters

Main

Function — Function the block performs

`sqrt` (default) | `signedSqrt` | `rSqrt`

Specify the mathematical function that the block calculates. The block icon changes to match the function you select.

Function	Block Icon
<code>sqrt</code>	
<code>signedSqrt</code>	
<code>rSqrt</code>	

Dependency

When this parameter is set to `signedSqrt`, the **Intermediate results data type** parameter is disabled.

Programmatic Use**Block Parameter:** Operator**Type:** character vector**Values:** 'sqrt' | 'signedSqrt' | 'rSqrt'**Default:** 'sqrt'**Output signal type** — Output signal type

auto (default) | real | complex

Specify the output signal type of the block.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
sqrt	real	real for nonnegative inputs NaN for negative inputs	real for nonnegative inputs NaN for negative inputs	complex
	complex	complex	error	complex
signedSqrt	real	real	real	complex
	complex	error	error	error
rSqrt	real	real	real	error
	complex	error	error	error

Programmatic Use**Block Parameter:** OutputSignalType**Type:** character vector**Values:** 'auto' | 'real' | 'complex'**Default:** 'auto'**Sample time** — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use**Block Parameter:** SampleTime**Type:** string scalar or character vector**Default:** "-1"**Algorithm****Method** — Method to compute reciprocal of square root

Exact (default) | Newton-Raphson

Specify the method for computing the reciprocal of a square root. This parameter is only valid for the `rSqrt` function.

Method	Data Types Supported	When to Use This Method
Exact	Floating point	You do not want an approximation. Note The input or output must be floating point.
Newton-Raphson	Floating-point, fixed-point, and built-in integer types	You want a fast, approximate calculation.

The Exact method provides results that are consistent with MATLAB computations.

Note The algorithms for `sqrt` and `signedSqrt` are always of Exact type, no matter what selection appears on the block dialog box.

Programmatic Use

Block Parameter: AlgorithmType

Type: character vector

Values: 'Exact' | 'Newton-Raphson'

Default: 'Exact'

Number of iterations — Number of iterations used for Newton Raphson algorithm

3 (default) | integer

Specify the number of iterations to perform the Newton-Raphson algorithm. This parameter is valid with the `rSqrt` function and the Newton-Raphson value for **Method**.

Note If you enter 0, the block output is the initial guess of the Newton-Raphson algorithm.

Programmatic Use

Block Parameter: Iterations

Type: character vector

Values: integer

Default: '3'

Data Types

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Intermediate results data type — Data type of intermediate results

```
Inherit: Inherit via internal rule (default) | Inherit: Inherit from input |
Inherit: Inherit from output | double | single | int8 | uint8 | int16 | uint16 | int32 |
uint32 | int64 | uint64 | fixdt(1,16,,0) | fixdt(1,16,2^0,0) | <data type expression>
```

Specify the data type for intermediate results when you set **Function** to `sqrt` or `rSqrt` on the **Main** pane.

The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Note To avoid overflow, the intermediate data type must be larger than or equal to a data type that can contain the square of the output data type.

Follow these guidelines on setting an intermediate data type explicitly for the square root function, `sqrt`:

Input and Output Data Types	Intermediate Data Type
Input or output is double.	Use double.
Input or output is single, and any non-single data type is <i>not</i> double.	Use single or double.
Input and output are fixed point.	Use fixed point.

Follow these guidelines on setting an intermediate data type explicitly for the reciprocal square root function, `rSqrt`:

Input and Output Data Types	Intermediate Data Type
Input is double and output is not single.	Use double.
Input is not single and output is double.	Use double.
Input and output are fixed point.	Use fixed point.

Caution Do not set **Intermediate results data type** to `Inherit:Inherit` from output when:

- You select Newton-Raphson to compute the reciprocal of a square root.
- The input data type is floating point.
- The output data type is fixed point.

Under these conditions, selecting `Inherit:Inherit` from output yields suboptimal performance and produces an error.

To avoid this error, convert the input signal from a floating-point to fixed-point data type. For example, insert a Data Type Conversion block in front of the Sqrt block to perform the conversion.

Dependencies

This parameter is disabled when the **Function** parameter is set to `signedSqrt`.

Programmatic Use

Block Parameter: `IntermediateResultsDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule' | 'Inherit: Inherit from input' | 'Inherit: Inherit from output' | 'double' | 'single', 'int8', 'uint8', 'int16,`

```
'uint16', 'int32', 'uint32', 'int64', 'uint64', fixdt(1,16,0), fixdt(1,16,2^0,0).
'<data type expression>'
```

Default: 'Inherit: Inherit via internal rule'

Output — Output data type

```
Inherit: Same as first input (default) | Inherit: Inherit via internal rule |
Inherit: Inherit via back propagation | double | single | half | int8 | int32 | uint32 |
int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...
```

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Dependencies

When input is a floating-point data type smaller than single precision, the `Inherit: Inherit via internal rule` output data type depends on the setting of the “Inherit floating-point output type smaller than single precision” configuration parameter. Data types are smaller than single precision when the number of bits needed to encode the data type is less than the 32 bits needed to encode the single-precision data type. For example, `half` and `int16` are smaller than single precision.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'Inherit: Same as first input' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'Inherit: Same as first input'

Minimum — Minimum output value for range checking

```
[] (default) | scalar
```

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the `Minimum` parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode.

For more information, see [Optimize using the specified minimum and maximum values \(Embedded Coder\)](#).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: scalar

Default: '[]'

Maximum — Maximum output value for range checking

[] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see [Optimize using the specified minimum and maximum values \(Embedded Coder\)](#).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: scalar

Default: '[]'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Saturate on integer overflow — Choose the behavior when integer overflow occurs

off (default) | on

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	double fixed point half integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Version History

Introduced in R2010a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Sqrt Function Modes

For the Sqrt block with **Function** set to `sqrt`, the code generator supports various architectures and data types.

The `sqrtfunction` architecture supports code generation for fixed-point types and floating-point types. When you use floating-point types, set “Floating Point IP Library Parameters” (HDL Coder) to **Native Floating Point**. You can specify the **LatencyStrategy** and **CustomLatency** HDL properties to choose from a range of frequency values when targeting your design on the hardware platform.

Use the **UseMultiplier** HDL block property in combination with the **LatencyStrategy** and **CustomLatency** properties to specify whether to compute the square root by using a pipelined shift and add or multiplication algorithm

Native Floating Point Settings for Different Modes

For this architecture, you can specify the **HandleDenormals** and **LatencyStrategy** settings from the **Native Floating Point** tab in the HDL Block Properties dialog box.

Architecture	Fixed-Point	Native Floating-Point	HandleDenormals	LatencyStrategy
<code>sqrtfunction</code>	✓	✓	✓	✓
<code>sqrtnewton</code>	✓	—	—	—
<code>sqrtnewtonsingle</code> <code>rate</code>	✓	—	—	—
<code>recipsqrtnewton</code>	✓	—	—	—
<code>recipsqrtnewtonsin</code> <code>glerate</code>	✓	—	—	—

HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

Architecture	Parameter	Additional cycles of latency	Description
SqrtFunction (default)	<ul style="list-style-type: none"> UseMultiplier LatencyStrategy CustomLatency 	Depends on parameter choices, output word length, and input and output fraction lengths.	<p>To specify this architecture, set Function to <code>sqrt</code> or <code>rSqrt</code>.</p> <p>Compute the square root by using a pipelined shift/addition algorithm or multiplication-based algorithm.</p> <p>The <code>SqrtFunction</code> architecture has a maximum latency that is determined by the output word length, and input and output fraction lengths, for fixed-point data. For example, the maximum latency is 11 for output word length of 17.</p> <p>To see the latency calculation, see HDLMathLib <code>Sqrt</code>.</p> <p>Improve design frequency and reduce resource utilization by setting the UseMultiplier to <code>off</code> and LatencyStrategy to <code>inherit</code>.</p>
SqrtNewton	Iterations	Iterations + 3	<p>To specify this architecture, set Function to <code>sqrt</code>.</p> <p>Use the iterative Newton method. Select this option to optimize area.</p> <p>The default value for <code>Iterations</code> is 3.</p> <p>The recommended value for <code>Iterations</code> is from 2 through 10. If <code>Iterations</code> is outside the recommended range, HDL Coder generates a message.</p>
SqrtNewtonSingleRate	Iterations	(Iterations * 4) + 6	<p>To specify this architecture, set Function to <code>sqrt</code>.</p> <p>Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation.</p> <p>The default value for <code>Iterations</code> is 3.</p> <p>The recommended value for <code>Iterations</code> is from 2 through 10. If <code>Iterations</code> is outside the recommended range, the coder generates a message.</p>

Architecture	Parameter	Additional cycles of latency	Description
RecipSqrtNewton	Iterations	Iterations + 2	To specify this architecture, set Function to rSqrt. Use the iterative Newton method. Select this option to optimize area.
RecipSqrtNewtonSingleRate	Iterations	(Iterations * 4) + 5	To specify this architecture, set Function to rSqrt. Use the single rate pipelined Newton method. Select this option to optimize speed, or if you want a single rate implementation.

The Newton-Raphson iterative method:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i(1.5 - 0.5ax_i^2)$$

ReciprocalRsqrtBasedNewton and ReciprocalRsqrtBasedNewtonSingleRate implement the Newton-Raphson method with:

$$f(x) = \frac{1}{x^2} - 1$$

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
Iterations	Number of iterations for SqrtNewton or SqrtNewtonSingleRate implementation.
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
UseMultiplier	Select algorithm for SqrtFunction implementation. By default, this property is set to off, and the block computes square root by using the shift-add algorithm. When the property is set to on, the square root is computed by using multipliers. Increase design frequency and reduce resource utilization by setting the UseMultiplier to off and LatencyStrategy to inherit .

General	
LatencyStrategy	<p>Specify whether to map the blocks in your design to MAX, MIN, CUSTOM, or ZERO latency for fixed-point and floating-point types. The default is MAX. The block settings for floating-point types overrides the model-level settings. For fixed-point types, the block-level setting determines the latency strategy. See also “LatencyStrategy” (HDL Coder) .</p> <p>Increase design frequency and reduce resource utilization by setting the UseMultiplier to off and LatencyStrategy to inherit .</p>
CustomLatency	<p>When LatencyStrategy is set to CUSTOM and if you use fixed-point types, use this property to specify a custom latency value between ZERO and MAX for fixed-point types. For floating-point types, this value becomes the custom latency of the operator. See also “NFPCustomLatency” (HDL Coder).</p>

Native Floating Point	
HandleDenormals	<p>Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is inherit. See also “HandleDenormals” (HDL Coder).</p>

Restrictions

- Input must be an unsigned scalar value.
- Output is a fixed-point scalar value.

Squeeze

Remove singleton dimensions from multidimensional signal

Libraries:
Simulink / Math Operations

Description

The Squeeze block removes singleton dimensions from its multidimensional input signal. A singleton dimension is any dimension whose size is one. The Squeeze block operates only on signals whose number of dimensions is greater than two. Scalar, vector, and matrix signals pass through the Squeeze block unchanged.

Ports

Input

Port_1 — Multidimensional input signal
multidimensional signal

Input signal that has any singleton dimensions removed in the output.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal with no singleton dimensions
multidimensional signal

Output signal with no singleton dimensions. For example, a multidimensional array of size 3-by-1-by-2 changes into a 3-by-2 signal. If there are no singleton dimensions in the input, then the input signal is passed through unchanged to the output.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

State Reader

Read a block state

Libraries:
Simulink / Signal Routing

Description

The State Reader block reads the current state of a supported state owner block.

State Reader blocks can read state from these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- Discrete FIR Filter
- Integrator
- Second-Order Integrator
- Output of conditional subsystem blocks such as Enabled Subsystem, Triggered Subsystem, and Function-Call Subsystem
- S-Function with multiple discrete states

To configure an S-Function block as a state owner block, each data type work vector must be declared as a discrete state vector using `ssSetDWorkUsedAsDState` and named using `ssSetDWorkName` or `ssSetDWorkRTWIdentifier` in `mdlInitializeSizes`.

Tip You can determine whether a block is a supported state owner block by the value of the block's `IsStateOwnerBlock` parameter. The expression

```
get_param(blk, 'IsStateOwnerBlock')
```

where `blk` is a block name or handle, returns 'on' if the block is a supported state owner block and 'off' otherwise.

To add a State Reader or State Writer block to your model, click on a state owner block to highlight it. Then, from the current block tab of the Simulink toolstrip, click **Reader-Writer**. From the menu, select **State Reader Block** or **State Writer Block**.

Note The current block tab of the toolstrip might be labeled with the name of the highlighted block, for example, **Output**, or it might be labeled **Block**, depending on the type of block you highlight.

If the state owner block has multiple states, then the State Reader or State Writer block dialog opens. Select a state from the **State Owner Selector Tree**.

Note Before adding a State Reader or State Writer block for a Second-Order Integrator block, you must explicitly name the states. See “Specifying the State Names” on page 1-1935.

After you create a State Reader or State Writer block, a  badge appears above the state owner block, and the name of the state owner block appears next to the State Reader or State Writer block.

A State Reader or State Writer block cannot remain in the same system as its state owner block. After you create a State Reader or State Writer block, cut and paste it to move it to the desired location within the model hierarchy.

Alternatively, you can add a State Reader or State Writer block to your model from the Simulink Library Browser, then set the **State owner block** parameter from the block parameters dialog.

Note When you create a library block with a State Reader or State Writer block, you must also include the corresponding state owner block in the library block.

You can select a State Reader or State Writer block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Ports

Output

Out — State value

scalar | vector

State value read from a state owner block.

The dimension of the output is the dimension of the full state vector. Refer to the **Initial conditions** parameter for specific blocks. For example, for a Delay block with a **Delay length** of N, the State Reader block returns a state vector of length [1xN].

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

State owner block — Name of state owner block

none (default)

Name of state owner block whose state this block is reading. To change the state owner block, select a block from the **State Owner Selector Tree**.

Note If the name of a state owner block contains a slash (/), the slash appears as two slashes (//) in the State Reader block parameters dialog. This notation distinguishes the slash in the block name itself from slashes that separate names at different levels of the model hierarchy.

Programmatic Use

Block Parameter: StateOwnerBlock

Type: character vector

Value: '' | '<model path/block name>'

Default: ''

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

State Writer

Write to a block state

Libraries:
Simulink / Signal Routing

Description

The State Writer block sets the state of a supported state owner block.

State Writer blocks can write state to these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- Discrete FIR Filter
- Integrator
- Second-Order Integrator
- Output of conditional subsystem blocks such as Enabled Subsystem, Triggered Subsystem, and Function-Call Subsystem
- S-Function with multiple discrete states

To configure an S-Function block as a state owner block, each data type work vector must be declared as a discrete state vector using `ssSetDWorkUsedAsDState` and named using `ssSetDWorkName` or `ssSetDWorkRTWIdentifier` in `mdlInitializeSizes`.

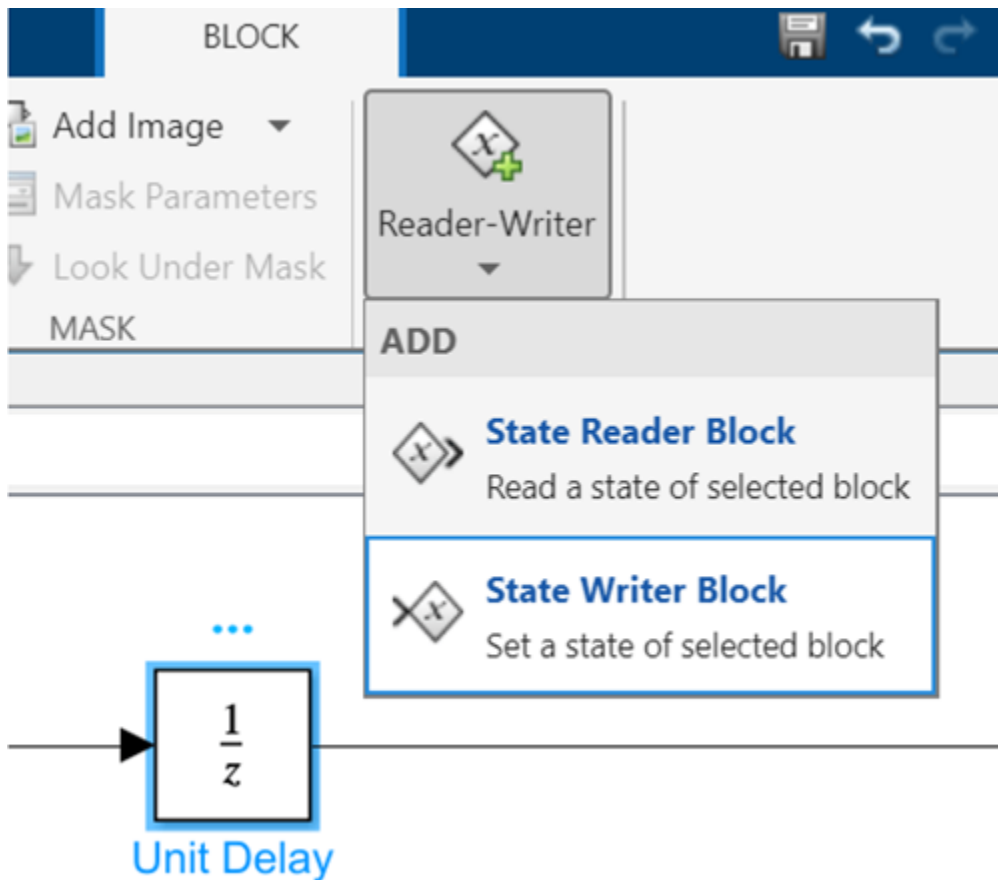

Tip You can determine whether a block is a supported state owner block by the value of the block's `IsStateOwnerBlock` parameter. The expression

```
get_param(blk, 'IsStateOwnerBlock')
```

where `blk` is a block name or handle, returns 'on' if the block is a supported state owner block and 'off' otherwise.

To add a State Reader or State Writer block to your model, click on a state owner block to highlight it. Then, from the current block tab of the Simulink toolstrip, click **Reader-Writer**. From the menu, select **State Reader Block** or **State Writer Block**.

Note The current block tab of the toolstrip might be labeled with the name of the highlighted block, for example, **Output**, or it might be labeled **Block**, depending on the type of block you highlight.

If the state owner block has multiple states, then the State Reader or State Writer block dialog opens. Select a state from the **State Owner Selector Tree**.

Note Before adding a State Reader or State Writer block for a Second-Order Integrator block, you must explicitly name the states. See “Specifying the State Names” on page 1-1935.

After you create a State Reader or State Writer block, a  badge appears above the state owner block, and the name of the state owner block appears next to the State Reader or State Writer block.

A State Reader or State Writer block cannot remain in the same system as its state owner block. After you create a State Reader or State Writer block, cut and paste it to move it to the desired location within the model hierarchy.

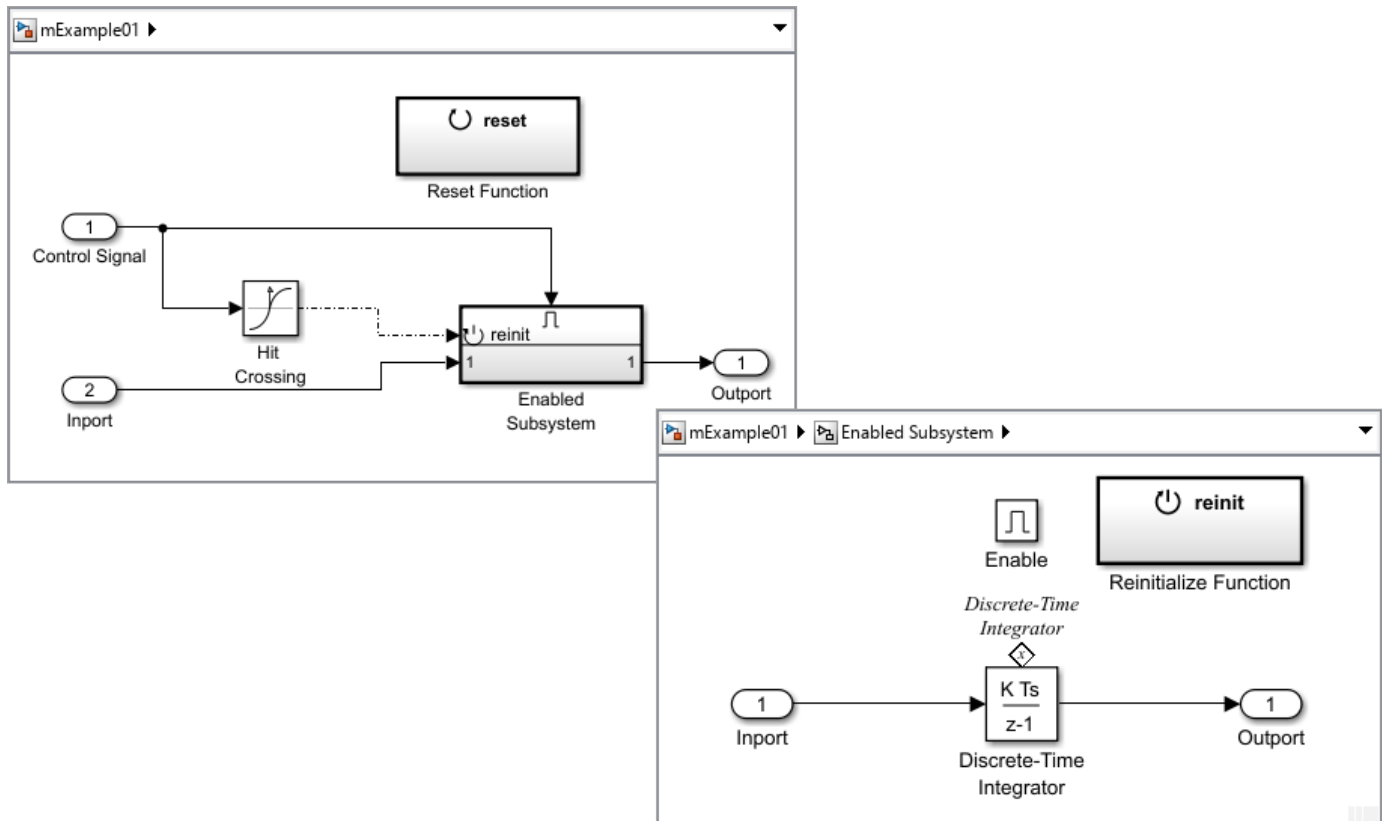

Alternatively, you can add a State Reader or State Writer block to your model from the Simulink Library Browser, then set the **State owner block** parameter from the block parameters dialog.

Note When you create a library block with a State Reader or State Writer block, you must also include the corresponding state owner block in the library block.

You can select a State Reader or State Writer block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select **Related Blocks**  from the action bar. When multiple blocks correspond to the selected block, a list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Limitations

The State Writer block does not support resettable states inside an Enabled Subsystem block. You must use a Reinitialize Function block to implement resettable states inside an Enabled Subsystem block. An external signal received at the enable port of the Enabled Subsystem triggers the execution of the Reinitialize Function block inside the subsystem. For more information on configuring Reinitialize Function block settings, see “Reinitialize States of Blocks in Subsystem”.

Ports

Input

In — State value
scalar | vector

State value written to a state owner block.

When writing to a state owner block with an input scalar, the scalar value is expanded to match the dimension of the state. All elements of the state are set to the same value.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

State owner block — Name of state owner block
none (default)

Name of state owner block whose state this block is writing. To change the state owner block, select a block from the **State Owner Selector Tree**.

Note If the name of a state owner block contains a slash (/), the slash appears as two slashes (//) in the State Writer block parameters dialog. This notation distinguishes the slash in the block name itself from slashes that separate names at different levels of the model hierarchy.

Programmatic Use**Block Parameter:** StateOwnerBlock**Type:** character vector**Value:** '' | '<model path/block name>'**Default:** ''**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

State-Space

Implement linear state-space system

Libraries:
Simulink / Continuous

Description

The State-Space block implements a system whose behavior you define as

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx + Du \\ x|_{t=t_0} &= x_0,\end{aligned}$$

where x is the state vector, u is the input vector, y is the output vector, and x_0 is the initial condition of the state vector. The A , B , C , and D matrices can be specified as either sparse matrices or dense matrices. The matrix coefficients must have these characteristics:

- A must be an n -by- n matrix, where n is the number of states.
- B must be an n -by- m matrix, where m is the number of inputs.
- C must be an r -by- n matrix, where r is the number of outputs.
- D must be an r -by- m matrix.

In general, the block has one input port and one output port. The number of rows in C or D matrix is the same as the width of the output port. The number of columns in the B or D matrix are the same as the width of the input port. If you want to model an autonomous linear system with no inputs, set the B and D matrices to empty. In this case, the block acts as a source block with no input port and one output port, and implements the following system:

$$\begin{aligned}\dot{x} &= Ax \\ y &= Cx \\ x|_{t=t_0} &= x_0.\end{aligned}$$

Simulink software converts a matrix containing zeros to a sparse matrix for efficient multiplication.

Ports

Input

Port_1 — Input signal
scalar | vector

Real-valued input vector of type `double`, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-2149.

Data Types: `double`

Output

Port_1 — Output vector

scalar | vector

Real-valued output vector of data type `double`, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-2149.

Data Types: `double`

Parameters

A — Matrix coefficient, A

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient A, as a real-valued n -by- n matrix, where n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-2149.

Programmatic Use

Block Parameter: A

Type: character vector, string

Values: scalar | vector | matrix | sparse matrix

Default: '1'

B — Matrix coefficient, B

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient B, as a real-valued n -by- m matrix, where n is the number of states and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-2149.

Programmatic Use

Block Parameter: B

Type: character vector, string

Values: scalar | vector | matrix | sparse matrix

Default: '1'

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient C as a real-valued r -by- n matrix, where r is the number of outputs and n is the number of states. For more information on the matrix coefficients, see “Description” on page 1-2149.

Programmatic Use

Block Parameter: C

Type: character vector, string

Values: scalar | vector | matrix | sparse matrix
Default: '1'

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient **D** as a real-valued r -by- m matrix, where r is the number of outputs and m is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-2149.

Programmatic Use

Block Parameter: D

Type: character vector, string

Values: scalar | vector | matrix | sparse matrix

Default: '1'

Initial conditions — Initial state vector

0 (default) | scalar | vector

Specify the initial state vector.

Limitations

The initial conditions of this block cannot be `inf` or `NaN`.

Programmatic Use

Block Parameter: X0

Type: character vector, string

Values: scalar | vector

Default: '0'

Parameter tunability — Choose tunable representation of block parameters

Auto (default) | Optimized | Unconstrained

Tunability level of the state-space matrices (A,B,C, and D) for accelerated simulation modes and deployed simulations using the Simulink Compiler™. When set to `Auto`, Simulink chooses the appropriate parameter tunability level.

For sparse matrix coefficients, set the parameter to `Optimized` to allow tunability of non-zero elements while keeping the pattern and number of non-zero elements constant. Set this parameter to `Unconstrained` to allow all elements to be tunable, so long as the number of non-zero elements is kept constant, that is, you can change the pattern of the sparse matrix.

For dense matrix coefficients, select `Optimized` to allow tunability of all matrix elements, provided the number of non-zero elements initially specified in the matrix is kept constant. Set this parameter to `Unconstrained` to allow full tunability of all matrix elements.

Note To tune the **D** matrix of the block when $D = 0$, you must enable the **Allow non-zero values for D matrix initially specified as zero** parameter.

Programmatic Use**Block Parameter:** ParameterTunability**Type:** character vector | string**Values:** 'Auto' | 'Optimized' | 'Unconstrained'**Default:** 'Auto'**Allow non-zero values for D matrix initially specified as zero** — Allow tunability of D matrix when $D = 0$

off (default) | on

Enable this parameter to support tunability of **D** even when $D = 0$.

Note Enabling this parameter enables direct feedthrough for the State-Space block.

Programmatic Use**Block Parameter:** AllowTunableDMatrix**Type:** character vector | string**Values:** 'off' | 'on'**Default:** 'off'**Absolute tolerance** — Absolute tolerance for computing block states

auto (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify `auto` or `-1`.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use**Block Parameter:** AbsoluteTolerance**Type:** character vector, string**Values:** 'auto' | '-1' | any positive real-valued scalar or vector**Default:** 'auto'**State Name (e.g., 'position')** — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use

Block Parameter: ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Discrete State-Space | Transfer Fcn

Topics

“State”

Step

Generate step function

Libraries:
Simulink / Sources

Description

The Step block provides a step between two definable levels at a specified time. If the simulation time is less than the **Step time** parameter value, the block's output is the **Initial value** parameter value. For simulation time greater than or equal to the **Step time**, the output is the **Final value** parameter value.

The numeric block parameters must be of the same dimensions after scalar expansion. If the **Interpret vector parameters as 1-D** option is off, the block outputs a signal of the same dimensions and dimensionality as the parameters. If the **Interpret vector parameters as 1-D** option is on and the numeric parameters are row or column vectors (that is, single-row or column 2-D arrays), the block outputs a vector (1-D array) signal. Otherwise, the block outputs a signal of the same dimensionality and dimensions as the parameters.

Ports

Output

Port_1 — Output step signal
scalar | vector

Output step function signal defined by the parameters **Step time**, **Initial value**, and **Final value**.

Data Types: double | single

Parameters

Step time — Time when step occurs

1 (default) | scalar

Specify the time, in seconds, when the output jumps from the **Initial value** parameter to the **Final value** parameter.

Programmatic Use

Block Parameter: Time

Type: character vector

Values: '1' | real- or complex-valued scalar, vector, or matrix

Default: '1'

Initial value — Output value before step

0 (default) | scalar

Specify the block output until the simulation time reaches the **Step time** parameter.

Programmatic Use

Block Parameter: Before

Type: character vector

Values: '1' | real- or complex-valued scalar, vector, or matrix

Default: '0'

Final value — Output value after step

1 (default) | scalar

Specify the block output when the simulation time reaches and exceeds the **Step time** parameter.

Programmatic Use

Block Parameter: After

Type: character vector

Values: '1' | real- or complex-valued scalar, vector, or matrix

Default: '1'

Sample time — Sample rate

0 (default) | scalar

Specify the sample rate of step. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '0'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use

Block Parameter: VectorParams1D

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector | string

Values: 'off' | 'on'

Default: 'on'

Output data type — Output data type

double (default) | Inherit: Inherit via back propagation | single | <data type expression>

Output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select `Inherit: Inherit via back propagation`, the block uses the data type of the driving block.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'double' | 'single' | <data type expression>

Default: 'double'

Mode — Category of data type

Inherit (default) | Built in | Expression

Category of data type, specified as `Inherit`, `Built in`, or `Expression`. For more information on using this parameter, see “Specify Data Types Using Data Type Assistant”.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- When you select `Inherit`, Simulink inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

- When you select `Off`, Simulink ignores the data type override setting of its context.

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Dependencies

To enable this parameter, click the **Show data type assistant** button, and set the **Mode** to **Built in**.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Block Characteristics

Data Types	double

Stop Simulation

Stop simulation when input is nonzero

Libraries:
Simulink / Sinks
HDL Coder / Sinks

Description

The Stop Simulation block stops the simulation when the input is nonzero. The simulation completes the current time step before terminating. If the block input is a vector, any nonzero vector element causes the simulation to stop.

When you use the Stop Simulation block in a For Iterator subsystem, the stop action occurs after execution of *all* iterations in the subsystem during a time step. The stop action does not interrupt execution until the start of the next time step.

You cannot use the Stop Simulation block to pause the simulation. To create a block that pauses the simulation, see “Pause Simulation Using Assertion Blocks”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Stop simulation when input signal is nonzero. This port accepts real signals of `double` or `Boolean` data types.

Data Types: `double` | `Boolean`

Block Characteristics

Data Types	Boolean double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely varying execution times. While the code is functionally valid and acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Generated code stops executing when the stop condition is true.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used to stop simulation when used with subsystems that generates code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

String Compare

Compare two input strings

Libraries:
Simulink / String

Description

String Compare compares two strings. To see if two strings are identical, use this block. You can specify if the match is case sensitive and how much of the string to compare.

Ports

Input

Port_1 — First string to compare
scalar

First string to compare, specified as a scalar.

Data Types: `string`

Port_2 — Second string to compare
scalar

Second string to compare, specified as a scalar.

Data Types: `string`

Output

Port_1 — True or false result
scalar

True or false result, specified as a scalar:

- 1 — Match.
- 0 — No match.

Data Types: `Boolean`

Parameters

Case sensitive — Case sensitivity for string comparison
on (default) | off

Case sensitivity for string comparison:

on

Consider string case when comparing strings.

off

Do not consider string case when comparing strings.

Programmatic Use**Block Parameter:** CaseSensitive**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Compare Option** — Amount of characters to compare

Entire string (default) | First N characters

Amount of string to compare:

- Entire string — Compare both entire strings.
- First N characters — Compare the first *N* characters of both strings.

Dependencies

Setting this parameter to First N characters enables the **Number of characters** parameter.

Programmatic Use**Block Parameter:** CompareOption**Type:** character vector**Values:** 'Entire string' | 'First N characters'**Default:** 'Entire string'**Number of characters** — Number of characters to compare

1 (default) | scalar

Number of characters to compare

Dependencies

This parameter is enabled when the **Compare Option** parameter is set to First N characters.

Programmatic Use**Block Parameter:** CompareOption**Type:** character vector**Values:** scalar**Default:** '1'**Block Characteristics**

String Concatenate

Concatenate input strings to form one output string

Libraries:
Simulink / String

Description

The String Concatenate block concatenates multiple input strings, in order of their input, to form one output string. Use this block if you want to combine multiple strings into a single string.

Ports

Input

Port_1 — First input string
scalar

First input string, specified as a scalar.

Data Types: `string`

Port_2 — Second input string
scalar

Second input string, specified as a scalar.

Data Types: `string`

Output

Port_1 — Concatenated string
scalar

Concatenated string, specified as a scalar.

Data Types: `string`

Parameters

Number of Inputs — Number of input strings
scalar

Number of input strings to concatenate, specified as a scalar. You can specify from 2 to 512 input ports.

Programmatic Use**Block Parameter:** Inputs**Type:** character vector**Values:** scalar from 2 to 512**Default:** '2'**Output data type** — Output data type`string (default) | <data type expression> | scalar`

Output data type, specified using the string data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(N)`. For example, `stringtype(128)` creates a string data type with a maximum length of 128 characters.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use**Block Parameter:** OutDataTypeStr**Type:** character vector**Values:** 'string' | <data type expression>**Default:** 'string'**Mode** — Category of data`stringtype(128) (default) | scalar`

Use the `stringtype` function, for example, `stringtype(128)`.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

“Simulink Strings”

String Constant

Output specified string

Libraries:
Simulink / String

Description

The String Constant block outputs a string specified by the **String** parameter. Use this block when you want a constant whose type is string.

Ports

Output

Port_1 — Output string
scalar

Output string, specified as a scalar.

Data Types: `string`

Parameters

String — Input string
"Hello!" (default) | scalar

Input string, specified as a scalar.

Programmatic Use

Block Parameter: `String`

Type: character vector

Values: `'"Hello!"'` | scalar

Default: `'"Hello!"'`

Output data type — Output data type
`string` (default) | `<data type expression>`

Output data type, specified using the `string` data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(N)`. For example, `stringtype(31)` creates a string data type with a maximum length of 31 characters.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'string' | *<data type expression>*

Default: 'string'

Mode — Category of data

string (default) | scalar

Use the `stringtype` function, for example, `stringtype(31)`.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Block Characteristics

Data Types	string
Direct Feedthrough	no
Multidimensional Signals	no

String Contains, String Starts With, String Ends With

Determine if string contains, starts with, or ends with pattern

Libraries:
Simulink / String

Description

The String Contains, String Starts With, and String Ends With blocks determine if a string (**str**) contains, starts with, or ends with a pattern (**sub**).

The String Contains, String Starts With, and String Ends With blocks are identical. When **Function** is set to Contains, the block determines if the string contains a specified pattern. When **Function** is set to Starts with, the block determines if the string starts with a specified pattern. When **Function** is set to Ends with, the block determines if the string ends with a specified pattern.

Ports

Input

str — String to search
scalar

String to search for the pattern in, specified as a scalar.

Data Types: `string`

sub — String pattern to search for
scalar

String pattern to search for in string, specified as a scalar.

Data Types: `string`

Output

T/F — String pattern detected
1 | 0

Whether the string pattern was detected, returned as detected (1) or not detected (0).

Data Types: `Boolean`

Parameters

Case sensitive — Case sensitivity
on (default) | off

Case sensitivity for the pattern detection:

on

Consider string case when searching for the pattern.

off

Do not consider string case when searching for the pattern.

Programmatic Use

Block Parameter: CaseSensitive

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Function — Pattern search function

Contains | Starts with | Ends with

Pattern search function, specified as:

- Contains

Search for the pattern anywhere in the string. This is the default for the String Contains block.

- Starts with

Search for the pattern only at the beginning of the string. This is the default for the String Starts With block.

- Ends with

Search for the pattern only at the end of the string. This is the default for the String Ends With block.

Programmatic Use

Block Parameter: Function

Type: character vector

Values: 'Contains' | 'Starts with' | 'Ends with'

Default: 'Contains' for String Contains block, 'Starts with' for String Starts With block, 'Ends with' for String Ends With block

Block Characteristics

Data Types	Boolean string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

“Simulink Strings”

String Count

Count occurrences of pattern in string

Libraries:
Simulink / String

Description

The String Count block counts the occurrences of the pattern (**sub**) in a string (**str**). If the input at **sub** matches part or all of the input at **str**, the block counts the occurrence as 1.

Ports

Input

str — String to search
scalar

String to search for the pattern in, specified as a scalar.

Data Types: `string`

sub — String pattern to search for
scalar

String pattern to search for in string, specified as a scalar.

Data Types: `string`

Output

n — Number of times pattern was found in string
scalar

Number of times the string pattern was found in the string, `str`, returned as a scalar.

Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`

Parameters

Case sensitive — Case sensitivity
`on` (default) | `off`

Case sensitivity for the string count:

`on`

Consider string case when counting found strings.

off

Do not consider string case when counting found strings.

Programmatic Use

Block Parameter: CaseSensitive

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output data type — Output data type

Inherit: `Inherit via internal rule (default)` | `Inherit via back propagation` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `<data type expression>`

Output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.

Click the Show data type assistant button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | `<data type expression>`

Default: 'Inherit: Inherit via internal rule'

Mode — Category of data type

`Inherit (default)` | `Built in` | `Expression`

Category of data type, specified as `Inherit`, `Built in`, or `Expression`. For more information on using this parameter, see “Specify Data Types Using Data Type Assistant”.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

“Simulink Strings”

String Find

Return index of first occurrence of pattern string

Libraries:
Simulink / String

Description

The String Find block returns the index of the first occurrence of the pattern string **sub** in the text string **str**.

Ports

Input

str — String in which to find pattern
scalar

String in which to find pattern (**str**), specified as a scalar.

Data Types: `string`

sub — Pattern
scalar

Pattern to be found in string (**str**), specified as a scalar.

Data Types: `string`

Output

idx — Position index of found pattern
scalar

Position index of the found pattern, specified as a positive integer scalar.

- If the block does not find the pattern, it returns -1.
- If the **sub** parameter is empty (""), the block returns 1, indicating that it matched the beginning of the searched string.

Data Types: `int8` | `int16` | `int32`

Parameters

Output data type — Output data type

Inherit: `Inherit via internal rule (default)` | `Inherit via back propagation` | `int8` | `int16` | `int32` | `<data type expression>`

Output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- **Inherit: Inherit via internal rule** — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware.
- **Inherit: Inherit via back propagation** — Use data type of the driving block.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'int8' | 'int16' | 'int32' | <data type expression>`

Default: `'Inherit: Inherit via internal rule'`

Mode — Category of data type

`Inherit (default) | Built in | Expression`

Category of data type, specified as `Inherit`, `Built in`, or `Expression`. For more information on using this parameter, see “Specify Data Types Using Data Type Assistant”.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Block Characteristics

Data Types	<code>integer string</code>
Direct Feedthrough	<code>yes</code>
Multidimensional Signals	<code>no</code>
Variable-Size Signals	<code>no</code>
Zero-Crossing Detection	<code>no</code>

Version History

Introduced in R2018a

String Length

Output number of characters in input string

Libraries:
Simulink / String

Description

The String Length block outputs the number of characters in the input string. For example, you can use the String Length block to move focus of attention to a particular location in a string.

Ports

Input

Port_1 — Input string
scalar

Input string, specified as a scalar.

Data Types: `string`

Output

Port_1 — Number of characters
scalar

Number of characters in the input string, specified as a scalar.

Data Types: `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`

Parameters

Output data type — Output data type

Inherit: `Inherit via internal rule (default)` | `Inherit: Inherit via back propagation` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `<data type expression>`

Output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | *<data type expression>*

Default: 'Inherit: Inherit via internal rule'

Mode — Category of data type

Inherit (default) | Built in | Expression

Category of data type, specified as Inherit, Built in, or Expression. For more information on using this parameter, see “Specify Data Types Using Data Type Assistant”.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2018a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).

String to ASCII

Convert string signal to uint8 vector

Libraries:
Simulink / String

Description

The String To ASCII block converts a string signal to a uint8 vector. The block converts each character in the string to its corresponding ASCII value. For example, the block converts the input string "Hello" to [72 101 108 108 111].

Ports

Input

Port_1 — Input string signal
scalar

Input string signal, specified as a scalar.

Data Types: `string`

Output

Port_1 — Converted uint8 vector signal
vector

Converted `uint8` vector signal of ASCII characters from input string signal, specified as a vector. The block converts each element in the string into its ASCII character equivalent and outputs the ASCII equivalents as a vector. If there are fewer characters than the maximum length, the block fills the remaining space with zeros at simulation. At code generation, the block fills the remaining space with null characters.

Data Types: `uint8`

Parameters

Output vector size — Size of output vector
31 (default) | scalar

Size of output string vector, specified as a scalar.

Programmatic Use

Block Parameter: `OutputVectorSize`

Type: character vector

Values: scalar

Default: '31'

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2018a

String to Double

Convert string signal to double signal

Libraries:
Simulink / String

Description

Scan String scans an input string and converts it to signals per the format specified by the **Format** parameter. The block converts values to their decimal (base 10) representation and outputs the results as numeric or string signals. For example, if the **Format** parameter is set to "%s is %f.", the block outputs two parts, a string signal and a single signal. If the input is the string "Pi is 3.14", the two outputs are "Pi" and "3.14".

The Scan String, String to Double, and String to Single blocks are identical blocks. When configured for String to Double, the block converts the input string signal to a double numerical output. When configured for String to Single, the block converts the input string signal to a single numerical output.

For code generation, configure models that contain this block for non-finite number support by selecting the **Configuration Parameters > Code Generation > Interface > Support non-finite numbers** check box.

Ports

Input

Port_1 — Input string
scalar

Input string, specified as a scalar.

Data Types: `string`

Output

d — Output data whose format matches %d format
scalar

Output data whose format matches specified format, defined as a scalar. Total maximum number of outputs is 128.

If the block cannot match an input string to a format operator specified in **Format**, it returns a warning and outputs an appropriate value (0 or "") for each unmatched format operator.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

f — Output data whose format matches %f format
scalar

Output data whose format matches the %f format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Port_N — Output data whose format matches N format
scalar

Output data whose format matches N format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Format — Format operator for input
"%lf" (default) | format string | character vector

Format operator for input, specified as a scalar. If the block cannot match the input string with the specified format, it returns 0. The return of 0 differs from the `sscanf` function return, which is an empty matrix if the function cannot match the input with the specified format.

- For the String to Double block, this parameter has a default value of %lf.
- For the String to Single block, this parameter has a default value of %f.

For more information about acceptable format operators, see the Algorithms section.

Programmatic Use

Block Parameter: Format

Type: character vector

Values: '<filename>'

Default: '"%lf"' if the block is String to Double, '"%f"' if the block is String to Single

Block Characteristics

Data Types	<code>double</code> <code>integer</code> <code>single</code> <code>string</code>
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The Scan String block uses this format specifier prototype:

%[width][length]specifier

Numeric Fields

This table lists available conversion specifiers to convert text to numeric outputs. The block converts values to their decimal (base 10) representation.

Output Port Data Type	Conversion Specifier	Description
Integer, signed	%d	Base 10
Integer, unsigned	%u	Base 10
Floating-point number	%f, %e, or %g	Floating-point values. Input fields can contain NaN (case sensitive). Input fields that represents floating-point numbers can include leading + or - symbols and exponential notation using e or E. The conversion specifiers %f, %e, and %g all treat input fields the same way.

Character Fields

This table lists available conversion specifiers to convert text so that the output is a character array.

Character Field Type	Conversion Specifier	Description
String scalar	%s	Read the text until the block encounters white space.
	%c	Read any single character, including white space. To read multiple characters at a time, specify field width. For example, %10c reads 10 characters at a time.
Pattern-matching	%[. . .]	Read only characters in the brackets up to the first nonmatching character or white space. Example: %[mus] reads 'summer' as 'summ'.
	%[^ . . .]	Read any characters not in the brackets up to the first matching character or white space. Example: %[^m] reads 'summer' as 'su'.

Optional Operators

- **Field Width** — To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, %10s reads up to 10 characters at a time, including white space. %4f reads up to four digits at a time, including the decimal point.
- **Literal Text to Ignore** — This block must match the specified text immediately before or after the conversion specifier.

Example: Hell%s reads "Hello!" as "o!".

Length Specifiers

The Scan String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings.

Length	i	u	f e g	s c
No length specifier	int	unsigned int	single	string
<code>h</code>	short	unsigned short	—	—
<code>l</code>	long	unsigned long	double	—

Notes for Specifiers that Specify Integer Data Types (d, u)

- Target `int`, `long`, `short` type sizes are controlled by settings in the **Configuration Parameters > Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. For this example, the Scan String block requires that the output type be exactly `int32`. It cannot be any other data type.

Version History

Introduced in R2018a

String to Enum

Input string signal to enumerated signal

Libraries:
Simulink / String

Description

The String To Enum block converts the input string signal to an enumerated signal. To use this block, create an enumeration class in the current folder and use that class name in the **Output data type** parameter.

Ports

Input

Port_1 — Input string signal
scalar

Input string signal, specified as a scalar.

Data Types: `string`

Output

Output 1 — Enumerated number
scalar

Enumerated number associated with the input string, specified as a scalar.

Data Types: `enumerated`

Parameters

Output data type — Output data type
`SlDemoSign (default) | <data type expression>`

Use a data type object, for example, `Simulink.IntEnumType`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: 'Enum: SLDemoSign' | <data type expression>

Default: 'Enum: SLDemoSign'

Mode — Category of data

Enumerated (default) | <data type expression>

Use a data type object, for example, `Simulink.IntEnumType`.

- Enumerated — Enumerated data class object.
- <data type expression> — Expressions that evaluate to data types. Selecting Expression enables a second menu/text box to the right, where you can enter the expression.

Dependency

Clicking the **Show data type assistant** button enables this parameter.

Block Characteristics

Data Types	enumerated string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

String to Single

Convert string signal to single signal

Libraries:
Simulink / String

Description

Scan String scans an input string and converts it to signals per the format specified by the **Format** parameter. The block converts values to their decimal (base 10) representation and outputs the results as numeric or string signals. For example, if the **Format** parameter is set to "%s is %f.", the block outputs two parts, a string signal and a single signal. If the input is the string "Pi is 3.14", the two outputs are "Pi" and "3.14".

The Scan String, String to Double, and String to Single blocks are identical blocks. When configured for String to Double, the block converts the input string signal to a double numerical output. When configured for String to Single, the block converts the input string signal to a single numerical output.

For code generation, configure models that contain this block for non-finite number support by selecting the **Configuration Parameters > Code Generation > Interface > Support non-finite numbers** check box.

Ports

Input

Port_1 — Input string
scalar

Input string, specified as a scalar.

Data Types: `string`

Output

d — Output data whose format matches %d format
scalar

Output data whose format matches specified format, defined as a scalar. Total maximum number of outputs is 128.

If the block cannot match an input string to a format operator specified in **Format**, it returns a warning and outputs an appropriate value (0 or "") for each unmatched format operator.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

f — Output data whose format matches %f format
scalar

Output data whose format matches the %f format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Port_N — Output data whose format matches N format
scalar

Output data whose format matches N format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Format — Format operator for input
"%f" (default) | format string | character vector

Format operator for input, specified as a scalar. If the block cannot match the input string with the specified format, it returns 0. The return of 0 differs from the `sscanf` function return, which is an empty matrix if the function cannot match the input with the specified format.

- For the String to Double block, this parameter has a default value of %lf.
- For the String to Single block, this parameter has a default value of %f.

For more information about acceptable format operators, see the Algorithms section.

Programmatic Use

Block Parameter: Format

Type: character vector

Values: '<filename>'

Default: '"%f"'

Block Characteristics

Data Types	double integer single string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

The Scan String block uses this format specifier prototype:

%[width][length]specifier

Numeric Fields

This table lists available conversion specifiers to convert text to numeric outputs. The block converts values to their decimal (base 10) representation.

Output Port Data Type	Conversion Specifier	Description
Integer, signed	%d	Base 10
Integer, unsigned	%u	Base 10
Floating-point number	%f, %e, or %g	Floating-point values. Input fields can contain NaN (case sensitive). Input fields that represents floating-point numbers can include leading + or - symbols and exponential notation using e or E. The conversion specifiers %f, %e, and %g all treat input fields the same way.

Character Fields

This table lists available conversion specifiers to convert text so that the output is a character array.

Character Field Type	Conversion Specifier	Description
String scalar	%s	Read the text until the block encounters white space.
	%c	Read any single character, including white space. To read multiple characters at a time, specify field width. For example, %10c reads 10 characters at a time.
Pattern-matching	%[. . .]	Read only characters in the brackets up to the first nonmatching character or white space. Example: %[mus] reads 'summer' as 'summ'.
	%[^ . . .]	Read any characters not in the brackets up to the first matching character or white space. Example: %[^m] reads 'summer' as 'su'.

Optional Operators

- **Field Width** — To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, %10s reads up to 10 characters at a time, including white space. %4f reads up to four digits at a time, including the decimal point.
- **Literal Text to Ignore** — This block must match the specified text immediately before or after the conversion specifier.

Example: Hell%s reads "Hello!" as "o!".

Length Specifiers

The Scan String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings.

Length	i	u	f e g	s c
No length specifier	int	unsigned int	single	string
<code>h</code>	short	unsigned short	—	—
<code>l</code>	long	unsigned long	double	—

Notes for Specifiers that Specify Integer Data Types (d, u)

- Target `int`, `long`, `short` type sizes are controlled by settings in the **Configuration Parameters > Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. For this example, the Scan String block requires that the output type be exactly `int32`. It cannot be any other data type.

Submatrix

Select subset of elements (submatrix) from matrix input

Libraries:
Simulink / Matrix Operations

Description

The Submatrix block extracts a contiguous submatrix, y , from the M -by- N input matrix u . For more information about selecting the rows and columns to extract, see “Range Specification Options” on page 1-2198.

Ports

Input

Port_1 — Input signal
vector | matrix

Input signal, from which the block extracts the specified submatrix.

This block supports Simulink virtual buses.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Selected submatrix
vector | matrix

Submatrix selected from the input signal. The data type of the output is the same as the input.

This block supports Simulink virtual buses.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

For more information about selecting the subset of elements to form the submatrix, see “Range Specification Options” on page 1-2198.

Row span — Range of rows
All rows (default) | One row | Range of rows

The range of input rows to be retained in the output.

Row — First row of output
First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input row to be used as the first and only row of the output.

Dependencies

To enable this parameter, set **Row span** to One row.

Starting row — First row of output

First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input row to be used as the first row of the output.

Dependencies

To enable this parameter, set **Row span** to Range of rows.

Row index — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to One row and **Row** to Index.

Starting row index — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to Range of rows and **Starting row** to Index.

Row offset — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to One row and **Row** to Offset from last or Offset from middle.

Starting row offset — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to Range of rows and **Starting row** to Offset from last or Offset from middle.

Ending row — Last row

Last (default) | Index | Offset from last | Offset from middle | Middle

The input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Row span** to `Range` of rows and set **Starting row** to any value except `Last`.

Ending row index — Index of last row

`1` (default) | positive integer

The index of the input row to be used as the last row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending row** to `Index`.

Ending row offset — Offset of last row

`1` (default) | positive integer

The offset of the input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Ending row** to `Offset from middle` or `Offset from last`.

Column span — Range of input columns

`All columns` (default) | `One column` | `Range of columns`

The range of input columns to be retained in the output.

Column — First column

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input column to be used as the first and only column of the output.

Dependencies

To enable this parameter, set **Column span** to `One column`.

Starting column — First column

`First` (default) | `Index` | `Offset from last` | `Last` | `Offset from middle` | `Middle`

The input column to be used as the first column of the output.

Dependencies

To enable this parameter, set **Column span** to `Range` of columns.

Starting column index — Index of first column

`1` (default) | positive integer

The index of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to `Range` of columns and **Starting column** to `Index`.

Column index — Index of first column

1 (default) | positive integer

The index of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to One column and **Column** to Index.

Column offset — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to One column and **Column** to Offset from last or Offset from middle.

Starting column offset — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to Range of columns and **Starting column** to Offset from last or Offset from middle.

Ending column — Last column

Last (default) | Index | Offset from last | Offset from middle | Middle

The input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Column span** to Range of columns and set **Starting column** to any value except Last.

Ending column index — Index of last column

1 (default) | positive integer

The index of the input column to be used as the last column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending column** to Index.

Ending column offset — Offset of last column

1 (default) | positive integer

The offset of the input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Ending column** to `Offset from middle` or `Offset from last`.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Range Specification Options

The block treats length- M unoriented vector input as an M -by-1 matrix. The **Row span** parameter provides three options for specifying the range of rows in u to be retained in submatrix output y :

- `All rows`
Specifies that y contains all M rows of u .
- `One row`
Specifies that y contains only one row from u . Selecting `One row` enables the **Row** parameter to allow selection of the desired row.
- `Range of rows`
Specifies that y contains a range of rows from u . Selecting `Range of rows` enables the **Starting row** and **Ending row** parameters to allow selection of the desired range of rows.

The **Column span** parameter contains a corresponding set of three options for specifying the range of columns in u to be retained in submatrix y : `All columns`, `One column`, or `Range of columns`. The `One column` option enables the **Column** parameter, and `Range of columns` options enable the **Starting column** and **Ending column** parameters.

When you select `One row` or `Range of rows` from the **Row span** parameter, you specify the desired row or range of rows in the **Row** parameter, or the **Starting row** and **Ending row** parameters. Similarly, when you select `One column` or `Range of columns` from the **Column span** parameter, you specify the desired column or range of columns in the **Column** parameter, or the **Starting column** and **Ending column** parameters.

The **Row**, **Column**, **Starting row**, or **Starting column** can be specified in six ways:

- `First`
For rows, this specifies that the first row of u should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1, :) = u(1, :)$.

For columns, this specifies that the first column of u should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,1)$.

- Index

For rows, this specifies that the row of u , `firstrow`, forward-indexed by the **Row index** parameter or the **Starting row index** parameter, should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1,:) = u(\text{firstrow},:)$.

For columns, this specifies that the column of u , forward-indexed by the **Column index** parameter or the **Starting column index** parameter, `firstcol`, should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,\text{firstcol})$.

- Offset from last

For rows, this specifies that the row of u offset from row M by the **Row offset** or **Starting row offset** parameter, `firstrow`, should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1,:) = u(M-\text{firstrow},:)$.

For columns, this specifies that the column of u offset from column N by the **Column offset** or **Starting column offset** parameter, `firstcol`, should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,N-\text{firstcol})$.

- Last

For rows, this specifies that the last row of u should be used as the only row of y . When all columns are to be included, this is equivalent to $y = u(M,:)$.

For columns, this specifies that the last column of u should be used as the only column of y . When all rows are to be included, this is equivalent to $y = u(:,N)$.

- Offset from middle

When you select this option, the block selects the first row or column of the output y by adding the specified offset to the middle row or column of the input u . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as $\text{ceil}(X/2)$.

When all columns are to be included, the following code defines the starting row: $y(1,:) = u(\text{MiddleRow}+\text{Offset},:)$, where `Offset` is the value of the **Row offset** or **Starting row offset** parameter. When all rows are to be included, the following code defines the starting column: $y(1,:) = u(:,\text{MiddleColumn}+\text{Offset})$, where `Offset` is the value of the **Column offset** or **Starting column offset** parameter.

- Middle

When you select this option, the block uses the middle row or column of the input u as the first row or column of the output y . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as $\text{ceil}(X/2)$.

When all columns are to be included, the following code defines the starting row: $y = u(\text{MiddleRow},:)$. When all rows are to be included, the following code defines the starting column: $y = u(:,\text{MiddleColumn})$.

The **Ending row** or **Ending column** can similarly be specified in five ways:

- Index

For rows, this specifies that the row of u forward-indexed by the **Ending row index** parameter, `lastrow`, should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(lastrow,:)`.

For columns, this specifies that the column of u forward-indexed by the **Ending column index** parameter, `lastcol`, should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,lastcol)`.

- Offset from last

For rows, this specifies that the row of u offset from row M by the **Ending row offset** parameter, `lastrow`, should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(M-lastrow,:)`.

For columns, this specifies that the column of u offset from column N by the **Ending column offset** parameter, `lastcol`, should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,N-lastcol)`.

- Last

For rows, this specifies that the last row of u should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(M,:)`.

For columns, this specifies that the last column of u should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,N)`.

- Offset from middle

When you select this option, the block selects the last row or column of the output y by adding the specified offset to the middle row or column of the input u . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as `ceil(X/2)`.

When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Ending row offset** parameter. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Ending column offset** parameter.

- Middle

When you select this option, the block uses the middle row or column of the input u as the last row or column of the output y . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as `ceil(X/2)`.

When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow,:)`. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn)`.

Version History

Introduced before R2006a

R2021b: Create Submatrix Block Moved to Simulink Matrix Operations Library

Behavior changed in R2021b

The Submatrix block has been moved from the **DSP System Toolbox > Math Functions > Matrices and Linear Algebra > Matrix Operations** library to the **Simulink > Matrix Operations** library. All existing models continue to work.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

See Also**Blocks**

Variable Selector | Reshape | Selector

Functions

reshape

Topics

“Split Multichannel Signals into Several Multichannel Signals” (DSP System Toolbox)

Substring

Extract substring from input string signal

Libraries:
Simulink / String

Description

The Substring block extracts a substring from the input string signal. The block extracts the substring starting from the letter corresponding to **idx** and includes a **len** number of characters starting at **idx**. For example, if the input string is "hello 123", input **idx** is 1, and input **len** is 5, the output is "hello". The block extracts a substring starting at 1 and the next 4 characters for a total of 5 characters (hello).

Ports

Input

str — Input string signal
scalar

Input string signal, specified as a string.

Data Types: `string`

idx — Start of string to extract
scalar

Start of string to extract, specified as a positive scalar integer.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

len — Length of string to extract
scalar

Length of string to extract, specified as a scalar. If **len** causes the substring to extend beyond the end of the string, the output signal contains fewer than **len** characters.

Data Types: `uint8` | `uint16` | `uint32`

Output

sub — Extracted string
scalar

Extracted string, specified as a scalar.

Data Types: `string`

Parameters

Inherit maximum length from input — Use same maximum length as input string
on (default) | off

Use same maximum length as the input string source block.

on

Use same maximum length. The substring includes the characters starting from the character at **idx** to the end of the string.

off

Do not use same maximum length.

Dependencies

Selecting this check box enables the **Output data type** parameter.

Programmatic Use

Block Parameter: InheritMaximumLength

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Output data type — Output data type
string (default) | <data type expression>

Output data type, specified using the string data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(N)`. For example, `stringtype(31)` creates a string data type with a maximum length of 31 characters.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Dependencies

To enable this parameter, select **Inherit maximum length from input**.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'string' | <data type expression>

Default: 'string'

Output string from 'idx' to end — Extract string from idx to end
off (default) | on

Extract string from idx to end of input string.

on

Extract string from `idx` to end of input string.

off

Do not extract string from `idx` to end of input string.

Dependencies

Selecting this parameter removes the third input port.

Programmatic Use

Block Parameter: `StringFromIdxToEnd`

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	integer string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2018a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Subsystem

Group blocks to create model hierarchy

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Ports & Subsystems
 HDL Coder / Ports & Subsystems

Description

A Subsystem block contains a subset of blocks within a model or system. The Subsystem block can represent a virtual subsystem or a nonvirtual subsystem.

- Nonvirtual subsystem - Control when the contents of the subsystem are evaluated as a single unit (atomic execution). Create conditionally executed subsystems that run only when an event occurs on a triggering, function-call, action, or enabling input (see “Conditionally Executed Subsystems and Models”).
- Virtual subsystem - Subsystem is neither conditionally nor atomically executed. Virtual subsystems do not have checksums. To determine if a subsystem is virtual, use the `get_param` function for the Boolean block parameter `IsSubsystemVirtual`.

An Atomic Subsystem block is a Subsystem block with the block parameter **Treat as atomic unit** selected, representing a nonvirtual subsystem.

A Code Reuse Subsystem block is a Subsystem block with the parameter **Treat as atomic unit** selected and the parameter **Function packaging** set to `Reusable` function, specifying the function code generation format for the subsystem.

To create a subsystem, do one of the following:

- Copy a Subsystem block from the Ports & Subsystems library into your model. Then add blocks to the subsystem by opening the Subsystem block and copying blocks into it.
- Select all blocks and lines that make up the subsystem, and then in the **Multiple** tab, click **Create Subsystem**. Simulink replaces the blocks with a Subsystem block, along with the necessary Inport and Outport blocks to reflect signals entering and leaving the subsystem.

The number of input ports drawn on the Subsystem block icon corresponds to the number of Inport blocks in the subsystem. Similarly, the number of output ports drawn on the block corresponds to the number of Outport blocks in the subsystem.

The Subsystem block supports signal label propagation through subsystem Inport and Outport blocks.

Note A referenced subsystem is a subsystem stored in a separate file that is referenced using a Subsystem Reference block. To reuse that subsystem, add multiple Subsystem Reference blocks that reference that same subsystem file. A referenced subsystem behaves identically to a regular subsystem during run-time.

Ports

Input

In — Signal input to a subsystem
scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the Subsystem block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

reinit — Control signal for subsystem reinitialize event
scalar

A reinitialize event port provides a function-call control signal that triggers a subsystem reinitialize event, which resets the states of the subsystem.

The subsystem must contain a Reinitialize Function block that corresponds to each subsystem reinitialize event. For more information, see “Using Initialize, Reinitialize, Reset, and Terminate Functions”.

To specify the port name, use the **Event name** parameter of the Event Listener block in the Reinitialize Function block.

Dependencies

To enable this type of port, select the **Show subsystem reinitialize ports** check box.

Output

Out — Signal output from a subsystem
scalar | vector | matrix

Placing an Outport block in a subsystem adds an output port from the Subsystem block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

Main

Show port labels — Display options for port labels

FromPortIcon (default) | FromPortBlockName | SignalName

Select how to display port labels on the Subsystem block icon.

none

Do not display port labels.

FromPortIcon

If the corresponding port icon displays a signal name, display the signal name on the Subsystem block. Otherwise, display the port block name or the port number if the block name is a default name.

FromPortBlockName

Display the name of the corresponding port block on the Subsystem block.

SignalName

If the signal connected to the port is named, display the name of the signal on the Subsystem block. Otherwise, display the name of the corresponding port block.

For port label editing on Subsystem blocks, see “Edit Port Labels on Subsystems”.

Programmatic Use

Parameter: ShowPortLabels

Type: character vector

Value: 'FromPortIcon' | 'FromPortBlockName' | 'SignalName'

Default: 'FromPortIcon'

Read/Write permissions — Levels of access to contents of subsystem

ReadWrite (default) | ReadOnly | NoReadOrWrite

Control user access to the contents of the subsystem.

ReadWrite

Enable opening and modification of subsystem contents.

ReadOnly

Enable opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

NoReadOrWrite

Disable opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

Note You do not receive a response if you attempt to view the contents of a subsystem whose **Read/Write permissions** parameter is set to **NoReadOrWrite**. For example, when double-clicking such a subsystem, Simulink does not open the subsystem and does not display any messages.

Programmatic Use

Parameter: Permissions

Type: character vector

Value: 'ReadWrite' | 'ReadOnly' | 'NoReadOrWrite'

Default: 'ReadWrite'

Name of error callback function — Name of function to be called if error occurs

' ' (default) | function name

Enter name of a function to be called if an error occurs while Simulink is executing the subsystem.

Simulink passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink displays a generic error message if executing the subsystem causes an error.

Programmatic Use

Parameter: ErrorFcn

Type: character vector

Value: ' ' | '<function name>'

Default: ' '

Permit hierarchical resolution — Resolution for workspace variable names

All (default) | ExplicitOnly | None

Select whether to resolve names of workspace variables referenced by this subsystem.

For more information, see “Symbol Resolution” and “Symbol Resolution Process”.

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

ExplicitOnly

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

Programmatic Use

Parameter: PermitHierarchicalResolution

Type: character vector

Value: 'All' | 'ExplicitOnly' | 'None'

Default: 'All'

Treat as atomic unit — Option to execute subsystem as one unit

off (default) | on

Causes Simulink to treat the subsystem as a unit when determining the execution order of block methods.

off

Treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

on

Treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the Subsystem block.

Programmatic Use**Parameter:** TreatAsAtomicUnit**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Show subsystem reinitialize ports** — Option to display reinitialize event ports

off (default) | on

Select this parameter to display the reinitialize event ports. Clear this parameter to remove the ports.

Dependencies

To enable this parameter, select the **Treat as atomic unit** check box.

Programmatic Use**Block parameter:** ShowSubsystemReinitializePorts**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Minimize algebraic loop occurrences** — Option to eliminate artificial algebraic loops

off (default) | on

Try to eliminate any artificial algebraic loops that include the atomic subsystem

 off

Do not try to eliminate any artificial algebraic loops that include the atomic subsystem.

 on

Try to eliminate any artificial algebraic loops that include the atomic subsystem.

Dependencies

To enable this parameter, select the **Treat as atomic unit** parameter.

Programmatic Use**Parameter:** MinAlgLoopOccurrences**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Schedule As** — Type of scheduling

Sample Time (default) | Periodic Partition | Aperiodic Partition

Specify how to schedule the subsystem.

Sample time

Specify whether all blocks in this subsystem must run at the same rate or can run at different rates.

Periodic Partition

Schedule the subsystem as a periodic partition. Specify a partition name and a sample time corresponding to the rate at which the partition runs.

Aperiodic Partition

Schedule the subsystem as an aperiodic partition. Specify a partition name.

Dependencies

To enable this parameter, select the **Treat as atomic unit** parameter.

Programmatic Use

Parameter: ScheduleAs

Type: character vector

Value: 'SampleTime' | 'PeriodicPartition' | 'AperiodicPartition'

Default: 'SampleTime'

Partition Name — Name of partition

character vector

Specify name of the partition for the subsystem.

Dependencies

To enable this parameter, select the **Treat as atomic unit** parameter, and set **Schedule As** to Periodic Partition or Aperiodic Partition.

Programmatic Use

Parameter: PartitionName

Type: character vector

Value: ''

Default: ''

Sample time — Time interval

-1 (default) | [Ts 0]

Specify whether all blocks in this subsystem must run at the same rate or can run at different rates.

- If the blocks in the subsystem can run at different rates, specify the subsystem sample time as inherited (-1).
- If all blocks must run at the same rate, specify the sample time corresponding to this rate as the value of the **Sample time** parameter.
- If any of the blocks in the subsystem specify a different sample time (other than -1 or `inf`), Simulink displays an error message when you update or simulate the model. For example, suppose all the blocks in the subsystem must run 5 times a second. To ensure this, specify the sample time of the subsystem as 0.2. In this example, if any of the blocks in the subsystem specify a sample time other than 0.2, -1, or `inf`, Simulink displays an error when you update or simulate the model.

-1

Specify inherited sample time. Use this sample time if the blocks in the subsystem can run at different rates.

[Ts 0]

Specify periodic sample time.

Dependencies

To enable this parameter, select the **Treat as atomic unit** parameter.

Programmatic Use

Parameter: SystemSampleTime

Type: character vector

Value: '-1' | '[Ts 0]'

Default: '-1'

Variant control — Variant control (condition) expression

Variant (default) | logical expression

Specify variant control (condition) expression that executes a variant Simulink Function block when the expression evaluates to `true`.

For more information, see `Simulink.Variant`.

Variant

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a logical expression.

The function is activated when the expression evaluates to `true`.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependencies

Enable this parameter by adding a Subsystem block inside a Variant Subsystem block.

Programmatic Use

Block parameter: VariantControl

Type: character vector

Value: 'Variant' | '<logical expression>'

Default: 'Variant'

Treat as grouped when propagating variant conditions — Option to treat subsystem as unit when propagating variant conditions

on (default) | off

Causes Simulink to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

on

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

Programmatic Use

Parameter: TreatAsGroupedWhenPropagatingVariantConditions

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Code Generation

Parameters on the Code Generation tab require a Simulink Coder or Embedded Coder license.

Function packaging — Code format

Auto (default) | Inline | Nonreusable function | Reusable function

Select the code format to be generated for an atomic (nonvirtual) subsystem.

Auto

Simulink Coder and Embedded Coder choose the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

Inline

Simulink Coder and Embedded Coder inline the subsystem unconditionally.

Nonreusable function

If **Filename options** is set to Auto, Simulink Coder and Embedded Coder package separate functions in the model file. If **File name options** is set to Use subsystem name, Use function name, or User specified using different file names, Simulink Coder and Embedded Coder package separate functions in separate files.

Subsystems with this setting generate functions that might have arguments depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0. These functions are not reentrant.

Reusable function

Simulink Coder and Embedded Coder generate a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

For more information, see:

- “Generate Code and Executables for Individual Subsystems” (Simulink Coder)
- “Generate Inlined Subsystem Code” (Simulink Coder)
- “Generate Subsystem Code as Separate Function and Files” (Simulink Coder)
- “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder)

Tips

- When you want multiple instances of a subsystem to be represented as one reusable function, you can designate each one of them as **Auto** or as **Reusable function**. It is best to use one or the other, as using both creates two reusable functions, one for each designation. The outcomes of these choices differ only when reuse is not possible. Selecting **Auto** does not allow control of the function or file name for the subsystem code.
- The **Reusable function** and **Auto** options both try to determine if multiple instances of a subsystem exist and if the code can be reused. The difference between the options' behavior is that when reuse is not possible:
 - **Auto** yields inlined code, or if circumstances prohibit inlining, separate functions for each subsystem instance.
 - **Reusable function** yields a separate function with arguments for each subsystem instance in the model.
- If you select **Reusable function** while your generated code is under source control, set **File name options** to **Use subsystem name**, **Use function name**, or **User specified**. Otherwise, the names of your code files change whenever you modify your model, which prevents source control on your files.
- If you select an option other than **Auto** or **Inline** and the model configuration parameter **States**, the code generator produces separate output and update methods. The code generator does not take into account the **Combine output and update methods for code generation and simulation** specification.

Dependencies

- This parameter requires Simulink Coder for code generation.
- To enable this parameter, select **Treat as atomic unit**.

Programmatic Use**Parameter:** RTWSystemCode**Type:** character vector**Value:** 'Auto' | 'Inline' | 'Nonreusable function' | 'Reusable function'**Default:** 'Auto'**Function name options** — How to name generated function`Auto (default) | Use subsystem name | User specified`

Select how Simulink Coder names the function it generates for the subsystem.

If you have an Embedded Coder license, you can control function names with options on the Configuration Parameter **Code Generation > Identifiers** pane.

Auto

Assign a unique function name using the default naming convention, `model_subsystem()`, where `model` is the name of the model and `subsystem` is the name of the subsystem (or that of an identical one when code is being reused).

If you select `Reusable` function for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **Function name options** must be set to `Auto`.

Use subsystem name

Use the subsystem name as the function name. By default, the function name uses the naming convention `model_subsystem`.

Note When a subsystem is in a library block and the subsystem parameter “Function packaging” on page 1-0 is set to `Reusable` function, if you set the `Use subsystem name` option, the code generator uses the name of the library block for the subsystem function name and file name.

User specified

Enable the **Function name** field. Enter any legal C or C++ function name, which must be unique.

For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

- This parameter requires a Simulink Coder license.
- To enable this parameter, set **Function packaging** to `Nonreusable` function or `Reusable` function.

Programmatic Use

Parameter: `RTWFcnNameOpts`

Type: character vector

Value: `'Auto' | 'Use subsystem name' | 'User specified'`

Default: `'Auto'`

Function name — Name of function for subsystem code

`''` (default) | function name

Specify a unique, valid C or C++ function name for subsystem code.

Use this parameter if you want to give the function a specific name instead of allowing the Simulink Coder code generator to assign its own autogenerated name or use the subsystem name. For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

- This parameter requires a Simulink Coder license.
- To enable this parameter, set the **Function name options** parameter to `User specified`.

Programmatic Use**Parameter:** RTWFcnName**Type:** character vector**Value:** '' | '<function name>'**Default:** ''**File name options** — How to name generated file

Auto (default) | Use subsystem name | Use function name | User specified

Select how Simulink Coder names the separate file for the function it generates for the subsystem.

Auto

Depending on the configuration of the subsystem and how many instances are in the model, Auto yields different results:

- If the code generator does *not* generate a separate file for the subsystem, the subsystem code is generated within the code module generated from the subsystem parent system. If the subsystem parent is the model itself, the subsystem code is generated within *model.c* or *model.cpp*.
- If you select Reusable function for the **Function packaging** parameter and your generated code is under source control, consider specifying a **File name options** value other than Auto. This prevents the generated file name from changing due to unrelated model modifications, which is problematic for using source control to manage configurations.
- If you select Reusable function for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **File name options** must be set to Auto.

Use subsystem name

The code generator generates a separate file, using the subsystem (or library block) name as the file name.

Note When **File name options** is set to Use subsystem name, the subsystem file name is mangled if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the file name for the subsystem consists of the subsystem name prefixed by the model name.

Use function nameThe code generator uses the function name specified by **Function name options** as the file name.**User specified**This option enables the **File name (no extension)** text entry field. The code generator uses the name you enter as the file name. Enter any file name, but do not include the .c or .cpp (or any other) extension. This file name need not be unique.

Note While a subsystem source file name need not be unique, you must avoid giving nonunique names that result in cyclic dependencies (for example, *sys_a.h* includes *sys_b.h*, *sys_b.h* includes *sys_c.h*, and *sys_c.h* includes *sys_a.h*).

Dependencies

- This parameter requires a Simulink Coder license.
- To enable this parameter, set **Function packaging** to Nonreusable function or Reusable function.

Programmatic Use**Parameter:** RTWFileNameOpts**Type:** character vector**Value:** 'Auto' | 'Use subsystem name' | 'Use function name' | 'User specified'**Default:** 'Auto'**File name (no extension)** — Name of generated file`'' (default) | file name`

The file name that you specify does not have to be unique. However, avoid giving non-unique names that result in cyclic dependencies (for example, `sys_a.h` includes `sys_b.h`, `sys_b.h` includes `sys_c.h`, and `sys_c.h` includes `sys_a.h`).

For more information, see “Generate Subsystem Code as Separate Function and Files” (Simulink Coder).

Dependencies

- This parameter requires a Simulink Coder license.
- To enable this parameter, set **File name options** to User specified.

Programmatic Use**Parameter:** RTWFileName**Type:** character vector**Value:** '' | '<file name>'**Default:** ''**Function interface** — Select to use arguments with generate function`void_void (default) | Allow arguments (Optimized) | Allow arguments (Match graphical interface)`

Select to use arguments with generated function.

void_void

Generate a function without arguments and pass data as global variables. For example:

```
void subsystem_function(void)
```

Allow arguments (Optimized)

Generate a function that uses arguments instead of passing data as global variables. This specification reduces global RAM. It might reduce code size and improve execution speed and enable the code generator to apply additional optimizations. For example:

```
void subsystem_function(real_T rtu_In1, real_T rtu_In2,
                       real_T *rty_Out1)
```

In some cases, when generating optimized code, the code generator might not generate a function that has arguments.

Allow arguments (Match graphical interface)

Generate a function interface that uses arguments that match the Subsystem graphical block interface. The generated function interface is predictable and does not change. A predictable interface can be useful for debugging and testing your code and integrating with external applications. For example, if a model has two Inports and two Outports, then the generated function interface is:

```
void subsystem_function(real_T rtu_In1, real_T rtu_In2,
                      real_T *rty_Out1, real_T *rty_Out2)
```

For more information, see:

- “Reduce Global Variables in Nonreusable Subsystem Functions” (Embedded Coder)
- “Generate Predictable Function Interface to Match Graphical Block Interface” (Embedded Coder)
- “Generate Modular Function Code for Nonvirtual Subsystems” (Embedded Coder)

Dependencies

- This parameter requires Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function`.

Programmatic Use

Parameter: FunctionInterfaceSpec

Type: character vector

Value: 'void_void' | 'Allow arguments (Optimized)' | 'Allow arguments (Match graphical interface)'

Default: 'void_void'

Function with separate data — Control code generation for subsystem

off (default) | on

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

off

Do not generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

on

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and DWork data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

For details on how to generate modular function code for an atomic subsystem, see “Generate Modular Function Code for Nonvirtual Subsystems” (Embedded Coder).

For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function`.

Programmatic Use

Parameter: `FunctionWithSeparateData`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Memory section for initialize/terminate functions — Select how to apply memory sections

`Inherit from model (default) | Default | The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem initialization and termination functions.

`Inherit from model`

Apply the root model memory sections to the subsystem function code

`Default`

Do not apply memory sections to the subsystem system code, overriding any model-level specification

`The memory section of interest`

Apply one of the model memory sections to the subsystem

Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation” (Simulink Coder).
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model package contains.
- These options can be useful for overriding the model memory section settings for the given subsystem. For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` or `Reusable function`.

Programmatic Use

Parameter: `RTWMemSecFuncInitTerm`

Type: character vector

Value: 'Inherit from model' | 'Default' | 'The memory section of interest'
Default: 'Inherit from model'

Memory section for execution functions — Select how to apply memory sections

Inherit from model (default) | Default | The memory section of interest

Select how Embedded Coder applies memory sections to the subsystem execution functions.

Inherit from model

Apply the root model memory sections to the subsystem function code

Default

Do not apply memory sections to the subsystem system code, overriding any model-level specification

The memory section of interest

Apply one of the model memory sections to the subsystem

Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation” (Simulink Coder).
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model package contains.
- These options can be useful for overriding the model memory section settings for the given subsystem. For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` or `Reusable function`.

Programmatic Use

Parameter: `RTWMemSecFuncExecute`

Type: character vector

Value: 'Inherit from model' | 'Default' | 'The memory section of interest'

Default: 'Inherit from model'

Memory section for constants — Select how to apply memory sections

Inherit from model (default) | Default | The memory section of interest

Select how Embedded Coder applies memory sections to the subsystem constants.

Inherit from model

Apply the root model memory sections to the subsystem data

Default

Not apply memory sections to the subsystem data, overriding any model-level specification

The memory section of interest

Apply one of the model memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Standard Data Structures” (Simulink Coder).
- The possible values vary depending on what (if any) package of memory sections you have set for the model configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder).
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model package contains.
- These options can be useful for overriding the model memory section settings for the given subsystem. For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter.

Programmatic Use

Parameter: `RTWMemSecDataConstants`

Type: character vector

Value: `'Inherit from model' | 'Default' | 'The memory section of interest'`

Default: `'Inherit from model'`

Memory section for internal data — Select how to apply memory sections

`Inherit from model` (default) | `Default` | `The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem internal data.

Inherit from model

Apply the root model memory sections to the subsystem data

Default

Not apply memory sections to the subsystem data, overriding any model-level specification

The memory section of interest

Apply one of the model memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Standard Data Structures” (Simulink Coder).

- The possible values vary depending on what (if any) package of memory sections you have set for the model configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder).
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model package contains.
- These options can be useful for overriding the model memory section settings for the given subsystem. For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter.

Programmatic Use

Parameter: `RTWMemSecDataInternal`

Type: character vector

Value: `'Inherit from model' | 'Default' | 'The memory section of interest'`

Default: `'Inherit from model'`

Memory section for parameters — Select how to apply memory sections

`Inherit from model (default) | Default | The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem parameters.

`Inherit from model`

Apply the root model memory sections to the subsystem function code

`Default`

Not apply memory sections to the subsystem system code, overriding any model-level specification

`The memory section of interest`

Apply one of the model memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structure in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Standard Data Structures” (Simulink Coder).
- The possible values vary depending on what (if any) package of memory sections you have set for the model configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder).
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model package contains.
- These options can be useful for overriding the model memory section settings for the given subsystem. For details on how to apply memory sections to atomic subsystems, see “Override Default Memory Placement for Subsystem Functions and Data” (Embedded Coder).

Dependencies

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter.

Programmatic Use**Parameter:** RTWMemSecDataParameters**Type:** character vector**Value:** 'Inherit from model' | 'Default' | 'The memory section of interest'**Default:** 'Inherit from model'**Subsystem Reference****Subsystem file name** — File name of referenced subsystem

string scalar | character vector

Specify the subsystem file you want to reference. For information about subsystem references, see “Subsystem Reference”.

Dependencies

To access this parameter, in the **Subsystem Reference** section, click **Convert**.

For more information on how to convert a subsystem to a referenced subsystem, see “Convert an Existing Subsystem to a Referenced Subsystem”.

Programmatic Use**Parameter:** ReferencedSubsystem**Type:** character vector**Value:** '' | '<filename>'**Default:** ''**Block Characteristics**

Version History

Introduced in R2007a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	<p>Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code.</p> <p>The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.</p>
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).

General	
DSPStyle	Synthesis attributes for multiplier mapping. The default is none. See also "DSPStyle" (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is inherit. See also "FlattenHierarchy" (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also "Resource Sharing" (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also "Streaming" (HDL Coder).

If this block is not the DUT, the block property settings in the **Target Specification** tab are ignored. In the HDL Workflow Advisor, if you use the **IP Core Generation** workflow, these target specification block property values are saved with the model. If you specify these target specification block property values using `hdlset_param`, when you open HDL Workflow Advisor, the fields are populated with the corresponding values.

Target Specification	
AdditionalTargetInterfaces	<p>Additional target interfaces, specified as a character vector.</p> <p>To save this block property on the model, in the Set Target Interface task of the IP Core Generation workflow, corresponding to the DUT ports that you want to add more interfaces, select Add more... You can then add more interfaces in the Add New Target Interfaces dialog box. Specify the type of interface, number of additional interfaces, and a unique name for each additional interface.</p> <p>Values: '' (default) cell array of character vectors</p> <p>Example: <code>'{'AXI4-Stream', 'InterfaceID', 'AXI4-Stream1'}'</code></p>
ProcessorFPGASynchronization	<p>Processor/FPGA synchronization mode, specified as a character vector.</p> <p>To save this block property on the model, specify the Processor/FPGA Synchronization in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: Free running (default) Coprocessing - blocking</p> <p>Example: 'Free running'</p>

Target Specification	
TestPointMapping	<p>To save this block property on the model, specify the mapping of test point ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: ' ' (default) cell array of character vectors</p> <p>Example: '{{'TestPoint','AXI4-Lite','x"108"'}}</p>
TunableParameterMapping	<p>To save this block property on the model, specify the mapping of tunable parameter ports to target platform interfaces in the Set Target Interface task of the IP Core Generation workflow.</p> <p>Values: ' ' (default) cell array of character vectors</p> <p>Example: '{{'myParam','AXI4-Lite','x"108"'}}</p>
AXI4RegisterReadback	<p>To save this block property on the model, specify whether you want to enable readback on AXI4 subordinate write registers in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>
AXI4SlaveIDWidth	<p>To save this block property on the model, specify the number of AXI manager interfaces that you want to connect the DUT IP core to by using the AXI4 Slave ID Width setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Define Multiple AXI Master Interfaces in Reference Designs to Access DUT AXI4 Slave Interface” (HDL Coder).</p> <p>Values: 'off' (default) 'on'</p>
AXI4SlavePortToPipelineRegisterRatio	<p>To save this block property on the model, specify the number of AXI4 subordinate ports for which you want a pipeline register to be inserted by using the AXI4 Slave port to pipeline register ratio setting in the Generate RTL Code and IP Core task of the IP Core Generation workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” (HDL Coder).</p> <p>Values: 'off' (default) 'on' '10' '20' '35' '50'</p>
GenerateDefaultAXI4Slave	<p>To save this block property on the model, specify whether you want to disable generation of default AXI4 subordinate interfaces in the Generate RTL Code and IP Core task of the IP Core Generation workflow.</p> <p>Values: 'on' (default) 'off'</p>

Target Specification	
IPCoreAdditionalFiles	<p>Verilog or VHDL files for black boxes in your design. Specify the full path to each file, and separate file names with a semicolon (;).</p> <p>You can set this property in the HDL Workflow Advisor, in the Additional source files field.</p> <p>Values: ' ' (default) character vector</p> <p>Example: 'C:\myprojfiles \led_blinking_file1.vhd;C:\myprojfiles \led_blinking_file2.vhd;'</p>
IPCoreName	<p>IP core name, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core name field. If this property is set to the default value, the HDL Workflow Advisor constructs the IP core name based on the name of the DUT.</p> <p>Values: ' ' (default) character vector</p> <p>Example: 'my_model_name'</p>
IPCoreVersion	<p>IP core version number, specified as a character vector.</p> <p>You can set this property in the HDL Workflow Advisor, in the IP core version field. If this property is set to the default value, the HDL Workflow Advisor sets the IP core version.</p> <p>Values: ' ' (default) character vector</p> <p>Example: '1.3'</p>
IPDataCaptureBuffer Size	<p>FPGA Data Capture buffer size, specified as a character vector. Use FPGA Data Capture to observe signals in a design when running on an FPGA.</p> <p>The buffer size uses values that are $128 \cdot 2^n$, where n is an integer. By default, the buffer size is 128 (n=0). The maximum value of n is 13, which means that the maximum value for buffer size is 1048576 ($=128 \cdot 2^{13}$).</p> <p>Values: ' ' (default) character vector</p> <p>Example: '1.3'</p>

Restrictions

If your DUT is a masked subsystem, you can generate code only if it is at the top level of the model.

For more information, see:

- “External Component Interfaces” (HDL Coder)
- “Generate Black Box Interface for Subsystem” (HDL Coder)

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Subsystem must be atomic to support PLC code generation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Switch

Switch output between first input and third input based on value of second input

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Signal Routing
 HDL Coder / Commonly Used Blocks
 HDL Coder / Signal Routing

Description

Types of Block Inputs

The Switch block passes through the first input or the third input based on the value of the second input. The first and third inputs are called data inputs. The second input is called the control input. Specify the condition under which the block passes the first input by using the **Criteria for passing first input** and **Threshold** parameters.

To immediately back propagate a known output data type to the first and third input ports, set the **Output data type** parameter to `Inherit: Inherit via internal rule` and select the **Require all data port inputs to have the same data type** check box.

Limitations on Data Inputs

The sizes of the two data inputs can be different if you select **Allow different data input sizes**. However, this block does not support variable-size input signals. Therefore, the size of each input cannot change during simulation.

If the data inputs to the Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name mismatch** diagnostic to `error`. For more information, see “Model Configuration Parameters: Connectivity Diagnostics”.

Block Icon Appearance

The block icon helps you identify **Criteria for passing first input** and **Threshold** without having to open the block dialog box.

For information about port order for various block orientations, see “Identify Port Location on Rotated or Flipped Block”.

Block Behavior for Boolean Control Input

When the control input is a Boolean signal, use one of these combinations of criteria and threshold value:

- $u_2 \geq \text{Threshold}$, where the threshold value equals 1
- $u_2 > \text{Threshold}$, where the threshold value equals 0

- `u2 ~=0`

Otherwise, the Switch block ignores the threshold and uses the Boolean input for signal routing. For a control input of 1, the block passes the first input, and for a control input of 0, the block passes the third input. In this case, the block icon changes after compile time and uses T and F to label the first and third inputs, respectively.

Data Type Support

The control input can be of any data type that Simulink supports, including fixed-point and enumerated types. The control input cannot be complex. If the control input is enumerated, the **Threshold** parameter must be a value of the same enumerated type.

The data inputs can be of any data type that Simulink supports. If either data input is of an enumerated type, the other must be of the same enumerated type.

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

For more information, see “Data Types Supported by Simulink”.

Ports

Input

Port_1 — First data input signal

scalar | vector

First of two data inputs. The block propagates either the first or second data input to the output. The block selects which input to pass based on the control input. Specify the condition for the control input to pass the first input using the **Criteria for passing first input** and **Threshold** parameters.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Port_2 — Control input signal

scalar | vector

Control signal the block uses to determine whether to pass the first or second data input to the output. If the control input meets the condition set in the **Criteria for passing first input** parameter, then the block passes the first data input. Otherwise, the block passes the second data input.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Port_3 — Second data input signal

scalar | vector

Second of two data inputs. The block propagates either the first or second data input to the output. The block selects which input to pass based on the control input. Specify the condition for the control input to pass the first or second input using the **Criteria for passing first input** and **Threshold** parameters.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Output

Port_1 — Output signal

scalar | vector

Output signal propagated from either the first or second input signal, based on the control signal value.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Parameters

Main

Criteria for passing first input — Selection criteria to pass first data input

`u2 > Threshold (default) | u2 >= Threshold | u2 ~= 0`

Select the condition under which the block passes the first data input. If the control input meets the condition set in the **Criteria for passing first input** parameter, the block passes the first input. Otherwise, the block passes the second data input signal from input Port_3.

`u2 >= Threshold`

Checks whether the control input is greater than or equal to the threshold value.

`u2 > Threshold`

Checks whether the control input is greater than the threshold value.

`u2 ~= 0`

Checks whether the control input is nonzero.

Note The Switch block does not support `u2 ~= 0` mode for enumerated data types.

Tip

When the control input is a Boolean signal, use one of these combinations of condition and threshold value:

- `u2 >= Threshold`, where the threshold value equals 1
- `u2 > Threshold`, where the threshold value equals 0
- `u2 ~= 0`

Otherwise, the Switch block ignores threshold values and uses the Boolean value for signal routing. For a value of 1, the block passes the first input, and for a value of 0, the block passes the third input. A warning message that describes this behavior also appears in the MATLAB Command Window.

Programmatic Use

Block Parameter: Criteria

Type: character vector

Value: 'u2 >= Threshold' | 'u2 > Threshold' | 'u2 ~= 0'

Default: 'u2 > Threshold'

Threshold — Threshold used in criteria

0 (default) | scalar

Assign the threshold used in the **Criteria for passing first input** that determines which input the block passes to the output. **Threshold** must be greater than **Output minimum** and less than **Output maximum**.

To specify a nonscalar threshold, use brackets. For example, the following entries are valid:

- [1 4 8 12]
- [MyColors.Red, MyColors.Blue]

Dependencies

Setting **Criteria for passing first input** to `u2 ~= 0` disables this parameter.

Programmatic Use

Block Parameter: Threshold

Type: character vector

Value: scalar

Default: '0'

Enable zero-crossing detection — Enable zero-crossing detection

on (default) | off

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector | string

Values: 'off' | 'on'

Default: 'on'

Signal Attributes

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Require all data port inputs to have the same data type — Require data ports to have the same data type

off (default) | on

Require all data inputs to have the same data type.

Programmatic Use

Block Parameter: InputSameDT

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | scalar**Default:** '[]'**Output data type** — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | Inherit: Same as first input | double | single | half | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | string | Enum: <class name> | <data type expression> | Simulink.ImageType(480,640,3)

Specify the output data type.

Inherit: Inherit via internal rule

Uses the following rules to determine the output data type.

Data Type of First Input Port	Output Data Type
Has a larger positive range than the third input port	Inherited from the first input port
Has the same positive range as the third input port	Inherited from the third input port
Has a smaller positive range than the third input port	
Is a Boolean value and third input port is uint8	
Is uint8 and third input port is a Boolean value	
Is a Boolean value and other is int8	Set to a Boolean value
Is uint8 and other is a Boolean value	

Data Types of Two Input Ports	Output Data Type
Has one input type as a Boolean value and another as uint8	Set to data type of the third data port
Has one input as a Boolean value and another as int8	Set to a Boolean value

Inherit: Inherit via back propagation

Uses data type of the driving block.

Inherit: Inherit same as first input

Uses data type of the first data input port.

double

Specifies output data type is double.

single

Specifies output data type is single.

`half`

Specifies output data type is `half`.

`int8`

Specifies output data type is `int8`.

`uint8`

Specifies output data type is `uint8`.

`int16`

Specifies output data type is `int16`.

`uint16`

Specifies output data type is `uint16`.

`int32`

Specifies output data type is `int32`.

`uint32`

Specifies output data type is `uint32`.

`int64`

Specifies output data type is `int64`.

`uint64`

Specifies output data type is `uint64`.

`fixdt(1,16,0)`

Specifies output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Specifies output data type is fixed point `fixdt(1,16,2^0,0)`.

`Enum: <class name>`

Uses an enumerated data type, for example, `Enum: BasicColors`.

`Simulink.ImageType(480,640,3)`

Uses a `Simulink.ImageType` object if you have Computer Vision Toolbox.

`string`

Specifies output data type is `string`.

`<data type expression>`

Uses a data type object, for example, `Simulink.NumericType`.

Tip

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'Inherit: Inherit via internal rule'|'Inherit: Inherit via back propagation'|'Inherit: Same as first input'|'double'|'single'|'half'|'int8'|'uint8'|'int16'|'uint16', 'int32'|'uint32'|'int64'|'uint64'|`

'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | Enum: <class name> |
Simulink.ImageType(480,640,3) | 'string' | '<data type expression>'
Default: 'Inherit: Inherit via internal rule'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'
Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

- **off** — Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- **on** — Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
 - In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.
-

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Allow different data input sizes — Allow different data input sizes

off (default) | on

Select this check box to allow input signals with different sizes. The block propagates the input signal size to the output signal. If the two data inputs are variable-size signals, the maximum size of the signals can be equal or different.

Programmatic Use

Block Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	yes

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Multiport Switch | Manual Switch

Switch Case

Select subsystem execution using logic similar to switch statement

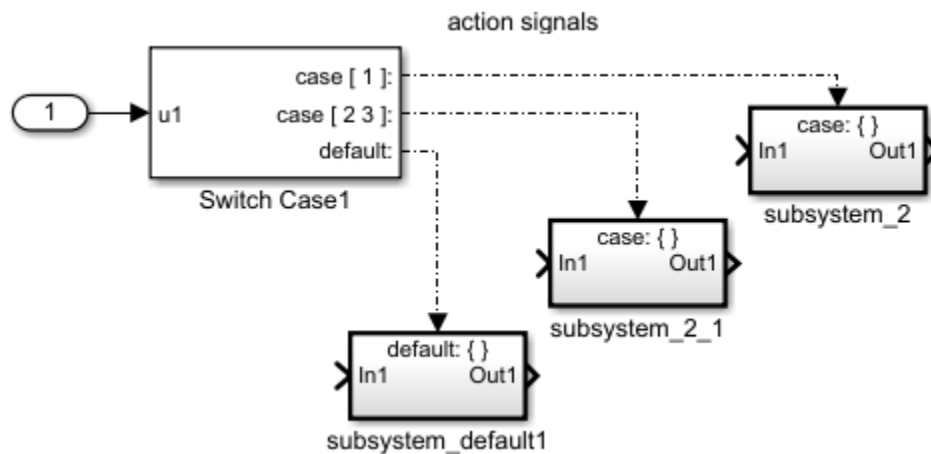

Libraries:

Simulink / Ports & Subsystems

Description

The Switch Case block with Switch Case Action Subsystem blocks containing Action Port blocks, implements switch logic to control subsystem execution.

A Switch Case block has a single input. To select a case, define the input value using the **Case conditions** parameter. The cases are evaluated top down starting with the first case.

Each case is associated with an output port that is attached to a Switch Case Action Subsystem block. When a case is selected, the associated output port sends an action signal to execute the subsystem.

A `default` case is selected after all of the other case conditions evaluate to false. Providing a `default` case is optional, even if the other case conditions do not exhaust every possible input value.

Cases for the Switch Case block contain an implied break after a Switch Case Action Subsystem block is executed. Therefore, there is no fall through behavior for the Simulink Switch Case block as found in standard C switch statements.

Limitations

The Switch Case block does not support tunable parameters. Values for `Case conditions` cannot be tuned during a simulation in normal or accelerator mode, or when running generated code.

Ports

Input

u1 (logical operator) — Value for case selection
scalar

Input to the port labeled **u1** of a Switch Case block can be:

- A scalar value with a built-in data type that Simulink supports. However, the Switch Case block does not support Boolean or fixed-point data types, and it truncates numeric inputs to 32-bit signed integers.
- A scalar value of any enumerated data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `enumerated`

Output

case — Action signal for a Switch Case Action Subsystem block
scalar

Output from the **Case** and **default** ports are action signals connected to Switch Case Action Subsystem blocks.

Parameters

Case conditions — Specify case values

`{1}` (default) | list of cases

Specify the cases values using MATLAB cell notation.

`{1}`

Specify the output port labeled `case[1]` outputs an action signal when the input port value is 1.

list of ports with case assignments

Specify multiple cases and ports using MATLAB cell notation. For example, entering `{1, [7,9,4]}` specifies that output port `case[1]` is run when the input value is 1, and output port `case [7 9 4]` is run when the input value is 7, 9, or 4.

You can use colon notation to specify a range of integer case conditions. For example, entering `{[1:5]}` specifies that output port `case[1 2 3 4 5]` is run when the input value is 1, 2, 3, 4, or 5.

Depending on block size, cases from a long list of case conditions are displayed in shortened form on the face of the Switch Case block, using a terminating ellipsis (...).

You can use the name of an enumerated type to specify case conditions that include a case for every value in that enumerated type.

Programmatic Use

Block Parameter: `CaseConditions`

Type: character vector

Values: `'{1}'` | `'<list of cases>'`

Default: '{1}'

Show default case — Control display of default output port

on (default) | off

Control display of default output port.

on

Display default output port as the last case on the Switch Case block. This allows you to specify a default case that executes when the input value does not match any of the other case values.

off

Hide default output port.

Programmatic Use

Block Parameter: ShowDefaultCase

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block Parameter: ZeroCross

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	double enumerated integer single
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	yes

Select Subsystem Execution

Switch Case Action Subsystem

Subsystem whose execution is enabled by Switch Case block

Libraries:
Simulink / Ports & Subsystems

Description

The Switch Case Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is controlled by a Switch Case block. The input port to a Switch Case block selects a case defined using the **Case conditions** parameter. Depending on input value and case selected, an action signal is sent to execute a Switch Case Action Subsystem block. Execution of the subsystem is controlled by an Action Port block placed inside the subsystem.

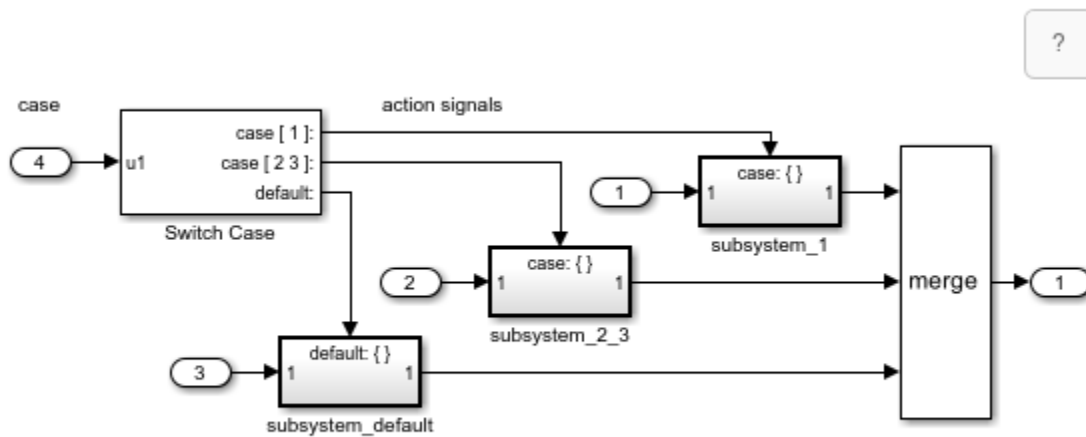

Simulink ignores a priority set on an Switch Case Action Subsystem block. Instead, set the priority on the Switch Case block that initiates execution of the subsystem.

All blocks in a Switch Case Action Subsystem block must run at the same rate as the driving Switch Case block. You can achieve this requirement by setting each block sample time parameter to be either inherited (-1) or the same value as the Switch Case block sample time.

Merge Signals from Switch Case Action Subsystem Blocks

The example model `ex_switch_case_block` shows how to create one signal from multiple subsystem output signals.

Copyright 2018-2022 The MathWorks, Inc.

The Switch Case block selects the execution of one If Action Subsystem block from a set of subsystems. Regardless of which subsystem the Switch Case block selects, you can create one resulting signal with a Merge block.

Ports

Input

In1 — Signal input to a subsystem

scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the Subsystem block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Action — Control signal input to a subsystem

scalar | vector | matrix

Placing an Action Port block in a subsystem adds an external input port to the Subsystem block and changes the block to a Switch Case Action Subsystem block.

Dot-dash lines from a Switch Case block to an Switch Case Action Subsystem block represent *action* signals. An action signal is a control signal connected to the action port of an Switch Case Action Subsystem block. A message on the action signal initiates execution of the subsystem.

Data Types: action

Output

Out1 — Signal output from a subsystem

scalar | vector | matrix

Placing an Outputport block in a subsystem adds an output port from the Subsystem block. The port label on the subsystem block is the name of the Outputport block.

Use Outputport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code. The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is <code>0</code> . See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is <code>0</code> , which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Restrictions

If the output of the subsystem is a bus then **Initial condition** of the output must be `0`.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Tapped Delay

Delay scalar signal multiple sample periods and output all delayed versions

Libraries:

Simulink / Discrete
HDL Coder / Discrete

Description

The Tapped Delay block delays an input by the specified number of sample periods and provides an output signal for each delay. For example, when you specify 4 for **Number of delays** and **Order output starting with** is **Oldest**, the block provides four outputs — the first delayed by four sample periods, the second delayed by three, and so on. Use this block to discretize a signal in time or resample a signal at a different rate.

The block accepts one scalar input and generates an output vector that contains data for each incremental delay. Specify the order of the delayed signals in the output vector with the **Order output vector starting with** parameter:

- **Oldest** orders the output vector starting with the oldest delay version and ending with the newest delay version.
- **Newest** orders the output vector starting with the newest delay version and ending with the oldest delay version.

Specify the output vector for the first sampling period with the **Initial condition** parameter. Careful selection of this parameter can mitigate unwanted output behavior.

Specify the time between samples with the **Sample time** parameter. Specify the number of delays with the **Number of delays** parameter. A value of -1 instructs the block to inherit the number of delays by backpropagation. Each delay is equivalent to the z^{-1} discrete-time operator, which the Unit Delay block represents.

Ports

Input

Port_1 — Input signal
scalar

Input signal to delay.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Delayed versions of input signal
scalar | vector

All versions of the delayed input signal. Use the **Order output vector starting with** parameter to specify the order of delayed signals in the output vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Initial condition — Initial output

`0.0` (default) | scalar

Specify the initial output of the simulation. The **Initial condition** parameter is converted from a double to the input data type offline using round-to-nearest and saturation.

Limitations

The initial condition of this block cannot be `inf` or `NaN`.

Programmatic Use

Block Parameter: `vinit`

Type: character vector

Values: scalar

Default: `'0.0'`

Sample time — Time between samples

`-1` (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: `samptime`

Type: character vector

Values: scalar | vector

Default: `'-1'`

Number of delays — Number of discrete-time operators

`4` (default) | positive scalar | `-1` (for inherited)

Specify the number of discrete-time operators as a positive scalar, or `-1` for inherited.

Programmatic Use

Block Parameter: `NumDelays`

Type: character vector

Values: positive scalar | `-1` (inherited)

Default: `'4'`

Order output vector starting with — Order of output

`Oldest` (default) | `Newest`

Specify whether to output the oldest delay version first, or the newest delay version first.

Programmatic Use**Block Parameter:** DelayOrder**Type:** character vector**Values:** 'Oldest' | 'Newest'**Default:** 'Oldest'**Include current input in output vector** — Include current input in output vector

off (default) | on

Select this check box to include the current input in the output vector.

Terminate Function

Execute subsystem on model terminate event

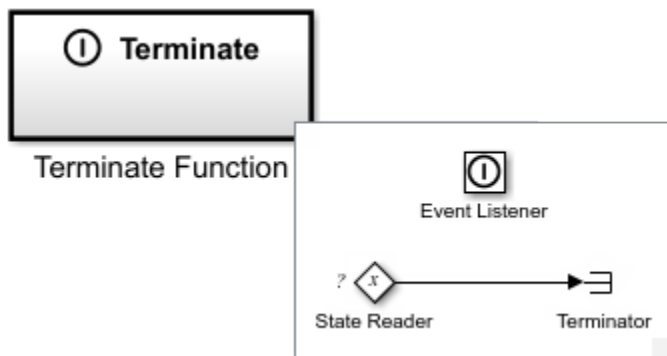

Libraries:
Simulink / User-Defined Functions

Description

The Terminate Function block is a preconfigured Subsystem block that executes on a model terminate event. By default, the Terminate Function block includes:

- An Event Listener block with the **Event type** set to Terminate
- A Terminator block
- A State Reader block with no **State owner block** set

Customize the contents of the Terminate Function block by, for example, specifying a **State owner block** for the State Reader block and replacing the Terminator block with blocks to save the state value from the State Reader block.

Conditionally executed subsystems with output ports are fully supported within Terminate Function blocks.

For a list of unsupported blocks and features, see “Initialize, Reinitialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_terminate` function that is called once at the end of model execution.

You can select an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block or a corresponding state owner block to highlight blocks related to it. To show a related block in an open diagram or new tab, pause on the ellipsis that appears after selection. Then, select

Related Blocks  from the action bar. When multiple blocks correspond to the selected block, a

list of related blocks opens. You can filter the list of related blocks by entering a search term in the text box. After you select a related block from the list, window focus goes to the open diagram or new tab that shows the related block.

Terminator

Terminate unconnected output port

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Sinks
 HDL Coder / Sinks

Description

Use the Terminator block to cap blocks whose output ports do not connect to other blocks. If you run a simulation with blocks having unconnected output ports, Simulink issues warning messages. Using Terminator blocks to cap those blocks helps prevent warning messages.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | n-D array | bus

Use this port to direct signals from output ports that are otherwise unconnected during a simulation. The port accepts real or complex signals of all data types.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus | image

Block Characteristics

Timed-Based Linearization

Generate linear models in base workspace at specific times

Libraries:

Simulink / Model-Wide Utilities

Description

This block calls `linmod` or `dlinmod` to create a linear model for the system when the simulation clock reaches the time specified by the **Linearization time** parameter. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

Note `linmod` and `dlinmod` provide only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Timed_Based_Linearization`, for example, `vdp_Timed_Based_Linearization`. The structure has the following fields:

Field	Description
<code>a</code>	The A matrix of the linearization
<code>b</code>	The B matrix of the linearization
<code>c</code>	The C matrix of the linearization
<code>d</code>	The D matrix of the linearization
<code>StateName</code>	Names of the model's states
<code>OutputName</code>	Names of the model's output ports
<code>InputName</code>	Names of the model's input ports
<code>OperPoint</code>	A structure that specifies the operating point of the linearization. The structure specifies the operating point time (<code>OperPoint.t</code>). The states (<code>OperPoint.x</code>) and inputs (<code>OperPoint.u</code>) fields are not used.
<code>Ts</code>	The sample time of the linearization for a discrete linearization

Tip To generate models conditionally, use the Trigger-Based Linearization block.

Parameters

Linearization time — Time at which to generate a linear model

1 (default) | scalar | vector

Time at which you want the block to generate a linear model. Enter a vector of times if you want the block to generate linear models at more than one time step.

Programmatic Use

Block Parameter: LinearizationTime

Type: character vector

Values: scalar | vector

Default: '1'

Sample time (of linearized model) — Sample time

0 (default) | scalar | vector

Specify a sample time for the linear model. To create a continuous-time model using `linmod`, specify a sample time of 0. Otherwise, to create a discrete-time model using `dlinmod`, specify a positive sample time (see “Discrete-Time System Linearization” on page 2-44).

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '0'

Block Characteristics

Data Types	
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2010a

Trigger-Based Linearization | `dlinmod` | `linmod`

Topics

“Discrete-Time System Linearization” on page 2-44

To File

Write data to file

Libraries:
 Simulink / Sinks
 HDL Coder / Sinks

Description

The To File block writes input signal data into a MAT-file. The block writes to the output file incrementally, with minimal memory overhead during simulation. If the output file exists when the simulation starts, the block overwrites the file. The file automatically closes when you pause the simulation or the simulation completes. If simulation terminates abnormally, the To File block saves the data it has logged up until the point of the abnormal termination.

The To File block icon shows the name of the output file.

Control Amount of Data Saved

If you specify data logging intervals with the **Configuration Parameters > Data Import/Export > Logging intervals** parameter, the To File block logs only data inside of the intervals. For example, the block logs no data if the intervals are empty ([]). The block stores the logged data in the file associated with the block instead of in the variable that you specify for the **Single simulation output** parameter.

For variable-step solvers, to control the amount of data available to the To File block, use the **Configuration Parameters > Data Import/Export > Additional parameters > Output options** parameter. For example, to write data at identical time points over multiple simulations, select the **Produce specified output only** option.

Block parameters also control the amount of data saved. See “Decimation” on page 1-0 and “Sample time” on page 1-0 .

Pause Simulation

After pausing a simulation, do not alter any file that a To File block logs into. For example, do not save such a file with the MATLAB save command. Altering the file can cause an error when you resume the simulation. If you want to alter the file after pausing, copy the file and work with the copy of the file.

If you pause using the Simulation Stepper, the To File block captures the simulation data up to the point of the pause. When you step back, the To File data file no longer contains any simulation data past the new reduced time of the last output.

Limitations

When a To File block is in a referenced model, that model must be a single-instance model. Only one instance of such a model can exist in a model hierarchy. See “Model Reuse” for more information.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | array

Signal to store in file. Each sample consists of a timestamp and an associated data value. The data can be in array format or MATLAB timeseries format. The To File block accepts real or complex signal data of any data type that Simulink software supports, except fixed-point data with a word length greater than 32 bits.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

File name — Path or file name

untitled.mat (default) | MAT-file path or name

Specify the path or file name of the MAT-file in which to store the output. On UNIX systems, the path name can start with a tilde (~) character signifying your home folder. If you specify a file name without path information, Simulink software stores the file in the MATLAB working folder. (To determine the working folder, at the MATLAB command line, enter pwd.) If the file exists, Simulink software overwrites it.

Programmatic Use

Block Parameter: FileName

Type: character vector

Values: MAT-file path or name

Default: 'untitled.mat'

Variable name — Matrix name

ans (default) | character vector

Specify the name of the matrix contained in the file.

Programmatic Use

Block Parameter: MatrixName

Type: character vector

Values: character vector

Default: 'ans'

Save format — Data format

Timeseries (default) | Array

Specify the data format that the To File block uses for writing data.

Use the Array format only for vector, double, noncomplex signals.

For the Timeseries format, the To File block:

- Writes data in a MATLAB `timeseries` object.
- Supports writing multidimensional, real, or complex output values.
- Supports writing output values that have any built-in data type, including `Boolean`, enumerated (`enum`), and fixed-point data with a word length of up to 32 bits.
- For virtual and nonvirtual bus input signals, creates a MATLAB structure that matches the bus hierarchy. Each leaf of the structure is a MATLAB `timeseries` object.

For the Array format, the To File block:

- Writes data into a matrix containing two or more rows. The matrix has the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u_{11} & u_{12} & \dots & u_{1final} \\ \dots & & & \\ u_{n1} & u_{n2} & \dots & u_{nfinal} \end{bmatrix}$$

Simulink software writes one column to the matrix for each data sample. The first element of the column contains the timestamp. The remainder of the column contains data for the corresponding output values.

- Supports writing data that is one-dimensional, double, and noncomplex.

The From File block can use data written by a To File block in any format (`Timeseries` or `Array`) without any modifications to the data or other special provisions.

The From Workspace block can read data that is in the `Array` format and is the transposition of the data written by the To File block. To provide the required format, use MATLAB commands to load and transpose the data from the MAT-file.

The following table shows how simulation mode support depends on the **Save format** value.

Simulation Mode	Timeseries	Array
Normal	Supported	Supported
Accelerator	Supported	Supported
Rapid Accelerator	Supported	Supported
Software-in-the-loop (SIL)	Not supported	Supported if MAT-file logging is enabled
Processor-in-the-loop (PIL)	Not supported	Supported if MAT-file logging is available and enabled
External	Not supported	Supported if MAT-file logging is enabled
RSim target	Supported	Supported if MAT-file logging is enabled

Programmatic Use

Block Parameter: `SaveFormat`

Type: character vector

Values: `'Timeseries'` | `'Array'`

Default: `'Timeseries'`

Decimation — Decimation factor that determines when data writes

1 (default) | scalar | vector

Specify the decimation factor, n , that writes data at every n th time that the block executes. The default value has this block writing data at every time step.

Programmatic Use

Block Parameter: Decimation

Type: character vector

Values: scalar | vector

Default: '1'

Sample time — Sample period and offset

-1 (default) | scalar | vector

Specifies the sample period and offset at which to collect data points. This parameter is useful when you are using a variable-step solver where the interval between time steps is not constant. The default value causes the block to inherit the sample time from the driving block. See “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar | vector

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point ^a integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

^a Supports up to 32-bit fixed-point data types.

Tips

- If MATLAB encounters memory issues when you log many signals in a long simulation that has many time steps, consider logging to persistent storage. When you log to persistent storage, the Dataset format logging data is stored in a MAT-file. Compared to logging to persistent storage, connecting a To File block to signals:
 - Is a per-signal approach that can clutter a model with several To File blocks attached to individual signals.
 - Creates a separate MAT-file for each To File block, compared to the one MAT-file that logging to persistent storage uses.

For details, see “Log Data to Persistent Storage”.

- To avoid the overhead of compressing data in real time, the To File block writes an uncompressed Version 7.3 MAT-file. To compress the data within the MAT-file, load and save the file in MATLAB. The resaved file is smaller than the original MAT-file that the To File block created, because the **Save** command compresses the data in the MAT-file.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.

To generate code for a To File block, on the **Code Generation > Interface** pane, select the configuration parameter MAT-file logging (Simulink Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for writing simulation results to a file when used with subsystems that generate HDL code, but is not included in the hardware implementation

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

To Workspace

Log data to workspace from Simulink model

Libraries:
 Simulink / Sinks
 DSP System Toolbox / Sinks
 HDL Coder / Sinks

Description

The To Workspace block logs the data connected to its input port to a workspace from a Simulink model. Typically, logged data is returned in the base workspace. When you simulate a model programmatically inside a function, logged data is returned in the workspace for the function. During simulation, logged data streams to the Simulation Data Inspector. Logged data is written to the workspace when the simulation pauses or stops.

You can use the To Workspace block to log data for a signal, a bus, or an array of buses. The To Workspace block supports logging scalar and multidimensional data, including data for variable-size signals.

You can configure the name of the variable that stores the data the To Workspace block logs, and you can specify the format for the logged data. You can also control which values the To Workspace block logs by specifying block or model parameters. For more information, see “Specify Signal Values to Log”.

Access Logged Data

How simulation results are returned to the workspace depends on how you simulate and configure the model. Simulation results are returned in a single `Simulink.SimulationOutput` object in any of these situations:

- You enable the **Single simulation output** parameter.

By default, the **Single simulation output** parameter is enabled when you create a new model. You can enable the parameter using the Configuration Parameters dialog box. On the **Modeling** tab, under **Settings**, click **Model Settings**. Then, in the Configuration Parameters dialog box, select **Data Import/Export** and select **Single simulation output**.

- You run a set of simulations using the **Multiple Simulations** pane.
- You simulate the model programmatically using one or more `Simulink.SimulationInput` objects.

You can configure simulations using `SimulationInput` objects when you run simulations using the `sim`, `parsim`, and `batchsim` functions.

- You simulate the model using a `sim` function syntax that returns results as a single simulation output.

For more information, see `sim`.

When simulation results are returned in a single output, the `SimulationOutput` object contains a variable for each To Workspace block in the model. To access the data logged by a To Workspace block:

- Use a dot with the variable name specified using the **Variable name** parameter of the block. By default, models are configured to return a single simulation output using the variable name `out`, and the To Workspace block saves data to a variable named `simout`.

```
toWksData = out.simout;
```

- Use the `get` function with the name of the variable that contains the logged data.

```
toWksData = get(out,simout);
```

In the model, the To Workspace block indicates how to access the data in the workspace. By default, the block shows `out.simout`. The block appearance updates when you:

- Specify a different value for the **Variable name** parameter on the block.
- Specify a different variable name for the single simulation output.
- Clear the **Single simulation output** configuration parameter.

Ports

Input

Port_1 — Data to log to workspace
scalar | vector | matrix | array | bus

Input port that receives data to log to workspace. The To Workspace block supports logging real and complex data of any built-in data type or user-defined data types such as buses, enumerations, and fixed-point data.

Tips

Logging fixed-point data requires a license for Fixed-Point Designer.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `string` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Variable name — Name of variable for saved data

`simout` (default) | string | character vector

Specify a name for the variable that contains the logged data. By default, the To Workspace block saves logged data in a variable called `simout`. When a model contains multiple To Workspace blocks, the **Variable name** parameter value for each block must be unique.

For information about naming MATLAB variables, see “Variable Names”.

Programmatic Use

t

Block Parameter: `VariableName`

Type: string | character vector
Value: Valid MATLAB variable name
Default: 'simout'

Limit data points to last — Number of samples to log

inf (default) | scalar | vector

When you want to save or analyze only the data from the end of a simulation, specify the number of samples you want to log as a positive whole number greater than zero. By default, the To Workspace block logs data for the entire simulation, and the value for the **Limit data points to last** parameter is inf.

For more information about controlling which samples are logged during simulation, see “Specify Signal Values to Log”.

Programmatic Use

Block Parameter: MaxDataPoints

Type: string | character vector

Values: 'inf' | positive integer greater than zero

Default: 'inf'

Decimation — Decimation factor

1 (default) | scalar

Specify a decimation factor to reduce the effective sample rate for the logged data. For a decimation factor, n , the To Workspace block logs every n^{th} sample value. For example, when you specify the **Decimation** value as 2, the To Workspace block logs every other data point.

For more information about controlling which samples are logged during simulation, see “Specify Signal Values to Log”.

Programmatic Use

Block Parameter: Decimation

Type: string | character vector

Values: scalar

Default: '1'

Save format — Format for data logged to workspace

Timeseries (default) | Structure With Time | Structure | Array

Specify the format for the data logged to the workspace. To log data for a bus or array of buses input, use Timeseries format.

Save Format Value	Workspace Data Format	Simulation Workflow Support
Timeseries	<p>Nonbus input logged as a <code>timeseries</code> object.</p> <p>Bus input logged as a structure of <code>timeseries</code> objects. The hierarchy and names for fields in the structure matches the hierarchy and names specified in the <code>Simulink.Bus</code> object that defines the bus.</p> <p>Array of buses input logged as an array of structures of <code>timeseries</code> objects.</p>	<p>Supported:</p> <ul style="list-style-type: none"> • Normal mode simulation • Accelerator mode simulation • Rapid accelerator mode simulation • External mode simulation that uses XCP communication provided <code>StreamToWks</code> is set to 'on' and <code>MATFileLogging</code> is set to 'off' <p>Not supported:</p> <ul style="list-style-type: none"> • External mode simulation that uses TCP/IP or serial communication • Software-in-the-loop (SIL) simulation • Processor-in-the-loop (PIL) simulation • Code generation for Simulink Coder targets
Structure With Time	<p>Nonbus input logged as a structure that contains these fields:</p> <ul style="list-style-type: none"> • <code>time</code> — Column vector of simulation time hits for which input value was logged. • <code>signals</code> — Structure with sample values that contains the fields: <ul style="list-style-type: none"> • <code>values</code> — Array of sample values. • <code>dimensions</code> — Sample dimensions. • <code>label</code> — Name of signal line in model. • <code>blockName</code> — Name of the To Workspace block. 	<p>Always supported:</p> <ul style="list-style-type: none"> • Normal mode simulation. • External mode simulation that uses XCP communication provided <code>StreamToWks</code> is set to 'on' and <code>MATFileLogging</code> is set to 'off' <p>Supported except when the To Workspace block is in a referenced model:</p> <ul style="list-style-type: none"> • Accelerator mode simulation • Rapid accelerator mode simulation • External mode simulation that uses TCP/IP or serial communication <p>Supported if MAT-file logging is enabled for generated code, except when the To Workspace block is in a referenced model:</p>

Save Format Value	Workspace Data Format	Simulation Workflow Support
Structure	<p>Nonbus input logged as a structure that matches the Structure With Time format, but the time field of the structure is empty.</p>	<ul style="list-style-type: none"> • Software-in-the-loop (SIL) simulation • Processor-in-the-loop (PIL) simulation • Code generation for Simulink Coder targets
Array	<p>Sample values for nonbus input saved as N-dimensional array, where N is one greater than the dimensions of the input. For example:</p> <ul style="list-style-type: none"> • Scalar signal data is logged as a column vector. • Vector signal data is logged as a matrix. • Matrix signal data is logged as a 3-D array. <p>The structure of the values in the array depends on the dimensions of the input signal data:</p> <ul style="list-style-type: none"> • For scalar and vector signals, each sample value is a row in the output array. The first dimension of the array aligns with time such that <code>simout(1, :)</code> returns the first logged signal value. • For matrix signals, the third dimension of the output array aligns with time such that <code>simout(:, :, 1)</code> returns the first logged signal value. • For N-dimensional signals, the last dimension aligns with time, such that the number of elements in the last dimension is equal to the number of samples logged from simulation. <p>The output array contains only signal values and does not contain time data.</p>	

Tips

- To log data as frame-based instead of sample-based:
 - Configure the **Save format** parameter to log data using the Structure format or the Array format.
 - Specify the **Save 2-D signals as** parameter as 2-D array (concatenate along first dimension)
- When you want to load the logged data using a From Workspace block, consider using the Timeseries or Structure With Time formats. When you log data using the Array format, you need to incorporate the sample time values into the array before loading the data.

Programmatic Use

Block Parameter: SaveFormat

Type: string | character vector

Values: 'Timeseries' | 'Structure with Time' | 'Structure' | 'Array'

Default: 'Timeseries'

Save 2-D signals as — Arrangement of 2-D sample values in logged data

3-D array (concatenate along third dimension) (default) | 2-D array (concatenate along first dimension)

Specify whether to log 2-D input data as a 3-D array or a 2-D array.

Logging as a 3-D array is well suited for sample-based input data. Samples are concatenated along the third dimension, allowing easy access of 2-dimensional sample data.

Logging as a 2-D array is well suited for frame-based input data. Samples are concatenated along the first dimension, which in effect removes the frame buffering from the first dimension.

Input Data Dimensions	Save 2-D Signal As...	Workspace Data Dimensions
<i>M</i> -by- <i>N</i>	2-D array (concatenate along first dimension)	<i>K</i> -by- <i>N</i> matrix, where <i>K</i> is equal to <i>M</i> times the number of samples logged from simulation. For example, logging ten samples of a 2-by-4 matrix input creates a 20-by-4 matrix.
	3-D array (concatenate along first dimension)	<i>M</i> -by- <i>N</i> -by- <i>K</i> array, where <i>K</i> is equal to the number of samples logged from simulation. For example, logging ten samples of a 2-by-4 matrix input creates a 2-by-4-by-10 array.

Dependencies

To enable this parameter, set the **Save format** to Array or Structure.

Programmatic Use

Block Parameter: Save2DSignal

Type: string | character vector

Values: '2-D array (concatenate along first dimension)' | '3-D array (concatenate along third dimension)'

Default: '3-D array (concatenate along third dimension)'

Log fixed-point data as a fi object — Data type for logged fixed-point data

on (default) | off

Specify how to log fixed-point input data. By default, the To Workspace block logs fixed-point data as a `fi` object. When you clear this parameter, the To Workspace block logs fixed-point input data as `double`.

The To Workspace block always logs fixed-point data as a `fi` object when you:

- Simulate the model in rapid accelerator mode.
- Specify the **Save format** parameter as `Timeseries`.

Using the To Workspace block to log fixed-point data requires a license for Fixed-Point Designer.

Programmatic Use

Block Parameter: `FixptAsFi`

Type: string | character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Sampling interval and optional time offset

-1 (default) | scalar

Specify when the block logs the input value during simulation. By default, the sample time is inherited (-1). For continuous sample time, specify the value as \emptyset . To use a discrete sample time, specify the **Sample time** parameter as a scalar. For more information, see “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`

Type: string | character vector

Values: scalar

Default: '-1'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Tips

- You can convert data logged using the To Workspace block to `Dataset` format. Converting the data can make post-processing easier if you use other logging techniques, such as signal logging, that use the `Dataset` format. For more information, see “Convert timeseries object to Dataset object”.
- When you call a function that simulates a model, data logged in simulation is returned to the function workspace. To return data logged from a simulation in a function to the base workspace, use the `assignin` function. For example, this function called `myfunc` simulates the model `myModel`, which includes a To Workspace block that logs data to the variable `simout` and sends the data logged by the To Workspace block to the base workspace.

```
function myfunc
    out = sim("myModel");
    toWksData = get(out,"simout");
    assignin("base","toWksData",toWksData);
end
```

Version History

Introduced before R2006a

R2022a: Log data to the Simulation Data Inspector as well as the workspace

Behavior changed in R2022a

Data is automatically logged to the Simulation Data Inspector as well as the workspace. The Simulation Data Inspector automatically retains results from each simulation. Because data logged using the To Workspace block streams to the Simulation Data Inspector, this data is also retained.

In previous releases, data logged using the To Workspace block only logged to the workspace and was overwritten for each simulation unless you changed the logging variable names or manually saved the results.

In most cases, you do not need to make any changes to your code. Logging large amounts of data or running many simulations can produce large amounts of data that fill up disk space. To learn how to control the amount of data retained in the Simulation Data Inspector, see “Limit the Size of Logged Data”.

R2022a: Log `int64` and `uint64` data using built-in data types

Behavior changed in R2022a

Log `int64` and `uint64` data using the built-in data types.

In previous releases, the To Workspace block logged `int64` and `uint64` data as a `fi` object when a license for Fixed-Point Designer was available and as `double` when the license was not available.

R2022a: Log signals with `string` and `half` data types

The To Workspace block supports logging signals with `string` and `half` data types.

R2022a: Log arrays of buses

The To Workspace block supports logging an array of buses.

R2022a: Log data using the Timeseries format in rapid accelerator simulations

Previously, only normal mode simulation or accelerator mode simulation could be used to log data in Timeseries format.

R2022a: Log data using the Timeseries format for To Workspace blocks inside for-each subsystems

You can use the Timeseries format to log data in a To Workspace block inside for-each subsystems.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

To generate code that logs the input to the To Workspace block to a MAT file, enable the **MAT-file logging** parameter. For more information, see **MAT-file logging**.

Code generation is not supported for blocks inside referenced models or blocks that log data using the Timeseries format. For more information, see **Save format**.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Toggle Switch

Change parameter or variable value using switch with customizable appearance

On

Libraries:

Simulink / Dashboard / Customizable Blocks

Description

Use the Toggle Switch block to change the value of the connected variable or parameter before or during simulation. When you use the Toggle Switch block in the Customizable Blocks library, you can customize the appearance of the block to look like a real switch in your system. You can configure the switch with any number of states to customize the behavior. For example, you could design a three-way toggle switch or a gearbox. Use the Toggle Switch block with other dashboard blocks to create an interactive dashboard for your model.

Note Double-clicking the Toggle Switch block does not open its dialog box during simulation or when the block is selected. To edit the block parameters, you can use the Property Inspector or open the block dialog box by:

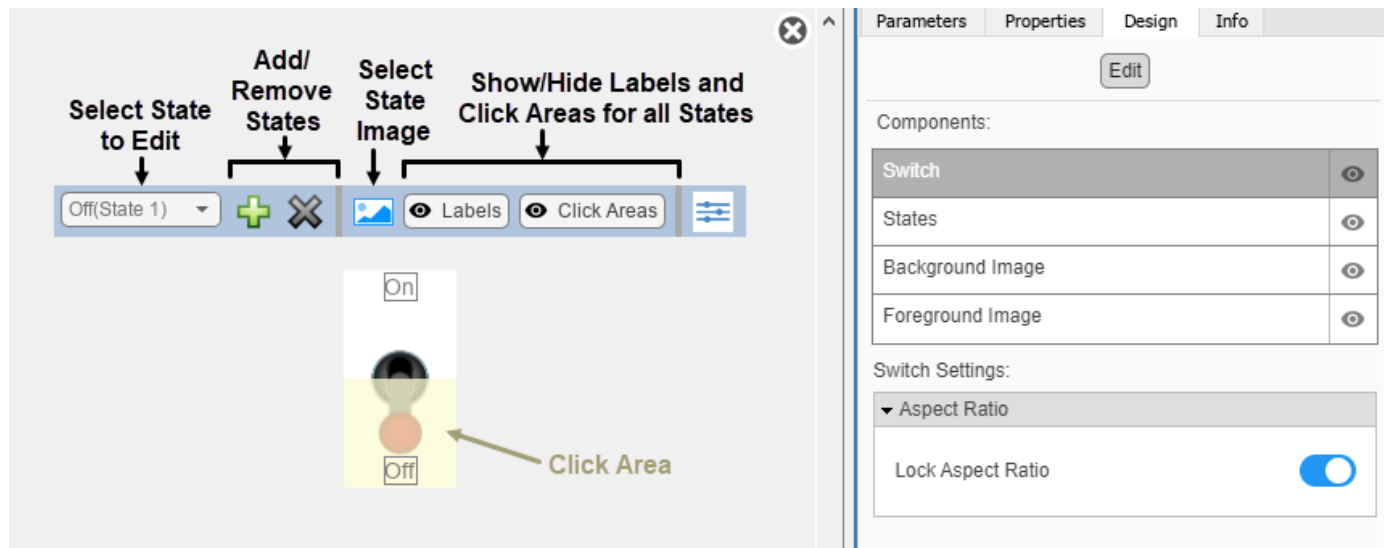

- Double-clicking the block when the block is not selected and the model is not simulating
 - Right-clicking the block and selecting **Block Parameters** from the context menu
-

Customize Toggle Switch Blocks

When you add a Toggle Switch block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can add any number of states to the block. To add or delete states, use the toolbar above the block.

For each state, you can:

- Upload an image that defines the appearance of the block in the state.
- Configure the size and position of the click area for the state.
- Specify the State Value.
- Specify the State Label text, color, and position.

To upload an image for a state, use the toolbar above the block.

To resize the click area of a state, in the toolbar above the block, select the state from the drop-down menu. Then, click and drag the grab points of the yellow click area in the canvas. To reposition the click area, click and drag it in the canvas.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the State Value.
- Specify the State Label.
- Upload a foreground image.
- Upload a background image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at

once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

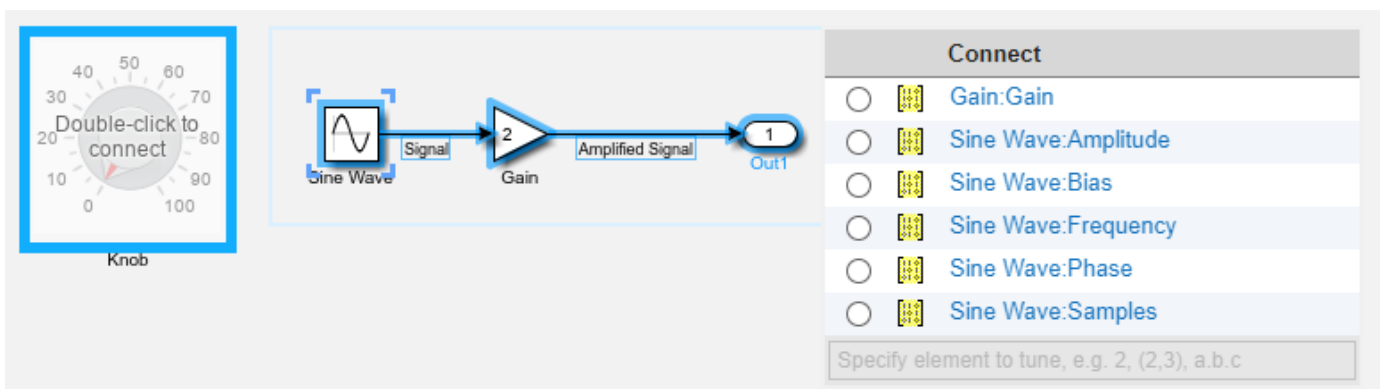

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect** and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.

- To exit bind mode, click **Done Connecting**  over the dashboard block.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Label — Position of label displaying name of connected element

Hide (default) | Bottom | Top

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify `Hide`.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use

Block Parameter: `LabelPosition`

Type: character vector

Values: `'Hide'` | `'Bottom'` | `'Top'`

Default: `'Hide'`

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States — Pairings of value with label
scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of 0.
- In the **On** state, the block assigns the connected variable or parameter a value of 1.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the + button. To delete the current state, click the - button.

Tip You can configure a variety of other parameters for a state besides the value and label in design mode. For example, you can select an image that will appear on the switch when it is in the state. To configure parameters in design mode:

- 1 Enter design mode. In the Property Inspector, on the **Design** tab, click the **Edit** button.
 - 2 On the **Design** tab, open the **States** component, expand the **Select State** section, and select the state that you want to configure from the drop-down menu.
 - 3 Configure the parameter values for the selected state, either using the toolbar above the block, or in the **States** component on the **Design** tab in the Property Inspector.
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;  
leftState.Label = 'Off';  
rightState.Value = 1;  
rightState.Label = 'On';  
switchStates = [leftState rightState];
```

Block Parameter: States

Type: two element array of structures

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Switch

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

States**Select State** — Management and configuration of states

scalar and character vector

Each state pairs a **State Value** with a **State Label**. When the block is in a given state, it assigns the **State Value** for that state to the connected variable or parameter. You can use the **State Label** to display the value assigned to the connected variable or parameter on the block or to provide a descriptive text label.

By default, the switch has two states, one corresponding to each switch position:

- In the **Off** state, the block assigns the connected variable or parameter a value of **0**.
- In the **On** state, the block assigns the connected variable or parameter a value of **1**.

You can use a customizable switch block to design a switch with any number of states greater than or equal to 1. To add a new state, click the **+** button. To delete the current state, click the **X** button.

To configure a state, in the **States** component, expand the **Select State** section and select the state.

You can configure the value, label text, and a variety of other parameters for the selected state in the **States** component on the **Design** tab in the Property Inspector. For example, you can select an image that will appear on the switch when it is in the state.

All changes that you make to parameter values in the **States** component are applied only to the selected state. To configure a different state, in the **Select State** section, select the state in the drop-down menu. Then, configure the parameter values of that state in the **States** component.

Tip Alternatively, you can:

- Configure the parameters for the selected state using the toolbar that appears above the switch block in design mode
 - Configure the values and label text of the states for the block using the **Parameters** tab in the Property Inspector
-

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.

- **Label** — String or character array to use as the label for the switch position.

```
leftState.Value = 0;  
leftState.Label = 'Off';  
rightState.Value = 1;  
rightState.Label = 'On';  
switchStates = [leftState rightState];
```

Block Parameter: States**Type:** two element array of structures**Value** — State value

scalar

Each state pairs a **State Value** with a **State Label**. Specify the **State Value** that activates the state selected in the **Design** tab.

Text — State label text

string | character array

Each state pairs a **State Value** with a **State Label**. Specify the text for the **State Label** of the state selected in the **Design** tab.

Label Color — Button label font color

[r g b] vector

Choose a font color for the button label from the palette of standard colors, or specify a custom color. The color is applied to the button label for the state that is selected in the **Select State** section of the **States** component on the **Design** tab.

Label X Offset — Horizontal offset of text center from left edge of block

scalar

Specify the horizontal offset of the center of the **State Label** from the left edge of the block as a ratio of the block width. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text left, and an offset with a positive value moves the text right.

Label Y Offset — Vertical offset of text center from top edge of block

scalar

Specify the vertical offset of the center of the **State Label** from the top edge of the block as a ratio of the block height. Relative to the position of the text when the offset is 0, an offset with a negative value moves the text up, and an offset with a positive value moves the text down.

Image X Offset — Horizontal offset of left edge of image from left edge of block

scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width

scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Click Area X Offset — Horizontal offset of left edge of click area from left edge of block

scalar

Specify the horizontal offset of the left edge of the click area from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Click Area Y Offset — Vertical offset of top edge of click area from top edge of block

scalar

Specify the vertical offset of the top edge of the click area from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Click area width

scalar

Specify the click area width as a ratio of the block width.

Example: 0.5

Height — Click area height

scalar

Specify the click area height as a ratio of the block height.

Example: 0.5

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block

scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width

scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Tips

- When you want to design a circular switch that distributes the state labels and the click areas that cause state transitions on an arc, consider using the Rotary Switch block.
- To design a control that applies values to a connected variable or parameter from a continuous range, use the Knob, Horizontal Slider, or Vertical Slider blocks.

Version History

Introduced in R2021b

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

[“Getting Started with Panels”](#)

Toggle Switch

Toggle parameter between two values

Libraries:
Simulink / Dashboard

Description

The Toggle Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Toggle Switch block to a Switch block in your model and change its state during simulation. Use the Toggle Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Toggle Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

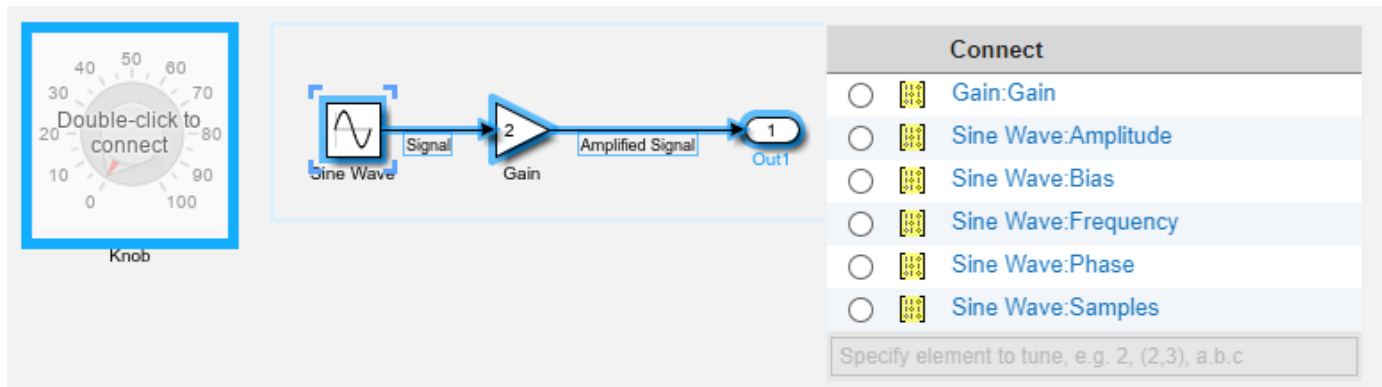

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus

or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify `a.b` to connect to scalar element `b` of the structure or bus `a` nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.

- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Connection — Select a variable or block parameter to connect
variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. To connect the block to a signal:

- 1 Make a selection in the model that includes one or more blocks.
- 2 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1,3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 3 Click **Apply**.

To facilitate understanding and debugging your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some of the properties apply to connecting dashboard blocks to parameters, and some apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: []

States — Pair values and labels
scalar and character vector

Pairs of values to assign to the connected variable or parameter and text to display on the block. Switches have two states — **Top** and **Bottom** — one corresponding to each switch position. Each state contains a **Value** and a **Label**.

- **Value** — Value to assign to the connected variable or parameter when the switch is in the corresponding position.
- **Label** — Text to display on the block for the corresponding position.

This table describes the default configuration for the block.

States

Position	State Value	State Label
Top	0	on
Bottom	1	off

Programmatic Use

To configure the **States** for the block programmatically, specify the value of the **States** parameter as a structure array containing two elements with fields:

- **Value** — Scalar double value for the state.
- **Label** — String or character array to use as the label for the switch position.

```
topState.Value = 0;
topState.Label = 'Off';
bottomState.Value = 1;
bottomState.Label = 'On';
switchStates = [topState bottomState];
```

Block Parameter: States

Type: two element array of structures

Label — Block label position

Top (default) | Bottom | Hide

Position of the block label. When the block is connected to an element in the model, the label is the name of the connected element.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no

Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2015a

R2021a: Tune matrix and structure elements using dashboard blocks

Starting in R2021a, you can connect a block from the Dashboard library to a scalar element of a matrix or structure that defines the value of a tunable block parameter. When you connect a dashboard block to a tunable parameter, you first select one or more blocks. Then, in a dialog box, you select the parameter to which you want to connect. When you select a parameter that has a nonscalar value, specify the element you want to tune using the text box in the dialog box.

R2020b: Simulink Toolstrip support for dashboard blocks

Starting in R2020b, the **Block** tab in the Simulink Toolstrip turns into a block-specific tab when you select a block in your model that is from the Dashboard library in the Simulink library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can jump to the model element connected to the selected block, and you can add the selected block to a panel.

R2019a: Programmatically add and configure dashboard blocks

Starting in R2019a, you can use functions such as `add_block` and `set_param` to create and configure blocks from the Dashboard library in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

To String

Convert input signal to string signal

Libraries:
Simulink / String

Description

The To String block creates a string signal from an input signal. For example, consider using this signal to convert a logical value 1 or 0 to its string equivalent "false" or "true".

When a MinGW compiler compiles code generated from the block, running the compiled code may produce nonstandard results for floating-point inputs. For example, a numeric input of 501.987 returns the string "5.019870e+002" instead of the expected string "5.019870e+02".

Ports

Input

Port_1 — Input signal
scalar

Input signal, specified as a scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Output string
scalar

Output string, specified as a scalar. This block returns the output as a string, surrounded by double quotes.

- If the input is a Boolean, the output is a logical value (1 or 0) and the block returns its textual equivalent (true or false).
- If the input is a numeric data type, such as an integer, single, double, or fixed point, the block returns the number as a string. For example, an input of 1 converts to "1" and an input of 0 converts to "0".

Note The output string might not contain all the digits of the numeric value from the input port.

Data Types: string

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single string
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2018a

Transfer Fcn

Model linear system by transfer function

Libraries:
Simulink / Continuous

Description

The Transfer Fcn block models a linear system by a transfer function of the Laplace-domain variable s . The block can model single-input single-output (SISO) and single-input multiple-output (SIMO) systems.

Conditions for Using This Block

The Transfer Fcn block assumes the following conditions:

- The transfer function has the form

$$H(s) = \frac{y(s)}{u(s)} = \frac{num(s)}{den(s)} = \frac{num(1)s^{nn-1} + num(2)s^{nn-2} + \dots + num(nn)}{den(1)s^{nd-1} + den(2)s^{nd-2} + \dots + den(nd)},$$

where u and y are the system input and outputs, respectively, nn and nd are the number of numerator and denominator coefficients, respectively. $num(s)$ and $den(s)$ contain the coefficients of the numerator and denominator in descending powers of s .

- The order of the denominator must be greater than or equal to the order of the numerator.
- For a multiple-output system, all transfer functions have the same denominator and all numerators have the same order.

Modeling a Single-Output System

For a single-output system, the input and output of the block are scalar time-domain signals. To model this system:

- Enter a vector for the numerator coefficients of the transfer function in the **Numerator coefficients** field.
- Enter a vector for the denominator coefficients of the transfer function in the **Denominator coefficients** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- Enter a matrix in the **Numerator coefficients** field.

Each *row* of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.

- Enter a vector of the denominator coefficients common to all transfer functions of the system in the **Denominator coefficients** field.

Specifying Initial Conditions

A transfer function describes the relationship between input and output in Laplace (frequency) domain. Specifically, it is defined as the Laplace transform of the response (output) of a system with zero initial conditions to an impulse input.

Operations like multiplication and division of transfer functions rely on zero initial state. For example, you can decompose a single complicated transfer function into a series of simpler transfer functions. Apply them sequentially to get a response equivalent to that of the original transfer function. This will not be correct if one of the transfer functions assumes a non-zero initial state. Furthermore, a transfer function has infinitely many time domain realizations, most of whose states do not have any physical meaning.

For these reasons, Simulink presets the initial conditions of the Transfer Fcn block to zero. To specify initial conditions for a given transfer function, convert the transfer function to its controllable, canonical state-space realization using `tf2ss`. Then, use the State-Space block. The `tf2ss` utility provides the A, B, C, and D matrices for the system.

For more information, type `help tf2ss` or see the Control System Toolbox™ documentation.

Transfer Function Display on the Block

The Transfer Fcn block displays the transfer function depending on how you specify the numerator and denominator parameters.

- If you specify each parameter as an expression or a vector, the block shows the transfer function using the specified coefficients for the powers of s . If you specify a variable in parentheses, the block evaluates the variable.

For example, if you specify the **Numerator coefficients** parameter value as `[3 2 1]` and the **Denominator coefficients** parameter value as `(den)`, where `den` is a workspace variable with a value of `[7 5 3 1]`, the block displays the equation using the specified values.

$$\frac{3s^2 + 2s + 1}{7s^3 + 5s^2 + 3s + 1}$$

Tip When the block size is too small to accommodate the full numerator or denominator, the block icon displays the numerator as `num(s)` and the denominator as `den(s)`.

$$\frac{\text{num}(s)}{\text{den}(s)}$$

If you want the block to show the equation for the transfer function it implements, resize the block by dragging a corner.

$$\frac{3s^2 + 2s + 1}{7s^3 + 5s^2 + 3s + 1}$$

Transfer Fcn

- If you specify each parameter as a variable, the block shows the variable name followed by (s).

For example, if you specify the **Numerator coefficients** parameter as `num` and the **Denominator coefficients** parameter as `den`, the block icon shows the numerator of the transfer function as `num(s)` and the denominator as `den(s)`

Ports

Input

Port_1 — Input signal
scalar

Input signal, specified as a scalar with data type `double`.

Data Types: `double`

Output

Port_1 — Output signal
scalar | vector

Output signal, provided as a scalar or vector with data type `double`.

- For a single-output system, the input and output of the block are scalar time-domain signals.
- For a multiple-output system, the input is a scalar, and the output is a vector, where each element is an output of the system.

Data Types: `double`

Parameters

Numerator coefficients — Vector or matrix of numerator coefficients

[1] (default) | vector | matrix

Define the numerator coefficients of the transfer function.

- For a single-output system, enter a vector for the numerator coefficients of the transfer function.
- For a multiple-output system, enter a matrix. Each row of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.

Programmatic Use

Block Parameter: Numerator

Type: character vector, string

Values: vector | matrix

Default: ' [1] '

Denominator coefficients — Row vector of denominator coefficients

[1 1] (default) | vector

Define the row vector of denominator coefficients.

- For a single-output system, enter a vector for the denominator coefficients of the transfer function.
- For a multiple-output system, enter a vector containing the denominator coefficients common to all transfer functions of the system.

Programmatic Use

Block Parameter: Denominator

Type: character vector | string

Values: vector

Default: '[1 1]'

Parameter tunability — Tunable representation of block parameters in code

Auto (default) | Optimized | Unconstrained

Tunability level of the numerator and denominator coefficients for Accelerated simulation modes and deployed simulations using Simulink Compiler. Set this parameter to `Auto` to allow Simulink to choose the appropriate level of parameter tunability.

Set this parameter to `Optimized` to generate a representation of numerator and denominator coefficients in generated code for accelerated and deployed simulations that is optimized for better simulation performance.

Set this parameter to `Unconstrained` to generate a fully tunable (between simulations) representation of the numerator and denominator coefficients in the generated code for accelerated and deployed simulations. To let Simulink determine the appropriate tunability level, select `Auto`.

Programmatic Use

Block Parameter: ParameterTunability

Type: character vector, string

Values: 'Auto' | 'Optimized' | 'Unconstrained'

Default: 'Auto'

Absolute tolerance — Absolute tolerance for computing block states

auto (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify `auto` or `-1`.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use

Block Parameter: AbsoluteTolerance

Type: character vector, string

Values: 'auto' | '-1' | any positive real-valued scalar or vector

Default: 'auto'

State Name (e.g., 'position') — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use

Block Parameter: ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Transfer Fcn Direct Form II

Implement Direct Form II realization of transfer function

$$\frac{0.2 + 0.3z^{-1} + 0.2z^{-2}}{1 - 0.9z^{-1} + 0.6z^{-2}}$$

Libraries:

Simulink / Additional Math & Discrete / Additional Discrete

Description

The Transfer Fcn Direct Form II block implements a Direct Form II realization of the transfer function that the **Numerator coefficients** and **Denominator coefficients excluding lead** parameters specify. The block supports only single input-single output (SISO) transfer functions.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal, specified as a scalar or vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal

scalar | vector

Output signal, specified as a scalar or vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Numerator coefficients — Numerator coefficients

[0.2 0.3 0.2] (default) | vector

Specify the numerator coefficients as a vector.

Programmatic Use

Block Parameter: NumCoefVec

Type: character vector

Values: vector

Default: '[0.2 0.3 0.2]'

Denominator coefficients excluding lead — Denominator coefficient

[-0.9 0.6] (default) | vector

Specify the denominator coefficients, excluding the leading coefficient, which must be 1.0.

Programmatic Use

Block Parameter: DenCoeffVec

Type: character vector

Values: vector

Default: '[-0.9 0.6]'

Initial condition — Initial condition

0.0 (default) | scalar

Specify the initial condition as a scalar.

Programmatic Use

Block Parameter: vinit

Type: character vector

Values: scalar

Default: '0.0'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: DoSatur

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

“Fixed-Point Numbers”

Transfer Fcn Direct Form II Time Varying

Implement time varying Direct Form II realization of transfer function

Libraries:

Simulink / Additional Math & Discrete / Additional Discrete

Description

The Transfer Fcn Direct Form II Time Varying block implements a Direct Form II realization of the specified transfer function. The block supports only single input-single output (SISO) transfer functions.

The input signal labeled **Den No Lead** contains the denominator coefficients of the transfer function. The full denominator has a leading coefficient of one, but it is excluded from the input signal. For example, to use a denominator of $[1 \ -1.7 \ 0.72]$, specify a signal with the value $[-1.7 \ 0.72]$. The input signal labeled **Num** contains the numerator coefficients. The data types of the numerator and denominator coefficients can be different, but the length of the numerator vector and the full denominator vector must be the same. Pad the numerator vector with zeros, if needed.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

Ports

Input

u — Input signal
scalar | vector

Input signal, specified as a scalar or vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Num — Numerator coefficients
scalar | vector

Numerator coefficients of the transfer function, specified as a scalar or vector.

Dependencies

The data types of the numerator and denominator coefficients can be different, but the length of the numerator vector and the full denominator vector must be the same. Pad the numerator vector with zeros, if needed.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Den No Lead — Denominator coefficients
scalar | vector

Denominator coefficients of the transfer function, specified as a scalar or vector, without the leading coefficient of one. The full denominator has a leading coefficient of one, but it is excluded from the input signal.

Example: For a denominator coefficient of `[1 -1.7 0.72]`, specify a signal with value `[-1.7 0.72]`.

Dependencies

The data types of the numerator and denominator coefficients can be different, but the length of the numerator vector and the full denominator vector must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

y — Output signal
`scalar` | `vector`

Output signal, specified as a scalar or vector.

The block automatically selects the data types and scalings of the output and any temporary variables.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial condition

`0.0` (default) | `scalar`

Specify the initial condition as a scalar.

Programmatic Use

Block Parameter: `vinit`

Type: `character vector`

Values: `scalar`

Default: `'0.0'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `RndMeth`

Type: `character vector`

Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Transfer Fcn First Order

Implement discrete-time first order transfer function

Libraries:
Simulink / Discrete

Description

The Transfer Fcn First Order block implements a discrete-time first order transfer function of the input. The transfer function has a unity DC gain.

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal to the first order transfer function algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Transfer function output signal
scalar | vector

Output signal that is the discrete-time first order transfer function of the input with a unity DC gain.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Pole (in Z plane) — Pole

0.95 (default) | scalar

Specify the pole.

Programmatic Use

Block Parameter: PoleZ

Type: character vector

Value: real scalar

Default: '0.95'

Initial condition for previous output — Initial condition for previous output

0.0 (default) | scalar

Specify the initial condition for the previous output.

Programmatic Use

Block Parameter: ICPrevOutput

Type: character vector

Value: real scalar

Default: '0.0'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Transfer Fcn Lead or Lag | Transfer Fcn

Transfer Fcn Lead or Lag

Implement discrete-time lead or lag compensator

Libraries:
Simulink / Discrete

Description

The Transfer Fcn Lead or Lag block implements a discrete-time lead or lag compensator of the input. The instantaneous gain of the compensator is 1, and the DC gain is equal to $(1-z)/(1-p)$, where z is the zero and p is the pole of the compensator.

The block implements a lead compensator when $0 < z < p < 1$, and implements a lag compensator when $0 < p < z < 1$.

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal that the block applies the discrete-time lead or lag compensation to.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal
scalar | vector

Output signal that is discrete-time lead or lag compensation of the input sign.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Pole of compensator (in Z plane) — Pole

0.95 (default) | scalar

Specify the pole of the compensator.

Programmatic Use

Block Parameter: PoleZ

Type: character vector

Value: real scalar

Default: '0.95'

Zero of compensator (in Z plane) — Zero of compensator

0.75 (default) | scalar

Specify the zero of compensator in the Z plane.

Programmatic Use

Block Parameter: ZeroZ

Type: character vector

Value: real scalar

Default: '0.75'

Initial condition for previous input — Initial condition for previous input

0.0 (default) | scalar

Specify the initial condition for the previous input.

Programmatic Use

Block Parameter: ICPrevInput

Type: character vector

Value: real scalar

Default: '0.0'

Initial condition for previous output — Initial condition for previous output

0.0 (default) | scalar

Specify the initial condition for the previous output.

Programmatic Use

Block Parameter: ICPrevOutput

Type: character vector

Value: real scalar

Default: '0.0'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Transfer Fcn First Order | Transfer Fcn

Transfer Fcn Real Zero

Implement discrete-time transfer function that has real zero and no pole

Libraries:
Simulink / Discrete

Description

The Transfer Fcn Real Zero block implements a discrete-time transfer function that has a real zero and effectively no pole.

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal to the discrete-time transfer function algorithm.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal
scalar | vector

Output signal that is the discrete-time transfer function with a real zero and effectively no pole of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Zero (in Z plane) — Zero

0.75 (default) | scalar

Specify the zero in the Z plane.

Programmatic Use

Block Parameter: ZeroZ

Type: character vector

Value: real scalar

Default: '0.75'

Initial condition for previous input — Initial condition for previous input

0.0 (default) | scalar

Specify the initial condition for the previous input.

Programmatic Use

Block Parameter: ICPrevInput

Type: character vector

Value: real scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate to max or min when overflows occur — Method of overflow action

off (default) | on

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Transfer Fcn | Transfer Fcn Lead or Lag

Transport Delay

Delay input by given amount of time

Libraries:
Simulink / Continuous

Description

The Transport Delay block delays the input by a specified amount of time. You can use this block to simulate a time delay. The input to this block should be a continuous signal.

At the start of simulation, the block outputs the **Initial output** parameter until the simulation time exceeds the **Time delay** parameter. Then, the block begins generating the delayed input. During simulation, the block stores input points and simulation times in a buffer. You specify this size with the **Initial buffer size** parameter.

When you want output at a time that does not correspond to times of the stored input values, the block interpolates linearly between points. When the delay is smaller than the step size, the block extrapolates from the last output point, which can produce inaccurate results. Because the block does not have direct feedthrough, it cannot use the current input to calculate an output value. For example, consider a fixed-step simulation with a step size of 1 and the current time at $t = 5$. If the delay is 0.5, the block must generate a point at $t = 4.5$. Because the most recent stored time value is at $t = 4$, the block performs forward extrapolation.

The Transport Delay block does not interpolate discrete signals. Instead, the block returns the discrete value at the required time.

This block differs from the Unit Delay block, which delays and holds the output on sample hits only.

Tip Avoid using `linmod` to linearize a model that contains a Transport Delay block. For more information, see “Linearizing Models”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal to delay, specified as a scalar, vector, or matrix.

Data Types: `double`

Output

Port_1 — Delayed signal
scalar | vector | matrix

Input signal, delayed by specified amount of time. Output has the same dimensions and data type as the input signal.

Data Types: `double`

Parameters

Time delay — Time delay

1 (default) | scalar | vector | matrix

Specify the amount of simulation time to delay the input signal before propagation to the output as a nonnegative scalar, vector, or matrix.

Programmatic Use:

Block Parameter: `DelayTime`

Type: character vector, string

Values: nonnegative scalar, vector, or matrix

Default: '1'

Initial output — Initial output value

0 (default) | scalar | vector | matrix

Specify the output that the block generates until the simulation time first exceeds the time delay input as a scalar, vector, or matrix.

Limitations

The initial output of this block cannot be `inf` or `NaN`.

A Run-to-run tunable parameter cannot be changed during a simulation run time. However, changing it before a simulation begins does not cause Accelerator or Rapid Accelerator to regenerate code.

Programmatic Use

Block Parameter: `InitialOutput`

Type: character vector, string

Values: scalar | vector | matrix

Default: '0'

Initial buffer size — Initial memory allocation

1024 (default) | positive integer scalar

Define the initial memory allocation for the number of input points to store.

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message shows the total buffer size needed.

Tips

- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block can use a large amount of memory, particularly for dimensionalized input.

Programmatic Use**Block Parameter:** BufferSize**Type:** character vector, string**Value:** positive integer scalar**Default:** '1024'**Use fixed buffer size** — Use fixed-size buffer

off (default) | on

Select this check box to use a fixed-size buffer to save input data from previous time steps.

The **Initial buffer size** parameter specifies the size of the buffer. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

Note If you have a Simulink Coder license, ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

Tips

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so can yield inaccurate results.

Programmatic Use**Block Parameter:** FixedBuffer**Type:** character vector, string**Value:** 'off' | 'on'**Default:** 'off'**Direct feedthrough of input during linearization** — Enable direct feedthrough

off (default) | on

Cause the block to output its input during linearization and trim, which sets the block mode to direct feedthrough.

Tips

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:

- 1 Compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

- 2 Terminate the compilation with the following command.

```
model([],[],[],'term');
```

- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use**Block Parameter:** TransDelayFeedthrough**Type:** character vector, string**Value:** 'off' | 'on'**Default:** 'off'**Pade order (for linearization)** — Order of Pade approximation \emptyset (default) | scalar | vector | matrix

Set the order of the Pade approximation for linearization routines as a scalar, vector, or matrix of nonnegative integers.

- The default value is \emptyset , which results in a unity gain with no dynamic states.
- Setting the order to a positive integer n adds n states to your model, but results in a more accurate linear model of the transport delay.

Programmatic Use**Block Parameter:** PadeOrder**Type:** character vector, string**Values:** scalar | vector | matrix**Default:** ' \emptyset '**Block Characteristics**

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink

Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Transpose

Compute transpose of matrix

Libraries:
Simulink / Matrix Operations

Description

The Transpose block computes the transpose of an M -by- N matrix.

Ports

Input

Port_1 — Matrix
 M -by- N matrix

Matrix, specified as an M -by- N matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Transposed matrix
 N -by- M matrix

Transposed matrix, returned as an N -by- M matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Block Characteristics

Data Types	Boolean double fixed point half integer single
Direct Feedthrough	yes

Trigger

Add trigger or function port to subsystem or model

Libraries:

Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Trigger block adds an external signal or message port to control the execution of a subsystem or a model. To enable this functionality, add this block to a Subsystem block or at the root level of a model that is referenced in a Model block.

Then, configure the Trigger block to execute a subsystem or model:

- Once at each time step, when the value of the control signal changes in a way that you specify.
- Multiple times during a time step, when the control signal is a function-call event from a Stateflow chart, Function-Call Generator block, or S-Function block.
- Based on messages received at the control port.

Ports

Output

Port 1 — Value that describes control signal or message payload
scalar | vector | matrix

If the **Trigger type** is rising, falling, either, or function-call, the port outputs a value that identifies a control signal, returned as a scalar or vector. For each element of the input signal, the value at a given time step is:

- 1 for a signal that causes a rising trigger
- -1 for a signal that causes a falling trigger
- 2 for a function-call event
- 0 in all other cases

If the **Trigger type** is message, the port outputs data extracted from message received at the control port.

Dependencies

To enable this port, select **Show output port** or select message from the **Trigger type** list.

Data Types: double | int8

Parameters

Main

Trigger type — Select the type of control signal

`rising` (default) | `falling` | `either` | `function-call` | `message`

Select the type of control signal that executes a subsystem or model.

`rising`

Trigger execution of subsystem or model when the control signal rises from a negative or zero value to a positive value. If the initial value is negative, a rising signal to zero triggers execution.

`falling`

Trigger execution of subsystem or model when the control signal falls from a positive or a zero value to a negative value. If the initial value is positive, a falling signal to zero triggers execution.

`either`

Trigger execution of subsystem or model when the control signal is either rising or falling.

`function-call`

Execute subsystem or model when the control port receives a function-call event from a Stateflow chart, Function-Call Generator block, S-Function block, or Hit Crossing block.

`message`

Trigger execution of subsystem when a message is available at the control port.

Note If **Trigger type** is set to `message`, the block must be placed inside a subsystem.

Programmatic Use

Block Parameter: `TriggerType`

Type: character vector

Values: `'rising'` | `'falling'` | `'either'` | `'function-call'` | `'message'`

Default: `'rising'`

Treat as Simulink function — Create Simulink Function block

`off` (default) | `on`

Select this parameter to create a Simulink Function block by configuring a Subsystem block that is callable with arguments from a function caller. The Trigger block must reside within the subsystem. You can edit the function prototype that displays on the block face to specify input and output arguments for the block.

Clear this parameter to remove the configuration.

Dependencies

To display and enable this parameter, select `function-call` from the **Trigger type** list.

Programmatic Use

Block Parameter: `IsSimulinkFunction`

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Execute function call asynchronously — Whether caller request to call function can wait for service execution

off (default) | on

Specify whether to execute the Simulink Function block asynchronously for a subsystem containing this Trigger port block.

- Select this check box to model asynchronous execution where the caller (client) makes a request to call the function (server). The function is executed based on the ordering defined in the **Schedule Editor** and then returns the output arguments to the caller.
- Clear this check box to model synchronous execution where the caller calls the function and the function runs immediately then returns the output arguments to the caller.

Dependencies

To display and enable this parameter, from the **Trigger type** list, select `function-call`, then select the **Treat as a Simulink Function** parameter. Then, from the **Function visibility** list, select `port`.

Programmatic Use

Block Parameter: AsynchronousFunction

Type: character vector

Values: 'on' | 'off'

Default: 'off'

Function name — Specify function name for Simulink Function block

f (default) | function name

Specify the function name for a Simulink Function block. Alternatively, you can specify the name by editing the function prototype on the face of the block.

f

Default name for a Simulink Function block.

function name

Function name that displays on the face of a Simulink Function block.

Dependencies

To display and enable this parameter, select `function-call` from the **Trigger type** list and select the **Treat as a Simulink Function** check box.

Programmatic Use

Block Parameter: FunctionName

Type: character vector

Values: 'f' | '<function name>'

Default: 'f'

Function visibility — Select scope visibility of function

scoped (default) | global | port

Select scope of Simulink Function block within subsystem or model.

scoped

Limit accessibility of function to:

- Hierarchic level containing the Simulink Function block and levels below.
- One hierarchical level above with qualification.

global

Function accessible from any part of the model hierarchy.

port

Function accessible only through an exporting function port created by a Function Element block.

Dependencies

To display and enable this parameter, select `function-call` from the **Trigger type** list, then select the **Treat as a Simulink Function** check box.

Programmatic Use

Block Parameter: `FunctionVisibility`

Type: character vector

Values: `'scoped' | 'global' | 'port'`

Default: `'scoped'`

Scope to port — Specify name of exporting function port

`''` (default) | character vector

For a Simulink Function block with port visibility, specify the name of the exporting function port created by a Function Element block through which the function can be called.

Example: `'ServerPort'`

Dependencies

To display and enable this parameter, from the **Trigger type** list, select `function-call`, then select the **Treat as a Simulink Function** check box. Then, from the **Function visibility** list, select `port`.

Programmatic Use

Block Parameter: `ScopeName`

Type: character vector

Values: `'PortName'`

Default: `''`

Enable variant condition — Controls activating the variant control (condition)

`on` (default) | `off`

Control activating the variant control (condition) defined with the **Variant Control** parameter.

Select this parameter to activate variant control of the subsystem. Selecting this parameter:

- Enables the **Variant control** parameter.
- Displays a variant badge  on the face of the block indicating that variant conditions are enabled.

Clear this parameter to deactivate variant control of the subsystem.

Dependencies

To display and enable this parameter, select `function-call` from the **Trigger type** list and select the **Treat as Simulink function** check box.

Programmatic Use

Block Parameter: Variant

Type: character vector

Values: 'off' | 'on'

Default: 'on'

Variant control — Specify variant control (condition) expression

`(inherit)` (default) | logical expression

Specify variant control (condition) expression that executes a variant Simulink Function block when the expression evaluates to `true`.

`(inherit)`

Default value for variant control. Inherits the variant condition from the corresponding Function Caller blocks in the model. When **Variant Control** is set as `(inherit)` the value for **Generate preprocessor conditionals** is inherited automatically from the Function Caller block in the model.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a logical expression.

The function is activated when the expression evaluates to `true`.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependencies

To display and enable this parameter, select `function-call` from the **Trigger type** list, select the **Treat as a Simulink Function** check box, then select the **Enable variant condition** check box.

Programmatic Use

Block Parameter: VariantControl

Type: character vector

Values: '(inherit)' | <logical expression> | `Simulink.Variant` object

Default: '(inherit)'

Generate preprocessor conditionals — Control enclosing variant choices

`off` (default) | `on`

Control enclosing variant choices within C preprocessor conditional statements.

Select this parameter to enclose variant choices within C preprocessor conditional statements (`#if`) when generating code for an ERT target.

Dependencies

To display and enable this parameter, select the **Enable variant condition** check box.

Programmatic Use**Block Parameter:** GeneratePreprocessorConditionals**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**States when enabling** — Select how to set block state values`held (default) | reset | inherit`

Select how to set block state values when the subsystem or model is disabled.

held

Leave the block states at their current values.

reset

Reset the block state values.

inheritUse the `held` or `reset` setting from the parent subsystem initiating the function-call. If the parent of the initiator is the model root, the inherited setting is `held`. If the trigger has multiple initiators, set the parents of all initiators to either `held` or `reset`.**Dependencies**To enable this parameter, select `function-call` from the **Trigger Type** list.

This parameter setting applies only if the model explicitly enables and disables the function-call subsystem. For example:

- The function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the parent subsystem.
- The function-call initiator that controls the function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the enabled subsystem containing the function-call initiator.
- The function-call initiator is a Stateflow event bound to a particular state. See “Control Function-Call Subsystems by Using `bind` Actions” (Stateflow).
- The function-call initiator is an S-function that explicitly enables and disables the function-call subsystem. See `ssEnableSystemWithTid` for an example.

Programmatic Use**Block Parameter:** StatesWhenEnabling**Type:** character vector**Values:** 'held' | 'reset' | 'inherit'**Default:** 'held'**Propagate sizes of variable-size signals** — Select when to propagate variable-size signals`During execution (default) | Only when enabling`

Select when to propagate variable-size signals.

During execution

Propagate variable-size signals at each time step.

Only when enabling

Propagate variable-size signals when executing a Subsystem block or Model block containing an Enable port, Trigger port with **Trigger type** set to `function-call`, or Action Port block. When you select this option, sample time must be periodic.

Dependencies

To display and enable this parameter for a Trigger port block, select `Function-call` from the **Trigger type** list.

Programmatic Use

Block Parameter: `PropagateVarSize`

Type: character vector

Values: `'During execution' | 'Only when enabling'`

Default: `'During execution'`

Show output port — Control display of output port

`off (default) | on`

Control display of an output port for a signal that identifies the trigger signal or function-call event signal.

Select this parameter to display the output port and determine which signal caused the trigger signal or function-call event. The width of the output port signal is the width of the control signal. The signal value is:

- 1 for a signal that causes a rising trigger
- -1 for a signal that causes a falling trigger
- 2 for a function-call event
- 0 in all other cases

Clear this parameter to remove the output port.

Dependencies

To display and enable this parameter, select an option other than `message` from the **Trigger type** list.

Programmatic Use

Block Parameter: `ShowOutputPort`

Type: character vector

Values: `'off' | 'on'`

Default: `'off'`

Output data type — Select output port data type

`auto (default) | double | int8`

Select the output port data type for the signal that identifies the trigger signal or function-call event signal.

`auto`

Data type is the same as the port connected to the output.

double

Double value.

int8

Integer value

Dependencies

To enable this parameter, select the **Show output port** check box.

The Trigger block ignores the **Data type override** setting for the Fixed-Point Tool.

Programmatic Use

Block Parameter: OutputDataType

Type: character vector

Values: 'auto' | 'double' | 'int8'

Default: 'auto'

Sample time type — Select calling rate

triggered (default) | periodic

Select the calling rate for a subsystem or model.

triggered

Apply to applications that do not have a periodic function-call frequency. A function-call initiator can execute a triggered (aperiodic) function-call subsystem one or more times per time step and can provide a series of aperiodic function-call events.

periodic

A function-call initiator can execute a periodic function-call system only once per time step and must provide a series of periodic function-call events.. A Stateflow chart is an example of a function-call initiator.

Dependencies

To enable this parameter, select Function-call from the **Trigger type** list.

Programmatic Use

Block Parameter: SampleTimeType

Type: character vector

Values: 'triggered' | 'periodic'

Default: 'triggered'

Sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify the time interval between function calls to a subsystem or model containing this Trigger port block. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

-1

Inherit time interval from the control signal.

`Ts`

Scalar where `Ts` is the time interval.

`[Ts, To]`

Vector where `Ts` is the time interval and `To` is the initial time offset.

Dependencies

To enable this parameter, select `function-call` from the **Trigger type** list and `periodic` from the **Sample time type** list.

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: `'-1' | 'Ts' | '[Ts, To]'`

Default: `'-1'`

Enable zero-crossing detection — Control zero-crossing detection

`on (default) | off`

Select this parameter to detect zero crossings.

Dependencies

To enable this parameter, select `rising`, `falling`, or `either` from the **Trigger type** list.

Programmatic Use

Block Parameter: `ZeroCross`

Type: character vector

Values: `'on' | 'off'`

Default: `'on'`

Initial trigger signal state — Select the initial state of the trigger signal

`compatibility (no trigger on first evaluation) (default) | zero | positive | negative`

Select the initial state of the trigger control signal.

`compatibility (no trigger on first evaluation)`

No trigger at the first evaluation of trigger signal. If you choose this option and the Trigger block is in a subsystem where the states are reset, the block does not reset.

`zero`

Zero. Helps to evaluate a rising or falling trigger signal at the first time step.

`positive`

Positive value. Helps to evaluate a falling trigger signal at the first time step.

`negative`

Negative value. Helps to evaluate a rising trigger signal at the first time step.

Dependencies

To display and activate this parameter, select `rising`, `falling`, or `either` from the **Trigger type** list.

Programmatic Use**Block Parameter:** InitialTriggerSignalState**Type:** character vector**Values:** 'compatibility (no trigger on first evaluation)' | 'zero' | 'positive' | 'negative'**Default:** 'compatibility (no trigger on first evaluation)'**Trigger time** — Specify when message input triggers execution of subsystem`on message available (default) | on sample time hit`

For a subsystem triggered by message input, specify timing of execution.

on message available

Trigger execution of subsystem and pull messages whenever one or more messages are available at the control port.

on sample time hit

At each time step, check whether a message is available at the control port. If so, pull one message and trigger execution of subsystem. If no message is available, do not execute subsystem at that time step.

DependenciesTo display and activate this parameter, select message from the **Trigger type** list.**Programmatic Use****Block Parameter:** TriggerTime**Type:** character vector**Values:** 'on message available' | 'on sample time hit'**Default:** 'on message available'**Schedule as aperiodic partition** — Specify immediate mode or scheduled mode for execution`on (default) | off`

For a subsystem triggered by message availability, specify execution mode.

Clear this check box for immediate mode, in which the subsystem executes as soon as a message is available at the control port, which pushes the message to the subsystem without a queue buffering the message.

Select this check box for scheduled mode, which allows subsystem execution to be deferred after a specific Simulink task while staying at the same time step.

DependenciesTo display and activate this parameter, select message from the **Trigger type** list, then select on message available from the **Trigger time** list.**Programmatic Use****Block Parameter:** ScheduleAsAperiodic**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'

Signal Attributes

Port dimensions — Specify dimensions for the trigger signal

1 (default) | [n] | [m n]

Specify dimensions for the trigger signal attached externally a Model block and passed to the inside of the block.

1

Scalar signal.

[n]

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select rising, falling, or either from the **Trigger type** list.

Programmatic Use

Block Parameter: PortDimensions

Type: character vector

Values: '1' | '[n]' | '[m n]'

Default: '1'

Trigger signal sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify time interval between block method executions for the block driving the trigger signal.

-1

Inherit time interval.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select rising, falling, or either from the **Trigger type** list.

Programmatic Use

Block Parameter: TriggerSignalSampleTime

Type: character vector

Values: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Minimum — Specify minimum output value for the trigger signal

[] (default) | real scalar

Specify minimum value for the trigger signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See Optimize using the specified minimum and maximum values (Embedded Coder).

[]

Unspecified minimum value.

real scalar

Real scalar value.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select rising, falling, or either from the **Trigger type** list.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: '[]' | '<real scalar>'

Default: '[]'

Maximum — Specify maximum output value for the trigger signal

[] (default) | real scalar

Specify maximum value for the trigger signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See Optimize using the specified minimum and maximum values (Embedded Coder).

[]

Unspecified maximum value.

real scalar

Real scalar value.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select rising, falling, or either from the **Trigger type** list.

Programmatic Use**Block Parameter:** OutMax**Type:** character vector**Values:** '[]' | '<real scalar>'**Default:** '[]'**Data type** — Select output data type for the trigger signal

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 |
 boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0) | <data type expression>

Select data type for the trigger signal attached externally to a Model block and passed to the inside of the block.

double

Double-precision floating point.

single

Single-precision floating point.

int8

Signed 8-bit integer.

uint8

Unsigned 8-bit integer.

int16

Signed 16-bit integer.

uint16

Unsigned 16-bit integer.

int32

Signed 32-bit integer.

uint32

Unsigned 32-bit integer.

int64

Signed 64-bit integer.

uint64

Unsigned 64-bit integer.

boolean

Boolean with a value of true or false.

fixdt(1,16)

Signed 16-bit fixed point number with binary point undefined.

fixdt(1,16,0)

Signed 16-bit fixed point number with binary point set to zero.

fixdt(1,16,2^0)Signed 16-bit fixed point number with slope set to 2^0 and bias set to 0.

<data type expression>

Data type object, for example `Simulink.NumericType`. You cannot enter the name of a `Simulink.Bus` object as a data type expression.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or either from the **Trigger type** list.

Programmatic Use

Block Parameter: `OutDataTypeStr`

Type: character vector

Values: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Mode — Select data type category

`Built in (default) | Fixed point | Expression`

Select data type category and display drop-down lists to help you define the data type.

Built in

Display drop-down lists for data type and **Data type override**.

Fixed point

Display drop-down lists for **Signedness**, **Scaling**, and **Data type override**.

Expression

Display text box for entering an expression.

Dependencies

To enable this parameter, select the Show data type assistant button .

Programmatic Use

No equivalent command-line parameter.

Interpolate data — Control how missing workspace data is estimated

`on (default) | off`

Control how missing workspace data is estimated when loading data from the MATLAB workspace.

Select this parameter to linearly interpolate output at time steps for which no corresponding workspace data exists.

Clear this parameter to set the output at such time steps equal to the output at the most recent time step for which data exists.

Dependencies

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or either from the **Trigger type** list.

Programmatic Use**Block Parameter:** Interpolate**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	yes

Version History**Introduced before R2006a****Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. See also “HDL Code Generation” on page 1-2345.

HDL Architecture

This block has one default HDL architecture.

Restriction

You cannot generate HDL code for a Trigger Block that has **Trigger type** set to function-call or message.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Trigger-Based Linearization

Generate linear models in base workspace when triggered

Libraries:

Simulink / Model-Wide Utilities

Description

When triggered, this block calls `linmod` or `dlinmod` to create a linear model for the system at the current operating point. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

Note `linmod` and `dlinmod` provide only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Trigger_Based_Linearization`, for example, `vdp_Trigger_Based_Linearization`. The structure has the following fields:

Field	Description
<code>a</code>	The A matrix of the linearization
<code>b</code>	The B matrix of the linearization
<code>c</code>	The C matrix of the linearization
<code>d</code>	The D matrix of the linearization
<code>StateName</code>	Names of the model's states
<code>OutputName</code>	Names of the model's output ports
<code>InputName</code>	Names of the model's input ports
<code>OperPoint</code>	A structure that specifies the operating point of the linearization. The structure specifies the value of the model's states (<code>OperPoint.x</code>) and inputs (<code>OperPoint.u</code>) at the operating point time (<code>OperPoint.t</code>).
<code>Ts</code>	The sample time of the linearization for a discrete linearization

Tip Use the Timed-Based Linearization block to generate linear models at predetermined times.

Ports

Input

Port_1 — Input signal
scalar

Input trigger signal, specified as a scalar. Specify the type of event that triggers generation of a linear model using the **Trigger type** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Parameters

Trigger type — Signal type that triggers generation of a linear model

`rising` | `falling` | `either` | `function-call`

Type of event on the trigger input signal that triggers generation of a linear model. You can select:

- `rising` — Trigger execution of subsystem or model when the trigger signal rises from a negative or zero value to a positive value. If the initial value is negative, a rising signal to zero triggers execution.
- `falling` — Trigger execution of subsystem or model when the trigger signal falls from a positive or a zero value to a negative value. If the initial value is positive, a falling signal to zero triggers execution.
- `either` — Trigger execution of subsystem or model when the trigger signal is either rising or falling.
- `function-call` — Trigger execution of subsystem or model when the trigger signal is a function-call event from a Stateflow chart, Function-Call Generator block, S-Function block, or Hit Crossing block.

Programmatic Use

Block Parameter: `TriggerType`

Type: character vector

Values: `'rising'` | `'falling'` | `'either'` | `'function-call'`

Default: `'rising'`

Sample time (of linearized model) — Sample time

`0` (default) | scalar | vector

Specify a sample time for the linear model. To create a continuous-time model using `linmod`, specify a sample time of `0`. Otherwise, to create a discrete-time model using `dlinmod`, specify a positive sample time (see “Discrete-Time System Linearization” on page 2-44).

Programmatic Use

Block Parameter: `SampleTime`

Type: character vector

Values: scalar | vector

Default: '0'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Triggered Subsystem

Subsystem whose execution is triggered by external input

Libraries:

Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes each time the control signal has a trigger value.

Use Triggered Subsystem blocks to model:

- A task that runs with the detection of a trigger value.
- An interrupt from I/O hardware.
- A processor request to handle an exception or error.

Ports

Input

In — Signal input to a subsystem block
scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the Subsystem block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | image

Trigger — Control signal input to a subsystem block
scalar

Placing a Trigger block in a subsystem adds an external input port to the Subsystem block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Out — Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a subsystem adds an output port from the Subsystem block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

For an explanation of the Triggered Subsystem block parameters, see [Subsystem](#).

Block Characteristics

Data Types	<code>Boolean^a</code> <code>bus^a</code> <code>double^a</code> <code>enumerated^a</code> <code>fixed point^a</code> <code>half^a</code> <code>integer^a</code> <code>single^a</code> <code>string^a</code>
Direct Feedthrough	no
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For information about best practices, restrictions, and how you can use the trigger signal as a clock with the `TriggerAsClock` property, see “Using Triggered Subsystems for HDL Code Generation” (HDL Coder).

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem.
BlackBox	<p>Generate a black box interface. The generated HDL code includes only the input/output port definitions for the subsystem. Therefore, you can use a subsystem in your model to generate an interface to existing, manually written HDL code.</p> <p>The black-box interface generation for subsystems is similar to the Model block interface generation without the clock signals.</p>
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation, however, treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

General	
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Restrictions

- HDL code generation supports only boolean datatype at the trigger input.
- If the output of the subsystem is a bus then **Initial condition** of the output must be 0.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Trigonometric Function

Specified trigonometric function on input

Libraries:

Simulink / Math Operations
HDL Coder / Math Operations

Description

The Trigonometric Function block performs common trigonometric functions and outputs the result in rad or rev.

Supported Functions

You can select one of these functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
sin	Sine of the input	$\sin(u)$	sin
cos	Cosine of the input	$\cos(u)$	cos
tan	Tangent of the input	$\tan(u)$	tan
asin	Inverse sine of the input	$\text{asin}(u)$	asin
acos	Inverse cosine of the input	$\text{acos}(u)$	acos
atan	Inverse tangent of the input	$\text{atan}(u)$	atan
atan2	Four-quadrant inverse tangent of the input	$\text{atan2}(u)$	atan2
sinh	Hyperbolic sine of the input	$\sinh(u)$	sinh
cosh	Hyperbolic cosine of the input	$\cosh(u)$	cosh
tanh	Hyperbolic tangent of the input	$\tanh(u)$	tanh
asinh	Inverse hyperbolic sine of the input	$\text{asinh}(u)$	asinh
acosh	Inverse hyperbolic cosine of the input	$\text{acosh}(u)$	acosh
atanh	Inverse hyperbolic tangent of the input	$\text{atanh}(u)$	atanh

Function	Description	Mathematical Expression	MATLAB Equivalent
sincos	Sine of the input; cosine of the input	—	—
cos + jsin	Complex exponential of the input	—	—

CORDIC Approximation Method

CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations. For more information, see “More About” on page 1-2359. The block input has further requirements.

For more information on when you set **Function** to `sin`, `cos`, `sincos`, or `cos + jsin` and set the **Approximation method** to CORDIC, see “Port_1” on page 1-0 .

This table summarizes what happens for an invalid input.

Block Usage	Effect of Invalid Input
Simulation modes	An error appears.
Generated code	Undefined behavior occurs. Avoid relying on undefined behavior for generated code.

Lookup Approximation Method

For more information on when you set **Function** to `sin`, `cos`, `sincos`, or `cos + jsin` and set the **Approximation method** to Lookup, see “Port_1” on page 1-0 .

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input specified as a scalar, vector, or matrix. The block accepts input signals of the following data types:

Functions	Input Data Types
<ul style="list-style-type: none"> • <code>sin</code> • <code>cos</code> • <code>sincos</code> • <code>cos + jsin</code> • <code>atan2</code> 	<ul style="list-style-type: none"> • Floating point • Fixed point (only when Approximation method is CORDIC)

Functions	Input Data Types
<ul style="list-style-type: none"> • tan • asin • acos • atan • sinh • cosh • tanh • asinh • acosh • atanh 	<ul style="list-style-type: none"> • Floating point

CORDIC approximation fixed-point type propagations:

Input Data Type	Function	Output Data Type
Fixed point, signed or unsigned	sin, cos, sincos, and cos + jsin	fixdt(1, WL, WL - 2) where WL is the input word length This fixed-point type provides the best precision for the CORDIC algorithm.
Fixed point, signed	atan2	fixdt(1, WL, WL - 3)
Fixed point, unsigned	atan2	fixdt(1, WL, WL - 2)

Lookup approximation fixed-point type propagations:

Input Data Type	Function	Output Data Type
Fixed point, signed	sin, cos, sincos, cos + jsin, atan2	fixdt(1, WL, FL)
Fixed point, unsigned	sin, cos, sincos, cos + jsin, atan2	fixdt(1, WL - 1, FL)

Dependencies

- When you set **Function** to atan2, the block shows two input ports. The first input (**Port_1**) is the y-axis or imaginary part of the function argument. The second input (**Port_2**) is the x-axis or real part of the function argument.
- You can use floating-point input signals when you set **Approximation method** to None, CORDIC, or Lookup. However, the block output data type depends on which of these approximation method options you choose.

Input Data Type	Approximation Method	Output Data Type
Floating point	None	Depends on your selection for Output signal type . Options are auto (same data type as input), real, or complex.

Input Data Type	Approximation Method	Output Data Type
Floating point	CORDIC	Same as input. Output signal type is not available when you use the CORDIC approximation method to compute the block output.
Floating point	Lookup	Same as input. Output signal type is not available when you use the Lookup approximation method to compute the block output.

For CORDIC and Lookup approximations:

- Input must be real for the `sin`, `cos`, `sincos`, `cos + jsin`, and `atan2` functions.
- Output is real for the `sin`, `cos`, `sincos`, and `atan2` functions.
- Output is complex for the `cos + jsin` function.

Limitations

- You can use fixed-point input signals only when **Approximation method** is set to CORDIC or Lookup. The CORDIC and Lookup approximations are available for the `sin`, `cos`, `sincos`, `cos + jsin`, and `atan2` functions.
- Complex input signals are supported for all functions in this block except `atan2`.
- When you set **Approximation method** to Lookup, the number of data points are limited by:
 - $smallEnoughNumDataPoints = 2^{(inputFractionLen-2)+1}$
 - $bigEnoughFractionLen = \log_2(numberOfDataPoints - 1)+2$

where:

- *smallEnoughNumDataPoints* is the maximum number of data points represented by specified input fraction length, *inputFractionLen*.
- *bigEnoughFractionLen* is the minimum fraction length needed to represent specified number of data points, *numberOfDataPoints*.
- When you set **Function** to `sin`, `cos`, `sincos`, or `cos + jsin` and set the **Approximation method** to CORDIC, the block has these limitations:
 - When you use signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ rad.
 - When you use unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ rad.

When you set **Function** to `atan2` and the **Approximation method** to CORDIC, the block has these limitations:

- Inputs must be the same size, or at least one value must be a scalar value.
- Both inputs must have the same data type.
- When you use signed fixed-point types, the word length must be 126 or less.
- When you use unsigned fixed-point types, the word length must be 125 or less.
- When you set **Function** to `sin`, `cos`, `sincos`, or `cos + jsin` and set the **Approximation method** to Lookup, the block has these limitations.

- When you use signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi]$ rad.
- When you use unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ rad.
- When you set **Function** to atan2 and the **Approximation method** to Lookup, the block has these limitations:
 - Inputs must be the same size, or at least one value must be a scalar value.
 - Both inputs must have the same data type.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Port_2 — x-axis or real part of the function argument for atan2
scalar | vector | matrix

Input the x-axis or real part of the function argument for atan2. When you set **Function** to atan2, the block shows two input ports. The first input (**Port_1**) is the y-axis or imaginary part of the function argument. The second input (**Port_2**) is the x-axis or real part of the function argument. (See “Identify Port Location on Rotated or Flipped Block” for a description of the port order for various block orientations.)

Dependencies

To enable this port, set **Function** to atan2.

Limitations

- Fixed-point input signals are supported only when you set **Approximation method** to CORDIC or Lookup.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Specified trigonometric function of input
scalar | vector | matrix

Result of applying the specified trigonometric function to one or more inputs in rad. Each function supports:

- Scalar operations
- Element-wise vector and matrix operations

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

sin — Sine of input signal
scalar | vector | matrix

Sine of the input signal, in rad and rev.

Dependencies

To enable this port, set **Function** to sincos.

Limitations

Fixed-point input signals are supported only when you set **Approximation method** to CORDIC or Lookup.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

cos — Cosine of input signal

scalar | vector | matrix

Cosine of the input signal, in rad and rev.

Dependencies

To enable this port, set **Function** to sincos.

Limitations

Fixed-point input signals are supported only when you set **Approximation method** to CORDIC or Lookup.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters**Algorithm**

Function — Trigonometric function

sin (default) | cos | tan | asin | acos | atan | atan2 | sinh | cosh | tanh | asinh | acosh | atanh | sincos | cos + jsin

Specify the trigonometric function. The name of the function on the block icon changes to match your selection.

For more information on when you set **Function** to sin, cos, sincos, or cos + jsin and set the **Approximation method** to CORDIC, see “Limitations” on page 1-0 .

Programmatic Use

Block Parameter: Operator

Type: character vector

Values: 'sin' | 'cos' | 'tan' | 'asin' | 'acos' | 'atan' | 'atan2' | 'sinh' | 'cosh' | 'tanh' | 'asinh' | 'acosh' | 'atanh' | 'sincos' | 'cos + jsin'

Default: 'sin'

Approximation method — CORDIC, Lookup, or none

None (default) | CORDIC | Lookup

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate iterative calculation.
Lookup	Floating point and fixed point (double and single)	You want a fast, approximate lookup table implementation.

For more information on when you set **Function** to `sin`, `cos`, `sincos`, or `cos + jsin` and set the **Approximation method** to CORDIC, see “Limitations” on page 1-0 .

Dependencies

- To enable this parameter, set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- To use fixed-point input signals, you must set **Approximation method** to CORDIC or Lookup.
- To enable the **Table data type** parameter, set this method to Lookup.

Programmatic Use

Block Parameter: ApproximationMethod

Type: character vector

Values: 'None' | 'CORDIC' | 'Lookup'

Default: 'None'

Interpolation method — Method of interpolation between breakpoint values

Linear point-slope (default) | Flat

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Programmatic Use

Block Parameter: InterpMethod

Type: character vector

Values: 'Linear point-slope' | 'Flat'

Default: 'Linear point-slope'

Number of iterations — Number of iterations for CORDIC algorithm

11 (default) | positive integer, less than or equal to word length of fixed-point input

Specify the number of iterations to perform the CORDIC algorithm. The default value is 11.

- When the block input uses a floating-point data type, the number of iterations can be a positive integer.
- When the block input is a fixed-point data type, the number of iterations cannot exceed the word length.

For example, if the block input is `fixdt(1, 16, 15)`, the word length is 16. In this case, the number of iterations cannot exceed 16.

Dependencies

To enable this parameter, you must set the **Function** and **Approximation method** parameters as follows:

- Set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- Set **Approximation method** to `CORDIC`.

Programmatic Use

Block Parameter: `NumberOfIterations`

Type: character vector

Values: positive integer, less than or equal to word length of fixed-point input

Default: `'11'`

Angle unit — Angle unit

`radian (default) | revolution`

Specify the angle unit for lookup method as `radian` or `revolution`.

Dependencies

To enable this parameter:

- Set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- Set **Approximation method** to `Lookup`.

Programmatic Use

Block Parameter: `AngleUnit`

Type: character vector

Values: `'radian'` | `'revolution'`

Default: `'radian'`

Number of data points — Number of data points for lookup table

`16 (default) | scalar`

Specify the number of data points for lookup table as a scalar real number.

Dependencies

To enable this parameter:

- Set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- Set **Approximation method** to `Lookup`.

Programmatic Use

Block Parameter: `NumberOfDataPoints`

Type: character vector

Values: scalar

Default: `'16'`

Output signal type — Complexity of output signal

`auto (default) | real | complex`

Specify the output signal type of the Trigonometric Function block as `auto`, `real`, or `complex`.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
Any selection for the Function parameter	real	real	real	complex
	complex	complex	error	complex

Dependencies

Setting **Approximation method** to CORDIC disables this parameter.

Note When **Function** is `atan2`, complex input signals are not supported for simulation or code generation.

Programmatic Use

Block Parameter: `OutputSignalType`

Type: character vector

Values: `'auto'` | `'real'` | `'complex'`

Default: `'auto'`

Remove protection against out-of-range input — Remove protection against out-of-range input

`off` (default) | `on`

For `acos` and `asin`, select this check box to remove the protection against out-of-range inputs, which reduces redundancy.

- When you clear this check box, the protection is enabled. The block saturates out-of-range inputs to 1 or -1 before any operation is performed. Generated code contains code to check for out-of-range input.
- When you select this check box, the protection is removed. The block performs all operations on the input value without any changes. Generated code does not contain code to check for the out-of-range input.

Enabling this check box can eliminate redundancy if the input is already in range.

Dependencies

Setting **Function** to `acos` and `asin` enables this parameter.

Programmatic Use

Block Parameter: `RemoveProtectionAgainstOutOfRangeInput`

Type: character vector

Values: `'off'` | `'on'`

Default: `'off'`

Sample time — Sample time value other than -1

`-1` (default) | `scalar` | `vector`

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Data Types

Table data type — Data type of table

Inherit: `Inherit` via `input` (default) | `double` | `single` | `fixdt(1,16,0)` | <data type expression>

Data type for the lookup table, specified as:

- `Inherit`: `Inherit` via `input`
- `double`
- `single`
- `fixdt(1,16,0)`
- <data type expression>

For more information on setting data types, see “Control Data Types of Signals”.

Programmatic Use

Block Parameter: TableDataTypeStr

Type: string scalar or character vector

Values: `Inherit`: `Inherit` via `input` | `single` | `double` | `fixdt(1,16,0)` | data type expression

Default: `Inherit`: `Inherit` via `input`

Mode — Category of data to specify

`Inherit` (default) | `Built in` | `Fixed point` | `Expression`

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit`: `Inherit` via `internal` rule
- `Built in` — Lets you specify a built-in data type.
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Dependencies

To enable this parameter, click >> at the **Output data type** parameter.

Signedness — Specify signed or unsigned

Signed (default) | Unsigned

Specify the **Signedness** for the **Output** data type.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Scaling — Method for scaling fixed-point data

Binary point (default)

Specify the **Scaling** for the **Output** data type.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Data type override — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

For more information, see “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Tips

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Dependencies

To enable this parameter, click the **Show data type assistant** button, and set **Mode** to `Built in` or `Fixed point`.

Word length — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set **Mode** to `Fixed point`.

Fraction length — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type”.

Dependencies

To enable this parameter, set:

- **Mode** to Fixed point
- **Scaling** to Binary point

Block Characteristics

Data Types	double fixed point ^a half integer ^a single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

^a This block supports fixed-point and base integer data types for 'Approximation method' CORDIC.

More About

CORDIC

CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so increases the expense of the computation and adds latency.

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not all compilers support the `asinh`, `acosh`, and `atanh` functions. If you use a compiler that does not support those functions, a warning appears and the generated code fails to link.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for all functions of the block with floating-point data types and architecture set to `Trigonometric` in native floating-point mode. The native floating-point mode does not support `double` data types for the block.

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See "Generated Model and Validation Model" (HDL Coder).

The Trigonometric Function block supports HDL code generation for these functions in this table with CORDIC approximation method and `Cordic` HDL architecture for fixed-point data types.

- `sin`
- `cos`
- `sincos`
- `cos+jsin`
- `atan2`

The latency calculation depends on the word length and **LatencyStrategy** settings. To learn more, open the `HDLMathLib` library.

`HDLMathLib`

HDL Block Properties

General	
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder).

General	
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
LatencyStrategy	To enable this property for fixed-point types, set Function as <code>sin</code> , <code>cos</code> , <code>sincos</code> , <code>cos+jsin</code> , or <code>atan2</code> and Approximation method as <code>CORDIC</code> . Specify whether to map the blocks in your design to <code>MAX</code> , <code>CUSTOM</code> , or <code>ZERO</code> latency for fixed-point and floating-point types. The default is <code>MAX</code> . See also “LatencyStrategy” (HDL Coder).
CustomLatency	To enable this property for fixed-point types, set Function as <code>sin</code> , <code>cos</code> , <code>sincos</code> , <code>cos+jsin</code> , or <code>atan2</code> and Approximation method as <code>CORDIC</code> . When LatencyStrategy is set to <code>CUSTOM</code> , use this property to specify a custom latency value between <code>ZERO</code> and <code>MAX</code> for fixed-point types. See also “LatencyStrategy” (HDL Coder).
Native Floating Point	
InputRangeReduction	Use this property for the <code>sin</code> , <code>cos</code> , <code>tan</code> , <code>sincos</code> , and <code>cos+jsin</code> functions. If your input range is unbounded, enable this property for HDL Coder to insert additional logic to reduce the range of inputs to <code>[-pi, pi]</code> . See also “InputRangeReduction” (HDL Coder).
HandleDenormals	Specify whether you want HDL Coder to insert additional logic to handle denormal numbers in your design. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The default is <code>inherit</code> . See also “HandleDenormals” (HDL Coder).
LatencyStrategy	Specify whether to map the blocks in your design to <code>inherit</code> , <code>Max</code> , <code>Min</code> , or <code>Zero</code> for the floating-point operator. The default is <code>inherit</code> . See also “LatencyStrategy” (HDL Coder).
MultiplyStrategy	Use this property for the <code>sin</code> , <code>cos</code> , <code>tan</code> , <code>sincos</code> , and <code>cos+jsin</code> functions. The default is <code>inherit</code> . Specify whether you want to use <code>FullMultiplier</code> or <code>PartMultiplierPartAddShift</code> . See also “MantissaMultiplyStrategy” (HDL Coder).

To see the latency calculation for fixed-point types with the block, at the MATLAB command prompt, enter:

```
HDLMathLib
```

ULP Considerations

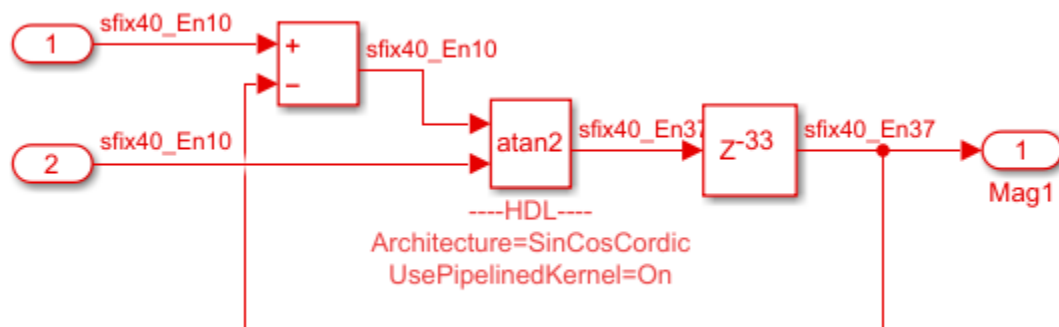

The Trigonometric Function blocks have nonzero units in the last place (ULP) error for floating point operations. For more information, see “ULP Considerations of Native Floating-Point Operators” (HDL Coder).

Restrictions

- For the `sin` and `cos` functions, only signed fixed-point data types are supported for CORDIC approximations.
- For functions that have the CORDIC mode such as `sin`, `cos`, `sincos`, `atan2`, and `cos+jsin`, fixed-point data types greater than 127 bits are not supported for HDL code generation.
- HDL Coder displays an error when you select these settings for a Trigonometric Function block inside a feedback loop:
 - HDL architecture as `SinCosCordic`
 - **UsePipelinedKernel** as `On`

The error occurs because the block is in a feedback loop and the code generator is unable to insert additional latency. To avoid this error, add a delay of length equal to the **Number of iterations** + 3 adjacent to the block. The code generator then absorbs this delay to meet the additional latency of the Trigonometric Function block.

For example, this Trigonometric Function block has **Number of iterations** set to 30. A Delay of length 33 adjacent to the block meets the additional latency.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block supports fixed-point and base integer data types when you set the **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2` and set the **Approximation method** to `CORDIC`.

Unary Minus

Negate input

Libraries:

Simulink / Math Operations
 HDL Coder / HDL Floating Point Operations
 HDL Coder / Math Operations

Description

The Unary Minus block negates the input.

Ports

Input

Port_1 — Signal to negate

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Data Types: half | single | double | int8 | int16 | int32 | int64 | fixed point

Output

Port_1 — Negation of input signal

scalar | vector | matrix | N-D array

Negation of the input signal. The output has the same data type and dimensions as the input.

Data Types: half | single | double | int8 | int16 | int32 | int64 | fixed point

Parameters

Saturate on integer overflow — Method of overflow action

off (default) | on

Select to have integer overflows saturate. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

For signed-integer data types, the unary minus of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block:

Parameter Setting	Block Behavior	Examples
Saturate on integer overflow = on	Values saturate to the most positive value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 maps to 127. For 16-bit signed integers, -32768 maps to 32767. For 32-bit signed integers, -2147483648 maps to 2147483647.
Saturate on integer overflow = off	Values wrap to the most negative value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 remains -128. For 16-bit signed integers, -32768 remains -32768. For 32-bit signed integers, -2147483648 remains -2147483648.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Sample time value other than -1

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime

Type: string scalar or character vector

Default: "-1"

Block Characteristics

Data Types	double fixed point ^a half integer ^a single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

^a This block only supports signed fixed-point data types.

Uniform Random Number

Generate uniformly distributed random numbers

Libraries:
Simulink / Sources

Description

The Uniform Random Number block generates uniformly distributed random numbers over an interval that you specify. To generate normally distributed random numbers, use the Random Number block. Both blocks use the Normal (Gaussian) random number generator ('v4': legacy MATLAB 4.0 generator of the `rng` function).

You can generate a repeatable sequence using any Uniform Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

Ports

Output

Port_1 — Random number output signal
scalar | vector

Output signal of generated uniformly distributed random numbers over the interval you specify.

Data Types: `double`

Parameters

Minimum — Minimum interval

0 (default) | scalar | vector | matrix | N-D array

Specify the minimum of the interval.

Programmatic Use

Block Parameter: Minimum

Type: character vector

Values: scalar

Default: '-1'

Maximum — Maximum interval

0 (default) | scalar | vector | matrix | N-D array

Specify the maximum of the interval.

Programmatic Use

Block Parameter: Maximum

Type: character vector

Values: scalar

Default: '1'

Seed — Random number seed

0 (default) | scalar | vector | matrix | N-D array

Specify the starting seed for the random number generator.

The seed must be 0 or a positive integer. Output is repeatable for a given seed.

Programmatic Use

Block Parameter: See

Type: character vector

Values: scalar

Default: '0'

Sample time — Sample time

0.1 (default) | scalar

Specify the time interval between samples. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '0.1'

Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use**Block Parameter:** VectorParams1D**Type:** character vector**Values:** 'on' | 'off'**Default:** 'on'**Block Characteristics**

Unit System Configuration

Restrict units to specified allowed unit systems

Libraries:

Simulink / Ports & Subsystems

Description

The Unit System Configuration block specifies allowed and disallowed unit systems for the component. It restricts units systems for a subsystem or top model and all its children, unless you override it with another Unit System Configuration block in a child.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Parameters

Disallowed unit systems — Disallowed unit systems

SI | English | SI (extended) | CGS

Displays a list of the disallowed unit systems. By default, the **Allow all unit systems** check box is selected, and all unit systems are allowed.

To designate a unit system as disallowed, select it in the **Allowed unit systems** column and click << **Disallow**.

Dependencies

To enable changes to this parameter, you must first clear the **Allow all unit systems** check box.

Allowed unit systems — Allowed unit systems

SI | English | SI (extended) | CGS

Displays a list of the allowed unit systems. By default, the **Allow all unit systems** check box is selected, and all unit systems are allowed.

To designate a unit system as allowed, use the **Allow >>** and << **Disallow** buttons to move unit systems between the **Disallowed unit systems** and **Allowed unit systems** columns.

Dependencies

To enable changes to this parameter, you must first clear the **Allow all unit systems** check box.

Programmatic Use

Block Parameter: UnitSystems

Type: cell array of character vectors

Values: cell array of the following character vectors: 'SI' | 'English' | 'SI (extended)' | 'CGS'

Default: {'SI', 'English', 'SI (extended)', 'CGS'}

Allow all unit systems — Allow all unit systems

on (default) | off

When you select this check box, all unit systems are allowed. To restrict the allowed unit systems to only the ones specified in the **Allowed unit systems** column, clear this check box.

Dependencies

Selecting the **Allow all unit systems** check box disables the **Disallowed unit systems** and **Allowed unit systems** parameters.

Programmatic Use

Block Parameter: AllowAllUnitSystems

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single

Unit Conversion

Convert units

Libraries:
Simulink / Signal Attributes

Description

The Unit Conversion block converts the unit of the input signal to the output signal. The block can perform the conversion if the units are separated by a scaling factor or offset, or are inverse units, for example:

- $y = a*U$
- $y = a*U+b$, where a is the scale and b is the offset
- $y = a/U$

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 — Output signal
scalar | vector | matrix | N-D array

Output signal with converted units with the same dimensions as the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Output data type — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation

Specify the output data type.

- **Inherit: Inherit via internal rule** — Simulink chooses intermediate and output data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change.
- **Inherit: Inherit via back propagation** — Output data type is inherited via back propagation. Internal rules determine the intermediate data types and Simulink casts the final results to the output data type.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit via internal rule' | 'Inherit via back propagation'

Default: 'Inherit via internal rule'

Block Characteristics

Unit Delay

Delay signal one sample period

Libraries:

Simulink / Discrete
HDL Coder / Discrete

Description

The Unit Delay block holds and delays its input by the sample period you specify. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block is equivalent to the z^{-1} discrete-time operator. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds and delays all elements of the vector by the same sample period.

You specify the block output for the first sampling period with the **Initial conditions** parameter. Careful selection of this parameter can minimize unwanted output behavior. You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

Note The Unit Delay block errors out if you use it to create a transition between blocks operating at different sample rates. Use the Rate Transition block instead.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> “Engine Timing Model with Closed Loop Control” on page 13-152 (Compression subsystem)
Memory on page 1-1350	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> “Building a Clutch Lock-Up Model” on page 13-156 (Friction Mode Logic/Lockup FSM subsystem) “Capture the Velocity of a Bouncing Ball with the Memory Block” on page 12-89

Block	Purpose of the Block	Reference Examples
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> “Developing the Apollo Lunar Module Digital Autopilot” on page 13-215 “Radar Tracking Using MATLAB Function Block” on page 13-244

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

String Support

The Unit Delay block can accept and output string data type only if the block is configured for a delay length of 0 or 1 or for direct feedthrough.

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal that the block delays by one sample period.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus | image

Output

Port_1 — Output signal
scalar | vector

Output signal that is the input delayed by one sample period.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus | image

Parameters

Main

Initial condition — First sample period output

0 (default) | scalar | vector

Specify the output of the simulation for the first sampling period, during which the output of the Unit Delay block is otherwise undefined.

Programmatic Use

Block Parameter: InitialCondition

Type: character vector

Value: scalar | vector

Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Sample time (-1 for inherited) — Discrete interval between sample time hits

-1 (default) | scalar

Enter the discrete interval between sample time hits or specify -1 to inherit the sample time.

See also “Specify Sample Time”.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Value: real scalar

Default: '-1'

State Attributes

State name — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use

Block Parameter: StateName

Type: character vector

Values: unique name

Default: ' '

State name must resolve to Simulink signal object — Option to require that state names resolve to signal object

off (default) | on

Specify whether state names are required to resolve to signal objects. If selected, the software generates an error at run time if you specify a state name that does not match the name of a signal object.

Selecting this parameter disables the **Code generation storage class** parameter.

Dependencies

Enabled when you specify a value for the **State name** parameter and set the **Signal resolution** model configuration parameter to a value other than None.

Programmatic Use

Block Parameter: StateMustResolveToSignalObject

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string

Delay | Propagation Delay | Resettable Delay

Variable Integer Delay

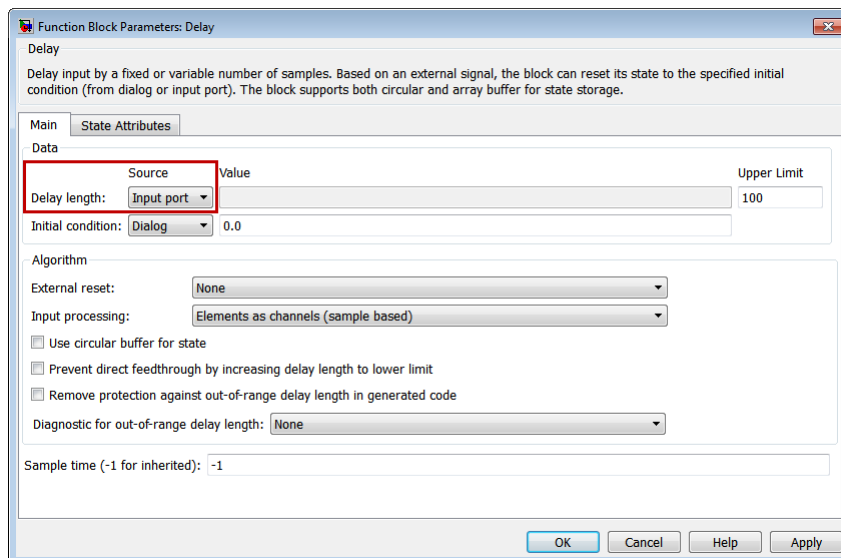

Delay input signal by variable sample period

Libraries:
Simulink / Discrete

Description

The Variable Integer Delay block is a variant of the Delay block that has the source of the delay length set to `Input port`, by default.

Ports

Input

u — Data input signal
scalar | vector

Input data signal delayed according to parameters settings.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

d — Delay length
scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as `Input port`.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Enable — External enable signal
scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

External reset — External reset signal
scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

x0 — Initial condition
scalar | vector

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as `Input port`.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

Output

Port_1 — Output signal
scalar | vector

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-338.

Data Types: `half` | `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Delay length — Delay length
`Dialog (default)` | `Input port`

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the `d` input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay)

casts it into the range. A non-integer value from an input port (variable delay) truncates it to the integer.

Programmatic Use

Block Parameter: DelayLengthSource

Type: character vector

Values: 'Dialog' | 'Input port' |

Default: 'Dialog'

Block Parameter: DelayLength

Type: character vector

Values: scalar

Default: '2'

Block Parameter: DelayLengthUpperLimit

Type: character vector

Values: scalar

Default: '100'

Initial condition — Initial condition

Dialog (default) | Input port

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to Dialog, enter the initial condition in the edit field under **Value**.
- If you set **Source** to Input port, verify that an upstream signal supplies an initial condition for the x0 input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal u using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is Input port, the block ignores the initial value of the signal object.

Programmatic Use

Block Parameter: InitialConditionSource

Type: character vector

Values: 'Dialog' | 'Input port' |

Default: 'Dialog'

Block Parameter: InitialCondition

Type: character vector

Values: scalar

Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: InputProcessing

Type: character vector

Values: 'Columns as channels (frame based)' | 'Elements as channels (sample based)'

Default: 'Elements as channels (sample based)'

Use circular buffer for state — Circular buffer for storing state

off (default) | on

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed:

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: UseCircularBuffer

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Prevent direct feedthrough — Prevent direct feedthrough

off (default) | on

Select to increase the delay length from zero to the lower limit for the **Input processing** mode:

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, *u*, to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, *x0*, to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** PreventDirectFeedthrough**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Remove delay length check in generated code — Remove delay length out-of-range check
off (default) | on

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** RemoveDelayLengthCheckInGeneratedCode**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'

Diagnostic for delay length — Diagnostic checks for delay length
None (default) | Warning | Error

Specify whether to produce a warning or error when the input d is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to Input port.

Programmatic Use**Block Parameter:** DiagnosticForDelayLength

Type: character vector
Values: 'None' | 'Warning' | 'Error'
Default: 'None'

Show enable port — Create enable port

off (default) | on

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: ShowEnablePort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

External reset — External state reset

None (default) | Rising | Falling | Either | Level | Level hold

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset
Rising	Reset on a rising edge
Falling	Reset on a falling edge
Either	Reset on either a rising or falling edge
Level	Reset in either of these cases: <ul style="list-style-type: none"> • When the reset signal is nonzero at the current time step • When the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

Programmatic Use

Block Parameter: ExternalReset

Type: character vector

Values: 'None' | 'Rising' | 'Falling' | 'Either' | 'Level' | 'Level hold'

Default: 'None'

Sample time (-1 for inherited) — Discrete interval between sample time hits

-1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. This block supports discrete sample time, but not continuous sample time.

Programmatic Use**Block Parameter:** SampleTime**Type:** character vector**Value:** real scalar**Default:** '-1'**State Attributes****State name** — Unique name for block state

' ' (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

Programmatic Use**Block Parameter:** StateName**Type:** character vector**Values:** unique name**Default:** ''

State name must resolve to Simulink signal object — Require state name resolve to a signal object

off (default) | on

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Programmatic Use**Block Parameter:** StateMustResolveToSignalObject**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Data Types	Boolean bus double enumerated fixed point half integer single string
-------------------	--

Direct Feedthrough	yes
Multidimensional Signals	yes

Variable Pulse Generator

Generate ideal, time varying pulse signal

Libraries:
Simulink / Discontinuities

Description

Use the Variable Pulse Generator block to create ideal modulated pulse signals.

Generally speaking, the output pulse of the block is described by

$$y(t) = \begin{cases} 1 & t_k < t < t_k + pw \\ 0 & t_{k+1} < t < t_k + pw \end{cases}$$

where pw is the output pulse width.

For an implementation of Pulse Width Modulation, see PWM.

Ports

Input

D — Duty Cycle
scalar

Desired duty cycle of the pulse P , specified as scalar within the range [0,1].

Data Types: double

P — Period
scalar

Time between rising edges of consecutive pulses of the output signal. A smaller value represents a higher frequency pulse.

Data Types: double

Output

Port 1 — Modulated pulse signal
scalar

Modulated output pulse signal corresponding to input duty cycle.

Data Types: double

Parameters

Allow zero pulse width — Allow zero magnitude of output signal

off (default) | on

Enable this parameter to allow the output pulse signal to support pulses of width 0.

Note Enabling this parameter causes the block to have direct feedthrough. This can cause algebraic loops in your model.

Run at fixed time intervals — Choose continuous or discrete-time behavior

continuous (default) | discrete

Select whether the block should operate in continuous or discrete sampling modes.

By default, the block uses `continuous` sampling mode as it improves simulation performance with variable step solvers.

Select `discrete` sampling mode if you need to:

- use a fixed-step solver
- generate code
- sample the block output

Sampling rate — Set pulse resolution

0.1 (default) | scalar

Specify the rate at which the block samples input duty cycle signal. This sampling rate becomes the resolution of the output pulse signal.

Dependencies

This parameter requires that **Sampling mode** is set to `discrete`

Block Characteristics

Data Types	double
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Continuous Sampling Mode

For a pulse starting at time t_k

$$y(t) = \begin{cases} 1 & t_k < t < t_k + pw \\ 0 & t_{k+1} < t < t_k + pw \end{cases}$$

where pw is the pulse width. For a given period P , pw is proportional to the duty cycle D

$$pw = D(t_k) * P(t_k)$$

Discrete Sampling Mode

In Discrete sampling mode, the input duty cycle signal is sampled at the rate specified by the **Run at fixed time intervals** parameter.

For a specified sampling rate t_s , the number of samples needed for a pulse of width pw can be expressed as follows

$$n_{pw} = \left\lceil \frac{D_k \cdot P_k}{T_S} \right\rceil \quad 0 < n_{pw} < n_P$$

$$n_P = \left\lceil \frac{P}{T_S} \right\rceil$$

where n_P is the number of samples needed to simulate a pulse of period P .

Consider a nominal pulse of period P with the sampling rate of the block set to be $t_s = 0.25 P$. The number of samples needed for one period of the pulse, $n_p = 4$. Thus, for the input duty cycle $D = 0.47$, the number of samples n_{pw} is floored to $\left\lfloor \frac{0.47P}{0.25} \right\rfloor = 1$. Therefore, the pulse is high for 1 of the 4 samples in the period.

Version History

Introduced in R2020b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Variable Time Delay

Delay input by variable amount of time

Libraries:
Simulink / Continuous

Description

The Variable Transport Delay and Variable Time Delay blocks appear as two blocks in the Simulink block library. However, they are the same Simulink block with different settings for the **Select delay type** parameter. Use this parameter to specify the mode in which the block operates.

Variable Time Delay

In this mode, the block has a data input, a time delay input, and a data output. (See “Identify Port Location on Rotated or Flipped Block” for a description of the port order for various block orientations.) The output at the current time step equals the value of its data input at a previous time step. This time step is the current simulation time minus a delay time specified by the time delay input.

$$y(t) = u(t - t_0) = u(t - \tau(t))$$

During the simulation, the block stores time and input value pairs in an internal buffer. At the start of simulation, the block outputs the value of the **Initial output** parameter until the simulation time exceeds the time delay input. Then, at each simulation step, the block outputs the signal at the time that corresponds to the current simulation time minus the delay time.

If you want the output at a time between input storing times and the solver is a continuous solver, the block interpolates linearly between points. If the time delay is smaller than the step size, the block extrapolates an output point from a previous point. For example, consider a fixed-step simulation with a step size of 1 and the current time at $t = 5$. If the delay is 0.5, the block must generate a point at $t = 4.5$, but the most recent stored time value is at $t = 4$. Thus, the block extrapolates the input at 4.5 from the input at 4 and uses the extrapolated value as its output at $t = 5$.

Extrapolating forward from the previous time step can produce a less accurate result than extrapolating back from the current time step. However, the block cannot use the current input to calculate its output value because the input port does not have direct feedthrough.

If the model specifies a discrete solver, the block does not interpolate between time steps. Instead, it returns the nearest stored value that precedes the required value.

Variable Transport Delay

In this mode, the block output at the current time step is equal to the value of its data (top, or left) input at an earlier time step equal to the current time minus a transport delay.

$$y(t) = u(t - t_d(t))$$

Simulink software finds the transport delay, $t_d(t)$, by solving the following equation:

$$\int_{-t_d(t)}^t \frac{1}{t_i(\tau)} d\tau = 1$$

This equation involves an instantaneous time delay, $t_i(t)$, given by the time delay (bottom, or right) input.

Suppose that you want to use this block to model the fluid flow through a pipe where the fluid speed varies with time. In this case, the time delay input to the block is

$$t_i(t) = \frac{L}{v_i(t)}$$

where L is the length of the pipe and $v_i(t)$ is the speed of the fluid.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix.

Data Types: double

t₀ — Time delay input
scalar | vector | matrix

Time delay input specified as a scalar, vector, or matrix. When the block is in **Variable time delay** mode, this value specifies the time delay. For more information about that calculation, see “Variable Time Delay” on page 1-2391.

Dependencies

To enable this port, set **Select delay type** to **Variable time delay**.

Data Types: double

t_i — Instantaneous time delay input
 scalar | vector | matrix

Instantaneous time delay input specified as a scalar, vector, or matrix. When the block is in `Variable transport delay` mode, this value is used to calculate the transport delay. For more information about that calculation, see “Variable Transport Delay” on page 1-2392.

Dependencies

To enable this port, set **Select delay type** to `Variable transport delay`.

Data Types: double

Output

Port_1 — Delayed signal
 scalar | vector | matrix

Output signal specified as a scalar, vector, or matrix.

Data Types: double

Parameters

Select delay type — Type of delay

Variable time delay | Variable transport delay

Specify the type of delay as `Variable time delay` or `Variable transport delay`.

The default value of this parameter depends on the block implementation: `Variable time delay` for the Variable Time Delay block, and `Variable transport delay` for the Variable Transport Delay block.

Dependencies

- Setting this parameter to `Variable time delay` enables the **Handle zero delay** parameter.
- Setting this parameter to `Variable transport delay` enables the **Absolute tolerance** and **State Name** parameters.

Programmatic Use

Block Parameter: `VariableDelayType`

Type: character vector, string

Values: `'Variable transport delay'` | `'Variable time delay'`

Maximum delay — Maximum value of time delay input

10 (default) | scalar | vector

Set the maximum value of the time delay input. This value defines the largest time delay input that this block allows. The block clips any delay that exceeds this value. This value cannot be negative. If the time delay becomes negative, the block clips it to zero and issues a warning message.

Programmatic Use

Block Parameter: `MaximumDelay`

Type: character vector, string

Value: scalar | vector

Default: '10'

Initial output — Initial output

0 (default) | scalar | vector

Specify the output that the block generates until the simulation time first exceeds the time delay input.

Dependencies

- The initial output of this block cannot be `inf` or `NaN`.
- A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins does not cause Accelerator or Rapid Accelerator to regenerate code.

Programmatic Use

Block Parameter: `InitialOutput`

Type: character vector, string

Values: scalar | vector

Default: '0'

Initial buffer size — Initial memory allocation

1024 (default) | scalar

Define the initial memory allocation for the number of input points to store. The input points define the history of the input signal up to the current simulation time.

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message displays if the buffer is not sufficient and more memory must be allocated.

Tips

- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block might use a large amount of memory, particularly for dimensionalized input.

Programmatic Use

Block Parameter: `MaximumPoints`

Type: character vector, string

Values: scalar | vector

Default: '1024'

Use fixed buffer size — Use fixed-size buffer

off (default) | on

Selecting this check box uses a fixed-size buffer to save input data from previous time steps. When you clear this check box, the block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the buffer size. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

Note ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

Tips

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so might yield inaccurate results.

Programmatic Use

Block Parameter: FixedBuffer

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Handle zero delay — Use direct feedthrough

off (default) | on

Selecting this check box converts this block to a direct feedthrough block. When you clear this check box, the block does not use direct feedthrough.

Dependencies

To enable this parameter, set **Select delay type** to Variable time delay.

Programmatic Use

Block Parameter: ZeroDelay

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization — Use direct feedthrough during linearization

off (default) | on

When you select this parameter, the block outputs its input during linearization and trim, which sets the block mode to direct feedthrough. To disable direct feedthrough, clear this check box.

Tips

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:

- 1 Compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

- 2 Terminate the compilation with the following command.

```
model([],[],[],'term');
```

- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use**Block Parameter:** `TransDelayFeedthrough`**Type:** character vector, string**Values:** `'off'` | `'on'`**Default:** `'off'`**Pade order (for linearization)** — Order of Pade approximation`0` (default) | scalar

Set the order of the Pade approximation for linearization routines.

- The default value is `0`, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer `n` adds `n` states to your model, but results in a more accurate linear model of the transport delay.

Programmatic Use**Block Parameter:** `PadeOrder`**Type:** character vector, string**Values:** scalar**Default:** `'0'`**Absolute tolerance** — Absolute tolerance for computing block state`auto` (default) | positive, real, scalar or vector

Specify the absolute tolerance for computing the block state.

DependenciesTo enable this parameter, set **Select delay type** to `Variable transport delay`.**Programmatic Use****Block Parameter:** `AbsoluteTolerance`**Type:** character vector, string**Values:** `'auto'` | `'-1'` | any positive real scalar or vector**Default:** `'auto'`**State Name (e.g., 'position')** — Unique name for each state`' '` (default) | character vector, string

Assign a unique name to each state. If this field is blank, no name assignment occurs.

Tips

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.

- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Dependencies

To enable this parameter, set **Select delay type** to `Variable transport delay`.

Programmatic Use

Block Parameter: `ContinuousStateAttributes`

Type: character vector, string

Values: ' ' | user-defined character vector, user-defined string

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Variable Transport Delay

Delay input by variable amount of time

Libraries:
Simulink / Continuous

Description

The Variable Transport Delay and Variable Time Delay blocks appear as two blocks in the Simulink block library. However, they are the same Simulink block with different settings for the **Select delay type** parameter. Use this parameter to specify the mode in which the block operates.

Variable Transport Delay

In this mode, the block output at the current time step is equal to the value of its data (top, or left) input at an earlier time step equal to the current time minus a transport delay.

$$y(t) = u(t - t_d(t))$$

Simulink software finds the transport delay, $t_d(t)$, by solving the following equation:

$$\int_{-t_d(t)}^t \frac{1}{t_i(\tau)} d\tau = 1$$

This equation involves an instantaneous time delay, $t_i(t)$, given by the time delay (bottom, or right) input.

Suppose that you want to use this block to model the fluid flow through a pipe where the fluid speed varies with time. In this case, the time delay input to the block is

$$t_i(t) = \frac{L}{v_i(t)}$$

where L is the length of the pipe and $v_i(t)$ is the speed of the fluid.

Variable Time Delay

In this mode, the block has a data input, a time delay input, and a data output. (See “Identify Port Location on Rotated or Flipped Block” for a description of the port order for various block orientations.) The output at the current time step equals the value of its data input at a previous time step. This time step is the current simulation time minus a delay time specified by the time delay input.

$$y(t) = u(t - t_0) = u(t - \tau(t))$$

During the simulation, the block stores time and input value pairs in an internal buffer. At the start of simulation, the block outputs the value of the **Initial output** parameter until the simulation time exceeds the time delay input. Then, at each simulation step, the block outputs the signal at the time that corresponds to the current simulation time minus the delay time.

If you want the output at a time between input storing times and the solver is a continuous solver, the block interpolates linearly between points. If the time delay is smaller than the step size, the block extrapolates an output point from a previous point. For example, consider a fixed-step simulation with a step size of 1 and the current time at $t = 5$. If the delay is 0.5, the block must generate a point at $t = 4.5$, but the most recent stored time value is at $t = 4$. Thus, the block extrapolates the input at 4.5 from the input at 4 and uses the extrapolated value as its output at $t = 5$.

Extrapolating forward from the previous time step can produce a less accurate result than extrapolating back from the current time step. However, the block cannot use the current input to calculate its output value because the input port does not have direct feedthrough.

If the model specifies a discrete solver, the block does not interpolate between time steps. Instead, it returns the nearest stored value that precedes the required value.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix.

Data Types: double

t₀ — Time delay input
scalar | vector | matrix

Time delay input specified as a scalar, vector, or matrix. When the block is in **Variable time delay** mode, this value specifies the time delay. For more information about that calculation, see “Variable Time Delay” on page 1-2399.

Dependencies

To enable this port, set **Select delay type** to **Variable time delay**.

Data Types: double

t_i — Instantaneous time delay input
scalar | vector | matrix

Instantaneous time delay input specified as a scalar, vector, or matrix. When the block is in `Variable transport delay` mode, this value is used to calculate the transport delay. For more information about that calculation, see “Variable Transport Delay” on page 1-2399.

Dependencies

To enable this port, set **Select delay type** to `Variable transport delay`.

Data Types: `double`

Output

Port_1 — Delayed signal

`scalar` | `vector` | `matrix`

Output signal specified as a scalar, vector, or matrix.

Data Types: `double`

Parameters

Select delay type — Type of delay

`Variable time delay` | `Variable transport delay`

Specify the type of delay as `Variable time delay` or `Variable transport delay`.

The default value of this parameter depends on the block implementation: `Variable time delay` for the Variable Time Delay block, and `Variable transport delay` for the Variable Transport Delay block.

Dependencies

- Setting this parameter to `Variable time delay` enables the **Handle zero delay** parameter.
- Setting this parameter to `Variable transport delay` enables the **Absolute tolerance** and **State Name** parameters.

Programmatic Use

Block Parameter: `VariableDelayType`

Type: character vector, string

Values: `'Variable transport delay'` | `'Variable time delay'`

Maximum delay — Maximum value of time delay input

`10` (default) | `scalar` | `vector`

Set the maximum value of the time delay input. This value defines the largest time delay input that this block allows. The block clips any delay that exceeds this value. This value cannot be negative. If the time delay becomes negative, the block clips it to zero and issues a warning message.

Programmatic Use

Block Parameter: `MaximumDelay`

Type: character vector, string

Value: `scalar` | `vector`

Default: `'10'`

Initial output — Initial output

0 (default) | scalar | vector

Specify the output that the block generates until the simulation time first exceeds the time delay input.

Dependencies

- The initial output of this block cannot be `inf` or `NaN`.
- A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins does not cause Accelerator or Rapid Accelerator to regenerate code.

Programmatic Use

Block Parameter: InitialOutput

Type: character vector, string

Values: scalar | vector

Default: '0'

Initial buffer size — Initial memory allocation

1024 (default) | scalar

Define the initial memory allocation for the number of input points to store. The input points define the history of the input signal up to the current simulation time.

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message displays if the buffer is not sufficient and more memory must be allocated.

Tips

- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block might use a large amount of memory, particularly for dimensionalized input.

Programmatic Use

Block Parameter: MaximumPoints

Type: character vector, string

Values: scalar | vector

Default: '1024'

Use fixed buffer size — Use fixed-size buffer

off (default) | on

Selecting this check box uses a fixed-size buffer to save input data from previous time steps. When you clear this check box, the block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the buffer size. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

Note ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

Tips

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so might yield inaccurate results.

Programmatic Use

Block Parameter: FixedBuffer

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Handle zero delay — Use direct feedthrough

off (default) | on

Selecting this check box converts this block to a direct feedthrough block. When you clear this check box, the block does not use direct feedthrough.

Dependencies

To enable this parameter, set **Select delay type** to Variable time delay.

Programmatic Use

Block Parameter: ZeroDelay

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization — Use direct feedthrough during linearization

off (default) | on

When you select this parameter, the block outputs its input during linearization and trim, which sets the block mode to direct feedthrough. To disable direct feedthrough, clear this check box.

Tips

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:
 - 1 Compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```
 - 2 Terminate the compilation with the following command.

```
model([],[],[],'term');
```
- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use

Block Parameter: TransDelayFeedthrough

Type: character vector, string

Values: 'off' | 'on'

Default: 'off'

Pade order (for linearization) — Order of Pade approximation

0 (default) | scalar

Set the order of the Pade approximation for linearization routines.

- The default value is 0, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer n adds n states to your model, but results in a more accurate linear model of the transport delay.

Programmatic Use

Block Parameter: PadeOrder

Type: character vector, string

Values: scalar

Default: '0'

Absolute tolerance — Absolute tolerance for computing block state

auto (default) | positive, real, scalar or vector

Specify the absolute tolerance for computing the block state.

Dependencies

To enable this parameter, set **Select delay type** to `Variable transport delay`.

Programmatic Use

Block Parameter: AbsoluteTolerance

Type: character vector, string

Values: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

State Name (e.g., 'position') — Unique name for each state

' ' (default) | character vector, string

Assign a unique name to each state. If this field is blank, no name assignment occurs.

Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Dependencies

To enable this parameter, set **Select delay type** to `Variable transport delay`.

Programmatic Use

Block Parameter: `ContinuousStateAttributes`

Type: character vector, string

Values: ' ' | user-defined character vector, user-defined string

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2007a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Variant Sink

Route amongst multiple outputs using variants

Libraries:
Simulink / Signal Routing

Description

The Variant Sink block enables you to include multiple implementations of a component on the destination (sink) of a signal in a single layer.

For example, suppose you want to simulate this model to control the speed of the car windshield wiper by using different rain sensors. The Variant Sourceblock switches between different rain sensors. The control logic uses this information to output the result to the Variant Sink block. The Variant Sink then switches between the wiper motor model during simulation and the command to the sensor during code generation. The variant blocks switch between choices based on the “Types of Variant Control Modes in Variant Blocks” you select. For more information, see “Introduction to Variant Controls”.

Note At most, one variant choice connected to output port of the Variant Sink block is active during simulation.

The Variant Sink block has only one input port and one or more output ports. You can connect the varying choices to the output port of the block so that, at most, one choice is active during model execution.

The Variant Sink block is associated with a “Variant control mode” on page 1-0 and a “Variant activation time” on page 1-0 . The variant control mode determines how to specify the variant control. The variant activation time determines a time to activate the choices and to decide whether to include only the active choice or both active and inactive choices in the generated code. During simulation, Simulink connects the active choice directly to the input port of the Variant Sink block and ignores the inactive choices.

Using a Variant Sink block allows you to:

- Propagate variant conditions throughout the model.
- Visualize all possible implementations of variant choices in a single layer of your model, which improves model readability.
- Simulink eliminates inactive blocks throughout the model, which improves runtime performance. If all the variant choices are inactive, Simulink removes the variant region completely from your model.
- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

The color and icon of the variant badge on the block icon changes depending on the values of the **Variant activation time**, **Variant control mode**, and **Allow zero active variant controls** parameters set on the block. For more information, see “Variant Badges”.

Limitations

The Variant Sink block works with time-based, function-call, and action signals. You cannot use SimEvents, Simscape Multibody™, or other non-time-based signals with these blocks.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal to be connected to the active output port.

You can auto insert inport on the Variant Sink block by hovering the mouse over the block side or by dragging the signal near the block boundary. You can delete the port by either clicking delete on the keyboard or with a mouse click.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus | struct

Output

Port_1 — Output from first variant
scalar | vector | matrix

Output signal from the first variant. The variant control that evaluates to `true` determines which output port is active.

You can auto insert outport on the Variant Sink block by hovering the mouse over the block side or by dragging the signal near the block boundary. You can delete the port by either clicking delete on the keyboard or with a mouse click.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Port_N — Output from *N*th variant
scalar | vector | matrix

Output signal from the *N*th variant. The variant control that evaluates to `true` determines which output port is active.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Variant control mode — Variant control mode

expression (default) | label | sim codegen switching

The variant control that determines the active variant choice can be any of these types.

- **expression** — In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Blocks”.

- **label** — In **label** mode, Simulink chooses the active variant based on the name of the variant. The variant control is a string and does not require you to create any variable in any workspaces. See “Switch Between Choices Using Labels in Variant Blocks”.
- **sim codegen switching** — To automatically switch between the variants for simulation and code generation workflows without creating any workspace variable, use **sim codegen switching** mode. When you simulate a model, Simulink automatically chooses the **sim** branch as the active choice. Similarly, when you do a software-in-the-loop (SIL) or processor-In-Loop (PIL) simulation, generate code, or use external mode, Simulink automatically chooses the **codegen** branch. This mode is not supported for models configured with an ERT-based system target file and service code interface. See “Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks”.

For more information on variant control modes, see “Introduction to Variant Controls”. For a comparison between different types of variant control modes, see “Compare Different Types of Variant Control Modes in Variant Blocks”.

Dependencies

The availability of different variant activation times depends on the type of the **Variant control mode** that you specify. The **Variant activation time** parameter determines the time when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: VariantControlMode

Type: character vector

Values: expression | label | sim codegen switching |

Default: expression

Variant activation time — Time when Simulink chooses active variant choice

update diagram(default) | update diagram analyze all choices | code compile |
startup | inherit from Simulink.VariantControl

This parameter determines which variability to include in the simulation and code generation workflows. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow”.

You can set the **Variant activation time** parameter as:

- **update diagram** — When you execute the model, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.

- **update diagram analyze all choices** — When you execute the model, both active and inactive choices are analyzed for consistency across the model. However, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.
- **code compile** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. Generated code contains both the active and inactive choices enclosed in the preprocessor conditionals `#if` and `#elif`. However, the executable built from the generated code contains only active choice.
- **startup** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. With this option, you can improve the speed of iterative simulations using fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart”. Code generated from the model contains both the active and inactive choices that are enclosed in regular `if` conditions. The executable built from the generated code also contains both active and inactive choices.
- **inherit from Simulink.VariantControl** — When you execute the model, the block inherits the activation time from its variant control variables of type `Simulink.VariantControl`. If a variant block has multiple variant control variables of type `Simulink.VariantControl`, then all those variables must have the same activation time.

Dependencies

The availability of different variant activation times depends on the type of the variant control mode that you specify. The **Variant activation time** parameter determines when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: `VariantActivationTime`

Type: character vector

Values: `update diagram` | `update diagram analyze all choices` | `code compile` | `startup`

Default: `update diagram`

Port and associated conditions — Table of variant choices, variant controls, and conditions
empty table (default)

The table has a row for each variant choice connected to the output port of the Variant Sink block. If there are no variant choices, the table is empty.

You can use buttons to the left of the **Port and associated conditions** table to modify the elements in the table.

To...	Click...
Add a new output port: Create a new output port as a variant choice and add an entry for the new choice in the table.	
Delete selected port: Delete the selected variant choice from the block and its entry from the table.	
Create/Edit selected variant object: Create or edit a Simulink.Variant object for the selected variant choice in the global workspace and specify the variant condition using the Simulink.Variant object parameter dialog box.	
Note For a model that uses the base workspace, this operation creates the Simulink.Variant object in the base workspace, and the object is available only for the current MATLAB session. To permanently store the data, save the object in a MAT file or MATLAB script.	

Port — Number of connected output port
no default

Number of the output port that is connected to one variant choice upstream of the Variant Sink block. This value is read-only.

Click  to add a port or  to delete an existing one.

Variant control label — Name of choice in label mode

true or false (default) | string

A name for a choice, specified as a string.

Dependencies

To enable this parameter, set **Variant control mode** to label.

Variant control expression — Condition expression that determines the active choice

true or false (default) | boolean condition expression | a Simulink.Variant object representing a boolean condition expression | (default)

Specify the condition expression to determine the active choice. When a condition expression evaluates to true, Simulink activates the corresponding variant choice. When a condition expression evaluates to false, Simulink deactivates the corresponding variant choice.

The variant controls can be:

- Boolean condition expression for rapid prototyping. For example, `A == 1`, `A ~= B`, `A && B == 1`, and so on.
- A Simulink.Variant object that contains a condition expression for condition reuse. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks”.

- “Default Variant Choice” if none of the choices evaluates to `true`.

Here, A and B are operands called as variant control variables. `==`, `~=`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control variables, see “Types of Variant Control Variables (Operands) in Variant Blocks” and “Storage Locations for Variant Control Variables (Operands) in Variant Blocks”. For information on operators, see “Types of Operators in Variant Blocks for Different Activation Times”.

For more information, see “Switch Between Choices Using Condition Expressions in Variant Blocks”.

Note In Variant Assembly Subsystem block, this parameter is a list of auto-generated boolean expressions with **Variant control variable** on the left-hand side and the members of the **Variant enumeration choice** are on the right-hand side of the expressions. Both the sides of the expressions are connected with `==`. This parameter is read-only.

Programmatic Use

Structure field: Represented by the read-only `variant.Name` field in the `Variant` parameter structure

Type: character vector

Value: variant control that is associated with the variant choice

Default: 'variant'

Condition (read-only) — Condition expression in `Simulink.Variant` object

N/A (default)

This parameter is read-only.

This parameter displays the condition expression specified as `Simulink.Variant` object. To change or edit the condition expression, use the `Simulink.Variant` parameter dialog box that appears when you double-click the object in the workspace.

Note The operands that you specify in a condition expression of type `Simulink.Variant` must be defined in the base workspace or a data dictionary. Specifying operands that are defined in the mask or model workspace is not supported.

Label mode active choice — Name of active choice in label mode

`true(Subsystem)` (default) | `false(Subsystem1)`

This list contains the labels of all the variant choices. To set an active choice, select a label from the list. The corresponding choice becomes active. Alternatively, you can follow the approaches described in “Set Active Choices Using Variant Control Labels” to change the active choice in label mode.

Dependencies

To enable this parameter, set the **Variant control mode** parameter to `label`.

Programmatic Use

Parameter: `LabelModeActivechoice`

Type: character vector

Value: if no label mode active choice is specified, the value is empty. If label mode active choice is specified, the value is the name of the label mode active choice.

Default: ''

Allow zero active variant controls — Simulate model without active variant choice

off (default) | on

- off — Simulink generates an error when there is no active variant choice.
- on — When you select this parameter and if there is no active variant choice, Simulink simulates the model without any active variant choice connected to the Variant Sink block. Simulink disconnects all the blocks connected to the input and output stream of Variant Sink block, thus removing the variant regions completely from the model execution.

Consider the car windshield wiper example in the “Description” on page 1-2406 section. Suppose you do not want to pass the wiper speed to either of the variant choices, wiper motor and D/A. When you simulate the model with **Allow zero active variant controls** set to on and if there is no active variant choice in the Variant Sink controlled by mode block, Simulink disconnects the Variant Sink controlled by mode block and all its connected blocks, which removes the variant region completely from the model.

This table shows the code that you generate with and without the **Allow zero active variant controls** parameter for the code compile activation time. In the code that you generate with **Allow zero active variant controls** set to off, only the variant choices wiper motor and D/A are conditional, whereas the Gain block is unconditional. The Gain block is unconditional, and so it executes for either of the choices. This code support only scenarios where either of the choices evaluate to true. If none of the choices evaluate to true, both the choices are removed from compilation. The output of the Gain remains unused and this results in an error. In the code that you generate with **Allow zero active variant controls** set to on, the variant choices wiper motor, D/A, and the connected Gain blocks are conditional. So, if none of the choices evaluate to true, the Gain block is also removed, thus enabling you to completely remove the variant region from code compilation.

Generated code without Allow zero active variant controls	Generated code with Allow zero active variant controls
<pre> /* If none of the conditions Mode == 1 or Mode == 2 evaluate to true, the output of Gain remains results in an error.*/ /* logic for Gain; */ # if Mode == 1 /* logic for wiper motor; */ # elif Mode == 2 /* logic for digital to analog conversion; */ # endif </pre>	<pre> # if Mode == 1 /* logic for wiper motor; */ # elif Mode == 2 /* logic digital to analog conversion; */ # endif /* The logic for Gain is executed only if either of the conditions evaluate to true. Gain is removed from code compilation if none of the condition evaluates to true. */ # if (Mode == 1) (Mode == 2) /* logic for Gain; */ # endif </pre>

Dependencies

This parameter is available only if you set **Variant control mode** to expression.

Programmatic Use**Block Parameter:** AllowZeroVariantControls**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Show variant condition on block** — Annotate block ports

off (default) | on

When you select this option, Simulink annotates the variant condition expression on each port of the Variant Sink block.

Programmatic Use**Block Parameter:** ShowConditionOnBlock**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Block Characteristics**

Variant Source

Route among multiple inputs using variants

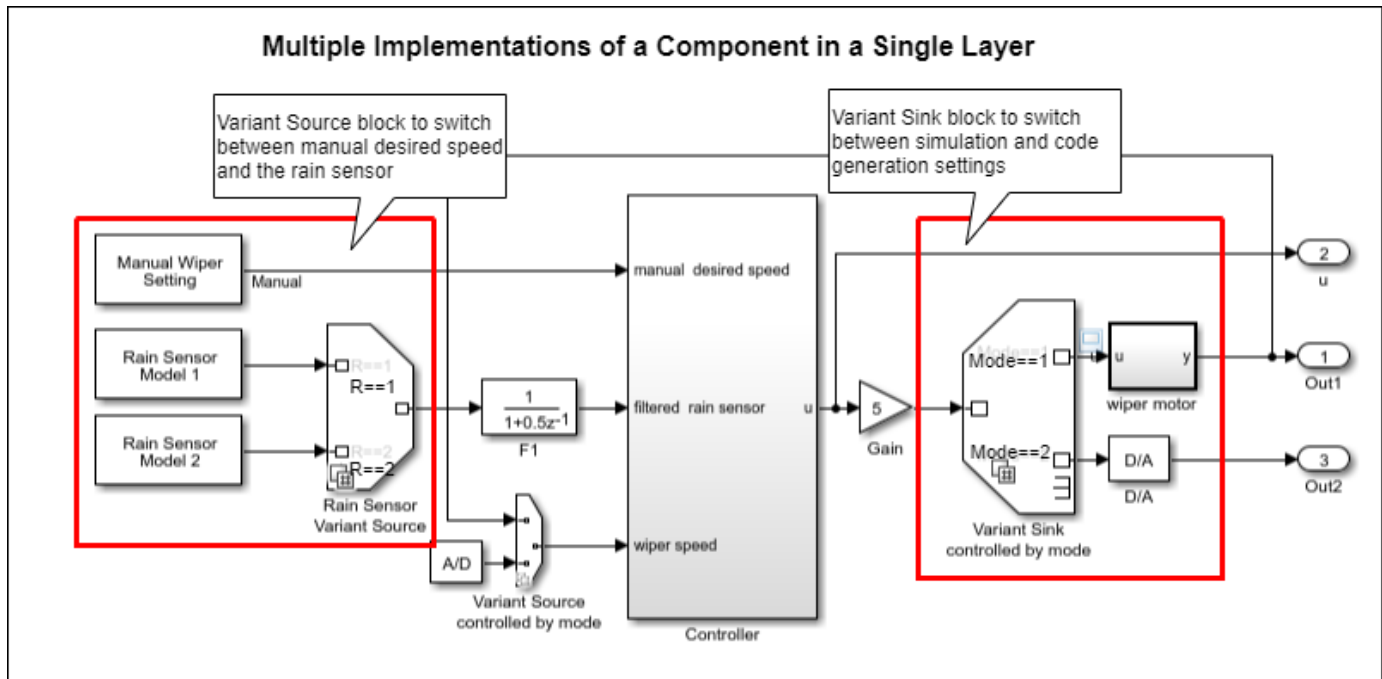

Libraries:
Simulink / Signal Routing

Description

The Variant Source block enables you to include multiple implementations of a component on the source of a signal in a single layer.

For example, suppose you want to simulate this model to control the speed of the car windshield wiper by using different rain sensors. The Variant Source block switches between different rain sensors. The control logic uses this information to output the result to the Variant Sink block. The Variant Sink block then switches between the wiper motor model during simulation and the command to the sensor during code generation. The variant blocks switch between choices based on the “Types of Variant Control Modes in Variant Blocks” you select. For more information, see “Introduction to Variant Controls”.

Note At most, one variant choice connected to input port of the Variant Source block is active during simulation.

The Variant Source block has one or more input ports and only one output port. You can connect the varying choices to the input port of the block so that, at most, one choice is active during model execution.

The Variant Source block is associated with a “Variant control mode” on page 1-0 and a “Variant activation time” on page 1-0 . The variant control mode determines how to specify the variant control. The variant activation time determines a time to activate the choices and to decide whether to include only the active choice or both active and inactive choices in the generated code. During simulation, Simulink connects the active choice directly to the output port of the Variant Source block and ignores the inactive choices.

Using a Variant Source block allows you to:

- Propagate variant conditions throughout the model.
- Visualize all possible implementations of variant choices in a single layer of your model, which improves model readability.
- Simulink eliminates inactive blocks throughout the model, which improves runtime performance. If all the variant choices are inactive, Simulink removes the variant region completely from your model.
- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

The color and icon of the variant badge on the block icon changes depending on the values of the **Variant activation time**, **Variant control mode**, and **Allow zero active variant controls** parameters. For more information, see “Variant Badges”.

Limitations

The Variant Source block works with time-based, function-call, and action signals. You cannot use SimEvents, Simscape Multibody, or other non-time-based signals with these blocks.

Ports

Input

Port_1 — Input port associated with first variant control

scalar | vector | matrix

Input port associated with the first variant control. The variant control that evaluates to `true`, determines which input port is active.

You can auto insert inport on the Variant Source block by hovering the mouse over the block side or by dragging the signal near the block boundary. You can delete the port by either clicking delete on the keyboard or with a mouse click.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Port_N — Input port associated with *N*th variant control

scalar | vector | matrix

Input port associated with the *N*th variant control. The variant control that evaluates to `true` determines which input port is active.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Output of active variant

scalar | vector | matrix

Output signal from the active variant.

You can auto insert outport on the Variant Source block by hovering the mouse over the block side or by dragging the signal near the block boundary. You can delete the port by either clicking delete on the keyboard or with a mouse click.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

Variant control mode — Variant control mode

`expression` (default) | `label` | `sim codegen switching`

The variant control that determines the active variant choice can be any of these types.

- `expression` — In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Blocks”.

- `label` — In `label` mode, Simulink chooses the active variant based on the name of the variant. The variant control is a string and does not require you to create any variable in any workspaces. See “Switch Between Choices Using Labels in Variant Blocks”.
- `sim codegen switching` — To automatically switch between the variants for simulation and code generation workflows without creating any workspace variable, use `sim codegen switching` mode. When you simulate a model, Simulink automatically chooses the `sim` branch as the active choice. Similarly, when you do a software-in-the-loop (SIL) or processor-In-Loop (PIL) simulation, generate code, or use external mode, Simulink automatically chooses the `codegen` branch. This mode is not supported for models configured with an ERT-based system target file and service code interface. See “Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks”.

For more information on variant control modes, see “Introduction to Variant Controls”. For a comparison between different types of variant control modes, see “Compare Different Types of Variant Control Modes in Variant Blocks”.

Dependencies

The availability of different variant activation times depends on the type of the **Variant control mode** that you specify. The **Variant activation time** parameter determines the time when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: `VariantControlMode`

Type: character vector

Values: `expression` | `label` | `sim codegen switching` |

Default: `expression`

Variant activation time — Time when Simulink chooses active variant choice

`update diagram`(default) | `update diagram analyze all choices` | `code compile` | `startup` | `inherit from Simulink.VariantControl`

This parameter determines which variability to include in the simulation and code generation workflows. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow”.

You can set the **Variant activation time** parameter as:

- `update diagram` — When you execute the model, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.

- **update diagram analyze all choices** — When you execute the model, both active and inactive choices are analyzed for consistency across the model. However, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.
- **code compile** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. Generated code contains both the active and inactive choices enclosed in the preprocessor conditionals `#if` and `#elif`. However, the executable built from the generated code contains only active choice.
- **startup** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. With this option, you can improve the speed of iterative simulations using fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart”. Code generated from the model contains both the active and inactive choices that are enclosed in regular `if` conditions. The executable built from the generated code also contains both active and inactive choices.
- **inherit from Simulink.VariantControl** — When you execute the model, the block inherits the activation time from its variant control variables of type `Simulink.VariantControl`. If a variant block has multiple variant control variables of type `Simulink.VariantControl`, then all those variables must have the same activation time.

Dependencies

The availability of different variant activation times depends on the type of the variant control mode that you specify. The **Variant activation time** parameter determines when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: `VariantActivationTime`

Type: character vector

Values: `update diagram` | `update diagram analyze all choices` | `code compile` | `startup`

Default: `update diagram`

Port and associated conditions — Table of variant choices, variant controls, and conditions
empty table (default)

The table has a row for each variant choice connected to the input port of the Variant Source block. If there are no variant choices, the table is empty.

You can use buttons to the left of the **Port and associated conditions** table to modify the elements in the table.

To...	Click...
Add a new input port: Create a new input port as a variant choice and add an entry for the new choice in the table.	
Delete selected port: Delete the selected variant choice from the block and its entry from the table.	
Create/Edit selected variant object: Create or edit a Simulink.Variant object for the selected variant choice in the global workspace and specify the variant condition using the Simulink.Variant object parameter dialog box.	
Note For a model that uses the base workspace, this operation creates the Simulink.Variant object in the base workspace, and the object is available only for the current MATLAB session. To permanently store the data, save the object in a MAT file or MATLAB script.	

Port — Number of connected input port
no default

Number of the input port that is connected to one variant choice upstream of the Variant Source block. This value is read-only.

Click  to add a port or  to delete an existing one.

Variant control label — Name of choice in label mode

true or false (default) | string

A name for a choice, specified as a string.

Dependencies

To enable this parameter, set **Variant control mode** to label.

Variant control expression — Condition expression that determines the active choice

true or false (default) | boolean condition expression | a Simulink.Variant object representing a boolean condition expression | (default)

Specify the condition expression to determine the active choice. When a condition expression evaluates to true, Simulink activates the corresponding variant choice. When a condition expression evaluates to false, Simulink deactivates the corresponding variant choice.

The variant controls can be:

- Boolean condition expression for rapid prototyping. For example, `A == 1`, `A ~= B`, `A && B == 1`, and so on.
- A Simulink.Variant object that contains a condition expression for condition reuse. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks”.

- “Default Variant Choice” if none of the choices evaluates to `true`.

Here, `A` and `B` are operands called as variant control variables. `==`, `~=`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control variables, see “Types of Variant Control Variables (Operands) in Variant Blocks” and “Storage Locations for Variant Control Variables (Operands) in Variant Blocks”. For information on operators, see “Types of Operators in Variant Blocks for Different Activation Times”.

For more information, see “Switch Between Choices Using Condition Expressions in Variant Blocks”.

Note In Variant Assembly Subsystem block, this parameter is a list of auto-generated boolean expressions with **Variant control variable** on the left-hand side and the members of the **Variant enumeration choice** are on the right-hand side of the expressions. Both the sides of the expressions are connected with `==`. This parameter is read-only.

Programmatic Use

Structure field: Represented by the read-only `variant.Name` field in the `Variant` parameter structure

Type: character vector

Value: variant control that is associated with the variant choice

Default: 'variant'

Condition (read-only) — Condition expression in `Simulink.Variant` object

N/A (default)

This parameter is read-only.

This parameter displays the condition expression specified as `Simulink.Variant` object. To change or edit the condition expression, use the `Simulink.Variant` parameter dialog box that appears when you double-click the object in the workspace.

Note The operands that you specify in a condition expression of type `Simulink.Variant` must be defined in the base workspace or a data dictionary. Specifying operands that are defined in the mask or model workspace is not supported.

Label mode active choice — Name of active choice in label mode

`true(Subsystem)` (default) | `false(Subsystem1)`

This list contains the labels of all the variant choices. To set an active choice, select a label from the list. The corresponding choice becomes active. Alternatively, you can follow the approaches described in “Set Active Choices Using Variant Control Labels” to change the active choice in label mode.

Dependencies

To enable this parameter, set the **Variant control mode** parameter to `label`.

Programmatic Use

Parameter: `LabelModeActivechoice`

Type: character vector

Value: if no label mode active choice is specified, the value is empty. If label mode active choice is specified, the value is the name of the label mode active choice.

Default: ''

Allow zero active variant controls — Simulate model without active variant choice

off (default) | on

- **off** — Simulink generates an error when there is no active variant choice.
- **on** — When you select this parameter and if there is no active variant choice, Simulink simulates the model without any active variant choice connected to the Variant Source block. Simulink disconnects all the blocks connected to the input and output stream of Variant Source block, thus removing the variant regions completely from the model execution.

In the generated code, all the blocks that are connected to the input and output stream of the Variant Source block becomes conditional.

Consider the car windshield wiper example in the “Description” on page 1-2415 section. Suppose you want to simulate only a manual windshield car wiper and you do not need any of the rain sensor settings in the model. When you set **Allow zero active variant controls** to on and if there is no active variant choice in the Rain Sensor Variant Source block, Simulink disconnects the Rain Sensor Variant Source block and all its connected blocks, which removes the variant region completely from the model.

This table shows the code that you generate with and without the **Allow zero active variant controls** parameter for the code compile activation time. In the code that you generate with **Allow zero active variant controls** set to off, only the variant choices Rain Sensor Model 1 and the Rain Sensor Model 2 are conditional. The F1 block is unconditional, and so it executes for either of the choices. This code support only scenarios where either of the choices evaluate to true. If none of the choices evaluate to true, both the choices are removed from compilation. The F1 block receives an invalid input and this results in an error. In the code that you generate with **Allow zero active variant controls** set to on, the variant choices Rain Sensor Model 1, Rain Sensor Model 2, and the connected F1 blocks are conditional. So, if none of the choices evaluate to true, the F1 block is also removed thus enabling you to completely remove the variant region from code compilation.

Generated code without Allow zero active variant controls	Generated code with Allow zero active variant controls
<pre># if R == 1 /* logic for Rain Sensor Model 1; */ # elif R == 2 /* logic for Rain Sensor Model 2; */ # endif /* If none of the conditions R == 1 or R == 2 evaluate to true, the filter F1 receives an invalid input which results in an error.*/ /* logic for filter F1; */</pre>	<pre># if R == 1 /* logic for Rain Sensor Model 1; */ # elif R == 2 /* logic for Rain Sensor Model 2; */ # endif /* The logic for filter F1 is executed only if either of the conditions evaluate to true. F1 is removed from code compilation if none of the condition evaluates to true. */ # if (R == 1) (R == 2) /* logic for filter F1; */ # endif</pre>

Dependencies

This parameter is available only if you set **Variant control mode** to expression.

Programmatic Use

Block Parameter: AllowZeroVariantControls

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output function call — Receive and output function-call signals

off (default) | on

When you select this parameter, Simulink enables the Variant Source block to receive function-call signals at its input ports and conditionally merge the signals at its output port. For more information, see “Propagate Variant Conditions from Variant Source Blocks to Conditionally Executed Subsystems”.

Programmatic Use

Block Parameter: OutputFunctionCall

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Show variant condition on block — Annotate block ports

off (default) | on

When you select this option, Simulink annotates the variant condition expression on each port of the Variant Source block.

Programmatic Use

Block Parameter: ShowConditionOnBlock

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean bus double enumerated fixed point half integer single string
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2016a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Variant Subsystem, Variant Model, Variant Assembly Subsystem

Template subsystem containing Subsystem, Model, or Subsystem Reference blocks as variant choices

**Libraries:**

Simulink / Ports & Subsystems
HDL Coder / Ports & Subsystems

Description

The Variant Subsystem block enables you to include multiple implementations of a component in a separate hierarchy.

For example, suppose you want to simulate a model that represents a vehicle with three possible engine configurations: 4-cylinder gas, 6-cylinder gas, and 8-cylinder gas. You could implement each engine model as a separate subsystem inside the Variant Subsystem and then switch between the subsystems based on the “Types of Variant Control Modes in Variant Blocks” you select. For more information, see “Introduction to Variant Controls”.

Note Only one implementation of a Variant Subsystem is active during simulation.

The Variant Subsystem block is a template preconfigured to contain two or more blocks to use as Variant choices. These choices represent multiple implementations of a system. Only one child block is active during model execution. The active child block is referred to as the active variant.

Each variant choice inside the Variant Subsystem block is associated with a “Variant control mode” on page 1-0 and a “Variant activation time” on page 1-0. The variant control mode determines how to select the active variant. The variant activation time determines a time to activate the choices and to decide whether to include only the active choice or both active and inactive choices in the generated code.

A Variant Subsystem block can contain a mixture of Subsystem blocks, Model blocks, or Subsystem Reference blocks as variant choices. A Variant Subsystem block with only Model blocks as choices is called a Variant Model block. For more information, see “Implement Variations in Separate Hierarchy Using Variant Subsystems”. A Variant Subsystem block with Model or Subsystem Reference blocks as choices that can be added or removed only from external files and not within the block is called a Variant Assembly Subsystem block.

Apart from the variant choices, you can include Inport, control port (Enable, Trigger, Reset, and Function-Call), Outport, or Connection Port (Simscape) blocks inside a Variant Subsystem block. There are no drawn connections between the blocks that are inside the Variant Subsystem blocks. Simulink automatically wires the active variant to the Inport and Outport blocks of the Variant Subsystem during model compilation. The blocks representing variant choices can have input and

output ports that differ in number from the input and output ports in the parent Variant Subsystem block. For more information, see “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 1-2428.

Using Variant Subsystem block allows you to:

- Mix Subsystem, Model, and Subsystem Reference blocks as variant choices.
- Model components that do not have similar interface. You can have different numbers of inports and outports for multiple variant choices inside a Variant Subsystem. However, the conditions listed in “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 1-2428 must be met.
- Establish a hierarchical block diagram, where the Variant Subsystem block is on one layer and the variant choices are on another layer.
- Keeps functionally related blocks together.
- Reduce the complexity of your model.
- During model compilation, Simulink eliminates inactive blocks throughout the model, depending on the variant activation time you select.

The color and icon of the variant badge on the block icon changes depending on the values of the **Variant activation time**, **Variant control mode**, and **Propagate conditions outside of variant subsystem** parameters set on the block. For more information, see “Variant Badges”.

Variant Assembly Subsystem

A Variant Assembly Subsystem block enables you to add or remove its variant choices from external sources without modifying the model. A Variant Assembly Subsystem block can contain Model blocks, “Subsystem Reference” on page 1-2223 blocks, or both as its variant choices. You specify the source of variant choices in the block parameter dialog box once and then modify the source to add or remove the variant choices from the block. Unlike Variant Subsystem, you cannot manage the variant choices from inside the Variant Assembly Subsystem block. For more information, see “Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files”.

Note To convert a Variant Subsystem block to a Variant Assembly Subsystem block, follow the steps in “Convert Variant Subsystem to Variant Assembly Subsystem”.

Ports

During simulation, Simulink disables the inactive ports in a Variant Subsystem block.

Input

In_1 — Input port corresponding to root-level Inport blocks contained in Variant Subsystem
same data types accepted by Inport blocks

Each Subsystem, Model, or Subsystem Reference block contained within a Variant Subsystem represents one variant choice. The variant choices can contain Inport, control port (Enable, Trigger, Reset, and Function-Call), or Connection Port (Simscape) blocks at its input. The variant choices can have input ports that differ in number from the input ports in the parent Variant Subsystem block. However, the conditions described in “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 1-2428 must be met.

Output

Out_1 — Output port corresponding to root-level Outputport blocks contained in Variant Subsystem same data types accepted by Outputport blocks

Each Subsystem, Model, or Subsystem Reference block contained within a Variant Subsystem represents one variant choice. The variant choices can contain Outputport or Connection Port (Simscape) blocks at its output. The variant choices can have output ports that differ in number from the output ports in the parent Variant Subsystem block. However, the conditions described in “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 1-2428 must be met.

Note The unconnected outputs (inactive outputs) of a Variant Subsystem outputs a ground value. To output a value other than ground, select the **Specify output when source is unconnected** parameter of the Outputport block and specify a value.

Map Inports and Outports of Variant Choices in Variant Subsystem

A Variant Subsystem block allows you to use a combination of Subsystem, Model, or Subsystem Reference blocks as variant choices. The inputs that the Variant Subsystem block receives from upstream model components map to the input and output ports of the variant choices.

The blocks that represent variant choices can have input and output ports that differ in number from the input and output ports in the parent Variant Subsystem block. However, the following conditions must be met:

- The variant choices must have same set of inports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- The variant choices must have same set of outports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- If the Variant Subsystem container block has control ports:
 - The type of control port blocks in all the variant choices must be same as the Variant Subsystem block. For example, you cannot use Enabled Subsystem and Function-Call Subsystem blocks as choices within a Variant Subsystem block.
 - The control port on the Variant Subsystem block and the corresponding control ports on its variant choices must have the same name. For example, if the name of the control port on the Variant Subsystem is `fcn`, then the name of the corresponding control ports on all its variant choices must also be `fcn`.

Parameters

To access these parameters, right-click the variant badge on the block icon and select **Block Parameters**. For more information, see “Variant Badges”.

Variant control mode — Variant control mode

`expression (default) | label | sim codegen switching`

The variant control that determines the active variant choice can be any of these types.

- `expression` — In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the

corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Blocks”.

- `label` — In `label` mode, Simulink chooses the active variant based on the name of the variant. The variant control is a string and does not require you to create any variable in any workspaces. See “Switch Between Choices Using Labels in Variant Blocks”.
- `sim codegen switching` — To automatically switch between the variants for simulation and code generation workflows without creating any workspace variable, use `sim codegen switching` mode. When you simulate a model, Simulink automatically chooses the `sim` branch as the active choice. Similarly, when you do a software-in-the-loop (SIL) or processor-In-Loop (PIL) simulation, generate code, or use external mode, Simulink automatically chooses the `codegen` branch. This mode is not supported for models configured with an ERT-based system target file and service code interface. See “Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks”.

For more information on variant control modes, see “Introduction to Variant Controls”. For a comparison between different types of variant control modes, see “Compare Different Types of Variant Control Modes in Variant Blocks”.

Dependencies

The availability of different variant activation times depends on the type of the **Variant control mode** that you specify. The **Variant activation time** parameter determines the time when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: `VariantControlMode`

Type: character vector

Values: `expression` | `label` | `sim codegen switching` |

Default: `expression`

Variant activation time — Time when Simulink chooses active variant choice

`update diagram`(default) | `update diagram analyze all choices` | `code compile` | `startup` | `inherit from Simulink.VariantControl`

This parameter determines which variability to include in the simulation and code generation workflows. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow”.

You can set the **Variant activation time** parameter as:

- **update diagram** — When you execute the model, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.
- **update diagram analyze all choices** — When you execute the model, both active and inactive choices are analyzed for consistency across the model. However, only the active choice is included in the simulation and the code generation workflow. Generated code contains only the active choice.
- **code compile** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. Generated code contains both the active and inactive choices enclosed in the preprocessor conditionals `#if` and `#elif`. However, the executable built from the generated code contains only active choice.
- **startup** — When you execute the model, both active and inactive choices are analyzed for consistency across the model, and all choices are included in the simulation and the code generation workflow. With this option, you can improve the speed of iterative simulations using fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart”. Code generated from the model contains both the active and inactive choices that are enclosed in regular `if` conditions. The executable built from the generated code also contains both active and inactive choices.
- **inherit from Simulink.VariantControl** — When you execute the model, the block inherits the activation time from its variant control variables of type `Simulink.VariantControl`. If a variant block has multiple variant control variables of type `Simulink.VariantControl`, then all those variables must have the same activation time.

Dependencies

The availability of different variant activation times depends on the type of the variant control mode that you specify. The **Variant activation time** parameter determines when Simulink sets the active choice. The parameter also determines which variability to include in the generated code. This table explains the variant activation time supported by each variant control mode.

Variant activation time				
Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	✓	x	x	x
sim codegen switching	✓	✓	x	x

Programmatic Use

Block Parameter: `VariantActivationTime`

Type: character vector

Values: `update diagram` | `update diagram analyze all choices` | `code compile` | `startup`

Default: `update diagram`

Variant control variable — Variable to determine active variant choices

`Simulink.VariantControl` | scalar variable | `Simulink.Parameter` | struct

When you specify a variable of type listed in “Types of Variant Control Variables (Operands) in Variant Blocks”, Simulink generates variant control expressions for the variant choices of the Variant Assembly Subsystem block. The **Variant control variable** that you specify here is on the left side and the members of the **Variant enumeration choice** are on the right side of the generated expressions. Both the sides are related by `==`.

The variant control variable acts as a switch to change the active variant choice. You specify a value for a variant control variable and run the simulation. During simulation, Simulink evaluates the variant control expressions to determine the active variant choice. When an expression evaluates to `true`, the corresponding variant choice is set active. To change the active variant, change the value of the variant control variable such that the corresponding variant control expression evaluates to `true` turns active.

Dependencies

This parameter is available only in Variant Assembly Subsystem block. To enable this parameter, set **Variant control mode** to expression.

Programmatic Use

Block Parameter: `VariantControlVariable`

Type: character vector

Values: `Simulink.VariantControl`, scalar variable, `Simulink.Parameter`, struct

Default: `''`

Variant choices enumeration — Enumeration class to add variant choices

enumeration class with model or subsystem filenames as its members

To add Model or Subsystem Reference blocks as variant choices to a Variant Assembly Subsystem block, specify an enumeration class name that contains the corresponding model or subsystem filenames as its members. You can then validate the enumeration class using the Refresh button in the **Variant choices** table. On a successful validation, the members of the enumeration class are added as variant choices to the Variant Assembly Subsystem block. Each choice has a variant control expression with **Variant control variable** on its left side and the members of the **Variant choices enumeration** that you specify here on its right side. Both the sides of the expression are related by `==`. The newly added variant choices and their corresponding control expressions are displayed in the **Variant choices** table.

To remove variant choices from a Variant Assembly Subsystem block, remove the corresponding members from the enumeration class that you specify here. You cannot manage the variant choices from inside the Variant Assembly Subsystem block.

The enumeration class that you specify must be on the search path of your current MATLAB session. For information on how to add files or folders to the search path, see `addpath`.

For more information on how to add choices using the **Variant choices enumeration** parameter, see “Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files”.

Dependencies

This parameter is available only in Variant Assembly Subsystem block. To enable this parameter, set **Variant control mode** to expression.

Programmatic Use

Block Parameter: `VariantChoicesEnumeration`

Type: character vector

Values: enumeration class defined using `classdef` or `Simulink.defineIntEnumType`

Default: ''

Variant choices specifier — MATLAB expression to add variant choices

any MATLAB expression that evaluates to a one-dimensional cell array of model or subsystem file names, or file name patterns that match the model or subsystem file names

To add Model or Subsystem Reference blocks as variant choices to a Variant Assembly Subsystem block, specify the corresponding model or subsystem file names. The file names must be specified as a MATLAB expression that returns a one-dimensional cell array of character vectors when evaluated. You can then validate the expression using the Refresh button in the **Variant choices** table. On a successful validation, the blocks that correspond to the specified files are added as variant choices to the Variant Assembly Subsystem block. For each choice, a variant control label is generated. The name of the variant control label is same as the name of the choice. The newly added variant choices and their corresponding control labels are displayed in the **Variant choices** table.

To remove variant choices from a Variant Assembly Subsystem block, modify the expression specified in this parameter. You cannot manage the variant choices of a Variant Assembly Subsystem block from inside the block.

The MATLAB expression that you specify must contain either of these:

- Model or subsystem file names that are on the search path of your current MATLAB session. For example, if you specify `{'model1.slx', 'subsystemRef1.slx'}` as a specifier, the blocks that correspond to the `model1.slx` and `subsystemRef1.slx` files are added as variant choices of the Variant Assembly Subsystem block.
- File name patterns that match the model or subsystem file names on the MATLAB path. The paths in the pattern can be absolute or relative to the parent folder of the model that contains the Variant Assembly Subsystem block. For example, if you specify `{'folder_1/* .slx', 'folder_2/* .slx'}` as a specifier, Simulink passes the character vectors `folder_1/*` and `folder2/*` to the `dir` function. The function then returns the model and the subsystem files that are located inside the `folder1` and `folder2` folders. The blocks that correspond to the returned files are added as variant choices of the Variant Assembly Subsystem block.

For information on how to add files or folders to the search path, see `addpath`.

For more information on how to specify choices in the **Variant choices specifier** parameter, see “Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files”.

Dependencies

This parameter is available only in Variant Assembly Subsystem block. To enable this parameter, set **Variant control mode** to `label`.

Programmatic Use

Parameter: `VariantChoicesSpecifier`

Type: character vector

Value: Any MATLAB expression that evaluate to a one-dimensional cell array of file names or file name patterns.

Default: ''

Variant choices (table of variant systems) — Table of variant choices, variant controls, and conditions

empty table (default)

The table has a row for each variant choice contained in the Variant Subsystem. If there are no variant choices, the table is empty.

You can use buttons to the left of the **Variant choices** table to modify the elements in the table.

To...	Click...
Create and add a new subsystem choice: Create a new Subsystem block as a variant choice and add an entry for the new choice in the table.	
Create and add a new model variant choice: Create a new Model block as a variant choice and add an entry for the new choice in the table.	
Create/Edit selected variant object: Create or edit a Simulink.Variant object in the global workspace and specify the variant condition using the Simulink.Variant object parameter dialog box.	
Note For a model that uses the base workspace, this operation creates the Simulink.Variant object in the base workspace and the object is available only for the current MATLAB session. To permanently store the data, save the object in a MAT file or MATLAB script.	
Open selected variant choice block: Open the Subsystem block for the selected row.	
Refresh dialog information from Variant Subsystem contents: Update the Variant choices table according to the variant choices and values of the variant control in the global workspace.	

Dependencies

The Variant Assembly Subsystem block allows you to only open the selected variant choice and refresh the list of variant choices using the buttons in this section. To add new variant choices to the Variant Assembly Subsystem block, see “Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files”.

Name (read-only) — Variant choice name

Subsystem and Subsystem1 (default) | name of choices contained in Variant Subsystem

This parameter is read-only.

This parameter displays the name of the choices. Each choice has a variant control in the form of labels, expressions, or switches. For Variant Assembly Subsystem in the `label` mode, no separate variant control is available. The name of the choice is used as a variant control to set the active choice.

Variant control label — Name of choice in `label` mode

true or false (default) | string

A name for a choice, specified as a string.

Dependencies

To enable this parameter, set **Variant control mode** to `label`.

Variant control expression — Condition expression that determines the active choice

`true` or `false` (default) | boolean condition expression | a `Simulink.Variant` object representing a boolean condition expression | (default)

Specify the condition expression to determine the active choice. When a condition expression evaluates to `true`, Simulink activates the corresponding variant choice. When a condition expression evaluates to `false`, Simulink deactivates the corresponding variant choice.

The variant controls can be:

- Boolean condition expression for rapid prototyping. For example, `A == 1`, `A ~= B`, `A && B == 1`, and so on.
- A `Simulink.Variant` object that contains a condition expression for condition reuse. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks”.
- “Default Variant Choice” if none of the choices evaluates to `true`.

Here, `A` and `B` are operands called as variant control variables. `==`, `~=`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control variables, see “Types of Variant Control Variables (Operands) in Variant Blocks” and “Storage Locations for Variant Control Variables (Operands) in Variant Blocks”. For information on operators, see “Types of Operators in Variant Blocks for Different Activation Times”.

For more information, see “Switch Between Choices Using Condition Expressions in Variant Blocks”.

Note In Variant Assembly Subsystem block, this parameter is a list of auto-generated boolean expressions with **Variant control variable** on the left-hand side and the members of the **Variant enumeration choice** are on the right-hand side of the expressions. Both the sides of the expressions are connected with `==`. This parameter is read-only.

Programmatic Use

Structure field: Represented by the read-only `variant.Name` field in the `Variant` parameter structure

Type: character vector

Value: variant control that is associated with the variant choice

Default: `'variant'`

Condition (read-only) — Condition expression in `Simulink.Variant` object

N/A (default)

This parameter is read-only.

This parameter displays the condition expression specified as `Simulink.Variant` object. To change or edit the condition expression, use the `Simulink.Variant` parameter dialog box that appears when you double-click the object in the workspace.

Note The operands that you specify in a condition expression of type `Simulink.Variant` must be defined in the base workspace or a data dictionary. Specifying operands that are defined in the mask or model workspace is not supported.

Label mode active choice — Name of active choice in label mode

`true(Subsystem) (default) | false(Subsystem1)`

This list contains the labels of all the variant choices. To set an active choice, select a label from the list. The corresponding choice becomes active. Alternatively, you can follow the approaches described in “Set Active Choices Using Variant Control Labels” to change the active choice in label mode.

Dependencies

To enable this parameter, set the **Variant control mode** parameter to `label`.

Programmatic Use

Parameter: `LabelModeActivechoice`

Type: character vector

Value: if no label mode active choice is specified, the value is empty. If label mode active choice is specified, the value is the name of the label mode active choice.

Default: `''`

Allow zero active variant controls — Whether to allow zero active variant choices

`off (default) | on`

- `off` — Simulink generates an error when there is no active variant choice.
- `on` — When you select this option and if there is no active variant choice, Simulink simulates the model without any active variant choice in the Variant Subsystem. Simulink disconnects all the blocks connected to the input and output stream of Variant Subsystem block, thus removing the variant regions completely from the model. The inactive outports of the Subsystem output a ground value. To output a value other than ground, select the **Specify output when source is unconnected** parameter of the Outport block and specify a value of your choice.

Dependencies

This parameter is available only if there are no `default` variant choices in the Variant Subsystem and if you set **Variant control mode** to `expression`.

Programmatic Use

Parameter: `AllowZeroVariantControls`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Propagate conditions outside of variant subsystem — Option to choose if components outside of the Variant Subsystem must be informed of the active and inactive state of underlying blocks

`off (default) | on`

When you select the **Propagate conditions outside of variant subsystem** parameter, Simulink propagates the variant condition of the underlying blocks to the Variant Subsystem container block so the subsystem can adapt its interface to the state of the underlying blocks. Ports that are mapped to

the ports on the active choice becomes active. Ports that are not mapped to the ports on the inactive choice becomes inactive. Selecting this option ensures that the components outside of the Variant Subsystem are aware of the active and inactive state of blocks within the Variant Subsystem block. For more information, see “Propagate Variant Conditions Outside Variant Subsystems” and “Use Variant Subsystem Blocks with Conditionally Executed Subsystems”

Note Variant conditions do not propagate outside a Variant Subsystem block if all variant choices within the block have the same interface.

Programmatic Use

Parameter: PropagateVariantConditions

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Version History

Introduced in R2010b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. Actual data type or capability support depends on block implementation.

HDL Architecture

Architecture	Description
Module (default)	Generate code for the subsystem and the blocks within the subsystem. HDL Coder generates code for all the variant choices.
BlackBox	<p>Generate a black-box interface. That is, the generated HDL code includes only the input/output port definitions for the subsystem. In this way, you can use a subsystem in your model to generate an interface to existing manually written HDL code.</p> <p>The black-box interface generated for subsystems is similar to the interface generated for Model blocks, but without generation of clock signals.</p>
No HDL	Remove the subsystem from the generated code. You can use the subsystem in simulation but treat it as a “no-op” in the HDL code.

Black Box Interface Customization

For the BlackBox architecture, you can customize port names and set attributes of the external component interface. See “Customize Black Box or HDL Cosimulation Interface” (HDL Coder).

HDL Block Properties

General	
AdaptivePipelining	Automatic pipeline insertion based on the synthesis tool, target frequency, and multiplier word-lengths. The default is <code>inherit</code> . See also “AdaptivePipelining” (HDL Coder).
BalanceDelays	Detects introduction of new delays along one path and inserts matching delays on the other paths. The default is <code>inherit</code> . See also “BalanceDelays” (HDL Coder).
ClockRatePipelining	Insert pipeline registers at a faster clock rate instead of the slower data rate. The default is <code>inherit</code> . See also “ClockRatePipelining” (HDL Coder).
ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is <code>0</code> . For more details, see “ConstrainedOutputPipeline” (HDL Coder).
DistributedPipelining	Pipeline register distribution, or register retiming. The default is <code>inherit</code> . See also “DistributedPipelining” (HDL Coder).
DSPStyle	Synthesis attributes for multiplier mapping. The default is <code>none</code> . See also “DSPStyle” (HDL Coder).
FlattenHierarchy	Remove subsystem hierarchy from generated HDL code. The default is <code>inherit</code> . See also “FlattenHierarchy” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is <code>0</code> . For more details, see “InputPipeline” (HDL Coder).

General	
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
SharingFactor	Number of functionally equivalent resources to map to a single shared resource. The default is 0. See also “Resource Sharing” (HDL Coder).
StreamingFactor	Number of parallel data paths, or vectors, that are time multiplexed to transform into serial, scalar data paths. The default is 0, which implements fully parallel data paths. See also “Streaming” (HDL Coder).

Target Specification

This block cannot be the DUT, so the block property settings in the **Target Specification** tab are ignored.

Restrictions

- The DUT cannot be a Variant Subsystem.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Vector Concatenate

Concatenate input vectors of same data type for iterative processing

Libraries:

Simulink / Commonly Used Blocks
 Simulink / Math Operations
 Simulink / Signal Routing
 HDL Coder / Math Operations
 HDL Coder / Signal Routing

Alternative Configurations of Vector Concatenate Block:

Matrix Concatenate

Description

The Vector Concatenate block concatenates input signals to create a nonscalar signal that you can iteratively process with a subsystem, for example, a for-each, while-iterator, or for-iterator subsystem.

You can use multiple Vector Concatenate blocks to create the output signal in stages, but the result is flat, as if you used a single block to concatenate the signals.

The signals in the output signal appear in the same order as the input signals for the block. For a description of the port order for various block orientations, see “Identify Port Location on Rotated or Flipped Block”.

You must use a Vector Concatenate or Matrix Concatenate block to define an array of buses. For more information, see “Group Nonvirtual Buses in Arrays of Buses”.

Examples

Concatenate Vectors

A Vector Concatenate block concatenates the vectors it receives, placing them side-by-side in the output vector.

For example, simulate the VectorConcatenation model.

Copyright 2022 The MathWorks, Inc.

The input vectors [1 2] and [3 4] are concatenated to create the output vector [1 2 3 4].

Ports

Input

Port_1 — First input to concatenate

scalar | vector | matrix | array

First input to concatenate, specified as a scalar, vector, matrix, or array.

- Inputs must be of the same data type.
- Matrix and array inputs are supported only when you set **Mode** to `Multidimensional array`.

When the data type is a `Simulink.Bus` object, the inputs must be nonvirtual buses.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Port_N — Nth input to concatenate

scalar | vector | matrix | array

Nth input to concatenate, specified as a scalar, vector, matrix, or array.

- Inputs must be of the same data type.
- Matrix and array inputs are supported only when you set **Mode** to `Multidimensional array`.

Dependencies

To add input ports, set **Number of inputs** to an integer greater than or equal to 2.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Output

Port_1 — Concatenation of input signals

scalar | vector | matrix | array

Concatenation of input signals along specified dimension. Outputs have the same data type as the input.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus` | `image`

Parameters

To edit block parameters interactively, use the **Property Inspector**. From the Simulink Toolstrip, on the **Simulation** tab, in the **Prepare** gallery, select **Property Inspector**.

Number of inputs — Number of input ports

2 (default) | positive integer

Specify the number of inputs for the block as a real-valued, positive integer, less than or equal to 65536.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	NumInputs
Values:	'2' (default) positive integer
Data Types:	char string

Example: `set_param(gcf, 'NumInputs', '3')`

Mode — Type of concatenation

Vector | Multidimensional array

Select whether the block operates in vector or multidimensional array concatenation mode. The default **Mode** of the Vector Concatenate block is **Vector**. The default **Mode** of the Matrix Concatenate block is **Multidimensional array**.

- When you select **Vector**, the block performs vector concatenation.
- When you select **Multidimensional array**, the block performs matrix concatenation.

Mode Setting	Input Signals	Output Signal
Vector	<ul style="list-style-type: none"> • Vectors • Row vectors (1-by-M matrices) • Column vectors (M-by-1 matrices) • Combination of vectors and either row or column vectors 	<p>When all inputs are vectors, the output is a vector.</p> <p>If any of the inputs are row or column vectors, the output is a row or column vector, respectively.</p>
Multidimensional array	Signals of any dimensionality (scalars, vectors, and matrices)	<p>The output is always an array.</p> <p>Trailing dimensions are assumed to be 1 for lower dimensionality inputs. For example, if the output is 4-D and the input is [2x3] (2-D), this block treats the input as [2x3x1x1].</p> <p>Concatenation is on the dimension that you specify with the Concatenate dimension parameter.</p>

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	Mode
Values:	'Vector' 'Multidimensional array'

Example: `set_param(gcf, 'Mode', 'Vector')`

Concatenate dimension — Output dimension along which to concatenate input arrays

scalar integer

Specify the output dimension along which to concatenate the input arrays.

- 1 — Concatenate inputs vertically. The vertical matrix concatenation stacks the input matrices on top of each other in the output matrix. When you insert a Vector Concatenate block and set **Mode** to `Multidimensional array`, the default is 1.
- 2 — Concatenate inputs horizontally. The horizontal matrix concatenation places the input matrices side-by-side in the output matrix. When you insert a Matrix Concatenate block, the default is 2.
- 3 or more — Perform multidimensional concatenation on the inputs.

The input matrices must have compatible sizes for concatenation. Vertical concatenation requires the input matrices to have the same number of columns. Horizontal concatenation requires input matrices to have the same number of rows.

Dependencies

To enable this parameter, set **Mode** to `Multidimensional array`.

Programmatic Use

To set the block parameter value programmatically, use the `set_param` function.

Parameter:	<code>ConcatenateDimension</code>
Values:	scalar integer
Data Types:	<code>char</code> <code>string</code>

Example: `set_param(gcb, 'ConcatenateDimension', '3')`

Block Characteristics

Data Types	<code>Boolean</code> <code>double</code> <code>enumerated</code> <code>fixed point</code> <code>half</code> <code>image</code> <code>integer</code> <code>single</code>
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Matrix Concatenate — Concatenate input matrices of same data type for iterative processing

The Matrix Concatenate block sets **Mode** to `Multidimensional array`.

Libraries:

Simulink / Math Operations

Simulink / Matrix Operations

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations

HDL Coder / Math Operations

Version History

Introduced in R2009b

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

This block supports code generation for complex signals.

FOR-GENERATE Loop Support

For this block, HDL Coder generates code using FOR-GENERATE loop when you set the target language to VHDL. For more information, see “Unroll For-Generate Loops in VHDL Code” (HDL Coder)

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Vertical Gauge

Display signal value during simulation on vertical gauge with customizable appearance

**Libraries:**

Simulink / Dashboard / Customizable Blocks

Description

The Vertical Gauge block displays the value of the connected signal on a linear gauge that you can customize to look like a gauge in a real system.

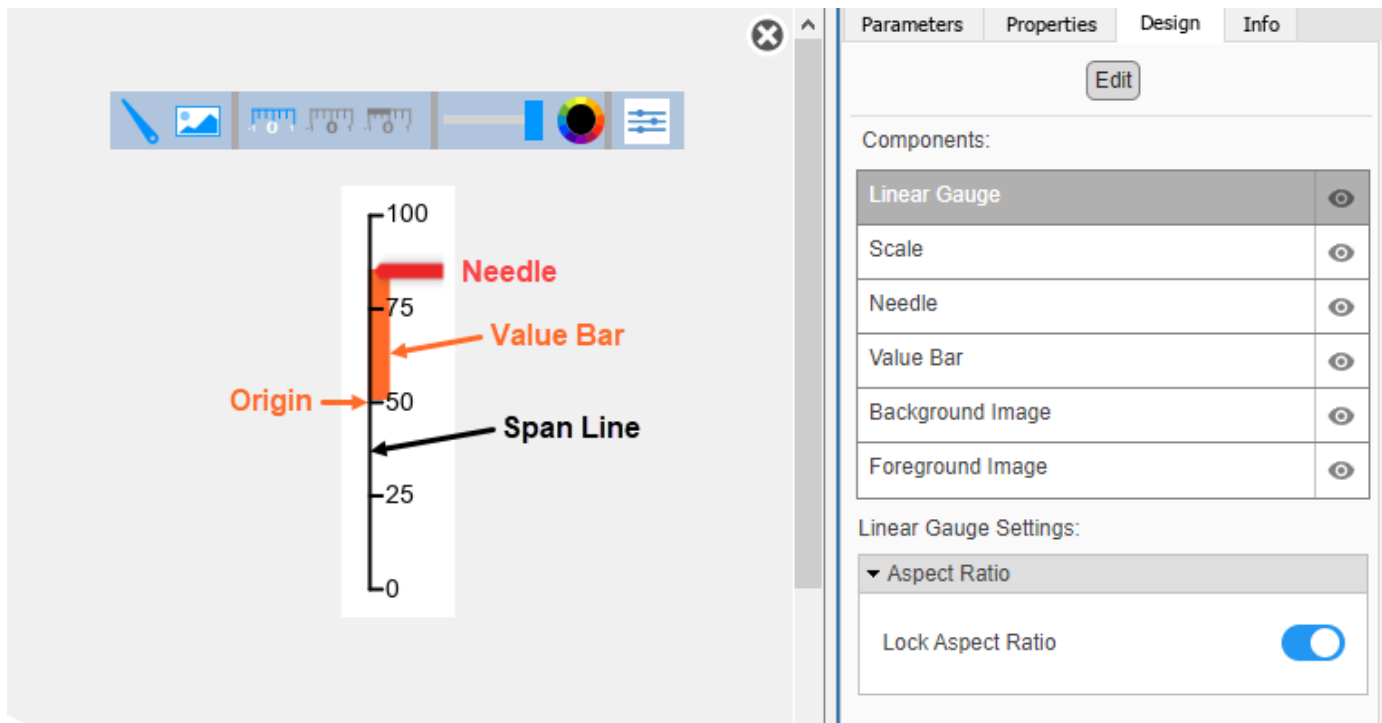

The Vertical Gauge block displays instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Vertical Gauge block to fit your data. Use the Vertical Gauge block with other dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Customize Vertical Gauge Blocks

When you add a Vertical Gauge block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can:

- Upload a needle image.
- Upload a background image or set a solid background color.
- Change the color and opacity of the scale, tick labels, and value bar.
- Change the size of the scale and needle.
- Reposition the scale and needle.
- Specify the location of the origin from which the value bar grows.
- Specify the scale direction as left to right or right to left.
- Upload a foreground image.

You can use the toolbar above the block to upload a needle or a background image and to change the color and opacity of the scale, tick labels, and value bar. To change the color and opacity, in the second section of the toolbar from the left, select a component. Then, click the color wheel in the toolbar to change the color of the component. Move the slider to change the opacity.

To resize the scale or needle, select the component you want to change in the canvas. Then, click and drag the grab points that define its dimensions.

To reposition the scale or needle, click and drag it in the canvas.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the scale direction.

- Specify the origin.
- Upload a foreground image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

Tip You can modify dashboard block connections during normal and accelerator mode simulations.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more signals or blocks, a list of signals that are available for connection appears. Select a signal from the list to connect to the selected dashboard block. To connect another dashboard block, pause on the block you want to connect and click the **Connect** button above it. Then, select one or more signals and blocks in the model and choose a signal to connect.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- You cannot connect a dashboard block to state activity or chart data in Stateflow during simulation.
- You cannot programmatically connect a dashboard block to state activity or chart data in Stateflow.
- Some signals do not have data available during simulation due to block reduction or optimization for accelerator mode simulations. To view such a signal using a dashboard block, mark the signal for logging.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection — Signal to connect and display
signal connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the signal that the block connects to. To connect the block to a signal:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a signal in the model.
- 3 In the table, select the signal you want to connect.
- 4 Click **Apply**.

To help understand and debug your model, you can connect dashboard blocks to signals in the model during simulation.

Tip You can also use bind mode select or change the signal that the block connects to. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, the **Connect** button  and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.

- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of signals that are available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the signal you want to connect.
- To exit bind mode, click **Done Connecting**  over the dashboard block.

Programmatic Use

Block Parameter: Binding

Type: Simulink.HMI.SignalSpecification

Default: []

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The parameter value must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The parameter value must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the Maximum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty, or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Tick Interval** — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the `Tick Interval` parameter, use a 1-by-3 vector containing values for the `Minimum`, `Tick Interval`, and `Maximum` parameters, in that order. To use the `auto` value for the `Tick Interval`, leave the `Tick Interval` position in the vector empty, or specify `-1`.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Scale Direction** — Direction of increasing scale values

'Bottom to top' (default) | 'Top to bottom'

Set the direction of increasing scale values.

Programmatic Use**Block Parameter: ScaleDirection****Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**Label** — Position of label displaying name of connected element

Top (default) | Bottom | Hide

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify `Hide`.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use**Block Parameter: LabelPosition****Type:** character vector**Values:** 'Top' | 'Bottom' | 'Hide'**Default:** 'Top'**Lock Aspect Ratio** — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Scale Colors — Color indications on gauge scale
 colors for scale ranges

Color specifications for value ranges on the scale. Click the **+** button to add a scale color. For each color added, specify the minimum and maximum values of the range in which you want to display that color.

Programmatic Use

To programmatically specify the `Scale Colors` parameter, use an array of structures with these fields:

- `Min` — Minimum value for the color range on the scale
- `Max` — Maximum value for the color range on the scale
- `Color` — 1-by-3 vector of `double` values between 0 and 1 that specify the color for the range in the form `[r g b]`

Include a structure in the array for each scale range for which you want to specify a color.

```
range1.Min = 0;
range1.Max = 10;
range1.Color = [0 0 1];
range2.Min = 10;
range2.Max = 15;
range2.Color = [0 1 0];
scaleRanges = [range1 range2];
```

Block Parameter: ScaleColors

Type: structure array

Default: 0x1 struct array

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Linear Gauge

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Scale

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The parameter value must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the **Minimum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The parameter value must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits**Type:** 1x3 vector**Default:** [0 -1 100]**Origin** — Value on scale from which needle moves and value bar grows

auto (default) | scalar

Specify the value on the scale from which the needle moves and the value bar grows. When set to `auto`, the `Origin` is the minimum of the scale.

Example: 0

Scale Direction — Direction of increasing scale values

'Bottom to top' (default) | 'Top to bottom'

Set the direction of increasing scale values.

Programmatic Use**Block Parameter:** ScaleDirection**Type:** character vector**Values:** 'Clockwise' | 'Counterclockwise'**Default:** 'Clockwise'**X Offset** — Horizontal offset of left edge of scale bounding box from left edge of block

scalar

Specify the horizontal offset of the left edge of the bounding box of the scale from the left edge of the block as a ratio of the block width. Relative to the position of the scale when the offset is 0, an offset with a negative value moves the scale left, and an offset with a positive value moves the scale right.

Example: 1

Y Offset — Vertical offset of top edge of scale bounding box from top edge of block

scalar

Specify the vertical offset of the top edge of the bounding box of the scale from the top edge of the block as a ratio of the block height. Relative to the position of the scale when the offset is 0, an offset with a negative value moves the scale up, and an offset with a positive value moves the scale down.

Example: 1

Width — Scale width

scalar

Specify the width of the bounding box of the scale as a ratio of the block width.

Example: 2

Height — Scale height

scalar

Specify the height of the bounding box of the scale as a ratio of the block height.

Example: 2

Lock Aspect Ratio — Option to maintain scale aspect ratio

on (default) | off

Enable on this option to maintain the aspect ratio when resizing the scale using the Property Inspector.

Tick Color — Color of scale tick marks, span line, and block name
[r g b] vector

Set the color of the scale tick marks, the span line, and the block name. Choose a color from the palette of standard colors, or specify a custom color.

Tip You can also set the **Tick Color** by choosing a **Foreground Color** on the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Label Color** parameter.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: [r g b] vector

Label Color — Scale label font color
[r g b] vector

Choose a font color for the scale label from the palette of standard colors, or specify a custom color.

Tip To specify the color of the scale, use the **Tick Color** parameter.

Label Offset — Horizontal distance of scale labels from free end of scale tick marks
0.3 (default) | scalar

Specify the horizontal distance from the scale labels to the free end of their corresponding tick marks on the scale as a ratio of the width of the bounding box of the scale.

Example: 0.5

Needle

Width — Needle image width
scalar

Specify the width of the needle image as a ratio of the block width.

Example: 1

Height — Needle image height
scalar

Specify the height of the needle image as a ratio of the block height.

Example: 1

Lock Aspect Ratio — Option to maintain image aspect ratio
on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

X Offset — Horizontal offset of left edge of needle image from scale span line
scalar

Specify the horizontal offset of the left edge of the needle image from the span line of the scale as a ratio of the needle image width. Relative to the position of the needle image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Y Offset — Vertical offset of needle image center from scale origin
scalar

Specify the vertical offset of the needle image center from the scale origin as a ratio of the needle image height. Relative to the position of the needle image when the offset is 0, an offset with a negative value moves the image up, and an offset with a positive value moves the image down.

Example: 1

Value Bar

Offset from Scale — Distance of left edge of value bar from span line
0 (default) | scalar

Specify the distance from the left edge of the value bar to the span line as a ratio of the width of the bounding box of the scale. Relative to the position of the value bar when the offset is 0, an offset with a negative value moves the value bar left, and an offset with a positive value moves the value bar right.

Example: 0.25

Size — Value bar thickness
scalar

Specify the thickness of the value bar as a ratio of the width of the bounding box of the scale.

Example: 0.3

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block
scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width
scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height

scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	Boolean double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2020a

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Change scale direction

Starting in R2022a, you can change the direction of the scale of these blocks from the **Customizable Blocks** library:

- Circular Gauge
- Horizontal Gauge
- Horizontal Slider
- Knob
- Vertical Gauge
- Vertical Slider

R2022a: Specify origin for value bar and needle

The origin of a scale is the value on the scale from which the needle moves and the value bar grows. Starting in R2022a, you can specify an origin for the scales of these blocks from the **Customizable Blocks** library:

- Circular Gauge
- Horizontal Gauge
- Horizontal Slider
- Knob
- Vertical Gauge
- Vertical Slider

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

R2021a: Customizable dashboard block gauges move to Customizable Blocks library

Behavior changed in R2021a

In prior releases, the Dashboard library contained the Circular Gauge, Horizontal Gauge, and Vertical Gauge blocks. Starting in R2021a, these blocks are in the Customizable Blocks sublibrary within the Dashboard library.

R2021a: Dashboard gauge blocks support foreground, background, and font color

Behavior changed in R2021a

Starting in R2021a, you can change the foreground, background, and font color of these blocks:

- Gauge
- Half Gauge
- Linear Gauge
- Quarter Gauge
- Circular Gauge
- Horizontal Gauge
- Vertical Gauge

R2020b: Simulink toolstrip support for dashboard blocks

Starting in R2020b, the Simulink Toolstrip opens a block-specific tab when you select a block in your model from the Simulink Dashboard library or from the Flight Instruments library in the Aerospace Blockset Flight Control Analysis Library. From the toolstrip, you can connect, disconnect, and modify connections for the selected block. You can also jump to the model element connected to the selected block and add the selected block to a panel.

R2020b: Add a foreground image to the Horizontal Gauge, Vertical Gauge, and Circular Gauge blocks

Starting in R2020b, you can add a foreground image to a Horizontal Gauge, Vertical Gauge, or Circular Gauge block in your model.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

“Tune and Visualize Your Model with Dashboard Blocks”

“Simulation Pacing”

“Getting Started with Panels”

Vertical Slider

Change parameter or variable value using vertical slider with customizable appearance

Libraries:

Simulink / Dashboard / Customizable Blocks

Description

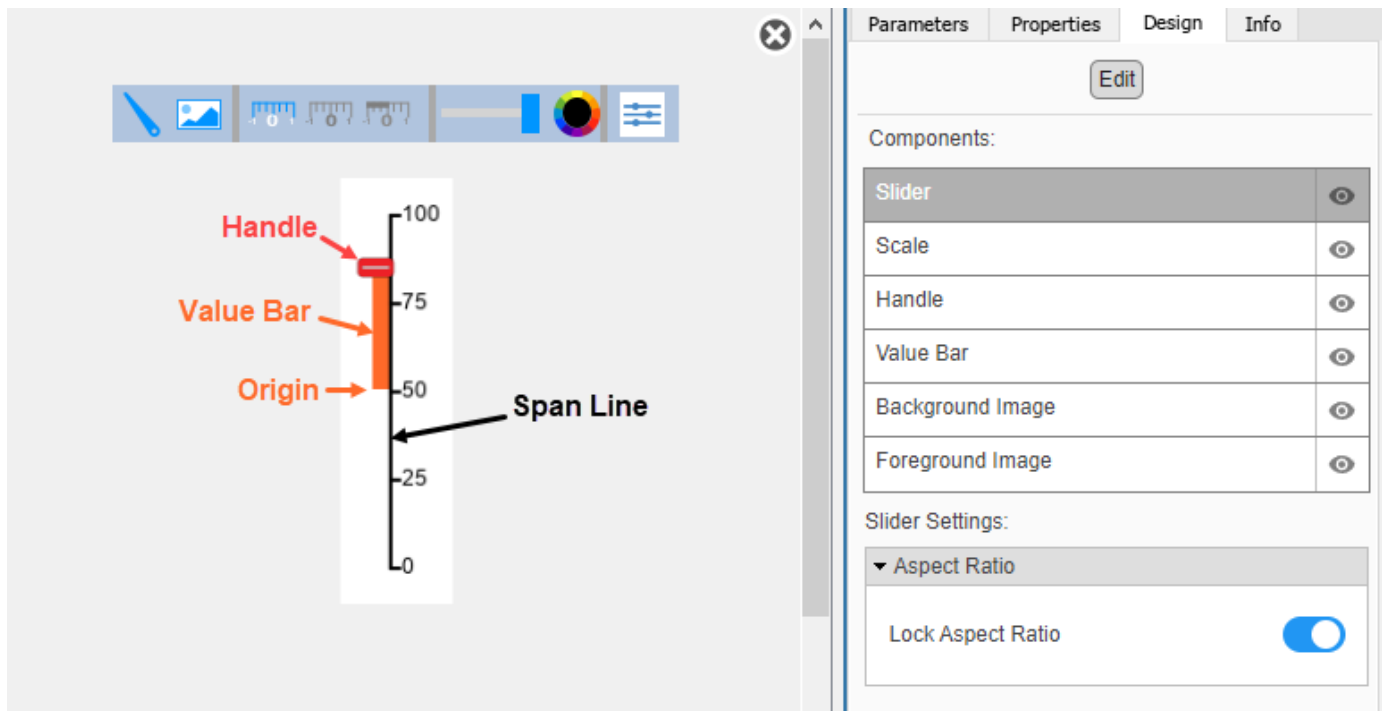

Use the Vertical Slider block to tune the value of a variable or block parameter during simulation. You can customize the appearance of the Vertical Slider block to look like a control in a real system. You can adjust the scale range and tick values to fit the desired range for the value you want to tune. Use the Vertical Slider block with other dashboard blocks to create an interactive dashboard to control your model.

Customize Vertical Slider Blocks

When you add a Vertical Slider block to your model, the block is preconfigured with a default design. You can use the block with the default design or customize the appearance of the block.

To customize the appearance of the block, use design mode. After selecting the block, you can enter design mode in one of three ways:

- On the **Gauge** tab, under **Design**, click **Edit**.
- In the **Property Inspector**, on the **Design** tab, click **Edit**.
- Pause on the ellipsis that appears over the block and click the **Edit Custom Block** button.

In design mode, you can:

- Upload a handle image.
- Upload a background image or set a solid background color.
- Change the color and opacity of the scale, tick labels, and value bar.
- Change the size of the scale and handle.
- Reposition the scale and handle.
- Specify the scale direction as left to right or right to left.
- Specify the location of the origin from which the value bar grows.
- Upload a foreground image.

You can use the toolbar above the block to upload a handle or a background image and to change the color and opacity of the scale, tick labels, and value bar. To change the color and opacity, in the second section of the toolbar from the left, select a component. Then, click the color wheel in the toolbar to change the color of the component. Move the slider to change the opacity.

To resize the scale or handle, select the component you want to change in the canvas. Then, click and drag the grab points that define its dimensions.

To reposition the scale or handle, click and drag it in the canvas.

You can use the **Design** tab in the Property Inspector for fine control over the block design and to enter exact values for design settings.

Use the **Design** tab to:

- Specify the scale direction.

- Specify the origin.
- Upload a foreground image.
- Set a solid background color.

When you finish editing the design, to exit design mode, click the **X** in the upper right of the canvas.

Connect Dashboard Blocks

Dashboard blocks do not use ports to connect to model elements. To connect dashboard blocks to variables and block parameters, use connect mode. Connect mode facilitates the process of connecting dashboard blocks in your model, especially when you want to connect multiple blocks at once. To connect a single dashboard block, you can also use the **Connection** table in the block dialog box.

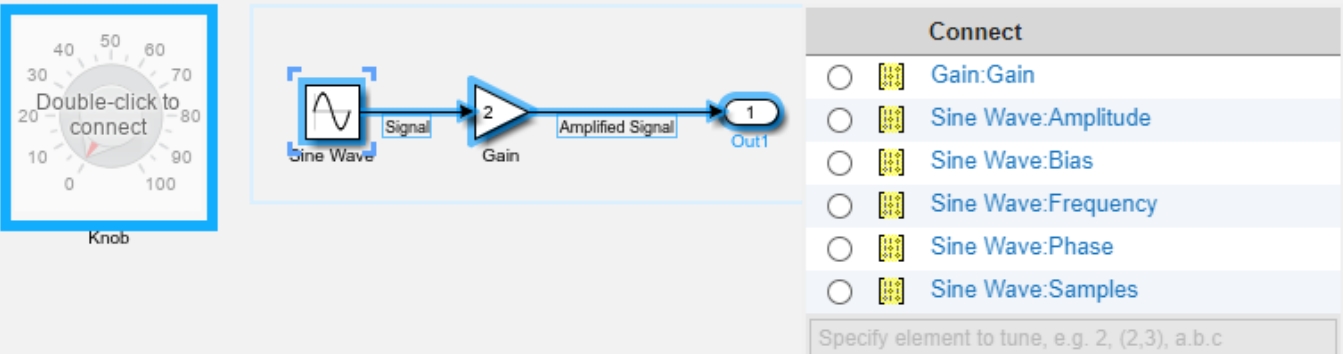

Tip You can modify dashboard block connections in your model during normal and accelerator mode simulations.

Note Dashboard blocks cannot connect to variables until you update the model diagram. To connect dashboard blocks to variables or modify variable values between opening your model and running a simulation, update the model diagram using **Ctrl+D**.

To enter connect mode, in the canvas, select the dashboard block to connect. On the Simulink Toolstrip, a tab named after the type of the selected block appears. On the block tab, click **Connect**. In connect mode, when you select one or more blocks, a list of parameters and variables available for connection appears. Select a variable or parameter from the list to connect to the selected dashboard block.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy, and omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

To connect another dashboard block, pause on another dashboard block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model and choose a model element to connect.

The image shows a Simulink interface. On the left, a 'Knob' dashboard block is shown with a scale from 0 to 100 and a red needle. A blue box highlights the knob with the text 'Double-click to connect'. In the center, a block diagram shows a 'Sine Wave' block connected to a 'Gain' block. The 'Sine Wave' block has a 'Signal' input and an 'Out1' output. The 'Gain' block has a 'Gain' parameter set to 2. The 'Gain' block is connected to the 'Out1' output of the 'Sine Wave' block. On the right, the 'Connect' dialog box is open, showing a list of parameters and variables available for connection. The list includes:

Connect	
<input type="radio"/>	Gain:Gain
<input type="radio"/>	Sine Wave:Amplitude
<input type="radio"/>	Sine Wave:Bias
<input type="radio"/>	Sine Wave:Frequency
<input type="radio"/>	Sine Wave:Phase
<input type="radio"/>	Sine Wave:Samples

At the bottom of the dialog box, there is a text box with the placeholder text 'Specify element to tune, e.g. 2, (2,3), a.b.c'.

When you finish connecting the dashboard blocks in your model, on the block tab, click **Done Connecting**.

Tip You can hide the message shown on unconnected blocks using the `set_param` function with the `ShowInitialText` block parameter. The message also disappears when you connect the block.

Parameter Logging

Tunable parameters connected to dashboard blocks are logged to the Simulation Data Inspector, where you can view the parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector by using the UI or the `Simulink.sdi.exportRun` function. For more information about exporting data using the Simulation Data Inspector UI, see “Export Data to the Workspace or a File”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Except for the Dashboard Scope block and the Display block, dashboard blocks can only connect to real scalar signals.
- The toolstrip does not support blocks that are inside a panel.
- You cannot use the **Connection** table in the block dialog to connect a dashboard block to a block that is commented out. When you connect a dashboard block to a commented block using connect mode, the dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to model elements inside referenced models.
- When you simulate a model hierarchy, dashboard blocks inside referenced models do not update.
- Dashboard blocks do not support rapid accelerator simulation.
- When you connect a dashboard block to a variable or parameter during simulation, the data for that variable or parameter is not logged to the Simulation Data Inspector. To log variable and parameter data to the Simulation Data Inspector, connect the dashboard block to the variable or parameter prior to simulation.
- When you simulate a model in external mode with the **Default parameter behavior** set to **Inlined**, dashboard blocks can appear to change parameter and variable values. However, the change does not propagate to the simulation. For example, Gain blocks display changes made to the **Gain** parameter using the dashboard blocks, but the **Gain** value used in the simulation does not change.

Parameters

Use the Property Inspector and the Block Parameters dialog box to specify the values of the block parameters. To set the core parameters of the dashboard block, use the Block Parameters dialog box or the **Parameters** tab in the Property Inspector. To customize the block, use the **Design** tab in the Property Inspector. To display the Block Parameters dialog box for a block, double-click the block. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**.

Parameters

To set the core parameters of the dashboard block, open the Property Inspector and click the **Parameters** tab.

Connection

Connection — Select variable or block parameter to connect
variable and parameter connection options

Use the **Connection** table in the Block Parameters dialog box to select or change the variable or block parameter to control. To connect the block to a variable or block parameter:

- 1 If the block is not connected, in the Property Inspector, on the **Parameters** tab, click **Connect** to open the Block Parameters dialog box. If the block is already connected and you want to change the signal to which it connects, click **Change**.
- 2 Select a block in the model.
- 3 Select the variable or parameter you want to connect.

When the value of the selected variable or block parameter is nonscalar, use the text box at the bottom of the **Connection** table to specify the element you want to connect to the dashboard block. To connect to an element of a vector, matrix, or array, specify the element index, for example, 3 or (1, 3). To connect to an element in a bus or structure, specify the element in the context of the bus or structure hierarchy by using dots to indicate different levels in the hierarchy. Omit the top level. For example, specify a.b to connect to scalar element b of the structure or bus a nested inside the selected composite variable or parameter.

- 4 Click **Apply**.

To help understand and debug your model, you can connect Dashboard blocks to variables and parameters in your model during simulation.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

Tip You can also use bind mode to select or change the variable or block parameter to control. To enter bind mode:

- If you are in design mode, exit by clicking the **Edit** button on the **Design** tab of the Property Inspector.
- Click the dashboard block in the canvas. If the dashboard block is not connected, **Connect**  and an ellipsis appear over the dashboard block. If the dashboard block is already connected, only the ellipsis appears.
- If the dashboard block is not connected, click **Connect**. If the dashboard block is connected, pause on the ellipsis. In the action menu that expands, click **Connect**. In either case, a list of parameters and variables available for connection appears.

To connect the dashboard block in bind mode:

- From the list, select the variable or parameter you want to connect.
- To exit bind mode, click **Done Connecting**  over the dashboard block.

Programmatic Use

To programmatically connect a dashboard block to a tunable parameter or a variable, use a `Simulink.HMI.ParamSourceInfo` object. The `Simulink.HMI.ParamSourceInfo` object contains four properties. Some properties apply to connecting dashboard blocks to parameters. Some properties apply to connecting dashboard blocks to variables. Not all fields have a value for a connection because a given dashboard block connects to either a parameter or a variable.

Block Parameter: Binding

Type: `Simulink.HMI.ParamSourceInfo`

Default: `[]`

Main

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The parameter value must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the Minimum parameter, use a 1-by-3 vector containing values for the Minimum, Tick Interval, and Maximum parameters, in that order. To use the auto value for the Tick Interval, leave the Tick Interval position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: `[0 -1 100]`

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The parameter value must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify **-1**.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify **-1**.

Block Parameter: Limits

Type: 1×3 vector

Default: [0 -1 100]

Scale Direction — Direction of increasing scale values

'Bottom to top' (default) | 'Top to bottom'

Set the direction of increasing scale values.

Programmatic Use

Block Parameter: ScaleDirection

Type: character vector

Values: 'Clockwise' | 'Counterclockwise'

Default: 'Clockwise'

Label — Position of label displaying name of connected element

Top (default) | Bottom | Hide

You can display the name of the element to which the dashboard block connects in a label positioned at the top or at the bottom of the block, or you can hide the label. If you want the label to be visible, specify the position of the block. If you do not want the label to be visible, specify **Hide**.

Note When the dashboard block is not connected to an element, the label is blank.

Programmatic Use

Block Parameter: LabelPosition

Type: character vector

Values: 'Top' | 'Bottom' | 'Hide'

Default: 'Top'

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Design

To customize the dashboard block, open the Property Inspector, click the **Design** tab, and click **Edit**.

Slider

Lock Aspect Ratio — Option to maintain block aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the block in the Simulink canvas.

Tip

- When the aspect ratio is locked, adding a new background image changes the aspect ratio of the block to match that of the background image.
 - When the aspect ratio is not locked, adding a new background image does not change the proportions of the block but instead stretches or scales the background image to fit the size of the block.
-

Scale

Minimum — Minimum tick mark value

0 (default) | scalar

Finite, real, double, scalar value specifying the minimum tick mark value for the scale. The parameter value must be less than the value of the **Maximum** parameter.

Programmatic Use

To programmatically set the **Minimum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Maximum — Maximum tick mark value

100 (default) | scalar

Finite, real, double, scalar value specifying the maximum tick mark value for the scale. The parameter value must be greater than the value of the **Minimum** parameter.

Programmatic Use

To programmatically set the **Maximum** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Tick Interval — Interval between major tick marks

auto (default) | scalar

Finite, real, positive, whole, scalar value specifying the interval of major tick marks on the scale. When set to **auto**, the block automatically adjusts the tick interval based on the values of the **Maximum** and **Minimum** parameters.

Programmatic Use

To programmatically set the **Tick Interval** parameter, use a 1-by-3 vector containing values for the **Minimum**, **Tick Interval**, and **Maximum** parameters, in that order. To use the **auto** value for the **Tick Interval**, leave the **Tick Interval** position in the vector empty, or specify -1.

Block Parameter: Limits

Type: 1x3 vector

Default: [0 -1 100]

Origin — Value on scale from which handle moves and value bar grows

auto (default) | scalar

Specify the value on the scale from which the handle moves and the value bar grows. When set to **auto**, the **Origin** is the minimum of the scale.

Example: 0

Scale Direction — Direction of increasing scale values

'Bottom to top' (default) | 'Top to bottom'

Set the direction of increasing scale values.

Programmatic Use

Block Parameter: ScaleDirection

Type: character vector

Values: 'Clockwise' | 'Counterclockwise'

Default: 'Clockwise'

X Offset — Horizontal offset of left edge of scale bounding box from left edge of block

scalar

Specify the horizontal offset of the left edge of the bounding box of the scale from the left edge of the block as a ratio of the block width. Relative to the position of the scale when the offset is 0, an offset with a negative value moves the scale left, and an offset with a positive value moves the scale right.

Example: 1

Y Offset — Vertical offset of top edge of scale bounding box from top edge of block
scalar

Specify the vertical offset of the top edge of the bounding box of the scale from the top edge of the block as a ratio of the block height. Relative to the position of the scale when the offset is 0, an offset with a negative value moves the scale up, and an offset with a positive value moves the scale down.

Example: 1

Width — Scale width
scalar

Specify the width of the bounding box of the scale as a ratio of the block width.

Example: 2

Height — Scale height
scalar

Specify the height of the bounding box of the scale as a ratio of the block height.

Example: 2

Lock Aspect Ratio — Option to maintain scale aspect ratio
on (default) | off

Enable on this option to maintain the aspect ratio when resizing the scale using the Property Inspector.

Tick Color — Color of scale tick marks, span line, and block name
[r g b] vector

Set the color of the scale tick marks, the span line, and the block name. Choose a color from the palette of standard colors, or specify a custom color.

Tip You can also set the **Tick Color** by choosing a **Foreground Color** on the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Label Color** parameter.

Programmatic Use

Specify the `ForegroundColor` parameter for the block as a string or a character vector that defines a 1-by-3 [r g b] vector with values between 0 and 1.

Block Parameter: `ForegroundColor`

Type: character vector | string

Values: [r g b] vector

Label Color — Scale label font color
[r g b] vector

Choose a font color for the scale label from the palette of standard colors, or specify a custom color.

Tip To specify the color of the scale, use the **Tick Color** parameter.

Label Offset — Horizontal distance of scale labels from free end of scale tick marks

0.3 (default) | scalar

Specify the horizontal distance from the scale labels to the free end of their corresponding tick marks on the scale as a ratio of the width of the bounding box of the scale.

Example: 0.5

Handle

Width — Handle image width

scalar

Specify the width of the handle image as a ratio of the block width.

Example: 1

Height — Handle image height

scalar

Specify the height of the handle image as a ratio of the block height.

Example: 1

Lock Aspect Ratio — Option to maintain image aspect ratio

on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

X Offset — Horizontal offset of left edge of handle image from scale span line

scalar

Specify the horizontal offset of the left edge of the handle image from the span line of the scale as a ratio of the handle image width. Relative to the position of the handle image when the offset is 0, an offset with a negative value moves the image up, and an offset with a positive value moves the image down.

Example: 1

Y Offset — Vertical offset of handle image center from scale origin

scalar

Specify the vertical offset of the handle image center from the scale origin as a ratio of the handle image height. Relative to the position of the handle image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Value Bar

Offset from Scale — Distance of left edge of value bar from span line

0 (default) | scalar

Specify the distance from the left edge of the value bar to the span line as a ratio of the width of the bounding box of the scale. Relative to the position of the value bar when the offset is 0, an offset with a negative value moves the value bar left, and an offset with a positive value moves the value bar right.

Example: 0.25

Size — Value bar thickness
scalar

Specify the thickness of the value bar as a ratio of the width of the bounding box of the scale.

Example: 0.3

Background Image

Use Background Color — Option to specify solid block background color
off (default) | on

For the block background, you can provide a background image or select a solid color. To select a solid background color, select this parameter. To provide a background image, clear this parameter.

Note Changing the background color using the **Format** tab of the Simulink Toolstrip removes the background image and enables the **Use Background Color** parameter.

Example: on

Color — Block background color
[r g b] vector

To select a solid background color, enable the **Use Background Color** parameter. Then, choose a background color from the palette of standard colors, or specify a custom color.

Tip You can also specify the **Background Color** in the **Format** tab of the Simulink Toolstrip.

To specify the color of the block text, use the **Font Color** parameter.

Programmatic Use

Specify the `BackgroundColor` parameter for the block as a 1-by-3 [r g b] vector with values between 0 and 1 that is formatted as a string or a character vector.

Block Parameter: `BackgroundColor`

Type: character vector | string

Values: [r g b] vector

Opacity — Block background opacity
1 (default) | scalar

Specify the block background opacity as a scalar value from 0 to 1.

Example: 0.5

Corner Radius — Corner radius of area with block background color
scalar

Specify the corner radius of the area covered by the block background color as a ratio of half of the smaller of the two block dimensions, width or height.

Example: 0.25

Foreground Image

Image X Offset — Horizontal offset of left edge of image from left edge of block
scalar

Specify the horizontal offset of the left edge of the image from the left edge of the block as a ratio of the block width. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image left, and an offset with a positive value moves the image right.

Example: 1

Image Y Offset — Vertical offset of top edge of image from top edge of block
scalar

Specify the vertical offset of the top edge of the image from the top edge of the block as a ratio of the block height. Relative to the position of the image when the offset is 0, an offset with a negative value moves the image up, and a positive value moves the image down.

Example: 1

Width — Image width
scalar

Specify the image width as a ratio of the block width.

Example: 0.5

Height — Image height
scalar

Specify the image height as a ratio of the block height.

Example: 0.5

Lock Aspect Ratio — Option to maintain image aspect ratio
on (default) | off

Enable this option to maintain the aspect ratio when resizing the image using the Property Inspector.

Block Characteristics

Data Types	double half integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced in R2021a

R2023a: Persistent Panels tab in Simulink Toolstrip

When you add a dashboard panel to a model, the **Panels** tab appears in the Simulink Toolstrip and shows options for managing and editing panels.

Previously, the **Panels** tab was only visible when a panel was selected. Starting in R2023a, the **Panels** tab stays visible when no panel is selected.

The **Panels** tab also contains these new options:

- You can add an empty panel.
- You can rename the selected panel.
- You can hide the selected panel.

R2022b: Undo and redo support for customizable dashboard blocks in panel

Starting in R2022b, you can undo and redo the changes you make to customizable dashboard blocks that are in a panel.

To undo or redo a change:

- 1 Click the panel or a block in the panel.
- 2 Press **Ctrl+Z** to undo the change, or press **Ctrl+Y** to redo the change.

Note The keyboard shortcuts are based on Windows. On a Mac, press **command** (⌘) instead of **Ctrl**.

R2022b: Toolstrip support for panels

Starting in R2022b, you can use the Simulink Toolstrip to manage and edit panels and the dashboard blocks that they contain.

When you click a dashboard block in a panel, the toolstrip tab for the block appears. For example, when you click a Circular Gauge block, the **Gauge** tab appears in the toolstrip.

When you click a panel, the **Panel** tab appears in the toolstrip. The tab provides these options:

- Manage the visibility of panels in the model.
- Fit all unhidden panels within the current view.
- Collapse the selected panel.
- Customize the size and the contents of the panel.
- Set a custom background image for the selected panel.
- Add a new tab to the selected panel.

For more information, see “Toolstrip support for panels”.

R2022b: Extended support for customizable Dashboard blocks on Raspberry Pi boards

Starting in R2022b, the Simulink Support Package for Raspberry Pi Hardware supports deploying these blocks from the **Customizable Blocks** library on your Raspberry Pi boards:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on a web browser you launch from a Raspberry Pi terminal.

R2022b: Extended support for customizable Dashboard blocks on Android devices

Starting in R2022b, the Simulink Support Package for Android Devices supports deploying these blocks from the **Customizable Blocks** library on your Android devices:

- Horizontal Gauge
- Horizontal Slider
- Lamp
- Push Button
- Rocker Switch
- Rotary Switch
- Slider Switch
- Toggle Switch
- Vertical Gauge
- Vertical Slider

You can customize the visual aspects of the blocks in a Simulink model and obtain the what you see is what you get (WYSIWYG) visualization on your Android device as well as on your web browser.

R2022a: Change scale direction

Starting in R2022a, you can change the direction of the scale of these blocks from the **Customizable Blocks** library:

- Circular Gauge

- Horizontal Gauge
- Horizontal Slider
- Knob
- Vertical Gauge
- Vertical Slider

R2022a: Specify origin for value bar and needle

The origin of a scale is the value on the scale from which the needle moves and the value bar grows. Starting in R2022a, you can specify an origin for the scales of these blocks from the **Customizable Blocks** library:

- Circular Gauge
- Horizontal Gauge
- Horizontal Slider
- Knob
- Vertical Gauge
- Vertical Slider

R2022a: Resize and reposition foreground image

The blocks in the Customizable Blocks library have an option to add a foreground image as part of the design for a block. Starting in R2022a, you can rotate, resize, and reposition the foreground image within the block design.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Dashboard blocks are ignored for code generation.

“Getting Started with Panels”

Waveform Generator

Output waveforms using signal notations

Libraries:
Simulink / Sources

Description

The Waveform Generator block outputs waveforms based on signal notations that you enter in the **Waveform Definition** table.

This block supports these syntaxes for the signal notations:

- Function syntax — Specify all arguments in the specific order for the signal syntax (see “Algorithms” on page 1-2485).
- Name-value syntax — Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`. For more information, see “Algorithms” on page 1-2485.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Supported Operators

Operation	Operator
Absolute value	<code>abs()</code>
Addition	<code>+</code>
Division	<code>/</code>
Multiplication	<code>*</code>
Parentheses	<code>()</code>
Subtraction	<code>-</code>
Unary minus	<code>-</code>

The Waveform block observes the following rules of operator precedence:

- 1 ()
- 2 + - (unary)
- 3 * /
- 4 + -

Supported Operations

The Waveform Generator block outputs one signal at a time. You can change this output signal. Express frequency and phase offset parameters in radians. You can also:

- Nest signal notations, for example:

```
sin('Amplitude',sin('Amplitude',1,'Frequency',1,'Phase',0),'Frequency',1,'Phase',1)
```

- Reference real scalar variables in the base or model workspace, for example:

```
sin('Amplitude',x,'Frequency',y,'Phase',z)
```

x , y , and z exist in the base workspace.

For more information on waveforms, see the Algorithms section.

To quickly determine the response of a system to different types of inputs, you can vary the output signal of the Waveform Generator block while a simulation is in progress.

Limitations

- You cannot tune the parameters of a waveform, such as frequency or amplitude, during execution of the code that you generate by using Simulink Coder. Instead, you can generate code that enables you to switch between waveform variants that you specify. For more information, see “Switch Between Output Waveforms During Code Execution for Waveform Generator Block” (Simulink Coder).

Ports

Output

Port_1 — Generated output signal
scalar | vector

Output signal specified by an entry in the **Waveform Definition** table.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

Parameters

Main

Output Signal — Waveform for output signal

1 (default) | integer

Select waveform definition to specify the output signal. The number corresponds to the line item in the **Waveform Definition** table. You can change this parameter while a simulation is running.

Programmatic Use

Block Parameter: SelectedSignal

Type: character vector

Values: scalar

Default: '1'

Waveform Definition — Waveform signal notations

constant | gaussian(mean, variance, seed) | pulse(amplitude, trigger_time, duration) | sawtooth(amplitude, frequency, phase_offset) | sin(amplitude, frequency, phase_offset) | square(amplitude, frequency, phase_offset) | step(step_time, initial_value, final_value)

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. For syntax details, see Algorithms.

Signal Attributes

The **Data Type Assistant** helps you set data attributes. To use the **Data Type Assistant**, click **Show**

data type assistant . For more information, see “Specify Data Types Using Data Type Assistant”.

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMin

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output maximum — Maximum output value for range checking

[] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: OutMax

Type: character vector

Values: ' [] ' | scalar

Default: ' [] '

Output data type — Specify the output data type

double (default) | Inherit: Inherit via back propagation | single | int8 | int32 | uint32 | int64 | uint64 | fixdt(1,16,2^0,0) | <data type expression> | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as Simulink.NumericType.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: , 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', int16, 'uint16', 'int32', 'uint32', 'int64', 'uint64', fixdt(1,16,0), fixdt(1,16,2^0,0), fixdt(1,16,2^0,0). '<data type expression>'

Default: 'Double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: LockScale

Values: 'off' | 'on'

Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB ceil function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer convergent function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

See Also

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (off).	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Sample time — Time interval between samples

0.1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: SampleTime

Type: character vector

Values: scalar

Default: '0.1'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. To add a waveform definition, click **Add**. The new waveform appears as an empty character vector. The block interprets empty character vectors or white space character vectors as ground.

To remove a waveform definition, click **Remove**. You can select multiple waveforms using **Ctrl+click** or **Shift+click**.

Constant

Constant values can be:

- Numbers
- Workspace variables
 - Scalar, real variables only
- Built-in MATLAB constant, `pi`

Examples

- `1`
- `1.1`
- `x`
- `pi`

Gaussian Noise

Syntax

```
gaussian(mean,variance,seed)
```

```
gaussian('Mean',mean,'Variance',variance,'Seed',seed)
```

Input Arguments

- `mean` — Mean value of the random variable output.
 - Default: 0
- `variance` — Standard deviation squared of the random variable output.
 - Default: 1
 - Value: Positive constant or positive real scalar variable
- `seed` — Initial seed value for the random number generator.
 - Default: 0
 - Value: Constant or real scalar variable

Example

```
gaussian('Mean',0,'Variance',10,'Seed',1)
```

Pulse

Syntax

```
pulse(amplitude,trigger_time,duration)
```

```
pulse('Amplitude',amplitude,'TriggerTime',trigger_time,'Duration',duration)
```

Input Arguments

- **amplitude** — Value of signal when pulse is high.
 - Default: 1
- **trigger_time** — Elapsed simulation time when signal changes to amplitude, in seconds.
 - Default: 1
 - Value: Constant or real scalar variable
- **duration** — How long the signal remains at the given amplitude before returning to ground, in seconds.
 - Default: 1
 - Value: Positive constant or positive real scalar variable

Example

```
pulse('Amplitude',1,'TriggerTime',1,'Duration',1)
```

Sawtooth

Syntax

```
sawtooth(amplitude,frequency,phase_offset)
```

```
sawtooth('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)
```

Input Arguments

- `amplitude` — Sawtooth peak value.
 - Default: 1
- `frequency` — Waveform frequency, in rad/s.
 - Default: 1
- `phase_offset` — Horizontal signal shift, based on elapsed simulation time, in seconds.
 - Default: 0

Example

```
sawtooth('Amplitude',1,'Frequency',1,'Phase',0)
```

Sine Wave

Syntax

```
sin(amplitude,frequency,phase_offset)
```

```
sin('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)
```

Input Arguments

- `amplitude` — Amplitude of sine wave.
 - Default: 1
- `frequency` — Waveform frequency, in rad/s.
 - Default: 1
- `phase_offset` — Phase offset, in rads.
 - Default: 0

Examples

```
sin('Amplitude',1,'Frequency',1,'Phase',0)
```

To get the cosine waveform:

```
sin('Amplitude',1,'Frequency',1,'Phase',pi/2)
```

Square

Syntax

```
square(amplitude,frequency,phase_delay,duty_cycle)
```

```
square('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_delay,...  
'DutyCycle',duty_cycle)
```

Input Arguments

- `amplitude` — Amplitude of signal.
 - Default: 1
- `frequency` — Waveform frequency in rad/s.

- Default: 1
- `phase_delay` — Horizontal signal shift based on elapsed simulation time, in seconds.
 - Default: 0
- `duty_cycle` — Percentage of high signal per period (0-100%). The block clips the minimum signal to 0% and the maximum signal to 100%.
 - Default: 50

Example

```
square('Amplitude',1,'Frequency',1,'Phase',0,'DutyCycle',50)
```

**Step****Syntax**

```
step(step_time,initial_value,final_value)
```

```
step('StepTime',step_time,'InitialValue',initial_value,'FinalValue',final_value)
```

Input Arguments

- `step_time` — Elapsed simulation time when signal changes from `initial_value` to `final_value`, in seconds.
 - Default: 1
 - Value: Constant or positive real scalar variable.
- `initial_value` — Value of signal when elapsed simulation time is less than `step_time`, in seconds.
 - Default: 0
- `final_value` — Value of signal when elapsed simulation time is greater than or equal to `step_time`, in seconds.
 - Default: 1

Example

```
step('StepTime',1,'InitialValue',0,'FinalValue',1)
```

Waveform Generator Block

Weighted Sample Time

Support calculations involving sample time

Libraries:
Simulink / Signal Attributes

Description

The Weighted Sample Time block outputs one of these values, depending on settings of the **Operation** and **Weight value** parameters and the execution context of the function that contains the block:

- Weighted sample time -- When used in a periodic function, the weighted sample time is the sample time of an input signal (T_s times a weight value w , or $T_s * w$). When used in an aperiodic or triggered function, the weighted sample time is the elapsed time since the last execution times the specified weight value.
- Weighted sample rate -- When used in a periodic function, the weighted sample rate is the reciprocal of the weighted sample time or $1 / (T_s * w)$. The weighted sample rate is not relevant when the block is used in an aperiodic function.
- Mathematically adjusted weighted sample time--- The block adds the value of an input signal u to, subtracts u from, or multiplies or divides u by a weighted sample time.

You specify the block operation by using the **Operation** parameter.

The sample time used to derive the output depends on whether the block is used within a periodic or aperiodic (or triggered) execution context. For a periodic execution context, the block uses the sample time of the model. For an aperiodic or triggered execution context, the block uses the sample time of the discrete signal.

Use the **Weight value** parameter to specify the sample time weight factor. If the weight value, w , is 1, that value does not appear in the equation on the block icon.

Tip You can use the Weighted Sample Time and Weighted Sample Time Math blocks to extract the sample time from a Simulink signal. Set the **Operation** parameter to **Ts Only** and the **Weight value** parameter to **1.0**. With this configuration, the block outputs the sample time of the input signal.

The block computes its output by using the precedence rules for MATLAB operators. For example, if the **Operation** parameter is set to **+**, the block calculates the output by using this expression:

$$u + (T_s * w)$$

If the **Operation** parameter is set to **/**, the block calculates the output by using this expression:

$$(u / T_s) / w$$

For more information, see “Operator Precedence”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Specify input signal as a scalar, vector, or matrix.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal
scalar | vector | matrix

Depending on settings of the **Operation** and **Weight value** parameters and the execution context of the function that contains the block, the block outputs a weighted sample time, weighted sample rate, or mathematically adjusted weighted sample time.

- Weighted sample time -- When used in a periodic function, the weighted sample time is the sample time of an input signal (T_s times the value specified for the **Weight value** parameter w), or $T_s * w$. When used in an aperiodic or triggered function, the weighted sample time is the elapsed time since the last execution times the weight value.
- Weighted sample rate -- When used in a periodic function, the weighted sample rate is the reciprocal of the weighted sample time $1/(T_s * w)$. The weighted sample rate is not relevant when the block is used in an aperiodic function.
- Mathematically adjusted weighted sample time -- The block adds the value of an input signal u to, subtracts u from, or multiplies or divides u by a weighted sample time.

The sample time used to derive the output and the data type of the output depend on whether the block is used within a periodic or aperiodic (or triggered) execution context.

Execution Context of Block	Sample Time Used to Derive Output	Data Type of Output Signal
Periodic	Sample time of the model	<ul style="list-style-type: none"> • Sign is the same sign as the value of the input signal. • Word length is the larger value of the input signal word length or half of a long long. • Scaling is best precision scaling of the weighted sample time.
Aperiodic or triggered	Elapsed time since the last execution	<ul style="list-style-type: none"> • Data type is unsigned. • Word length is large enough to account for the setting of model configuration parameter Application lifespan. • Scaling is best precision scaling of the setting of model configuration parameter Clock resolution.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean
| fixed point

Parameters

Main

Operation — Math operation

Ts Only (default) | + | - | * | / | 1/Ts Only

Specify the operation to use for adjusting the value of the input signal. For example, if you specify the + operation, the block adds the weighted sample time to the value of the input signal. The value 1/Ts Only is not relevant when you use the block in an aperiodic function.

Programmatic Use

Block Parameter: TsamMathOp

Type: character vector

Values: '+' | '-' | '*' | '/' | 'Ts Only' | '1/Ts Only'

Default: 'Ts Only'

Weight value — Weight for sample time

1.0 (default) | real-valued scalar

Enter the weight for the sample time as a real-valued scalar. The block multiplies the sample time of the input signal by the value that you specify. For example, if you use the block in a periodic function of a model that has a sample time of 0.2 and you specify a weight value of 3, the weighted sample time is 0.6.

Programmatic Use

Block Parameter: weightValue

Type: character vector

Values: real-valued scalar

Default: 1.0

Implement using — Method for adjusting sample time

Online Calculations (default) | Offline Scaling Adjustment

Select whether to adjust the sample time by applying online calculations or by applying offline scaling.

Result of $T_s * w$	Output Data Type of Two Modes	Block Execution
A power of 2, or an integer value	The same when Output data type is set to Inherit: Inherit via internal rule	Equally efficient in both modes
Not a power of 2 and not an integer value	Different	More efficient for the offline scaling mode

Note When the **Implement using** parameter is not enabled, operations default to online calculations.

Dependencies

To enable this parameter, set **Operation** to * or /.

Programmatic Use

Block Parameter: TsampMathImp

Type: character vector

Values: 'Online Calculations' | 'Offline Scaling Adjustment'

Default: 'Online Calculations'

Signal Attributes

Output data type — Data type of output signal

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | <data type expression>

Specify the data type for the block output signal.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters round to the nearest representable value. To control the rounding of a block parameter, enter an expression by using a MATLAB rounding function in the mask field.

Dependencies

To enable this parameter, set the **Operation** parameter to +, -, *, or /. If you set the **Operation** to * or /, you must also set the **Implement using** parameter to Online Calculations.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether integer overflows saturate or wrap.

Goal	Action	Overflow Behavior	Example
Model has possible overflow conditions and you want explicit saturation protection in the generated code.	Select check box (on).	Saturate to the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. A block operation result greater than this maximum value causes overflow of the 8-bit integer. When you select this parameter, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
You want to optimize generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Clear check box (off).	Wrap overflows to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. A block operation result greater than this maximum value causes overflow of the 8-bit integer. When you clear this parameter, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select **Saturate on integer overflow**, saturation applies to every internal operation on the block, not just the output, or result. When the code generator detects that overflow is not possible, it does not produce saturation code.

Dependencies

To enable this parameter, set the **Operation** parameter to +, -, *, or /. If you set **Operation** to * or /, you must also set the **Implement using** parameter to Online Calculations.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes

Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Weighted Sample Time Math

Support calculations involving sample time

Libraries:
Simulink / Math Operations

Description

The Weighted Sample Time Math block outputs one of these values, depending on the operation that you specify and the execution context of the function that contains the block:

- **Weighted sample time** --- When used in a periodic function, the weighted sample time is the sample time of an input signal (T_s times a weight value, or $T_s * w$). When used in an aperiodic or triggered function, the weighted sample time is the elapsed time since the last execution times a weight value.
- **Weighted sample rate** --- When used in a periodic function, the weighted sample rate is the value 1 divided by the weighted sample time or $1/(T_s * w)$. Weighted sample rate is not relevant when the block is used in an aperiodic function.
- **Mathematically adjusted weighted sample time** --- The block adds the value of an input signal u to, subtracts u from, or multiplies or divides u by a weighted sample time.

You specify the block operation by using the **Operation** parameter.

The sample time used to derive the output depends on whether the block is used within a periodic or aperiodic (or triggered) execution context. For a periodic execution context, the block uses the sample time of the model. For an aperiodic or triggered execution context, the block uses the sample time of the discrete signal.

Use the **Weight value** parameter to specify the sample time weight factor. If the weight value, w , is 1, that value does not appear in the equation on the block icon.

Tip You can use the Weighted Sample Time and Weighted Sample Time Math blocks to extract the sample time from a Simulink signal. Set the **Operation** parameter to **T_s Only** and the **Weight value** parameter to **1.0**. With this configuration, the block outputs the sample time of the input signal.

The block computes its output by using the precedence rules for MATLAB operators. For example, if the **Operation** parameter is set to **+**, the block calculates the output by using this expression:

$$u + (T_s * w)$$

If the **Operation** parameter is set to **/**, the block calculates the output by using this expression:

$$(u / T_s) / w$$

For more information, see “Operator Precedence”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Specify input signal as a scalar, vector, or matrix.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal
scalar | vector | matrix

Depending on settings of the **Operation** and **Weight value** parameters and the execution context of the function that contains the block, the block outputs a weighted sample time, weighted sample rate, or mathematically adjusted weighted sample time.

- Weighted sample time -- When used in a periodic function, the weighted sample time is the sample time of an input signal (T_s times the value specified for the **Weight value** parameter w), or $T_s * w$. When used in an aperiodic or triggered function, the weighted sample time is the elapsed time since the last execution times the weight value.
- Weighted sample rate -- When used in a periodic function, the weighted sample rate is the reciprocal of the weighted sample time $1/(T_s * w)$. The weighted sample rate is not relevant when the block is used in an aperiodic function.
- Mathematically adjusted weighted sample time -- The block adds the value of an input signal u to, subtracts u from, or multiplies or divides u by a weighted sample time.

The sample time used to derive the output and the data type of the output depend on whether the block is used within a periodic or aperiodic (or triggered) execution context.

Execution Context of Block	Sample Time Used to Derive Output	Data Type of Output Signal
Periodic	Sample time of the model	<ul style="list-style-type: none"> • Sign is the same sign as the value of the input signal. • Word length is the larger value of the input signal word length or half of a long long. • Scaling is best precision scaling of the weighted sample time.
Aperiodic or triggered	Elapsed time since the last execution	<ul style="list-style-type: none"> • Data type is unsigned. • Word length is large enough to account for the setting of model configuration parameter Application lifespan. • Scaling is best precision scaling of the setting of model configuration parameter Clock resolution.

Data Types: double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean
| fixed point

Parameters

Main

Operation — Math operation

+ (default) | - | * | / | Ts Only | 1/Ts Only

Specify the operation to use for adjusting the input signal. For example, if you specify the + operation, the block adds the weighted sample time to the value of the input signal. The value 1/Ts Only is not relevant when you use the block in an aperiodic function.

Programmatic Use

Block Parameter: TsamMathOp

Type: character vector

Values: '+' | '-' | '*' | '/' | 'Ts Only' | '1/Ts Only'

Default: '+'

Weight value — Weight for sample time

1.0 (default) | real-valued scalar

Enter the weight for the sample time as a real-valued scalar. The block multiplies the sample time of the input signal by the value that you specify. For example, if you use the block in a periodic function of a model that has a sample time of 0.2 and you specify a weight value of 3, the weighted sample time is 0.6.

Programmatic Use

Block Parameter: weightValue

Type: character vector

Values: real-valued scalar

Default: 1.0

Implement using — Method for adjusting sample time

Online Calculations (default) | Offline Scaling Adjustment

Select whether to adjust the sample time by applying online calculations or by applying offline scaling.

Result of $T_s * w$	Output Data Type of Two Modes	Block Execution
A power of 2, or an integer value	The same when Output data type is set to Inherit: Inherit via internal rule	Equally efficient in both modes
Not a power of 2 and not an integer value	Different	More efficient for the offline scaling mode

Note When the **Implement using** parameter is not enabled, operations default to online calculations.

Dependencies

To enable this parameter, set **Operation** to * or /.

Programmatic Use

Block Parameter: TsampMathImp

Type: character vector

Values: 'Online Calculations' | 'Offline Scaling Adjustment'

Default: 'Online Calculations'

Signal Attributes

Output data type — Data type of output signal

Inherit: Inherit via internal rule (default) | Inherit: Inherit via back propagation | <data type expression>

Specify the data type for the block output signal.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | '<data type expression>'

Default: 'Inherit: Inherit via internal rule'

Integer rounding mode — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters round to the nearest representable value. To control the rounding of a block parameter, enter an expression by using a MATLAB rounding function in the mask field.

Dependencies

To enable this parameter, set the **Operation** parameter to +, -, *, or /. If you set the **Operation** to * or /, you must also set the **Implement using** parameter to Online Calculations.

Programmatic Use

Block Parameter: RndMeth

Type: character vector

Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether integer overflows saturate or wrap.

Goal	Action	Overflow Behavior	Example
Model has possible overflow conditions and you want explicit saturation protection in the generated code.	Select check box (on).	Saturate to the minimum or maximum value that the data type can represent.	The maximum value that the int8 (signed, 8-bit integer) data type can represent is 127. A block operation result greater than this maximum value causes overflow of the 8-bit integer. When you select this parameter, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
You want to optimize generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Troubleshoot Signal Range Errors”.	Clear check box (off).	Wrap overflows to the appropriate value that is representable by the data type.	The maximum value that the int8 (signed, 8-bit integer) data type can represent is 127. A block operation result greater than this maximum value causes overflow of the 8-bit integer. When you clear this parameter, the software interprets the overflow-causing value as int8, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as int8, is -126.

When you select **Saturate on integer overflow**, saturation applies to every internal operation on the block, not just the output, or result. When the code generator detects that overflow is not possible, it does not produce saturation code.

Dependencies

To enable this parameter, set the **Operation** parameter to +, -, *, or /. If you set **Operation** to * or /, you must also set the **Implement using** parameter to Online Calculations.

Programmatic Use

Block Parameter: SaturateOnIntegerOverflow

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Block Characteristics

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes

While Iterator

Control block for while-iterator subsystem

Description

The While Iterator block, when placed in a Subsystem block, repeatedly executes the contents of the subsystem during the current time step while the value of the input condition is true or 1. Use this block to implement the block diagram equivalent of a `while` loop in a programming language.

The While Iterator Subsystem block is preconfigured with a While Iterator block. Placing a While Iterator block in a Subsystem block makes it an atomic subsystem.

Ports

Input

cond — Logical condition signal
scalar

Signal with the result from evaluating a logical condition. Because the subsystem is not externally triggered during a time step, evaluating a condition as true (1) or false (0) must reside within the subsystem.

The data type and values of the signal can be:

- Logical (Boolean) — true (1) or false (0) .
- Numerical — true (any positive or negative number) or false (0).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

IC — Initial logical condition
scalar

Signal with the initial logical condition. At the beginning of each time step:

- If IC is false (0), the subsystem does not execute during the time step.
- If IC is true (value not equal to 0), the subsystem starts executing and continues to repeat execution as long as the `cond` signal is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output Arguments

Iteration number — Signal with the number of iterations
scalar

Signal with the number of While Iterator Subsystem block executions during each time step.

Data Types: `double` | `int8` | `int16` | `int32`

Parameters

Maximum number of iterations — Specify maximum number of iterations

-1 (default) | integer

Specify maximum number of iterations allowed during a time step.

-1

Any number of iterations as long as the cond signal is true (value not equal to 0) . If you specify -1 and the cond signal never becomes false (0), the simulation runs in an infinite loop. In this case, the only way to stop the simulation is to terminate MATLAB.

integer

Maximum number of iterations during a time step.

Programmatic Use

Block Parameter: MaxIters

Type: character vector

Values: '5' | '-1' | '<integer>'

Default: '5'

While loop type — Select type of block

while (default) | do-while

Select type of block.

while

The While Iterator block has two inputs, a cond (logical condition) input and an IC (initial logical condition) input. The source of the IC signal must be external to the While Iterator Subsystem block.

At the beginning of each time step:

- If the IC input is true (value not equal to 0), the blocks in the subsystem repeat execution while the cond input is true. This process continues during a time step as long as the cond input is true and the number of iterations is less than or equal to the **Maximum number of iterations**.
- If the IC input is false, the While Iterator block does not execute the contents of the subsystem.

do-while

The While Iterator block has one input, the cond (while condition) input.

At each time step, the blocks in the subsystem repeat execution while the cond input is true (value not equal to 0). This process continues as long as the cond input is true and the number of iterations is less than or equal to the **Maximum number of iterations**.

Programmatic Use

Block Parameter: WhileBlockType

Type: character vector

Values: 'while' | 'do-while'

Default: 'while'

States when starting — Select block states between time steps

held (default) | reset

Select how to handle block states between time steps.

held

Hold block states between time steps. Block state values persist across time steps.

reset

Reset block states to their initial values at the beginning of each time step and before the first iteration loop.

Programmatic Use

Block Parameter: ResetStates

Type: character vector

Values: 'held' | 'reset'

Default: 'held'

Show iteration number port — Control display of output port

clear | select

Control display of output port for signal with number of block executions. The value of the signal from this port starts at 1 and is incremented by 1 for each succeeding iteration.

off

Remove output port.

on

Display output port for signal with iteration number.

Dependencies

Selecting this parameter enables the **Output data type** parameter.

Programmatic Use

Block Parameter: ShowIterationPort

Type: character vector

Values: 'off' | 'on'

Default: 'off'

Output data type — Select output data type for current iteration number

int32 (default) | uint32 | int16 | uint16 | int8 | uint8 | double

Select output data type for iteration number signal. The value of this signal is the number of iterations during a time step and the total number of iterations at the end of a time step.

int32

Signed 32-bit integer.

uint32

Unsigned 32-bit integer.

int16

Signed 16-bit integer.

uint16

unsigned 16-bit integer.

int8

Signed 8-bit integer.

uint8

Unsigned 8-bit integer.

double

Double-precision floating point.

Dependencies

Select the **Show iteration number port** check box to enable this parameter.

Programmatic Use

Block Parameter: OutputDataType

Type: character vector

Value: 'int32' | 'unt32' | 'int16' | 'uint16' | 'int8' | 'uint8' | 'double'

Default: 'int32'

Version History

Introduced before R2006a

Iterator Subsystem Execution

While Iterator Subsystem

Repeat subsystem execution during simulation time step while logical expression is true

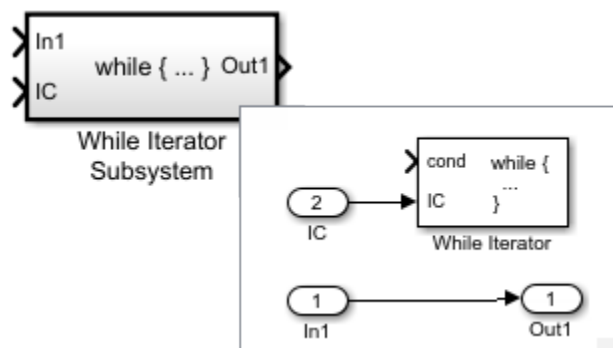

Libraries:

Simulink / Ports & Subsystems

Description

The While Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step while a logical condition is true. Execution is controlled by a While Iterator block inside the subsystem. For an example, see `ex_while_iterator_block`.

Use While Iterator Subsystem blocks to model:

- Block diagram equivalent of a program while or do-while loop.
- An iterative algorithm that converges on a more accurate solution after multiple iterations.

When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a While Iterator Subsystem block, Simulink displays an error.

If the output signal from a While Iterator Subsystem block is a function-call signal, Simulink displays an error when you simulate the model or update the diagram.

Ports

Input

In1 — Signal input to a subsystem block
scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

IC (initial logical condition) — Control initial execution of a subsystem block
scalar

Placing a While Iterator block connected to an Input block in a Subsystem block adds this external input port to the block.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Out — Signal output from a subsystem
scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	Boolean ^a bus ^a double ^a enumerated ^a fixed point ^a half ^a integer ^a single ^a string ^a
Direct Feedthrough	no
Multidimensional Signals	yes ^a
Variable-Size Signals	yes ^a
Zero-Crossing Detection	no

^a Actual data type or capability support depends on block implementation.

Width

Output width of input vector

Libraries:
Simulink / Signal Attributes

Description

The Width block generates as output the width of its input vector.

You can use an array of buses as an input signal to a Width block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix | N-D array

Input signal specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | string | Boolean | fixed point | enumerated | bus

Output

Port_1 — Width of input signal
scalar

Output is the width of the input signal, specified as a scalar.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Output data type mode — Output data type mode

Choose intrinsic data type (default) | Inherit via back propagation | All ports same datatype

Specify the output data type to be the same as the input, or inherit the data type by back propagation. You can also choose to specify a built-in data type from the drop-down list in the **Output data type** parameter.

Programmatic Use**Block Parameter:** OutputDataTypeScalingMode**Type:** character vector**Values:** 'Choose intrinsic data type' | 'Inherit via back propagation' | 'All ports same datatype'**Default:** 'Choose intrinsic data type'**Output data type** — Output data type

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32

This parameter is visible when you select **Choose intrinsic data type** for **Output data type mode**. Select a built-in data type from the drop-down list.

Programmatic Use**Block Parameter:** DataType**Type:** character vector**Values:** 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32'**Default:** 'double'**Block Characteristics**

Wrap To Zero

Set output to zero if input is above threshold

Libraries:

Simulink / Discontinuities

HDL Coder / Discontinuities

Description

The Wrap To Zero block sets the output to zero when the input is above the **Threshold** value. When the input is less than or equal to the **Threshold**, then the output is equal to the input.

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal, specified as a scalar or vector. Signal values equal to or greater than the value of **Threshold** are set to zero.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Output signal

scalar | vector

Output signal set to the input signal value or zero. The data type of the output is the same data type as the input.

Tip If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to warning or error.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

To edit the parameters for the Wrap to Zero block, double-click the block icon.

Threshold — Threshold for outputting zero

255 (default) | scalar

Threshold value for setting the output value to zero.

Programmatic Use**Block Parameter:** Threshold**Type:** character vector**Values:** scalar**Default:** '255'**Block Characteristics**

Data Types	Boolean double fixed point integer single
Direct Feedthrough	yes
Multidimensional Signals	yes
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has one default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).

OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
-----------------------	--

Restrictions

The input signal and **Threshold** parameter must have equal size. For example, if the input is a two-dimensional vector, **Threshold** must also be a two-dimensional vector.

Saturation | Saturation Dynamic

Zero-Order Hold

Implement zero-order hold sample period

Libraries:

Simulink / Discrete
HDL Coder / Discrete

Description

The Zero-Order Hold block holds its input for the sample period you specify. If the input is a vector, the block holds all elements of the vector for the same sample period.

You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

Tip Do not use the Zero-Order Hold block to create a fast-to-slow transition between blocks operating at different sample rates. Instead, use the Rate Transition block.

Bus Support

The Zero-Order Hold block is a bus-capable block. The input can be a virtual or nonvirtual bus signal. No block-specific restrictions exist. All signals in a nonvirtual bus input to a Zero-Order Hold block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Modify Sample Times for Nonvirtual Buses” and “Bus-Capable Blocks” for more information.

You can use an array of buses as an input signal to a Zero-Order Hold block. For details about defining and using an array of buses, see “Group Nonvirtual Buses in Arrays of Buses”.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> “Engine Timing Model with Closed Loop Control” on page 13-152 (Compression subsystem)

Block	Purpose of the Block	Reference Examples
Memory on page 1-1350	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> “Building a Clutch Lock-Up Model” on page 13-156 (Friction Mode Logic/Lockup FSM subsystem) “Capture the Velocity of a Bouncing Ball with the Memory Block” on page 12-89
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> “Developing the Apollo Lunar Module Digital Autopilot” on page 13-215 “Radar Tracking Using MATLAB Function Block” on page 13-244

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

Ports

Input

Port_1 — Input signal

scalar | vector

Input signal that the block holds by one sample period.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal that is the input held by one sample period.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Parameters

Sample time (-1 for inherited) — Discrete interval between sample time hits

-1 (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the online documentation for more information.

Do not specify a continuous sample time, either 0 or [0, 0]. This block supports only discrete sample times. When this parameter is -1, the inherited sample time must be discrete and not continuous.

Block Characteristics

Data Types	Boolean bus double enumerated fixed point integer single

Memory | Unit Delay

Zero-Pole

Model system by zero-pole-gain transfer function

Libraries:
Simulink / Continuous

Description

The Zero-Pole block models a system that you define with the zeros, poles, and gain of a Laplace-domain transfer function. This block can model single-input single-output (SISO) and single-input multiple-output (SIMO) systems.

Conditions for Using This Block

The Zero-Pole block assumes the following conditions:

- The transfer function has the form

$$H(s) = K \frac{Z(s)}{P(s)} = K \frac{(s - Z(1))(s - Z(2)) \dots (s - Z(m))}{(s - P(1))(s - P(2)) \dots (s - P(n))},$$

where Z represents the zeros, P the poles, and K the gain of the transfer function.

- The number of poles must be greater than or equal to the number of zeros.
- If the poles and zeros are complex, they must be complex-conjugate pairs.
- For a multiple-output system, all transfer functions must have the same poles. The zeros can differ in value, but the number of zeros for each transfer function must be the same.

Note You cannot use a Zero-Pole block to model a multiple-output system when the transfer functions have a differing number of zeros or a single zero each. Use multiple Zero-Pole blocks to model such systems.

Modeling a Single-Output System

For a single-output system, the input and the output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the zeros of the transfer function in the **Zeros** field.
- 2 Enter a vector for the poles of the transfer function in the **Poles** field.
- 3 Enter a 1-by-1 vector for the gain of the transfer function in the **Gain** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix of zeros in the **Zeros** field.

Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

- 2 Enter a vector for the poles common to all transfer functions of the system in the **Poles** field.
- 3 Enter a vector of gains in the **Gain** field.

Each element is the gain of the corresponding transfer function in **Zeros**.

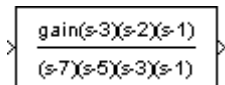

Each element of the output vector corresponds to a column in **Zeros**.

Transfer Function Display on the Block

The Zero-Pole block displays the transfer function depending on how you specify the zero, pole, and gain parameters.

- If you specify each parameter as an expression or a vector, the block shows the transfer function with the specified zeros, poles, and gain. If you specify a variable in parentheses, the block evaluates the variable.

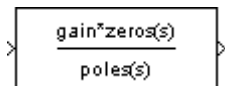

For example, if you specify **Zeros** as [3,2,1], **Poles** as (poles), where poles is [7,5,3,1], and **Gain** as gain, the block looks like this.

$$\frac{\text{gain}(s-3)(s-2)(s-1)}{(s-7)(s-5)(s-3)(s-1)}$$

- If you specify each parameter as a variable, the block shows the variable name followed by (s) if appropriate.

For example, if you specify **Zeros** as zeros, **Poles** as poles, and **Gain** as gain, the block looks like this.

$$\frac{\text{gain}^*\text{zeros}(s)}{\text{poles}(s)}$$

Ports

Input

Port_1 — Input signal

scalar

Input signal, specified as a scalar with data type double.

Data Types: double

Output

Port_1 — Output signal

scalar | vector

System modeled by a zero-pole gain transfer function, provided as a scalar or vector signal with data type double.

- When modeling a single-output system, the block outputs a scalar time-domain signal. For more information, see “Modeling a Single-Output System” on page 1-2520.

- When modeling a multiple-output system, the block outputs a vector, where each element is an output of the system. For more information, see “Modeling a Multiple-Output System” on page 1-2520.

Data Types: double

Parameters

Zeros — Matrix of zeros

[1] (default) | vector | matrix

Define the matrix of zeros.

- For a single-output system, enter a vector for the zeros of the transfer function.
- For a multiple-output system, enter a matrix. Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

Programmatic Use

Block Parameter: Zeros

Type: character vector, string

Value: vector | matrix

Default: '[1]'

Poles — Vector of poles

[0 -1] (default) | vector

Define the vector of poles.

- For a single-output system, enter a vector for the poles of the transfer function.
- For a multiple-output system, enter a vector for the poles common to all transfer functions of the system.

Programmatic Use

Block Parameter: Poles

Type: character vector, string

Value: vector

Default: '[0 -1]'

Gain — Vector of gains

[1] (default) | vector

Define the vector of gains.

- For a single-output system, enter a 1-by-1 vector for the gain of the transfer function.
- For a multiple-output system, enter a vector of gains. Each element is the gain of the corresponding transfer function in **Zeros**.

Programmatic Use

Block Parameter: Gain

Type: character vector, string

Value: vector
Default: '[1]'

Parameter tunability — Tunable representation of block parameters in code

Auto (default) | Optimized | Unconstrained

Tunability level of the zeros, poles, and gains for accelerated simulation modes and simulations deployed using Simulink Compiler. Set this parameter to **Auto** to allow Simulink to choose the appropriate level of parameter tunability.

Set this parameter to **Optimized** to generate an optimized representation zeros, poles, and gain in generated code for accelerated and deployed simulations.

Set this parameter to **Unconstrained** to support full tunability (between simulations) of zeros, poles, and gain parameters in accelerated and deployed simulations.

Programmatic Use

Block Parameter: ParameterTunability

Type: character vector, string

Values: 'Auto' | 'Optimized' | 'Unconstrained'

Default: 'Auto'

Absolute tolerance — Absolute tolerance for computing block states

auto (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify **auto** or **-1**.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.
- If you enter **auto** or **-1**, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use

Block Parameter: AbsoluteTolerance

Type: character vector, string

Values: 'auto' | '-1' | any positive real-valued scalar or vector

Default: 'auto'

State Name (e.g., 'position') — Assign unique name to each state

' ' (default) | 'position' | {'a', 'b', 'c'} | a | ...

Assign a unique name to each state. If this field is blank (' '), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'position'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use

Block Parameter: ContinuousStateAttributes

Type: character vector, string

Values: ' ' | user-defined

Default: ' '

Block Characteristics

Data Types	double
Direct Feedthrough	yes
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Version History

Introduced before R2006a

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

h = add_block(sourceIn,destIn,'CopyOption','duplicate')
h = add_block( ____,Name,Value)
```

Description

`h = add_block(source,dest)` adds a copy of the block `source` from a library or model to the specified destination model and block name. This syntax creates the block at the same location as it appears in the model or the library model.

If you are copying between models or from a library, load the destination model first.

`h = add_block(source,dest,'MakeNameUnique','on')` ensures that the destination block name is unique in the model. This syntax adds a number to the destination block name if a block with that name exists, incrementing to ensure a unique name.

`h = add_block(____, 'CopyOption','nolink')` copies the block or subsystem `source` from a library without creating a link to the library block.

`h = add_block(sourceIn,destIn,'CopyOption','duplicate')` duplicates an input port block in a subsystem, giving the destination block the same port number as the source block. Duplicate an input port block to branch a signal from an input port without creating a port or adding lines. For more information, see “Create Duplicate Inport Blocks” on page 1-921.

`h = add_block(____,Name,Value)` uses optional `Name,Value` arguments.

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

With the `add_block` function, you can use block parameter and value pairs. For a list of all the block parameters, see “Common Block Properties” on page 6-12 and “Block-Specific Parameters” on page 6-24.

Examples

Add Block to Model from a Library

Add the block from the Simulink library to the model `f14`.

Load or open the destination model.

```
open_system('f14');
```

Add the Scope block from the Simulink Sinks library to f14, naming the new block MyScope.

```
add_block('simulink/Sinks/Scope','f14/MyScope');
```

Add a Block from Another Model

Add a copy of a block from the model f14 to vdp.

Load or open the destination model.

```
open_system('vdp');
```

Add the Actuator Model block from f14 to vdp.

```
add_block('f14/Actuator Model','vdp/Actuator Model');
```

Add a Block Using a Unique Name

Add the block from the Simulink library to the model vdp. Because there is already a block named Scope in vdp, use the MakeNameUnique option to ensure that the new block name is unique.

Load or open the destination model.

```
open_system('vdp');
```

Add the Scope block from the Simulink Sinks library to vdp, ensuring that the name is unique.

```
add_block('simulink/Sinks/Scope','vdp/Scope','MakeNameUnique','on')
```

Duplicate an Inport Block in a Subsystem

Add an Inport block in the f14/Controller subsystem that uses the same port number as another Inport block in that subsystem.

Duplicate the Inport block named Stick Input (in) in the Controller subsystem, and name the copy Stick Input (in)2.

```
add_block('f14/Controller/Stick Input (in)',...
'f14/Controller/Stick Input (in)2','CopyOption','duplicate')
```

The resulting block uses the same port number as the block named Stick Input (in) but does not add an input port on the parent subsystem. The signal that enters that port branches to both Inport blocks.

Add a Block and Set Parameters

Add a block from a library to a model and set parameters using a Name, Value pair.

Load or open the destination model.

```
open_system('vdp');
```

Add a Gain block from the library to vdp, and set the Gain value to 5.

```
add_block('simulink/Math Operations/Gain','vdp/Five','Gain','5')
```

Input Arguments

source — Block to copy to model

block path | library block path

Block to copy to model, specified as:

- The full block path if you are copying the block from a model, for example, 'vdp/Mu'. This usage copies the block and its settings.
- The library block path if you want to add a block from a library, for example, 'simulink/Math Operations/Gain'.

To get the library block path, you can pause on the block in the Library Browser. Alternatively, you can open the library model, select the block, and enter `gcb` at the command line. To open the library model, in the Library Browser, right-click the library name in the library list and select **Open *library_name* library**.

You can also use the syntax `'built-in/blocktype'` as the source block path, where *blocktype* is the programmatic block name—the value of the `BlockType` parameter (see “Common Block Properties” on page 6-12). However, blocks added using `'built-in/blocktype'` sometimes have different default parameter values from library blocks.

For subsystems and masked blocks, use the library block path. Using the `BlockType` value (`SubSystem`) creates an empty subsystem.

Example: 'vdp/Mu', 'simulink/Sinks/Scope'

dest — Name and location of new block

block path

Name and location of the new block in the model, specified as the block path.

Example: 'f14/Controller/MyNewBlock'

sourceIn — Input port block to duplicate

block path

Input port block to duplicate, specified as the block path.

Example: 'f14/Controller/Stick Input (in)', 'myModel/mySubsystem/In1'

destIn — Input port block to create

block path

Input port block to create, specified as the block path. Create the destination block in the same system as the source block.

Example: 'myModel/mySubsystem/DupPortIn'

Output Arguments

h — New block

handle

New block, returned as a handle.

Version History

Introduced before R2006a

“Programmatically Create Bus Element Ports” on page 12-10

add_exec_event_listener

Register listener for block method execution event

Syntax

```
h = add_exec_event_listener(blk,event,listener);
```

Description

`h = add_exec_event_listener(blk,event,listener)` registers a listener for a block method execution event where the listener is a MATLAB program that performs some task, such as logging runtime data for a block, when the event occurs (see “Listen for Method Execution Events”). Simulink software invokes the registered listener whenever the specified event occurs during simulation of the model. You cannot register a listener for virtual blocks.

Note Simulink software can register a listener only while a simulation is running. Invoking this function when no simulation is running results in an error message. To ensure that a listener catches all relevant events triggered by a model's simulation, you should register the listener in the model's `StartFcn` callback function (see “Customize Model Behavior with Callbacks”).

Input Arguments

`blk`

Specifies the block whose method execution event the listener is intended to handle. May be one of the following:

- Full pathname of a block
- A block handle
- A block runtime object (see “Access Block Data During Simulation”).)

`event`

Specifies the type of event for which the listener listens. It may be any of the following:

Event	Occurs...
'PreDerivatives'	Before a block's Derivatives method executes
'PostDerivatives'	After a block's Derivatives method executes
'PreOutputs'	Before a block's Outputs method executes.
'PostOutputs'	After a block's Outputs method executes
'PreUpdate'	Before a block's Update method executes
'PostUpdate'	After a block's Update method executes

`listener`

Specifies the listener to be registered. It may be either a character vector specifying a MATLAB expression, e.g., `'disp(''here'')` or a handle to a MATLAB function that accepts two

arguments. The first argument is the block runtime object of the block that triggered the event. The second argument is an instance of `EventData` class that specifies the runtime object and the name of the event that just occurred.

Output Arguments

`add_exec_event_listener` returns a handle to the listener that it registered. To stop listening for an event, use the MATLAB `clear` command to clear the listener handle from the workspace in which the listener was registered.

Version History

Introduced before R2006a

add_line

Add line to Simulink model

Syntax

```
h = add_line(sys,out,in)
h = add_line(sys,out,in,'autorouting',autoOption)
h = add_line(sys,points)
```

Description

`h = add_line(sys,out,in)` adds a line in the model or subsystem `sys` that connects one block's output port `out` to another block's input port `in`. This syntax draws the most direct route from port to port, for example, diagonal lines or lines that go through other blocks.

You can connect ports when:

- The input port does not already have a connection.
- The ports are compatible for connecting.

`h = add_line(sys,out,in,'autorouting',autoOption)` connects blocks, specifying whether to route the lines around other blocks.

`h = add_line(sys,points)` adds a line drawn by (x,y) coordinate `points` relative to the upper-left corner of the Simulink Editor canvas before any canvas resizing. If either end of the line is within five pixels of a corresponding port, the function connects the line to it. The line can have multiple segments.

Examples

Connect Blocks Using Port Numbers

Use the block port numbers to add a line to connect blocks.

Create and open a model.

```
open_system(new_system('connect_model'));
```

Add and position a Constant block and a Gain block.

```
add_block('simulink/Commonly Used Blocks/Constant','connect_model/Constant');
set_param('connect_model/Constant','position',[140,80,180,120]);
add_block('simulink/Commonly Used Blocks/Gain','connect_model/Gain');
set_param('connect_model/Gain','position',[220,80,260,120]);
```

Connect the blocks. Specify port 1.

```
add_line('connect_model','Constant/1','Gain/1');
```

Connect Blocks Using Port Handles

Get the port handles and connect the ports using `add_line`.

Open the model `vdp`.

```
open_system('vdp');
```

Delete the line that connects the Gain block named `Mu` to the Sum block.

```
delete_line('vdp','Mu/1','Sum/2');
```

Get the port handles from the `Mu` block and the Sum block.

```
h = get_param('vdp/Mu','PortHandles');
h1 = get_param('vdp/Sum','PortHandles');
```

Look at the `h1` structure. Notice the two handles for the `Inport` property.

```
h1
```

```
h1 =
```

```
struct with fields:
    Inport: [47.0002 54.0002]
    Output: 39.0002
    Enable: []
    Trigger: []
    State: []
    LConn: []
    RConn: []
    Ifaction: []
    Reset: []
```

Index into the `Outputport` and `Inport` properties on the port handles to get the handles you want and connect them. Connect to the second inport.

```
add_line('vdp',h.Outputport(1),h1.Inport(2));
```

Add a Branched Line

You can branch a line by adding a connection programmatically. You can use the `points` syntax to draw the segment, or you can draw the line by specifying the ports to connect. When using the port, use automatic line routing to improve the look of the branched line.

Add a scope to the `vdp` model above the output.

```
vdp
add_block('simulink/Commonly Used Blocks/Scope','vdp/Scope1');
set_param('vdp/Scope1','position',[470,70,500,110]);
```

Connect the Integrator block `x1` to `Scope1`. This code branches the existing line from the `x1` output and connects it to the scope. With autorouting on, the resulting line is segmented.

```
add_line('vdp', 'x1/1', 'Scope1/1', 'autorouting', 'on')
```

Connect Blocks Using Points

You can use points on the canvas as the start and end of each segment. Get the port locations using `get_param` with the 'PortConnectivity' option.

Open the model `vdp` and delete the line that connects the Mu and Sum blocks.

```
vdp
delete_line('vdp', 'Mu/1', 'Sum/2')
```

Get the port locations for Mu. Mu has two ports. The first is the input port, and the second is the output port.

```
mu = get_param('vdp/Mu', 'PortConnectivity');
mu.Position
```

```
ans =
    190    150
```

```
ans =
    225    150
```

Get the port locations for Sum, which has three ports. The second position is the lower input port.

```
s = get_param('vdp/Sum', 'PortConnectivity');
s.Position
```

```
ans =
    250    135
```

```
ans =
    250    150
```

```
ans =
    285    145
```

Connect the ports using the output and input points.

```
add_line('vdp', [225 150; 250 150])
```

Connect Blocks Using Autorouting Options

Add lines with and without autorouting options.

Create a model route. Display default block names.

```
open_system(new_system('route'));
set_param('route','HideAutomaticNames','off')
```

Add two Subsystem blocks and a Gain block. Add an inport and outport to each Subsystem block.

Add lines to connect the outports of the Subsystem1 block to the inports of the Subsystem block.

```
add_line('route',{'Subsystem/1','Subsystem/2'},...
        {'Subsystem1/1','Subsystem1/2'})
```

Because you did not use the autorouting options, the function draws straight lines that cross over the Gain block.

Delete the lines. Add lines again, this time with the autorouting option set to 'on'.

```
add_line('route',{'Subsystem/1','Subsystem/2'},...
        {'Subsystem1/1','Subsystem1/2'},'autorouting','on')
```

The lines route around the Gain block.

Delete the lines. Add lines again, using the smart autorouting option. When you use an array to connect two sets of inports and outports, smart autorouting routes them together if doing so makes better use of the space.

```
add_line('route',{'Subsystem/1','Subsystem/2'},...
        {'Subsystem1/1','Subsystem1/2'},'autorouting','smart')
```

Input Arguments

sys – Model or subsystem to add line to

character vector

Model or subsystem to add the line to, specified as a character vector.

Example: 'vdp'

Example: 'f14/Controller'

out – Block output port to connect line from

block name/port number or name | port handle | array of port designators

Block output port to connect line from, specified as one of these values:

- The block name, a slash, and the port number. For a state port, use the port name `State` instead of a port number.
- The port handle that you want to connect from.
- An array of either of these port designators.

Use 'PortHandles' with `get_param` to get the handles.

Example: 'Mu/1'

Example: 'Subsystem/2'

Example: `h.Outport(1)`

Example: {'Subsystem/1', 'Subsystem/2'}

Tips

- Most block ports are numbered from top to bottom or from left to right. For a description of the port order for various block orientations, see "Identify Port Location on Rotated or Flipped Block".
- Moving a port on a Subsystem block can change the port number. For more information, see "Move Ports".

in – Block input port to connect line to

block name/port number or name | port handle | array of port designators

Block input port to connect line to, specified as one of these values:

- The block name, a slash, and the port number. Use a port name instead of a port number for these ports:
 - Enable port — Use `Enable`. For example, use this port name for the enable port on enabled subsystems.

- Trigger port — Use `Trigger`. For example, use this port name for the trigger port on triggered subsystems.
- Action port — Use `Ifaction`. For example, use this port name for the action port on if-action and switch-case-action subsystems.
- The port handle that you want to add the line to.
- An array of either of these port designators.

Use the `'PortHandles'` option with `get_param` to get handles.

Example: `'Mu/1'`

Example: `'Subsystem/2'`

Example: `h.Inport(1)`

Example: `{'Subsystem/1','Subsystem/2'}`

Tips

- Most block ports are numbered from top to bottom or from left to right. For a description of the port order for various block orientations, see “Identify Port Location on Rotated or Flipped Block”.
- Moving a port on a Subsystem block can change the port number. For more information, see “Move Ports”.

autoOption — Type of automatic line routing

`'off'` (default) | `'on'` | `'smart'`

Type of automatic line routing around other blocks, specified as:

- `'off'` for no automatic line routing
- `'on'` for automatic line routing
- `'smart'` for automatic line routing that takes the best advantage of the blank spaces on the canvas and avoids overlapping other lines and labels

points — Points of the line to draw

matrix

Points of the line to draw, specified as at least a 2-by-2 matrix. Add a row for every segment you want to draw. Specify points as (x,y) coordinates from the upper-left corner of the Editor before any canvas resizing.

Example: `[100 300; 200 300; 200 300; 200 500]`

Output Arguments

h — Line

handle

Line created by `add_line`, returned as a handle.

Version History

Introduced before R2006a

add_param

Add parameter to Simulink system

Syntax

```
add_param(sys,param1,val1,...,paramN,valN)
```

Description

`add_param(sys,param1,val1,...,paramN,valN)` adds the specified parameters to the specified system and initializes the parameters to the specified values. The parameters are saved in the corresponding SLX or MDL file. You can use the `set_param` and `get_param` functions on the parameters.

Examples

Add Parameters and Values to System

Add the parameters `DemoName` and `EquationOrder` to the `vdp` model with the values `'VanDerPolEquation'` and `'2'`, respectively.

```
add_param('vdp','DemoName','VanDerPolEquation','EquationOrder','2')
```

Use the `get_param` function to query the values of the new parameters.

```
get_param('vdp','DemoName')
```

```
ans =
```

```
    'VanDerPolEquation'
```

Input Arguments

sys — System name or handle

character vector | string scalar | numeric scalar

System name or handle, specified as a character vector, string scalar, or numeric scalar. The system must be an SLX or MDL file.

Data Types: double | char | string

paramN — Name of parameter

character vector | string scalar

Name of parameter, specified as a character vector or string scalar.

Parameter names are case insensitive. For example, `'ParameterName'` is equivalent to `'parametername'`.

You cannot add a parameter that has the same name as an existing parameter of the system.

Dependencies

To use this parameter, specify a corresponding `val1` argument.

Data Types: `char` | `string`

valN — Initial value of parameter

`character vector` | `string scalar`

Initial value of parameter, specified as a character vector or string scalar.

Values are case sensitive.

Dependencies

To use this parameter, specify a corresponding `param1` argument.

Data Types: `char` | `string`

Version History

Introduced before R2006a

See Also

`delete_param` | `get_param` | `set_param`

addterms

Add terminators to unconnected ports in model

Syntax

```
addterms('sys')
```

Description

`addterms('sys')` adds Terminator and Ground blocks to the unconnected ports in the Simulink block diagram `sys`.

Version History

Introduced before R2006a

See Also

`upgradeadvisor`

attachConfigSet

Associate configuration set or configuration reference with model

Syntax

```
attachConfigSet(model, configObj)  
attachConfigSet(model, configObj, allowRename)
```

Description

`attachConfigSet(model, configObj)` associates the configuration set or configuration reference `configObj` with `model`.

`attachConfigSet(model, configObj, allowRename)` associates the configuration set to the model and determines how Simulink handles a name conflict between `configObj` and any configuration objects that are already attached to the model.

If `allowRename` is `false` and the configuration object specified by `configObj` has the same name as a configuration object already attached to `model`, Simulink generates an error. If `allowRename` is `true` and a name conflict occurs, Simulink provides a unique name for `configObj` before associating it with the model.

Examples

Create and Attach a Configuration Set

Create a configuration set and attach it to a model.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')  
sldemo_fuelsys
```

Create a configuration set named `Config1` and attach it to the model.

```
configObj = Simulink.ConfigSet;  
set_param(configObj, 'Name', 'Config1')  
attachConfigSet('sldemo_fuelsys', configObj)
```

To use the configuration set for the model, activate it.

Attach and Rename a Configuration Set

Attach a configuration set to a model that already has a configuration set with the same name.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`. The model uses a configuration set with the default name `Configuration`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
```

Create another configuration set and name it Configuration.

```
configObj = Simulink.ConfigSet;
set_param(configObj, 'Name', 'Configuration')
```

Attach the configuration to the model. Specify allowRename as true.

```
attachConfigSet('sldemo_fuelsys', configObj, true)
```

Because the model already has a configuration set named Configuration, Simulink changes the name of configObj to Configuration1 before attaching it to the model.

To use the configuration for the model, activate Configuration1.

Input Arguments

model — Model to attach configuration set to

character vector | string scalar

Model to which you want to attach a configuration set, specified as a character vector or string scalar. The model must be open.

Example: 'my_model'

configObj — Configuration object

ConfigSet object | ConfigSetRef object

Configuration object that you want to attach to the model, specified as a ConfigSet object or a Simulink.ConfigSetRef object.

Example: myConfigObj

allowRename — Rename configuration object if there is a naming conflict

false (default) | true

Specification that determines if Simulink renames the configuration object in the case of a name conflict, specified as a Boolean. If allowRename is false and a name conflict occurs, Simulink generates an error. You cannot attach a configuration object to a model if the configuration object is already attached to another model.

Example: true

Version History

Introduced before R2006a

attachConfigSetCopy

Copy configuration set or configuration reference and associate it with model

Syntax

```
configObjCopy = attachConfigSetCopy(model, configObj)
attachConfigSetCopy(model, configObj, allowRename)
```

Description

`configObjCopy = attachConfigSetCopy(model, configObj)` creates a copy of the configuration set or configuration reference `configObj` and associates it with `model`. The function returns the copy of the configuration as a `Simulink.ConfigSet` object or a `Simulink.ConfigSetRef` object.

`attachConfigSetCopy(model, configObj, allowRename)` associates the configuration copy with the model and determines how Simulink handles a name conflict between the configuration and any configuration objects that are already attached to the model.

If `allowRename` is `false` and the configuration object specified by `configObj` has the same name as a configuration object already attached to `model`, Simulink generates an error. If `allowRename` is `true` and a name conflict occurs, Simulink provides a unique name for the copy of `configObj` before associating it with the model.

Examples

Copy Configuration From One Model to Another Model

This example shows to create a copy of the active configuration for the model `sldemo_bounce` and attach the copy to the model `sldemo_boiler`.

Open the model `sldemo_bounce` and get the active configuration object.

```
sldemo_bounce
slbounceConfigObj = getActiveConfigSet('sldemo_bounce');
```

Each model has a configuration with the default name `Configuration`. To avoid a naming conflict when you attach the configuration copy to `sldemo_boiler`, name the configuration `slbounceConfig`.

```
set_param(slbounceConfigObj, 'Name', 'slbounceConfig');
```

Open the model `sldemo_boiler`. Copy the configuration object `slbounceConfigObj` and attach it to `sldemo_boiler`.

```
sldemo_boiler
attachConfigSetCopy('sldemo_boiler', slbounceConfigObj);
```

To use the configuration in `sldemo_boiler`, activate it.

Copy and Rename Configuration Set

This example shows to create a copy of the active configuration for the model `sldemo_bounce` and attach the copy to the model `sldemo_boiler`. Use the `allowRename` argument to avoid naming conflicts.

Open the model `sldemo_bounce` and get the active configuration object.

```
sldemo_bounce
slbounceConfigObj = getActiveConfigSet('sldemo_bounce');
```

Open the model `sldemo_boiler`. Copy the configuration object `slbounceConfigObj` and attach it to `sldemo_boiler`. Specify `allowRename` as `true`.

```
sldemo_boiler
attachConfigSetCopy('sldemo_boiler',slbounceConfigObj,true);
```

Because the model already has a configuration set named `Configuration`, Simulink® changes the name of `slbounceConfigObj` to `Configuration1` before attaching it to `sldemo_boiler`.

To use the configuration in `sldemo_bounce`, activate `Configuration1`.

Input Arguments

model — Model to attach configuration set to

character vector | string scalar

Model to which you want to attach a configuration set, specified as a character vector or string scalar. The model must be open.

Example: `'my_model'`

configObj — Configuration object

ConfigSet object | ConfigSetRef object

Configuration object that you want to copy, specified as a `Simulink.ConfigSet` object or a `Simulink.ConfigSetRef` object.

Example: `myConfigObj`

allowRename — Rename configuration object copy if there is a naming conflict

false (default) | true

Specification that determines if Simulink renames the configuration object copy in the case of a name conflict, specified as a Boolean. If `allowRename` is `false` and a name conflict occurs, Simulink generates an error.

Example: `true`

Version History

Introduced in R2006b

sltrace

Trace signals in a model

Syntax

```
g = sltrace(p)
g = sltrace(block, direction)
g = sltrace( ____, Name, Value)
```

Description

`g = sltrace(p)` traces a signal oriented from the port `p` and stores the results in the `sltrace.Graph` object `g`.

`g = sltrace(block, direction)` traces a signal oriented from the `block` toward the `direction`, and stores the results in `g`. The argument `direction` includes 'source' and 'destination'.

`g = sltrace(____, Name, Value)` traces a signal using one or more `Name, Value` arguments.

Examples

Trace all sources in model

Trace from the first inport of 'vdp/Scope' to all sources.

```
vdp
g = sltrace('vdp/Scope', 'Source', 'Port', 1, 'TraceAll', 'on')
```

```
g =
```

Graph with properties:

```
SrcBlocks: [2.0001 5.0001 6.0001 7.0001 9.0001 10.0001 11.0001 12.0001 13.0001]
DstBlocks: []
TraceGraph: [1x1 digraph]
```

Trace using block path

Trace from the second inport handle of 'vdp/Sum' to Stop block 'vdp/Product' and display the results in `Simulink.BlockPath` format.

```
bPort = get_param('vdp/Sum', 'PortHandles').Inport(2);
G = sltrace(bPort, 'Stop', 'vdp/Product', 'BlockPath', 'On');
```

Input Arguments

p — Block port

port handle

Block port where tracing begins, specified as a port handle.

block — Block where tracing begins

block name | block handle | Simulink.BlockPath

Block where tracing begins, specified as a block name, block handle, or as Simulink.BlockPath object.

direction — Direction of traced signal

'Source' | 'Destination'

Direction of traced signal, specified as either 'Source' or 'Destination'.

Data Types: char | string

Name-Value Pair Arguments

Specify optional Name, Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'TraceAll', 'on', 'BlockPath', 'on'

TraceAll — Trace to all sources and destinations

off (default) | on

Trace to all sources or destinations, specified as 'off' or 'on'. By default, tracing stops at the first non-virtual block. Set this argument to 'on' to trace to all sources or destinations.

Example: 'TraceAll', 'on'

Stop — Block where tracing stops

block name | block handle | Simulink.BlockPath

Block where tracing stops, specified as a block name, block handle, or as Simulink.BlockPath object. If the block where tracing stops is not on the tracing path, sltrace traces to all blocks.

Example: 'Stop', 'vdp/Sum'

Port — Port where tracing begins

real positive scalar

Port where tracing begins, specified as a real positive scalar. When tracing from a block with multiple inports or outports, you can enable the 'Port' option to select a specific port to trace from. Without enabling 'Port', sltrace will trace from all inports or outports. You can omit 'Port' when tracing from a block port handle.

Example: 'Port', '2'

Data Types: `double` | `single`

Element — Bus element where tracing begins

bus element name

Bus element where tracing begins. `sltrace` supports tracing to the source from a Bus Creator block and tracing to a destination from a Bus Selector block. You do not need to specify this parameter if tracing from block port handle `p`.

Example: `'Element', 'b'`

Data Types: `char` | `string`

BlockPath — Option to return tracing information as Simulink.BlockPath

`'off'` (default) | `'on'`

Option to return tracing information as `Simulink.BlockPath` object, specified as `'off'` or `'on'`. If there are multiple instances of a referenced model, set `'BlockPath'` to `'on'` to obtain accurate tracing results for different model instances.

Output Arguments**g — Tracing results**

`sltrace.Graph` object

Tracing result, returned as a `sltrace.Graph` object.

Version History

Introduced in R2021b

batchsim

Offload simulations to run on a compute cluster

Syntax

```
simJob = batchsim(in)
simJob = batchsim(myCluster,in)
simJob = batchsim(...,Name,Value)
```

Description

`simJob = batchsim(in)` runs a batch job on a single worker to simulate a model using the inputs specified in the `SimulationInput` object, `in`.

`simJob = batchsim(myCluster,in)` runs a batch job on the cluster identified by the cluster object `myCluster`. If a cluster profile is not specified, `batchsim` uses a default cluster profile as set up in the parallel preferences. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

`simJob = batchsim(...,Name,Value)` runs a batch job that simulates a model using the inputs specified in the `SimulationInput` object and the options specified as `Name,Value` pair.

`batchsim` offloads simulations to a compute cluster, enabling you to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later. Use the 'Pool' argument to run simulations in parallel.

The `batchsim` command uses the Parallel Computing Toolbox™ and MATLAB Parallel Server™ licenses to run the simulations on compute cluster. `batchsim` runs the simulations in serial if a parallel pool cannot be created. If Parallel Computing Toolbox license is not available, `batchsim` errors out.

Examples

Run Parallel Simulations with batchsim

This example shows how to run parallel simulations in batch. `batchsim` offloads simulations to a compute cluster, enabling you to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later.

This example uses the `ex_sldemo_househeat` model and runs simulations in batch to observe the model behavior for different temperature set points.

Open the model.

```
openExample('simulink/OpenTheModelExample');
open_system('ex_sldemo_househeat');
load_system('ex_sldemo_househeat')
```

Define a set of values for different temperatures. Here, the `setPointValues` are a standard range of temperatures. The length of the vector helps create an array of `Simulink.SimulationInput` objects in the following step.

```
setPointValues = 65:2:85;
spv_Length = length(setPointValues);
```

Using the `setPointValues`, initialize an array of `Simulink.SimulationInput` objects.

```
in(1:spv_Length) = Simulink.SimulationInput('ex_sl-demo_househeat');
for i = 1:1:spv_Length
    in(i) = in(i).setBlockParameter('ex_sl-demo_househeat/Set Point',...
    'Value',num2str(setPointValues(i)));
end
```
