Specify the pool size of the number of workers to use. In addition to the number of workers used to run simulations in parallel, a head worker is required. In this case, let's assume that three workers are available to run a batch job for the parallel simulations. The job object returns useful metadata as shown. You can use the job ID to access the job object later from any machine. `NumWorkers` tells you how many workers are running the simulations. `NumWorkers` is always the number of workers specified in the 'Pool' argument and an additional head worker. 'Pool' is set to 3, you can change the value of 'Pool' based on the availability of the workers.

```
simJob = batchsim(in, 'Pool', 3)

      ID: 1
      Type: pool
      NumWorkers: 4
      Username: #####
      State: running
      SubmitDateTime: ##-###-#### #:##:##
      StartDateTime:
      Running Duration: 0 days 0h 0m 0s
```

Access the results of the batch job using the `fetchOutputs` method. `fetchOutputs` method retrieves the results from the workers and returns an array of `Simulink.SimulationOutput` objects.

```
out = fetchOutputs(simJob)
```

```
1x11 Simulink.SimulationOutput array
```

Input Arguments

in — `Simulink.SimulationInput` object used to simulate the model

object, array

Specified as a `Simulink.SimulationInput` object or an array of `Simulink.SimulationInput` objects that is used to specify changes to the model for simulation.

Example: `in = Simulink.SimulationInput('vdp')`

myCluster — `parallel.Cluster` object

object

Cluster object that is used to specify the cluster in which the batch job runs.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Pool', 5`

AdditionalPaths — Files to attach to parallel pool

character vector | cell array

Specified as a character vector, a cell array or an array of character vector to define paths to be added to the MATLAB search path of the workers before the simulations execute. The default search path might not be the same on the workers as it is on the client; the path difference could be the result of different current working folders (`pwd`), platforms, or network file system access. The `'AdditionalPaths'` property can assure that workers are looking in the correct locations for necessary code files, data files, model files, etc.

AttachedFiles — Files to attach to parallel pool

cell array

Specified as a cell array of additional files to attach to the parallel pool.

AutoAddClientPath — Whether user-added entries on client path are added to each worker path

true (default) | false

Specified as true or false to control whether user-added entries on the client path are added to each worker path.

AutoAttachFiles — Whether code files should be automatically attached to the job

true (default) | false

Specified as true or false to control whether code files are automatically attached to the job.

CaptureDiary — Whether diary is collected

true (default) | false

Specified as true or false to indicate collection of the diary.

CleanupFcn — Function handle to run once per worker after running simulations

function handle

Specify a function handle to `'CleanupFcn'` to run once per worker after the simulations are completed.

EnvironmentVariables — Names of environment variables copied from client session to workers

character vector | cell array

Specifies the names of environment variables copied from the client session to the workers. The names specified here are appended to the `'EnvironmentVariables'` property specified in the applicable parallel profile to form the complete list of environment variables. Any variables listed which are not set are not copied to the workers. These environment variables will be set on the workers for the duration of the batch job.

ManageDependencies — Manage model dependencies`'on' (default) | 'off'`

When `ManageDependencies` is set to `'on'`, model dependencies are automatically sent to the parallel workers if necessary. If `ManageDependencies` is set to `'off'`, explicitly attach model dependencies to the parallel pool.

Pool — Size of the number of workers for a parallel pool`integer`

An integer specifying the number of workers to make into a parallel pool for the job *in addition* to the worker running the batch job itself. The simulations use this pool for execution. Because the pool requires N workers in addition to the worker running the batch, there must be at least $N+1$ workers available on the cluster.

Profile — Cluster profile name`profile name`

The name of a cluster profile used to identify the cluster. If this option is omitted, the default profile is used to identify the cluster and is applied to the job and task properties.

SetupFcn — Function handle to run once per worker`function handle`

Specify a function handle to `'SetupFcn'` to run once per worker before the start of the simulations.

Note To avoid a compilation error, either set `'LoadExternalInput'` to `'off'` or ensure that the specified external input is available when using `buildRapidAcceleratorTarget`

ShowProgress — Show the progress of the simulations in diary`'on' | 'off'`

Set to `'on'`, to copy the progress of the simulations in the command window to diary of `Simulink.Simulation.Job` object. The progress is hidden when set to `'off'`.

StopOnError — Stop simulations on errors`'off' (default) | 'on'`

Setting `'StopOnError'` to `'on'` stops the execution of simulations if an error is encountered.

TransferBaseWorkspaceVariables — Transfer variables to the parallel workers`'off' (default) | 'on'`

When `TransferBaseWorkspaceVariables` is set to `true`, variables used in the model and defined in the base workspace are transferred to the parallel workers.

UseFastRestart — Use fast restart`'off' (default) | 'on'`

When `UseFastRestart` is set to `true`, simulations run on the workers using fast restart.

Note When using `batchsim`, use the `UseFastRestart` option and not the `FastRestart` option. See “Get Started with Fast Restart” for more information.

Output Arguments

simJob — `Simulink.Simulation.Job` job object
object

An object containing metadata of submitted batch job. Poll job object using its ID to check the status of simulations or to access outputs on completion of the job.

Version History

Introduced in R2018b

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

Using `batchsim` with Parallel Computing Toolbox installed, MATLAB automatically opens a worker and runs the job in the background on another session on your local machine. Specifying a pool size runs the simulations on the number of workers specified. Control parallel behavior with the parallel preferences, including scaling up to a cluster.

For details, see “Running Multiple Simulations”.

bdclose

Close any or all Simulink system windows unconditionally

Syntax

```
bdclose
bdclose(sys)
bdclose('all')
```

Description

`bdclose` closes the current system window unconditionally and without confirmation. Any changes made to the system since it was last saved are lost. To find out the current system, use `gcs`. If a model was only loaded, `bdclose` clears the model from memory.

`bdclose(sys)` closes the specified system window, discarding all changes.

`bdclose('all')` closes all open system windows, discarding all changes.

Examples

Close a System Without Saving

Open the `vdp` system. Then, close it without saving any changes.

```
open_system('vdp')
bdclose('vdp')
```

Input Arguments

sys — System to close

character vector | string scalar | cell array

System to close, specified as a character vector, string scalar, or cell array. To specify multiple systems to close, specify a cell array of system names.

Example: `bdclose("vdp")`

Example: `bdclose({'vdp', 'f14'})`

Data Types: `char` | `string` | `cell`

Version History

Introduced before R2006a

R2019b: Closing a window for a model hierarchy closes referenced models

Behavior changed in R2019b

Starting in R2019b, when you close a window for a model hierarchy by closing the top model, all referenced models that are not open in another window are also closed, which clears them from memory. To keep referenced models loaded in memory, use the `close_system` function and set the `'closeReferencedModels'` argument to `false`.

`close_system` | `new_system` | `open_system` | `save_system`

bdIsDirty

Determine whether model, subsystem, or library has unsaved changes

Syntax

```
tf = bdIsDirty(bd)
```

Description

`tf = bdIsDirty(bd)` returns whether the specified model, subsystem, or library has unsaved changes. Unsaved changes can include changes to the block diagram, configuration parameters, or properties.

Examples

Check Models for Unsaved Changes

Check if models contain unsaved changes using `bdIsDirty`.

Check if a single model is dirty.

```
vdp  
bdIsDirty('vdp')
```

```
ans =  
  
    logical  
  
     0
```

Check if multiple models are dirty.

```
vdp  
f14  
bdIsDirty({'f14','vdp'})
```

```
ans =  
  
    1×2 logical array  
  
     0     0
```

Input Arguments

bd — Name or handle of loaded model, subsystem, or library

numeric array | string array | character vector | cell array of character vectors

Name or handle of loaded model, subsystem, or library, specified as a numeric array, string array, character vector, or cell array of character vectors.

You cannot check whether blocks, such as Subsystem blocks, have unsaved changes. You can check whether referenced subsystems have unsaved changes. For more information, see “Subsystem Reference”.

Data Types: `double` | `char` | `string` | `cell`

Output Arguments

tf — True or false result

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

- 1 (`true`) — File has been modified in memory since it was loaded or last saved.
- 0 (`false`) — File has no unsaved changes.

When multiple files are specified, the function returns a logical array with one entry for each file.

Version History

Introduced in R2017a

`bdIsLoaded`

Topics

“Manage Shadowed and Dirty Models and Other Project Files”

bdIsLibrary

Determine whether block diagram is a library

Syntax

```
tf = bdIsLibrary(bd)
```

Description

`tf = bdIsLibrary(bd)` returns whether the specified block diagram is a library.

Examples

Check Whether Block Diagrams Are Libraries

Load the MLFB_library and vdp block diagrams. Get the handle for MLFB_library.

```
load_system({'MLFB_library','vdp'})  
h = get_param('MLFB_library','Handle');
```

Check whether vdp is a library. The returned value 0 indicates that it is not

```
bdIsLibrary('vdp')
```

```
ans = logical  
     0
```

Check whether MLFB_library and vdp are libraries. The returned value shows that MLFB_library is a library and vdp is not.

```
bdIsLibrary({'MLFB_library','vdp'})
```

```
ans = 1x2 logical array
```

```
     1     0
```

Using the handle to MLFB_library, check whether MLFB_library is a library. The value returned shows that it is.

```
bdIsLibrary(h)
```

```
ans = logical  
     1
```

Input Arguments

bd — Name or handle of loaded block diagram

numeric array | string array | character vector | cell array of character vectors

Name or handle of loaded block diagram, specified as a numeric array, string array, character vector, or cell array of character vectors.

Data Types: `double` | `char` | `string` | `cell`

Output Arguments

tf — True or false result

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

- 1 (`true`) — File is a library.
- 0 (`false`) — File is not a library.

When multiple files are specified, the function returns a logical array with one entry for each file.

Version History

Introduced in R2015a

See Also

`bdIsLoaded` | `bdroot` | `find_system`

bdIsLoaded

Determine whether model, subsystem, or library is loaded

Syntax

```
tf = bdIsLoaded(bd)
```

Description

`tf = bdIsLoaded(bd)` returns whether the specified model, subsystem, or library is loaded.

Examples

Check Whether Model Is Loaded

Check whether the f14 model is loaded.

```
bdIsLoaded('f14')
```

```
ans =  
    logical  
    0
```

The function returns a logical scalar, 0, which indicates that the file is not loaded.

To load the f14 model, use the `load_system` function.

```
load_system('f14')
```

Check Whether Multiple Models Are Loaded

Determine whether the f14 and vdp models are loaded.

```
bdIsLoaded({'f14','vdp'})
```

```
ans =  
    1×2 logical array  
    1    0
```

The function returns a 1-by-2 logical array, which indicates that the first model in the cell array (f14) is loaded and the second model in the cell array (vdp) is not loaded.

To load the vdp model, use the `load_system` function.

```
load_system('vdp')
```

Input Arguments

bd — Name of model, subsystem, or library

string array | character vector | cell array of character vectors

Name of model, subsystem, or library, specified as a string array, character vector, or cell array of character vectors.

Blocks, such as Subsystem blocks, cannot be loaded independently. Referenced subsystems can be loaded independently. For more information, see “Subsystem Reference”.

Data Types: `char` | `string` | `cell`

Output Arguments

tf — True or false result

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

- 1 (`true`) — File is loaded.
- 0 (`false`) — File is not loaded.

When multiple files are specified, the function returns a logical array with one entry for each file.

Version History

Introduced in R2008a

`find_system` | `bdIsLibrary` | `bdIsDirty`

bdroot

Top-level model of current system

Syntax

```
model = bdroot  
model = bdroot(elements)
```

Description

`model = bdroot` returns the top-level model of the current system. The current system is the currently active Simulink Editor window or the system in which a block is selected.

`model = bdroot(elements)` returns the top-level model of the specified model elements. Before using `bdroot`, make sure the top-level model of each element in `elements` is loaded.

Examples

Get Top-Level Model

This example shows how to get the top-level model.

Get Top-Level Model of Current System

Open the system Controller in the model f14.

```
load_system('f14')  
open_system('f14/Controller')
```

Get the top-level model of the current system.

```
bdroot
```

```
ans =  
'f14'
```

Get Top-Level Model of a System

Open the system Controller in the model f14.

```
load_system('f14')  
open_system('f14/Controller')
```

Get the top-level model of the current system.

```
bdroot(gcs)
```

```
ans =  
'f14'
```

Input Arguments

elements — Model elements whose top-level models to return

model name | block path name | handle | cell array of character vectors | string array | numeric array

Model elements whose top-level model to return, specified as the model name, block or system path name, handle, cell array of character vectors or string array of system names, or numeric array of handles.

Tip Use `bdroot` with `gcs`, `gcb`, and `gcbh` to get the top-level model of the current system or block.

Output Arguments

model — Top-level model

character vector | cell array | string array

Top-level model, returned as a character vector of the model name. If the input was an array, `model` is returned as an array of the same type as the input.

Version History

Introduced before R2006a

`gcb` | `gcs` | `gcbh`

dlinmod

Extract discrete-time linear state-space model around operating point

Syntax

```
argout = dlinmod('sys',Ts)
```

```
argout = dlinmod('sys',Ts,x,u)
```

```
argout = dlinmod('sys',Ts,x,u,para, 'v5')
```

```
argout = dlinmod('sys',Ts,x,u,para,xpert,upert, 'v5')
```

Arguments

<i>sys</i>	Name of the Simulink system from which the linear model is extracted.
<i>x</i> , <i>u</i>	State (<i>x</i>) and the input (<i>u</i>) vectors. If specified, they set the operating point at which the linear model is extracted. When a model has model references using the Model block, you must use the Simulink structure format to specify <i>x</i> . To extract the <i>x</i> structure from the model, use the following command: <pre>x = Simulink.BlockDiagram.getInitialState('sys');</pre> <p>You can then change the operating point values within this structure by editing <code>x.signals.values</code>.</p> <p>If the state contains different data types (for example, 'double' and 'uint8'), then you cannot use a vector to specify this state. You must use a structure instead. In addition, you can only specify the state as a vector if the state data type is 'double'.</p>
<i>Ts</i>	Sample time of the discrete-time linearized model
'v5'	An optional argument that invokes the perturbation algorithm created prior to MATLAB 5.3. Invoking this optional argument is equivalent to calling <code>linmodv5</code> .
<i>para</i>	A three-element vector of optional arguments: <ul style="list-style-type: none"> • <code>para(1)</code> — Perturbation value of delta, the value used to perform the perturbation of the states and the inputs of the model. This is valid for linearizations using the 'v5' flag. The default value is 1e-05. • <code>para(2)</code> — Linearization time. For blocks that are functions of time, you can set this parameter with a nonnegative value that gives the time (<i>t</i>) at which Simulink evaluates the blocks when linearizing a model. The default value is 0. • <code>para(3)</code> — Set <code>para(3)=1</code> to remove extra states associated with blocks that have no path from input to output. The default value is 0.

xpert, upert

The perturbation values used to perform the perturbation of all the states and inputs of the model. The default values are

```
xpert = para(1) + 1e-3*para(1)*abs(x)
upert = para(1) + 1e-3*para(1)*abs(u)
```

When a model has model references using the Model block, you must use the Simulink structure format to specify *xpert*. To extract the *xpert* structure, use the following command:

```
xpert = Simulink.BlockDiagram.getInitialState('sys');
```

You can then change the perturbation values within this structure by editing `xpert.signals.values`.

The perturbation input arguments are only available when invoking the perturbation algorithm created prior to MATLAB 5.3, either by calling `linmodv5` or specifying the 'v5' input argument to `linmod`.

argout

`linmod`, `dlinmod`, and `linmod2` return state-space representations if you specify the output (left-hand) side of the equation as follows:

- `[A,B,C,D] = linmod('sys', x, u)` obtains the linearized model of *sys* around an operating point with the specified state variables *x* and the input *u*. If you omit *x* and *u*, the default values are zero.

`linmod` and `dlinmod` both also return a transfer function and MATLAB data structure representations of the linearized system, depending on how you specify the output (left-hand) side of the equation. Using `linmod` as an example:

- `[num, den] = linmod('sys', x, u)` returns the linearized model in transfer function form.
- `sys_struct = linmod('sys', x, u)` returns a structure that contains the linearized model, including state names, input and output names, and information about the operating point.

Description

Note `dlinmod` provides only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

`dlinmod` computes a linear state-space model for a discrete-time system by linearizing each block in a model individually.

`linmod` obtains linear models from systems of ordinary differential equations described as Simulink models. Inputs and outputs are denoted in Simulink block diagrams using Inport and Outport blocks.

The default algorithm uses preprogrammed analytic block Jacobians for most blocks which should result in more accurate linearization than numerical perturbation of block inputs and states. A list of blocks that have preprogrammed analytic Jacobians is available in the Simulink Control Design documentation along with a discussion of the block-by-block analytic algorithm for linearization.

The default algorithm also allows for special treatment of problematic blocks such as the Transport Delay and the Quantizer. See the mask dialog of these blocks for more information and options.

Discrete-Time System Linearization

The function `dlinmod` can linearize discrete, multirate, and hybrid continuous and discrete systems at any given sampling time. Use the same calling syntax for `dlinmod` as for `linmod`, but insert the sample time at which to perform the linearization as the second argument. For example,

```
[Ad,Bd,Cd,DD] = dlinmod('sys', Ts, x, u);
```

produces a discrete state-space model at the sampling time T_s and the operating point given by the state vector x and input vector u . To obtain a continuous model approximation of a discrete system, set T_s to θ .

For systems composed of linear, multirate, discrete, and continuous blocks, `dlinmod` produces linear models having identical frequency and time responses (for constant inputs) at the converted sampling time T_s , provided that

- T_s is an integer multiple of all the sampling times in the system.
- The system is stable.

For systems that do not meet the first condition, in general the linearization is a time-varying system, which cannot be represented with the $[A,B,C,D]$ state-space model that `dlinmod` returns.

Computing the eigenvalues of the linearized matrix A_d provides an indication of the stability of the system. The system is stable if $T_s > \theta$ and the eigenvalues are within the unit circle, as determined by this statement:

```
all(abs(eig(Ad))) < 1
```

Likewise, the system is stable if $T_s = \theta$ and the eigenvalues are in the left half plane, as determined by this statement:

```
all(real(eig(Ad))) < 0
```

When the system is unstable and the sample time is not an integer multiple of the other sampling times, `dlinmod` produces A_d and B_d matrices, which can be complex. The eigenvalues of the A_d matrix in this case still, however, provide a good indication of stability.

You can use `dlinmod` to convert the sample times of a system to other values or to convert a linear discrete system to a continuous system or vice versa.

You can find the frequency response of a continuous or discrete system by using the `bode` command.

Notes

By default, the system time is set to zero. For systems that are dependent on time, you can set the variable `para` to a two-element vector, where the second element is used to set the value of t at which to obtain the linear model.

The ordering of the states from the nonlinear model to the linear model is maintained. For Simulink systems, a character vector variable that contains the block name associated with each state can be obtained using

```
[sizes,x0,xstring] = sys
```

where `xstring` is a vector of strings whose *ith* row is the block name associated with the *ith* state. Inputs and outputs are numbered sequentially on the diagram.

For single-input multi-output systems, you can convert to transfer function form using the routine `ss2tf` or to zero-pole form using `ss2zp`. You can also convert the linearized models to LTI objects using `ss`. This function produces an LTI object in state-space form that can be further converted to transfer function or zero-pole-gain form using `tf` or `zpk`.

The default algorithms in `linmod` and `dlinmod` handle Transport Delay blocks by replacing the linearization of the blocks with a Pade approximation. For the 'v5' algorithm, linearization of a model that contains Derivative or Transport Delay blocks can be troublesome. For more information, see “Linearizing Models”.

Linearization is not supported for models that contain one or more referenced models configured to use a local solver. For more information, see “Use Local Solvers in Referenced Models”.

Version History

Introduced in R2007a

`linmod` | `linmod2` | `linmodv5`

close_system

Close Simulink system window or block dialog box

Syntax

```
close_system
close_system(blockOrSys)
close_system(sys,saveflag)
close_system(sys,newsys)
close_system(sys, ___,Name,Value)
```

Description

`close_system` closes the current system or subsystem. If the current system is the top-level model and has been modified, `close_system` returns an error.

Use the `gcs` function to determine the current system.

Note You cannot use `close_system` in a block or menu callback to close the root-level model. Attempting to close the root-level model in a block or menu callback causes an error and discontinues the callback execution.

`close_system(blockOrSys)` closes the specified model or subsystem, or the block dialog box of the specified block. If the model was only loaded, that is, with `load_system`, this syntax clears the model from memory.

`close_system(sys,saveflag)` lets you specify whether to save the model with its current name or to close it without saving.

`close_system(sys,newsys)` saves the model to a file with the specified name before closing.

`close_system(sys, ___,Name,Value)` specifies additional options using one or more `Name,Value` pair arguments.

Examples

Close the Current System

Open the model `vdp` and then close it.

```
vdp
close_system
```

Close a Block Dialog Box

Open the model `vdp`.

vdp

In the model, double-click the Mu block to open its block dialog box.

Close the block dialog box

```
close_system('vdp/Mu');
```

Close a Model and Save with New Name

Open a model, modify it, save the model with a new name and close it.

Open the model vdp and add a block to it.

```
vdp
block = add_block('vdp/Mu','vdp/Mu','MakeNameUnique','on');
```

Close the model, saving it with a new name.

```
close_system('vdp','myvdp');
```

Close a Model Using Name,Value Options

This command tries to save the vdp system to a file with the name 'max', but returns an error because 'max' is the name of an existing MATLAB function.

```
close_system('vdp','max','ErrorIfShadowed',true)
```

Close a Top Model and Keep Referenced Models Loaded

Open a model hierarchy, load the referenced model, then close the top model, leaving the referenced model loaded.

Open the sldemo_mdhref_basic model and load its referenced model, sldemo_mdhref_counter.

```
openExample('sldemo_mdhref_basic')
load_system('sldemo_mdhref_counter')
```

Check what models are loaded in memory.

```
loadedModels = Simulink.allBlockDiagrams('model');
modelName = get_param(loadedModels,'Name')
```

```
modelName =
```

```
2x1 cell array
```

```
 {'sldemo_mdhref_counter'}
 {'sldemo_mdhref_basic' }
```

Close sldemo_mdhref_basic while keeping the referenced model loaded.

```
close_system('sldemo_mdhref_basic',0,'closeReferencedModels',false)
```

Check what models are loaded in memory.

```
loadedModels = Simulink.allBlockDiagrams('model');
modelName = get_param(loadedModels, 'Name')

modelName =

    'sldemo_mdhref_counter'
```

Closing the top model clears it from memory. By default, because they share a window, using `close_system` on the top model would also close the referenced model and clear it from memory. Setting `'closeReferencedModels'` to `false` keeps the referenced model, `sldemo_mdhref_counter`, loaded.

Input Arguments

blockOrSys — Block, model, or subsystem to close

character vector | cell array of character vectors | string array | handle | array of handles

Name of model, subsystem, or the block whose dialog box you want to close, specified as a character vector, cell array of character vectors, string array, handle, or array of handles. Do not use a file extension.

Example: "vdp/Mu" 'vdp'

sys — Name of model to close

character vector | cell array of character vectors | string array | handle | array of handles

Name of model to close, specified as a character vector, cell array of character vectors, string array, handle, or array of handles. Do not use a file extension.

saveFlag — Option to save file with current name

0 (default) | 1 | numeric array

Option to save model using the current file name, specified as 0 to close without saving or 1 to save and then close. If `sys` is an array, you can supply a single character to apply to all of the models in the array. Or you can provide a numeric array with values that correspond with each model in the `sys` array.

For information on rules for naming models, see “Choose Valid Model File Names”.

newsys — File to save to

character vector | cell array of character vectors | string array

File to save to, specified as a character vector, cell array of character vectors, or string array. You can specify a model name in the current folder or the full path name, with or without an extension.

When you specify a name without an extension, `close_system` saves to the file format specified in your Simulink preferences. Possible model extensions are `.slx` and `.mdl`.

For information on rules for naming models, see “Choose Valid Model File Names”.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example:

```
close_system('myModel', 'newModel', 'closeReferencedModels', false, 'ErrorIfShadowed', true, 'OverwriteIfChangedOnDisk', true, 'SaveModelWorkspace', true)
```

closeReferencedModels — Option to close all referenced models

true (default) | false | 'on' | 'off'

Option to close all referenced models when you close the window for the top model, specified as the comma-separated pair consisting of 'closeReferencedModels' and true, false, 'on', or 'off'. Referenced models that are open in another window are unaffected by this setting. To keep referenced models loaded, set this argument to false.

ErrorIfShadowed — Option to return an error if the new name is already used

false (default) | true | 'on' | 'off'

Option to return an error if the new name is already used on the MATLAB path or in the workspace, specified as the comma-separated pair consisting of 'ErrorIfShadowed' and true, false, 'on', or 'off'. To receive this error, you must use the newsys argument to save the model with a new name. To learn about shadowed files, see “Shadowed Files”.

OverwriteIfChangedOnDisk — Option to overwrite the file on disk

false (default) | true | 'on' | 'off'

Option to overwrite the file on disk when you save the model, even if it has been modified since the system was loaded, specified as the comma-separated pair consisting of 'OverwriteIfChangedOnDisk' and true, false, 'on', or 'off'. By default, if the file changed on disk since the model was loaded, close_system displays an error to prevent the changes on disk from being overwritten.

You can control whether saving the model displays an error if the file has changed on disk by using a Simulink preference. In the **Model File** pane of the Simulink Preferences dialog box, under **Change Notification**, select **Saving the model**. This preference is on by default.

SaveModelWorkspace — Option to save the model workspace

false (default) | true | 'on' | 'off'

Option to save the model workspace when you save the model, specified as the comma-separated pair consisting of 'SaveModelWorkspace' and true, false, 'on', or 'off'. The model workspace DataSource must be a MAT-file. If the data source is not a MAT-file, saving the model does not save the workspace. See “Specify Source for Data in Model Workspace”.

Version History

Introduced before R2006a

R2019b: Closing a window for a model hierarchy closes referenced models

Behavior changed in R2019b

Starting in R2019b, when you close a window for a model hierarchy by closing the top model, all referenced models that are not open in another window are also closed, which clears them from memory. To keep referenced models loaded in memory, set the 'closeReferencedModels' argument to false.

See Also

`bdclose` | `gcs` | `new_system` | `open_system` | `save_system` | `load_system`

closeDialog

Close configuration parameters dialog

Syntax

```
closeDialog(configObj)
```

Arguments

configObj

A configuration set (`Simulink.ConfigSet`) or configuration reference (`Simulink.ConfigSetRef`)

Description

`closeDialog` closes an open configuration parameters dialog box. If *configObj* is a configuration set, the function closes the dialog box that displays the configuration set. If *configObj* is a configuration reference, the function closes the dialog box that displays the referenced configuration set, or generates an error if the reference does not specify a valid configuration set. If the dialog box is already closed, the function does nothing.

Examples

The following example closes a configuration parameters dialog box that shows the current parameters for the current model. The parameter values derive from the active configuration set or configuration reference (configuration object). The code is the same in either case; the only difference is which type of configuration object is currently active.

```
myConfigObj = getActiveConfigSet(gcs);  
closeDialog(myConfigObj);
```

Version History

Introduced in R2006b

coder.allowpcode

Package: coder

Control code generation from P-code files

Syntax

```
coder.allowpcode('plain')
```

Description

`coder.allowpcode('plain')` allows you to generate P-code files that you can then compile into optimized MEX functions or embeddable C/C++ code. This function does not obfuscate the generated MEX functions or embeddable C/C++ code.

With this capability, you can distribute algorithms as P-code files that provide code generation optimizations.

Call this function in the top-level function before control-flow statements, such as `if`, `while`, `switch`, and function calls.

MATLAB functions can call P-code. When the `.m` and `.p` versions of a file exist in the same folder, the P-code file takes precedence.

`coder.allowpcode` is ignored outside of code generation.

Examples

Generate optimized embeddable code from P-code file

Write a function `p_abs` that returns the absolute value of its input:

```
function out = p_abs(in)    %#codegen
% The directive %#codegen indicates that the function
% is intended for code generation
coder.allowpcode('plain');
out = abs(in);
```

Generate P-code file. In the MATLAB Command Window, enter:

```
pcode p_abs
```

The P-code file, `p_abs.p`, appears in the current folder.

Generate a MEX function for `p_abs.p`, using the `-args` option to specify the size, class, and complexity of the input parameter (requires a MATLAB Coder license).

```
codegen p_abs -args { int32(0) }
```

`codegen` generates a MEX function in the current folder.

If you have MATLAB Coder, generate embeddable C code for `p_abs.p`.

```
codegen p_abs -config:lib -args { int32(0) };
```

`codegen` generates C library code in the `codegen\lib\p_abs` folder.

Version History

Introduced in R2011a

coder.ceval

Call external C/C++ function

Syntax

```
coder.ceval(cfun_name)
coder.ceval(cfun_name,cfun_arguments)

coder.ceval('-global',cfun_name)
coder.ceval('-global',cfun_name,cfun_arguments)

coder.ceval('-gpudevicefcn',devicefun_name,devicefun_arguments)

coder.ceval('-layout:rowMajor',cfun_name,cfun_arguments)
coder.ceval('-layout:columnMajor',cfun_name,cfun_arguments)
coder.ceval('-layout:any',cfun_name,cfun_arguments)

cfun_return = coder.ceval( ___ )
```

Description

`coder.ceval(cfun_name)` executes the external C/C++ function specified by `cfun_name`. Define `cfun_name` in an external C/C++ source file or library. Provide the external source, library, and header files to the code generator.

`coder.ceval(cfun_name,cfun_arguments)` executes `cfun_name` with arguments `cfun_arguments`. `cfun_arguments` is a comma-separated list of input arguments in the order that `cfun_name` requires.

By default, `coder.ceval` passes arguments by value to the C/C++ function whenever C/C++ supports passing arguments by value. To make `coder.ceval` pass arguments by reference, use the constructs `coder.ref`, `coder.rref`, and `coder.wref`. If C/C++ does not support passing arguments by value, for example, if the argument is an array, `coder.ceval` passes arguments by reference. If you do not use `coder.ref`, `coder.rref` or `coder.wref`, a copy of the argument can appear in the generated code to enforce MATLAB semantics for arrays.

`coder.ceval('-global',cfun_name)` executes `cfun_name` and indicates that `cfun_name` uses one or more MATLAB global variables. The code generator can then produce code that is consistent with this global variable usage.

Note The `-global` flag is only supported for code generation. You cannot include this flag while calling `coder.ceval` in MATLAB Function blocks.

`coder.ceval('-global',cfun_name,cfun_arguments)` executes `cfun_name` with arguments `cfun_arguments` and indicates that `cfun_name` uses one or more MATLAB global variables.

`coder.ceval('-gpudevicefcn',devicefun_name,devicefun_arguments)` allows you to call CUDA® GPU `__device__` functions from within kernels. `'-gpudevicefcn'` indicates to `coder.ceval` that the target function is on the GPU device. `devicefun_name` is the name of the

`__device__` function and `devicefun_arguments` is a comma-separated list of input arguments in the order that `devicefun_name` requires. This option requires the GPU Coder™ product.

`coder.ceval(' -layout:rowMajor', cfun_name, cfun_arguments)` executes `cfun_name` with arguments `cfun_arguments` and passes data stored in row-major layout. When called from a function that uses column-major layout, the code generator converts inputs to row-major layout and converts outputs back to column-major layout. For a shorter syntax, use `coder.ceval(' -row', ...)`.

`coder.ceval(' -layout:columnMajor', cfun_name, cfun_arguments)` executes `cfun_name` with arguments `cfun_arguments` and passes data stored in column-major layout. When called from a function that uses row-major layout, the code generator converts inputs to column-major layout and converts outputs back to row-major layout. For a shorter syntax, use `coder.ceval(' -col', ...)`.

`coder.ceval(' -layout:any', cfun_name, cfun_arguments)` executes `cfun_name` with arguments `cfun_arguments` and passes data with its current array layout, even when array layouts do not match. The code generator does not convert the array layout of the input or output data.

`cfun_return = coder.ceval(____)` executes `cfun_name` and returns a single scalar value, `cfun_return`, corresponding to the value that the C/C++ function returns in the `return` statement. To be consistent with C/C++, `coder.ceval` can return only a scalar value. It cannot return an array. Use this option with any of the input argument combinations in the previous syntaxes.

Examples

Call External C Function

Call a C function `foo(u)` from a MATLAB function from which you intend to generate C code.

Create a C header file `foo.h` for a function `foo` that takes two input parameters of type `double` and returns a value of type `double`.

```
double foo(double in1, double in2);
```

Write the C function `foo.c`.

```
#include <stdio.h>
#include <stdlib.h>
#include "foo.h"

double foo(double in1, double in2)
{
    return in1 + in2;
}
```

Write a function `callfoo` that calls `foo` by using `coder.ceval`. Provide the source and header files to the code generator in the function.

```
function y = callfoo %#codegen
y = 0.0;
if coder.target('MATLAB')
    % Executing in MATLAB, call MATLAB equivalent of
    % C function foo
    y = 10 + 20;
```

```

else
    % Executing in generated code, call C function foo
    coder.updateBuildInfo('addSourceFiles','foo.c');
    coder.cinclude('foo.h');
    y = coder.ceval('foo', 10, 20);
end
end

```

Generate C library code for function `callfoo`. The `codegen` function generates C code in the `\codegen\lib\callfoo` subfolder.

```
codegen -config:lib callfoo -report
```

Call a C Library Function

Call a C library function from MATLAB code.

Write a MATLAB function `myabsval`.

```

function y = myabsval(u)
%#codegen
y = abs(u);

```

Generate a C static library for `myabsval`, using the `-args` option to specify the size, type, and complexity of the input parameter.

```
codegen -config:lib myabsval -args {0.0}
```

The `codegen` function creates the library file `myabsval.lib` and header file `myabsval.h` in the folder `\codegen\lib\myabsval`. (The library file extension can change depending on your platform.) It generates the functions `myabsval_initialize` and `myabsval_terminate` in the same folder.

Write a MATLAB function to call the generated C library function using `coder.ceval`.

```

function y = callmyabsval(y)
%#codegen
% Check the target. Do not use coder.ceval if callmyabsval is
% executing in MATLAB
if coder.target('MATLAB')
    % Executing in MATLAB, call function myabsval
    y = myabsval(y);
else
    % add the required include statements to generated function code
    coder.updateBuildInfo('addIncludePaths','$(START_DIR)\codegen\lib\myabsval');
    coder.cinclude('myabsval_initialize.h');
    coder.cinclude('myabsval.h');
    coder.cinclude('myabsval_terminate.h');

    % Executing in the generated code.
    % Call the initialize function before calling the
    % C function for the first time
    coder.ceval('myabsval_initialize');

    % Call the generated C library function myabsval
    y = coder.ceval('myabsval',y);

```

```

% Call the terminate function after
% calling the C function for the last time
coder.ceval('myabsval_terminate');
end

```

Generate the MEX function `callmyabsval_mex`. Provide the generated library file at the command line.

```
codegen -config:mex callmyabsval codegen\lib\myabsval\myabsval.lib -args {-2.75}
```

Rather than providing the library at the command line, you can use `coder.updateBuildInfo` to specify the library within the function. Use this option to preconfigure the build. Add this line to the `else` block:

```
coder.updateBuildInfo('addLinkObjects','myabsval.lib','$(START_DIR)\codegen\lib\myabsval',100, true);
```

Note The `START_DIR` macro is only supported for generating code with MATLAB Coder.

Run the MEX function `callmyabsval_mex` which calls the library function `myabsval`.

```
callmyabsval_mex(-2.75)
```

```
ans =
```

```
2.7500
```

Call the MATLAB function `callmyabsval`.

```
callmyabsval(-2.75)
```

```
ans =
```

```
2.7500
```

The `callmyabsval` function exhibits the desired behavior for execution in MATLAB and in code generation.

Call C Function That Uses Global Variable

Use the `'-global'` flag when you call a C function that modifies a global variable.

Write a MATLAB function `useGlobal` that calls a C function `addGlobal`. Use the `'-global'` flag to indicate to the code generator that the C function uses a global variable.

```

function y = useGlobal()
global g;
t = g;
% compare execution with/without '-global' flag
coder.ceval('-global','addGlobal');
y = t;
end

```

Create a C header file `addGlobal.h` for the function `addGlobal`.

```
void addGlobal(void);
```

Write the C function `addGlobal` in the file `addGlobal.c`. This function includes the header file `useGlobal_data.h` that the code generator creates when you generate code for the function `useGlobal`. This header file contains the global variable declaration for `g`.

```
#include "addGlobal.h"
#include "useGlobal_data.h"
void addGlobal(void) {
    g++;
}
```

Generate the MEX function for `useGlobal`. To define the input to the code generator, declare the global variable in the workspace.

```
global g;
g = 1;
codegen useGlobal -report addGlobal.h addGlobal.c
y = useGlobal_mex();
```

With the `'-global'` flag, the MEX function produces the result `y = 1`. The `'-global'` flag indicates to the code generator that the C function possibly modifies the global variable. For `useGlobal`, the code generator produces this code:

```
real_T useGlobal(const emlrtStack *sp)
{
    real_T y;
    (void)sp;
    y = g;
    addGlobal();
    return y;
}
```

Without the `'-global'` flag, the MEX function produces `y = 2`. Because there is no indication that the C function modifies `g`, the code generator assumes that `y` and `g` are identical. This C code is generated:

```
real_T useGlobal(const emlrtStack *sp)
{
    (void)sp;
    addGlobal();
    return g;
}
```

Call C Function That Uses Different Array Layout

Suppose that you have a C function `testRM` that is designed to use row-major layout. You want to integrate this function into a MATLAB function `bar` that operates on arrays. The function `bar` is designed to use column-major layout, employing the `coder.columnMajor` directive.

```
function out = bar(in)
%#codegen
coder.columnMajor;
coder.ceval('-layout:rowMajor','testRM', ...
    coder.rref(in),coder.wref(out));
end
```

In the generated code, the code generator inserts a layout conversion from column-major layout to row-major layout on the variable `in` before passing it to `testRM`. On the output variable `out`, the code generator inserts a layout conversion back to column-major.

In general, if you do not specify the `layout` option for `coder.ceval`, the external function arguments are assumed to use column-major.

Call C Function That Takes Complex Number Inputs

Suppose you have a MATLAB function that calls custom C code that takes complex number inputs. You must define your C code input parameters so that the complex number inputs from your MATLAB function can map to your C code.

In generated code, complex numbers are defined as a `struct` that has two fields, `re` and `im`, which are the real and imaginary part of a complex number respectively. This `struct` is defined in the header file `rtwtypes.h`, which you can find in the `codegen\lib\functionName` folder of your current path. The `struct` is defined as follows:

```
typedef struct {
    real32_T re; /*Real Component*/
    real32_T im; /*Imaginary Component*/
} creal_T;
```

For more information, see “Mapping MATLAB Types to Types in Generated Code” (MATLAB Coder).

The C code that you want to integrate must include the `rtwtypes.h` header file. An example C code `foo.c` is shown below:

```
#include "foo.h"
#include<stdio.h>
#include<stdlib.h>
#include "rtwtypes.h"

double foo(creal_T x) {
    double z = 0.0;
    z = x.re*x.re + x.im*x.im;
    return (z);
}
```

The `struct` is named `creal_T`. A header file `foo.h` must also be defined as:

```
#include "rtwtypes.h"
double foo(creal_T x);
```

The MATLAB code executes `foo.c` by using the `coder.ceval` function that has a complex numbers input:

```
function y = complexCeval %#codegen
y = 0.0;
coder.updateBuildInfo('addSourceFiles','foo.c');
coder.cinclude('foo.h');
y = coder.ceval('foo', 10+20i);
end
```

The `coder.ceval` command takes the complex number input. The code generator maps the complex number to the `struct creal_T` variable `x` and its fields `re` and `im`.

Generate code for the function `complexCeval` by running this command:

```
codegen -config:lib -report complexCeval
```

Input Arguments

cfun_name — C/C++ function name

character vector | string scalar

Name of external C/C++ function to call.

Example: `coder.ceval('foo')`

Data Types: `char` | `string`

cfun_arguments — C/C++ function arguments

scalar variable | array | element of an array | structure | structure field | object property

Comma-separated list of input arguments in the order that `cfun_name` requires.

Example: `coder.ceval('foo', 10, 20);`

Example: `coder.ceval('myFunction', coder.ref(x));`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct`

Complex Number Support: Yes

Limitations

- You cannot use `coder.ceval` on functions that you declare extrinsic with `coder.extrinsic`.
- When the LCC compiler creates a library, it adds a leading underscore to the library function names. If the compiler for the library was LCC and your code generation compiler is not LCC, you must add the leading underscore to the function name, for example, `coder.ceval('_mylibfun')`. If the compiler for a library was not LCC, you cannot use LCC to generate code from MATLAB code that calls functions from that library. Those library function names do not have the leading underscore that the LCC compiler requires.
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties”.
- Variable-size matrices as entry-point parameters are not supported for row-major code generation.

Tips

- For code generation, before calling `coder.ceval`, you must specify the type, size, and complexity data type of return values and output arguments.
- To apply `coder.ceval` to a function that accepts or returns variables that do not exist in MATLAB code, such as pointers, FILE types for file I/O, and C/C++ macros, use the `coder.opaque` function.
- Use `coder.ceval` only in MATLAB for code generation. `coder.ceval` generates an error in uncompiled MATLAB code. To determine if a MATLAB function is executing in MATLAB, use `coder.target`. If the function is executing in MATLAB, call the MATLAB version of the C/C++ function.

- External code called by using `coder.ceval` and the generated code run within the same process and share memory. If external code erroneously writes to the memory that contains data structures used by the generated code, it might cause the process to behave unexpectedly or crash. For example, if the external code attempts to write data to an array after its end point, the process might behave unexpectedly or crash.
- MATLAB uses UTF-8 as its system encoding on Windows platform. As a result, system calls made from within a generated MEX function accept and return UTF-8 encoded strings. By contrast, the code generated by MATLAB Coder encodes text data by using the encoding specified by the Windows locale. So, if your MATLAB entry-point function uses `coder.ceval` to call external C/C++ functions that assume a different system encoding, then the generated MEX function might produce garbled text. If this happens, you must update the external C/C++ functions to handle this situation.

Version History

coder.cinclude

Include header file in generated code

Syntax

```
coder.cinclude(headerfile)
coder.cinclude(headerfile, 'InAllSourceFiles', allfiles)
```

Description

`coder.cinclude(headerfile)` includes a header file in generated C/C++ source code.

MATLAB Coder generates the include statement in the C/C++ source files that are generated from the MATLAB code that contains the `coder.cinclude` call.

In a Simulink model, when a `coder.cinclude` call appears in a MATLAB Function block, the code generator puts the include statement in the model header file.

Note Place a `coder.cinclude` call as close as possible to the `coder.ceval` call that requires the header file.

`coder.cinclude(headerfile, 'InAllSourceFiles', allfiles)` uses the `allfiles` option to determine whether to include the header file in almost all C/C++ source files.

If `allfiles` is true, MATLAB Coder generates the include statement in almost all C/C++ source files, except for some utility files. This behavior is the `coder.cinclude` behavior from R2016a and earlier releases. The presence of the include statement in these additional files can increase compile time and make the generated code less readable. Use this option only if your code depends on the legacy behavior. If `allfiles` is false, the behavior is the same as the behavior of `coder.cinclude(headerfile)`.

In a MATLAB Function block, `coder.cinclude(headerfile, 'InAllSourceFiles', allfiles)` is the same as `coder.cinclude(headerfile)`.

Examples

Include Header File in C/C++ Code Generated by Using the MATLAB Coder codegen Command

Generate code from a MATLAB function that calls an external C function. Use `coder.cinclude` to include the required header file in the generated C code.

In a writable folder, create a subfolder `mycfiles`.

Write a C function `myMult2.c` that doubles its input. Save it in `mycfiles`.

```
#include "myMult2.h"
double myMult2(double u)
```

```
{
    return 2 * u;
}
```

Write the header file `myMult2.h`. Save it in `mycfiles`.

```
#if !defined(MYMULT2)
#define MYMULT2
extern double myMult2(double);
#endif
```

Write a MATLAB function, `myfunc`, that includes `myMult2.h` and calls `myMult2` for code generation only.

```
function y = myfunc
%#codegen
y = 21;
if ~coder.target('MATLAB')
    % Running in generated code
    coder.cinclude('myMult2.h');
    y = coder.ceval('myMult2', y);
else
    % Running in MATLAB
    y = y * 2;
end
end
```

Create a code configuration object for a static library. Specify the locations of `myMult2.h` and `myMult2.c`.

```
cfg = coder.config('lib');
cfg.CustomInclude = fullfile(pwd, 'mycfiles');
cfg.CustomSource = fullfile(pwd, 'mycfiles', 'myMult2.c');
```

Generate the code.

```
codegen -config cfg myfunc -report
```

The file `myfunc.c` contains this statement:

```
#include "myMult2.h"
```

The include statement does not appear in any other file.

Include Header File in C/C++ Code Generated from a MATLAB Function Block in a Simulink Model

Generate code from a MATLAB Function block that calls an external C function. Use `coder.cinclude` to include the required header file in the generated C code.

In a writable folder, create a subfolder `mycfiles`.

Write a C function `myMult2.c` that doubles its input. Save it in `mycfiles`.

```
#include "myMult2.h"
double myMult2(double u)
```

```
{
    return 2 * u;
}
```

Write the header file `myMult2.h`. Save it in `mycfiles`.

```
#if !defined(MYMULT2)
#define MYMULT2
extern double myMult2(double);
#endif
```

Create a Simulink model that contains a MATLAB Function block connected to an Output block.

In the MATLAB Function block, add the function `myfunc` that includes `myMult2.h` and calls `myMult2`.

```
function y = myfunc
%#codegen
y = 21;
coder.cinclude('myMult2.h');
y = coder.ceval('myMult2', y);
% Specify the locations of myMult2.h and myMult2.c
coder.extrinsic('pwd', 'fullfile');
customDir = coder.const(fullfile(pwd, 'mycfiles'));
coder.updateBuildInfo('addIncludePaths', customDir);
coder.updateBuildInfo('addSourcePaths', customDir);
coder.updateBuildInfo('addSourceFiles', 'myMult2.c');
end
```

Open the Configuration Parameters dialog box.

On the **Solver** pane, select a fixed-step solver.

Save the model as `mymodel`.

Build the model.

The file `mymodel.h` contains this statement:

```
#include "myMult2.h"
```

To read more about integrating custom code in a MATLAB Function block, see “Integrate C Code by Using the MATLAB Function Block”.

Input Arguments

headerfile — Name of header file

character vector | string scalar

Name of a header file specified as a character vector or string scalar. `headerfile` must be a compile-time constant.

Enclose a system header file name in angle brackets < >. The generated `#include` statement for a system header file has the format `#include <sysheader>`. A system header file must be in a standard location or on the include path. Specify the include path by using code generation custom code parameters.

Example: `coder.cinclude('<sysheader.h>')`

For a header file that is not a system header file, omit the angle brackets. The generated `#include` statement for a header file that is not a system header file has the format `#include "myHeader"`. The header file must be in the current folder or on the include path. Specify the include path by using code generation custom code parameters.

Example: `coder.cinclude('myheader.h')`

Data Types: `char`

allfiles — All source files option

`true` | `false`

Option to include header file in all generated C/C++ source files. If `allfiles` is `true`, MATLAB Coder generates the include statement in almost all of the C/C++ source files, except for some utility files. If `allfiles` is `false`, the behavior is the same as the behavior of `coder.cinclude(headerfile)`.

In a MATLAB Function block, the code generator ignores the all source files option.

Data Types: `logical`

Limitations

- Do not call `coder.cinclude` inside run-time conditional constructs such as `if` statements, `switch` statements, `while`-loops, and `for`-loops. You can call `coder.cinclude` inside compile-time conditional statements, such as `coder.target`. For example:

```
...
if ~coder.target('MATLAB')
    coder.cinclude('foo.h');
    coder.ceval('foo');
end
...
```

Tips

- Before a `coder.ceval` call, call `coder.cinclude` to include the header file required by the external function that `coder.ceval` calls.
- Extraneous include statements in generated C/C++ code can increase compile time and reduce code readability. To avoid extraneous include statements in code generated by MATLAB Coder, follow these best practices:
 - Place a `coder.cinclude` call as close as possible to the `coder.ceval` call that requires the header file.
 - Do not set `allfiles` to `true`.

For the MATLAB Function block, the code generator generates the include statement in the model header file.

- In R2016a and earlier releases, for any `coder.cinclude` call, MATLAB Coder included the header file in almost all generated C/C++ source files, except for some utility files. If you have code that depends on this legacy behavior, you can preserve the legacy behavior by using this syntax:

```
coder.cinclude(headerfile,'InAllSourceFiles',true)
```

coder.columnMajor

Specify column-major array layout for a function or class

Syntax

```
coder.columnMajor
```

Description

`coder.columnMajor` specifies column-major array layout for the data used by the current function in generated code. When placed in a class constructor, `coder.columnMajor` specifies column-major layout for data used by the class.

Note By default, code generation uses column-major array layout.

Examples

Specify Column-Major Array Layout for a Function

Specify column-major array layout for a function by inserting `coder.columnMajor` into the function body.

Suppose that `myFunction` is the top-level function of your code. Your application requires you to perform matrix addition with column-major array layout and matrix multiplication with row-major layout.

```
function S = myFunction(A,B)
%#codegen
% check to make sure inputs are valid
if size(A,1) ~= size(B,1) || size(A,2) ~= size(B,2)
    disp('Matrices must be same size.')
    return;
end
% make both matrices symmetric
B = B*B';
A = A*A';
% add matrices
S = addMatrix(A,B);
end
```

Write a function for matrix addition called `addMatrix`. Specify column-major for `addMatrix` by using `coder.columnMajor`.

```
function S = addMatrix(A,B)
%#codegen
S = zeros(size(A));
coder.columnMajor; % specify column-major array layout
S = A + B;
end
```

Generate code for `myFunction`. Use the `codegen` command.

```
codegen myFunction -args {ones(10,20),ones(10,20)} -config:lib -launchreport -rowmajor
```

Because of the `codegen -rowmajor` option, the matrix multiplication in `myFunction` uses row-major layout. However, the generated code for `addMatrix` uses column-major array layout due to the `coder.columnMajor` call.

Tips

- The code generator uses column-major array layout by default.
- The specification of array layout inside a function supersedes the array layout specified with the `codegen` command. For example, if the function `foo` contains `coder.columnMajor`, and you generate code by using:

```
codegen foo -rowmajor
```

then the generated code still uses column-major layout.
- Other functions called from within a column-major function inherit the column-major specification. However, if one of the called functions has its own distinct `coder.rowMajor` call, the code generator changes the array layout accordingly. If a row-major function and a column-major function call the same function, which does not have its own array layout specification, the code generator produces a row-major version and column-major version of the function.
- `coder.columnMajor` is ignored outside of code generation and simulation.

coder.const

Fold expressions into constants in generated code

Syntax

```
out = coder.const(expression)
[out1,...,outN] = coder.const(handle,arg1,...,argN)
```

Description

`out = coder.const(expression)` evaluates `expression` and replaces `out` with the result of the evaluation in generated code.

`[out1,...,outN] = coder.const(handle,arg1,...,argN)` evaluates the multi-output function having handle `handle`. It then replaces `out1,...,outN` with the results of the evaluation in the generated code.

Examples

Specify Constants in Generated Code

This example shows how to specify constants in generated code using `coder.const`.

Write a function `AddShift` that takes an input `Shift` and adds it to the elements of a vector. The vector consists of the square of the first 10 natural numbers. `AddShift` generates this vector.

```
function y = AddShift(Shift) %#codegen
y = (1:10).^2+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator produces code for creating the vector. It adds `Shift` to each element of the vector during vector creation. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int k;
    for (k = 0; k < 10; k++) {
        y[k] = (double)((1 + k) * (1 + k)) + Shift;
    }
}
```

Replace the expression `(1:10).^2` with `coder.const((1:10).^2)`, and then generate code for `AddShift` again using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator creates the vector containing the squares of the first 10 natural numbers. In the generated code, it adds `Shift` to each element of this vector. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int i;
    static const signed char iv[10] = { 1, 4, 9, 16, 25, 36,
                                        49, 64, 81, 100 };

    for (i = 0; i < 10; i++) {
        y[i] = (double)iv[i] + Shift;
    }
}
```

Create Lookup Table in Generated Code

This example shows how to fold a user-written function into a constant in generated code.

Write a function `getsine` that takes an input `index` and returns the element referred to by `index` from a lookup table of sines. The function `getsine` creates the lookup table using another function `gettable`.

```
function y = getsine(index) %#codegen
    assert(isa(index, 'int32'));
    persistent tbl;
    if isempty(tbl)
        tbl = gettable(1024);
    end
    y = tbl(index);

function y = gettable(n)
    y = zeros(1,n);
    for i = 1:n
        y(i) = sin((i-1)/(2*pi*n));
    end
```

Generate code for `getsine` using an argument of type `int32`. Open the Code Generation Report.

```
codegen -config:lib -launchreport getsine -args int32(0)
```

The generated code contains instructions for creating the lookup table.

Replace the statement:

```
tbl = gettable(1024);
```

with:

```
tbl = coder.const(gettable(1024));
```

Generate code for `getsine` using an argument of type `int32`. Open the Code Generation Report.

The generated code contains the lookup table itself. `coder.const` forces the expression `gettable(1024)` to be evaluated during code generation. The generated code does not contain instructions for the evaluation. The generated code contains the result of the evaluation itself.

Specify Constants in Generated Code Using Multi-Output Function

This example shows how to specify constants in generated code using a multi-output function in a `coder.const` statement.

Write a function `MultiplyConst` that takes an input `factor` and multiplies every element of two vectors `vec1` and `vec2` with `factor`. The function generates `vec1` and `vec2` using another function `EvalConsts`.

```
function [y1,y2] = MultiplyConst(factor) %#codegen
    [vec1,vec2]=EvalConsts(pi.*(1./2.^(1:10)),2);
    y1=vec1.*factor;
    y2=vec2.*factor;

function [f1,f2]=EvalConsts(z,n)
    f1=z.^(2*n)/factorial(2*n);
    f2=z.^(2*n+1)/factorial(2*n+1);
```

Generate code for `MultiplyConst` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport MultiplyConst -args 0
```

The code generator produces code for creating the vectors.

Replace the statement

```
[vec1,vec2]=EvalConsts(pi.*(1./2.^(1:10)),2);
```

with

```
[vec1,vec2]=coder.const(@EvalConsts,pi.*(1./2.^(1:10)),2);
```

Generate code for `MultiplyConst` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport MultiplyConst -args 0
```

The code generator does not generate code for creating the vectors. Instead, it calculates the vectors and specifies the calculated vectors in generated code.

Read Constants by Processing XML File

This example shows how to call an extrinsic function using `coder.const`.

Write an XML file `MyParams.xml` containing the following statements:

```
<params>
  <param name="hello" value="17"/>
  <param name="world" value="42"/>
</params>
```

Save `MyParams.xml` in the current folder.

Write a MATLAB function `xml2struct` that reads an XML file. The function identifies the XML tag `param` inside another tag `params`.

After identifying `param`, the function assigns the value of its attribute `name` to the field name of a structure `s`. The function also assigns the value of attribute `value` to the value of the field.

```
function s = xml2struct(file)

s = struct();
doc = xmlread(file);
els = doc.getElementsByTagName('params');
for i = 0:els.getLength-1
    it = els.item(i);
    ps = it.getElementsByTagName('param');
    for j = 0:ps.getLength-1
        param = ps.item(j);
        paramName = char(param.getAttribute('name'));
        paramValue = char(param.getAttribute('value'));
        paramValue = evalin('base', paramValue);
        s.(paramName) = paramValue;
    end
end
```

Save `xml2struct` in the current folder.

Write a MATLAB function `MyFunc` that reads the XML file `MyParams.xml` into a structure `s` using the function `xml2struct`. Declare `xml2struct` as extrinsic using `coder.extrinsic` and call it in a `coder.const` statement.

```
function y = MyFunc(u) %#codegen
    assert(isa(u, 'double'));
    coder.extrinsic('xml2struct');
    s = coder.const(xml2struct('MyParams.xml'));
    y = s.hello + s.world + u;
```

Generate code for `MyFunc` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:dll -launchreport MyFunc -args 0
```

The code generator executes the call to `xml2struct` during code generation. It replaces the structure fields `s.hello` and `s.world` with the values 17 and 42 in generated code.

Input Arguments

expression — MATLAB expression or user-written function

expression with constants | single-output function with constant arguments

MATLAB expression or user-defined single-output function.

The expression must have compile-time constants only. The function must take constant arguments only. For instance, the following code leads to a code generation error, because `x` is not a compile-time constant.

```
function y=func(x)
    y=coder.const(log10(x));
```

To fix the error, assign `x` to a constant in the MATLAB code. Alternatively, during code generation, you can use `coder.Constant` to define input type as follows:

```
codegen -config:lib func -args coder.Constant(10)
```

Example: `2*pi, factorial(10)`

handle — Function handle

function handle

Handle to built-in or user-written function.

Example: `@log, @sin`

Data Types: `function_handle`

arg1, ..., argN — Arguments to the function with handle handle

function arguments that are constants

Arguments to the function with handle `handle`.

The arguments must be compile-time constants. For instance, the following code leads to a code generation error, because `x` and `y` are not compile-time constants.

```
function y=func(x,y)
    y=coder.const(@choosek,x,y);
```

To fix the error, assign `x` and `y` to constants in the MATLAB code. Alternatively, during code generation, you can use `coder.Constant` to define input type as follows:

```
codegen -config:lib func -args {coder.Constant(10),coder.Constant(2)}
```

Output Arguments

out — Value of expression

value of the evaluated expression

Value of expression. In the generated code, MATLAB Coder replaces occurrences of `out` with the value of expression.

out1, ..., outN — Outputs of the function with handle handle

values of the outputs of the function with handle `handle`

Outputs of the function with handle `handle`. MATLAB Coder evaluates the function and replaces occurrences of `out1, ..., outN` with constants in the generated code.

Tips

- When possible, the code generator constant-folds expressions automatically. Typically, automatic constant-folding occurs for expressions with scalars only. Use `coder.const` when the code generator does not constant-fold expressions on its own.
- When constant-folding computationally intensive function calls, to reduce code generation time, make the function call extrinsic. The extrinsic function call causes evaluation of the function call by MATLAB instead of by the code generator. For example:

```
function j = fcn(z)
zTable = coder.const(0:0.01:100);
jTable = coder.const(feval('besselj',3,zTable));
j = interp1(zTable,jTable,z);
end
```

See “Use coder.const with Extrinsic Function Calls” (MATLAB Coder).

- If `coder.const` is unable to constant-fold a function call, try to force constant-folding by making the function call extrinsic. The extrinsic function call causes evaluation of the function call by MATLAB instead of by the code generator. For example:

```
function yi = fcn(xi)
y = coder.const(feval('rand',1,100));
yi = interp1(y,xi);
end
```

See “Use coder.const with Extrinsic Function Calls” (MATLAB Coder).

coder.cstructname

Package: coder

Name C structure type in generated code

Syntax

```
coder.cstructname(var,structName)
coder.cstructname(var,structName,'extern','HeaderFile',headerfile)
coder.cstructname(var,structName,'extern','HeaderFile',
headerfile,'Alignment',alignment)

outtype = coder.cstructname(intype,structName)
outtype = coder.cstructname(intype,structName,'extern','HeaderFile',
headerfile)
outtype = coder.cstructname(intype,structName,'extern','HeaderFile',
headerfile,'Alignment',alignment)
```

Description

`coder.cstructname` names the generated or externally defined C structure type to use for MATLAB variables that are represented as structures in generated code.

`coder.cstructname(var,structName)` names the C structure type generated for the MATLAB variable `var`. The input `var` can be a structure or a cell array. Use this syntax in a function from which you generate code. Place `coder.cstructname` after the definition of `var` and before the first use of `var`. If `var` is an entry-point (top-level) function input argument, place `coder.cstructname` at the beginning of the function, before any control flow statements.

`coder.cstructname(var,structName,'extern','HeaderFile',headerfile)` specifies that the C structure type to use for `var` has the name `structName` and is defined in the external file, `headerfileName`.

It is possible to use the 'extern' option without specifying the header file. However, it is a best practice to specify the header file so that the code generator produces the `#include` statement in the correct location.

`coder.cstructname(var,structName,'extern','HeaderFile',headerfile,'Alignment',alignment)` also specifies the run-time memory alignment for the externally defined structure type `structName`. If you have Embedded Coder and use custom Code Replacement Libraries (CRLs), specify the alignment so that the code generator can match CRL functions that require alignment for structures. See “Data Alignment for Code Replacement” (Embedded Coder).

`outtype = coder.cstructname(intype,structName)` returns a structure or cell array type object `outtype` that specifies the name of the C structure type to generate. `coder.cstructname` creates `outtype` with the properties of the input type `intype`. Then, it sets the `TypeName` property to `structName`. Use this syntax to create a type object that you use with the `codegen -args` option. You cannot use this syntax in a function from which you generate code.

You cannot use this syntax in a MATLAB Function block.

`outtype = coder.cstructname(intype, structName, 'extern', 'HeaderFile', headerfile)` returns a type object `outtype` that specifies the name and location of an externally defined C structure type. The code generator uses the externally defined structure type for variables with type `outtype`.

You cannot use this syntax in a MATLAB Function block.

`outtype = coder.cstructname(intype, structName, 'extern', 'HeaderFile', headerfile, 'Alignment', alignment)` creates a type object `outtype` that also specifies the C structure type alignment.

You cannot use this syntax in a MATLAB Function block.

Examples

Name the C Structure Type for a Variable in a Function

In a MATLAB function, `myfun`, assign the name `MyStruct` to the generated C structure type for the variable `v`.

```
function y = myfun()
%#codegen
v = struct('a',1,'b',2);
coder.cstructname(v, 'myStruct');
y = v;
end
```

Generate standalone C code. For example, generate a static library.

```
codegen -config:lib myfun -report
```

To see the generated structure type, open `codegen/lib/myfun/myfun_types.h` or view `myfun_types.h` in the code generation report. The generated C structure type is:

```
typedef struct {
    double a;
    double b;
} myStruct;
```

Name the C Structure Type Generated for a Substructure

In a MATLAB function, `myfun1`, assign the name `MyStruct` to the generated C structure type for the structure `v`. Assign the name `mysubStruct` to the structure type generated for the substructure `v.b`.

```
function y = myfun()
%#codegen
v = struct('a',1,'b',struct('f',3));
coder.cstructname(v, 'myStruct');
coder.cstructname(v.b, 'mysubStruct');
y = v;
end
```

The generated C structure type `mysubStruct` is:

```
typedef struct {
    double f;
} mysubStruct;
```

The generated C structure type `myStruct` is:

```
typedef struct {
    double a;
    mysubStruct b;
} myStruct;
```

Name the Structure Type Generated for a Cell Array

In a MATLAB function, `myfun2`, assign the name `myStruct` to the generated C structure type for the cell array `c`.

```
function z = myfun2()
c = {1 2 3};
coder.cstructname(c, 'myStruct')
z = c;
```

The generated C structure type for `c` is:

```
typedef struct {
    double f1;
    double f2;
    double f3;
} myStruct;
```

Name an Externally Defined C Structure Type

Specify that a structure passed to a C function has a structure type defined in a C header file.

Create a C header file `mycadd.h` for the function `mycadd` that takes a parameter of type `mycstruct`. Define the type `mycstruct` in the header file.

```
#ifndef MYCADD_H
#define MYCADD_H

typedef struct {
    double f1;
    double f2;
} mycstruct;

double mycadd(mycstruct *s);
#endif
```

Write the C function `mycadd.c`.

```
#include <stdio.h>
#include <stdlib.h>
```

```
#include "mycadd.h"

double mycadd(mycstruct *s)
{
    return s->f1 + s->f2;
}
```

Write a MATLAB function `mymAdd` that passes a structure by reference to `mycadd`. Use `coder.cstructname` to specify that in the generated code, the structure has the C type `mycstruct`, which is defined in `mycadd.h`.

```
function y = mymAdd
%#codegen
s = struct('f1', 1, 'f2', 2);
coder.cstructname(s, 'mycstruct', 'extern', 'HeaderFile', 'mycadd.h');
y = 0;
y = coder.ceval('mycadd', coder.ref(s));
```

Generate a C static library for function `mymAdd`.

```
codegen -config:lib mymAdd mycadd.c
```

The generated header file `mymadd_types.h` does not contain a definition of the structure `mycstruct` because `mycstruct` is an external type.

Create a Structure Type Object That Names the Generated C Structure Type

Suppose that the entry-point function `myFunction` takes a structure argument. To specify the type of the input argument at the command line:

- 1 Define an example structure `S`.
- 2 Create a type `T` from `S` by using `coder.typeof`.
- 3 Use `coder.cstructname` to create a type `T1` that:
 - Has the properties of `T`.
 - Names the generated C structure type `myStruct`.
- 4 Pass the type to `codegen` by using the `-args` option.

For example:

```
S = struct('a',double(0),'b',single(0));
T = coder.typeof(S);
T1 = coder.cstructname(T,'myStruct');
codegen -config:lib myFunction -args T1
```

Alternatively, you can create the structure type directly from the example structure.

```
S = struct('a',double(0),'b',single(0));
T1 = coder.cstructname(S,'myStruct');
codegen -config:lib myFunction -args T1
```

Input Arguments

var — MATLAB structure or cell array variable

structure | cell array

MATLAB structure or cell array variable that is represented as a structure in the generated code.

structName — Name of C structure type

character vector | string scalar

Name of generated or externally defined C structure type, specified as a character vector or string scalar.

headerfile — Header file that contains the C structure type definition

character vector | string scalar

Header file that contains the C structure type definition, specified as a character vector or string scalar.

To specify the path to the file:

- Use the `codegen -I` option or the **Additional include directories** parameter on the MATLAB Coder app settings **Custom Code** tab.
- For a MATLAB Function block, on the **Simulation Target** and the **Code Generation > Custom Code** panes, under **Additional build information**, set the **Include directories** parameter.

Alternatively, use `coder.updateBuildInfo` with the `'addIncludePaths'` option.

Example: `'mystruct.h'`

alignment — Run-time memory alignment for structure

-1 (default) | power of 2

Run-time memory alignment for generated or externally defined structure.

intype — Type object or variable for creation of new type object

`coder.StructType` | `coder.CellType` | structure | cell array

Structure type object, cell array type object, structure variable, or cell array variable from which to create a type object.

Limitations

- You cannot apply `coder.cstructname` directly to a global variable. To name the structure type to use with a global variable, use `coder.cstructname` to create a type object that names the structure type. Then, when you run `codegen`, specify that the global variable has that type. See “Name the C Structure Type to Use With a Global Structure Variable” (MATLAB Coder).
- For cell array inputs, the field names of externally defined structures must be `f1`, `f2`, and so on.
- You cannot apply `coder.cstructname` directly to a class property.

Tips

- For information about how the code generator determines the C/C++ types of structure fields, see “Mapping MATLAB Types to Types in Generated Code” (MATLAB Coder).
- Using `coder.cstructname` on a structure array sets the name of the structure type of the base element, not the name of the array. Therefore, you cannot apply `coder.cstructname` to a structure array element, and then apply it to the array with a different C structure type name. For example, the following code is not allowed. The second `coder.cstructname` attempts to set the name of the base type to `myStructArrayName`, which conflicts with the previously specified name, `myStructName`.

```
% Define scalar structure with field a
myStruct = struct('a', 0);
coder.cstructname(myStruct, 'myStructName');
% Define array of structure with field a
myStructArray = repmat(myStruct,4,6);
coder.cstructname(myStructArray, 'myStructArrayName');
```

- Applying `coder.cstructname` to an element of a structure array produces the same result as applying `coder.cstructname` to the entire structure array. If you apply `coder.cstructname` to an element of a structure array, you must refer to the element by using a single subscript. For example, you can use `var(1)`, but not `var(1,1)`. Applying `coder.cstructname` to `var(:)` produces the same result as applying `coder.cstructname` to `var` or `var(n)`.
- Heterogeneous cell arrays are represented as structures in the generated code. Here are considerations for using `coder.cstructname` with cell arrays:
 - In a function from which you generate code, using `coder.cstructname` with a cell array variable makes the cell array heterogeneous. Therefore, if a cell array is an entry-point function input and its type is permanently homogeneous, then you cannot use `coder.cstructname` with the cell array.
 - Using `coder.cstructname` with a homogeneous `coder.CellType` object `intype` makes the returned object heterogeneous. Therefore, you cannot use `coder.cstructname` with a permanently homogeneous `coder.CellType` object. For information about when a cell array is permanently homogeneous, see “Specify Cell Array Inputs at the Command Line” (MATLAB Coder).
 - When used with a `coder.CellType` object, `coder.cstructname` creates a `coder.CellType` object that is permanently heterogeneous.
- When you use a structure named by `coder.cstructname` in a project with row-major and column-major array layouts, the code generator renames the structure in certain cases, appending `row_` or `col_` to the beginning of the structure name. This renaming provides unique type definitions for the types that are used in both array layouts.
- These tips apply only to MATLAB Function blocks:
 - MATLAB Function block input and output structures are associated with bus signals. The generated name for the structure type comes from the bus signal name. Do not use `coder.cstructname` to name the structure type for input or output signals. See “Create Structures in MATLAB Function Blocks”.
 - The code generator produces structure type names according to identifier naming rules, even if you name the structure type with `coder.cstructname`. If you have Embedded Coder, you can customize the naming rules. See “Construction of Generated Identifiers” (Embedded Coder).

coder.extrinsic

Declare a function as extrinsic and execute it in MATLAB

Syntax

```
coder.extrinsic(function)
coder.extrinsic(function1, ... ,functionN)

coder.extrinsic('-sync:on', function1, ... ,functionN)
coder.extrinsic('-sync:off', function1, ... ,functionN)
```

Description

`coder.extrinsic(function)` declares `function` as an extrinsic function. The code generator does not produce code for the body of the extrinsic function and instead uses the MATLAB engine to execute the call. This functionality is available only when the MATLAB engine is available during execution. Examples of situations where the MATLAB engine is available include execution of MEX functions, Simulink simulations, or function calls at the time of code generation (also known as compile time).

During standalone code generation, the code generator attempts to determine whether an extrinsic function only has a side effect (for example, by displaying a plot) or whether it affects the output of the function in which it is called (for example, by returning a value to an output variable). If there is no change to the output, the code generator proceeds with code generation, but excludes the extrinsic function from the generated code. Otherwise, the code generator produces a compilation error.

You cannot use `coder.ceval` on functions that you declare as extrinsic by using `coder.extrinsic`. Also, the `coder.extrinsic` directive is ignored outside of code generation.

See “Use MATLAB Engine to Execute a Function Call in Generated Code”.

Note The code generator automatically treats many common MATLAB visualization functions, such as `plot`, `disp`, and `figure`, as extrinsic. You do not have to explicitly declare them as extrinsic functions by using `coder.extrinsic`.

`coder.extrinsic(function1, ... ,functionN)` declares `function1` through `functionN` as extrinsic functions.

`coder.extrinsic('-sync:on', function1, ... ,functionN)` enables synchronization of global data between MATLAB execution and generated code execution or Simulink simulation before and after calls to the extrinsic functions `function1` through `functionN`. If only a few extrinsic calls use or modify global data, turn off synchronization before and after all extrinsic function calls by setting the global synchronization mode to `At MEX-function entry and exit`. Use the `'-sync:on'` option to turn on synchronization for only the extrinsic calls that do modify global data.

If you use MATLAB Coder to generate a MEX function, the `'-sync:on'` option enables verification of consistency of constant global data between MATLAB and MEX functions after calls to the extrinsic functions.

See “Generate Code for Global Data” (MATLAB Coder).

`coder.extrinsic('-sync:off', function1, ... ,functionN)` disables synchronization of global data between MATLAB execution and generated code execution before and after calls to the extrinsic functions `function1` through `functionN`. If most extrinsic calls use or modify global data, but a few do not, use the `'-sync:off'` option to turn off synchronization for the extrinsic calls that do not modify global data.

If you use MATLAB Coder to generate a MEX function, the `'-sync:off'` option disables verification of consistency of constant global data between MATLAB and MEX functions after calls to the extrinsic functions.

See “Generate Code for Global Data” (MATLAB Coder).

Examples

Declare a Function as Extrinsic

The MATLAB function `str2num` is not supported for code generation. This example shows how you can still use the functionality of `str2num` in your generated MEX function by declaring `str2num` as extrinsic in your MATLAB function.

This MATLAB code declares `str2num` as extrinsic in the local function `convertStringToNumber`. By declaring `str2num` as extrinsic, you instruct the code generator not to produce code for `str2num`. Instead, the code generator dispatches `str2num` to MATLAB for execution.

```
function n = convertStringToNumber(c)
    %#codegen
    coder.extrinsic('str2num');
    n = str2num(c);
end
```

Generate a MEX function for `convertStringToNumber`.

```
codegen convertStringToNumber -args {coder.typeof('c', [1 Inf])} -report
```

In the report, you can view the generated code.

```
/* Function Definitions */
static const mxArray *str2num(const emlrtStack *sp,
                             const mxArray *m1,emlrtMCInfo *location)
{
    const mxArray *m;
    const mxArray *pArray;
    pArray = m1;
    return emlrtCallMATLABR2012b((emlrtConstCTX)sp, 1, &m, 1,
                                &pArray, "str2num", true, location);
}
```

Return Output of Extrinsic Function to MATLAB at Run Time

The output that an extrinsic function returns at run time is an `mxArray`, also known as a MATLAB array. The only valid operations for an `mxArray` are storing it in a variable, passing it to another

extrinsic function, or returning it to MATLAB. To perform any other operation on an mxArray value, such as using it in an expression in your code, you must convert the mxArray to a known type at run time. To perform this action, assign the mxArray to a variable whose type is already defined by a prior assignment.

This example shows how to return an mxArray output from an extrinsic function directly to MATLAB. The next example shows how to convert the same mxArray output to a known type, and then use it in an expression inside your MATLAB function.

Define Entry-Point Function

Define a MATLAB function `return_extrinsic_output` that accepts source and target node indices for a directed graph as inputs and determines if the graph is acyclic by using the `hascycles` function. The `hascycles` function is not supported for code generation and is declared as extrinsic.

```
type return_extrinsic_output.m

function hasCycles = return_extrinsic_output(source,target)
coder.extrinsic('hascycles');
assert(numel(source) == numel(target))
G = digraph(source,target);
hasCycles = hascycles(G);
end
```

Generate and Call MEX Function

Generate MEX code for `return_extrinsic_output`. Specify the inputs to be unbounded vectors of type double.

```
codegen return_extrinsic_output -args {coder.typeof(0,[1 Inf]),coder.typeof(0,[1 Inf])} -report
```

Code generation successful: To view the report, open('codegen\mex\return_extrinsic_output\html\report.html')

Call the generated MEX function `return_extrinsic_output_mex` with suitable inputs:

```
return_extrinsic_output([1 2 4 4],[2 3 3 1])

ans = logical
     0
```

To visually inspect if the directed graph has cycles, plot the directed graph in MATLAB.

```
plot(digraph([1 2 4 4],[2 3 3 1]))
```

Use Output of Extrinsic Function in an Expression at Run Time

The output that an extrinsic function returns is an `mxAarray`, also known as a MATLAB array. The only valid operations for an `mxAarray` are storing it in a variable, passing it to another extrinsic function, or returning it to MATLAB. To perform any other operation on an `mxAarray` value, such as using it in an expression in your code, convert the `mxAarray` to a known type at run time. To perform this action, assign the `mxAarray` to a variable whose type is already defined by a prior assignment.

This example shows how to convert the `mxAarray` output of an extrinsic function to a known type, and then use the output in an expression inside your MATLAB function.

Define Entry-Point Function

Define a MATLAB function `use_extrinsic_output` that accepts source and target node indices for a directed graph as inputs and determines if the graph is acyclic by using the `hascycles` function. The `hascycles` function is not supported for code generation and is declared as extrinsic. The entry-point function displays a message based on the output of the `hascycles` function.

```

type use_extrinsic_output

function use_extrinsic_output(source,target) %#codegen
assert(numel(source) == numel(target))
G = digraph(source,target);

coder.extrinsic('hascycles');
  
```

```
hasCycles = true;

hasCycles = hascycles(G);
if hasCycles == true
    disp('The graph has cycles')
else
    disp('The graph does not have cycles')
end
end
```

The local variable `hasCycles` is first preassigned the Boolean value `true` before the assignment `hasCycles = hascycles(G)` occurs. This preassignment enables the code generator to convert the `mxAarray` that the extrinsic function `hascycles` returns to a Boolean before assigning it to the `hasCycles` variable. This conversion in turn enables you to compare `hasCycles` with the Boolean `true` in the condition of the `if` statement.

Generate and Call MEX Function

Generate MEX code for `use_extrinsic_output`. Specify the inputs to be unbounded vectors of type `double`.

```
codegen use_extrinsic_output -args {coder.typeof(0,[1 Inf]),coder.typeof(0,[1 Inf])} -report
```

Code generation successful: To view the report, open('codegen\mex\use_extrinsic_output\html\report.html')

Call the generated MEX function `use_extrinsic_output_mex` with suitable inputs:

```
use_extrinsic_output_mex([1 2 4 4],[2 3 3 1])
```

```
The graph does not have cycles
```

To see if the directed graph has cycles, plot the graph in MATLAB.

```
plot(digraph([1 2 4 4],[2 3 3 1]))
```

Evaluate Extrinsic Function Call at Compile Time by Using `coder.const`

This example shows how to call an extrinsic function at the time of code generation (also known as compile time) by using `coder.const`. Because the MATLAB engine is always available during the evaluation of the expression inside `coder.const`, you can use this coding pattern when generating either MEX or standalone code. Unlike the previous two examples that show run-time execution, you do not need to explicitly convert the output of the extrinsic function to a known type if its evaluation happens at compile time.

In this example, the entry-point function `rotate_complex` invokes another function `xml2struct` that uses the MATLAB API for XML processing. Because code generation does not support the MATLAB API for XML processing, the `xml2struct` function is declared as extrinsic in the body of the entry-point function. Also, the call to `xml2struct` inside the entry-point function returns a compile-time constant. So, this output is constant-folded by placing the function call inside the `coder.const` directive.

Inspect XML File Containing Parameters

The supporting file `complex.xml` contains the values of real and imaginary parts of a complex number.

```
type complex.xml
```

```
<params>
  <param name="real" value="3"/>
```

```
<param name="imaginary" value="4"/>
</params>
```

Define xml2struct Function

The MATLAB function `xml2struct` reads an XML file that uses the format of `complex.xml` to store parameter names and values, stores this information as structure fields, and returns this structure.

type `xml2struct.m`

```
function s = xml2struct(file)
s = struct();
import matlab.io.xml.dom.*
doc = parseFile(Parser,file);
els = doc.getElementsByTagName("params");
for i = 0:els.getLength-1
    it = els.item(i);
    ps = it.getElementsByTagName("param");
    for j = 0:ps.getLength-1
        param = ps.item(j);
        paramName = char(param.getAttribute("name"));
        paramValue = char(param.getAttribute("value"));
        paramValue = evalin("base", paramValue);
        s.(paramName) = paramValue;
    end
end
```

Define Entry-Point Function

Your MATLAB entry-point function `rotate_complex` first calls `xml2struct` to read the file `complex.xml`. It then rotates the complex number by an angle that is equal to the input argument `theta` in degrees and returns the resulting complex number.

type `rotate_complex.m`

```
function y = rotate_complex(theta) %#codegen
coder.extrinsic("xml2struct");
s = coder.const(xml2struct("complex.xml"));

comp = s.real + 1i * s.imaginary;
magnitude = abs(comp);
phase = angle(comp) + deg2rad(theta);
y = magnitude * cos(phase) + 1i * sin(phase);

end
```

The `xml2struct` function is declared as extrinsic and its output is constant-folded by placing the function inside the `coder.const` directive.

Generate and Inspect Static Library

Generate a static library for `read_complex` by using the `codegen` (MATLAB Coder) command. Specify the input type to be a scalar double.

```
codegen -config:lib rotate_complex -args {0} -report
```

Warning: Code generation is using a `coder.EmbeddedCodeConfig` object. Because Embedded Coder is not installed, this might cause some Embedded Coder features

to fail.

Code generation successful (with warnings): To view the report, open('codegen\lib\rotate_complex

Inspect the generated C++ file `rotate_complex.c`. Observe that the output of the `xml2struct` function is hardcoded in the generated code.

type `codegen/lib/rotate_complex/rotate_complex.c`

```

/*
 * File: rotate_complex.c
 *
 * MATLAB Coder version      : 5.6
 * C/C++ source code generated on : 03-Mar-2023 07:28:32
 */

/* Include Files */
#include "rotate_complex.h"
#include <math.h>

/* Function Definitions */
/*
 * Arguments      : double theta
 * Return Type    : creal_T
 */
creal_T rotate_complex(double theta)
{
    creal_T y;
    double y_tmp;
    y_tmp = 0.017453292519943295 * theta + 0.92729521800161219;
    y.re = 5.0 * cos(y_tmp);
    y.im = sin(y_tmp);
    return y;
}

/*
 * File trailer for rotate_complex.c
 *
 * [EOF]
 */

```

Input Arguments

function — MATLAB function name

character vector

Name of the MATLAB function that is declared as extrinsic.

Example: `coder.extrinsic('patch')`

Data Types: `char`

Limitations

- Extrinsic function calls have some overhead that can affect performance. Input data that is passed in an extrinsic function call must be provided to MATLAB, which requires making a copy of the

data. If the function has any output data, this data must be transferred back into the MEX function environment, which also requires a copy.

- The code generator does not support the use of `coder.extrinsic` to call functions that are located in a private folder.
- The code generator does not support the use of `coder.extrinsic` to call local functions.

Tips

- The code generator automatically treats many common MATLAB visualization functions, such as `plot`, `disp`, and `figure`, as extrinsic. You do not have to explicitly declare them as extrinsic functions by using `coder.extrinsic`.
- Use the `coder.screener` function to detect which functions you must declare as extrinsic. This function runs the Code Generation Readiness Tool that screens the MATLAB code for features and functions that are not supported for code generation.

coder.ignoreConst

Prevent use of constant value of expression for function specializations

Syntax

```
coder.ignoreConst(expression)
```

Description

`coder.ignoreConst(expression)` prevents the code generator from using the constant value of expression to create function specializations on page 2-93. `coder.ignoreConst(expression)` returns the value of expression.

Examples

Prevent Function Specializations Based on Constant Input Values

Use `coder.ignoreConst` to prevent function specializations for a function that is called with constant values.

Write the function `call_myfcn`, which calls `myfcn`.

```
function [x, y] = call_myfcn(n)
    %#codegen
    x = myfcn(n, 'mode1');
    y = myfcn(n, 'mode2');
end

function y = myfcn(n,mode)
    coder.inline('never');
    if strcmp(mode, 'mode1')
        y = n;
    else
        y = -n;
    end
end
```

Generate standalone C code. For example, generate a static library. Enable the code generation report.

```
codegen -config:lib call_myfcn -args {1} -report
```

In the code generation report, you see two function specializations for `call_myfcn`.

The code generator creates `call_myfcn>myfcn>1` for `mode` with a value of `'mode1'`. It creates `call_myfcn>myfcn>2` for `mode` with a value of `'mode2'`.

In the generated C code, you see the specializations `my_fcn` and `b_my_fcn`.

```
static double b_myfcn(double n)
{
    return -n;
}

static double myfcn(double n)
{
    return n;
}
```

To prevent the function specializations, instruct the code generator to ignore that values of the `mode` argument are constant.

```
function [x, y] = call_myfcn(n)
%#codegen
x = myfcn(n, coder.ignoreConst('mode1'));
y = myfcn(n, coder.ignoreConst('mode2'));
end

function y = myfcn(n,mode)
coder.inline('never');
if strcmp(mode,'mode1')
    y = n;
else
    y = -n;
end
end
```

Generate the C code.

```
codegen -config:lib call_myfcn -args {1} -report
```

In the code generation report, you do not see multiple function specializations.

In the generated C code, you see one function for `my_fcn`.

Input Arguments

expression — Expression whose value is to be treated as a nonconstant

MATLAB expression

Expression whose value is to be treated as a nonconstant, specified as a MATLAB expression.

More About

Function Specialization

Version of a function in which an input type, size, complexity, or value is customized for a particular invocation of the function.

Function specialization produces efficient C code at the expense of code duplication. The code generation report shows all MATLAB function specializations that the code generator creates. However, the specializations might not appear in the generated C/C++ code due to later transformations or optimizations.

Tips

- For some recursive function calls, you can use `coder.ignoreConst` to force run-time recursion. See “Force Code Generator to Use Run-Time Recursion”.
- `coder.ignoreConst(expression)` prevents the code generator from using the constant value of `expression` to create function specializations. It does not prevent other uses of the constant value during code generation.

coder.ignoreSize

Package: coder

Prevent code generator from creating function specializations for constant-size expressions

Syntax

```
coder.ignoreSize(expression)
```

Description

`coder.ignoreSize(expression)` declares that the code generator must not use the constant size of an expression to create function specializations.

Examples

Duplicate Functions Generated for Multiple Input Sizes

If your MATLAB code calls a function multiple times and passes inputs of different sizes, the code generator can create function specializations for each size. To avoid this issue, use `coder.ignoreSize` on the function input. For example, this code uses `coder.ignoreSize` to avoid creating multiple copies of the function `indexOf`:

```
function [out1, out2] = test1(in)
    a = 1:10;
    b = 2:40;
    % Without coder.ignoreSize duplicate functions are generated
    out1 = indexOf(coder.ignoreSize(a), in);
    out2 = indexOf(coder.ignoreSize(b), in);
end

function index = indexOf(array, value)
    coder.inline('never');
    for i = 1:numel(array)
        if array(i) == value
            index = i;
            return
        end
    end
    index = -1;
    return
end
```

To generate code, enter:

```
codegen test1 -config:lib -report -args {1}
```

Input Arguments

expression — Expression whose size is to be treated as nonconstant
MATLAB expression

```
Example: foo(coder.ignoreSize(1:10))
```

More About

Function Specialization

Version of a function in which an input type, size, complexity, or value is customized for a particular invocation of the function.

Function specialization produces efficient C code at the expense of code duplication. The code generation report shows all MATLAB function specializations that the code generator creates. However, the specializations might not appear in the generated C/C++ code due to later transformations or optimizations.

Tips

- If you assign an expression to a variable and declare the variable as variable-size by using `coder.varsize`, this declaration has the same effect as using `coder.ignoreSize` on the expression.

Topics

“Avoid Duplicate Functions in Generated Code”

coder.inline

Package: coder

Control inlining of a specific function in generated code

Syntax

```
coder.inline('always')
coder.inline('never')
coder.inline('default')
```

Description

`coder.inline('always')` forces inlining on page 2-97 of the current function in the generated code. Place the `coder.inline` directive inside the function that you want to inline. The code generator does not inline entry-point functions and recursive functions. Also, the code generator does not inline functions into `parfor` loops, or inline functions called from `parfor` loops.

`coder.inline('never')` prevents inlining of the current function in the generated code. Prevent inlining when you want to simplify the mapping between the MATLAB source code and the generated code.

Note If you use the `codegen` or the `fiaccl` command, you can disable inlining for all functions by using the `-O disable:inline` option.

If you generate C/C++ code by using the `codegen` command or the MATLAB Coder app, you might have different speed and readability requirements for the code generated for functions that you write and the code generated for MathWorks® functions. Certain additional global settings enable you to separately control the inlining behavior for these two parts of the generated code base and at the boundary between them. See “Control Inlining to Fine-Tune Performance and Readability of Generated Code” (MATLAB Coder).

In cases where the code generator does not prevent inlining of a function in the generated code even if it contains the `coder.inline('never')` directive, use the `coder.ignoreConst` function on an input at the function call site in your MATLAB code. For more information, see “Resolve Issue: `coder.inline('never')` Does Not Prevent Inlining of Function” (MATLAB Coder).

`coder.inline('default')` instructs the code generator to use internal heuristics to determine whether to inline the current function. Usually, the heuristics produce highly optimized code. Use `coder.inline` explicitly in your MATLAB functions only when you need to fine-tune these optimizations.

Examples

Prevent Function Inlining

In this example, function `foo` is not inlined in the generated code:

```
function y = foo(x)
    coder.inline('never');
    y = x;
end
```

Use coder.inline in Control Flow Statements

You can use `coder.inline` in control flow code. If the software detects contradictory `coder.inline` directives, the generated code uses the default inlining heuristic and issues a warning.

Suppose that you want to generate code for a division function that runs on a system with limited memory. To optimize memory use in the generated code, the `inline_division` function manually controls inlining based on whether it performs scalar division or vector division:

```
function y = inline_division(dividend, divisor)

% For scalar division, inlining produces smaller code
% than the function call itself.
if isscalar(dividend) && isscalar(divisor)
    coder.inline('always');
else
% Vector division produces a for-loop.
% Prohibit inlining to reduce code size.
    coder.inline('never');
end

if any(divisor == 0)
    error('Cannot divide by 0');
end

y = dividend / divisor;
```

More About

Inlining

Technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C++ code. Inlining can create opportunities for further optimization of the generated C/C++ code.

Topics

“Resolve Issue: `coder.inline('never')` Does Not Prevent Inlining of Function” (MATLAB Coder)

coder.isColumnMajor

Determine whether the current function or variable uses column-major layout

Syntax

```
coder.isColumnMajor
coder.isColumnMajor(arg)
```

Description

`coder.isColumnMajor` resolves as true in the generated code if the current function uses column-major array layout. Use the function as the expression in control flow (`if`, `else`, `switch`) statements.

`coder.isColumnMajor(arg)` resolves as true if the current variable uses column-major array layout.

Examples

Query Array Layout of a Function

To query the array layout of a function at compile time, use `coder.isColumnMajor` or `coder.isRowMajor`. This query can be useful for specializing your generated code when it involves row-major and column-major functions. For example, consider this function:

```
function S = addMatrixRouted(A,B)
    if coder.isRowMajor
        %execute this code if row major
        S = addMatrix_OptimizedForRowMajor(A,B);
    elseif coder.isColumnMajor
        %execute this code if column major
        S = addMatrix_OptimizedForColumnMajor(A,B);
    end
```

The function `addMatrixRouted` behaves differently depending on whether it uses row-major layout or column-major layout. The layout that the function uses, for example, can depend on whether it is called from a function that contains `coder.rowMajor` or `coder.columnMajor`. When `addMatrixRouted` uses row-major layout, it calls the `addMatrix_OptimizedForRowMajor` function, which has efficient memory access for row-major data. When the function uses column-major layout, it calls a version of the `addMatrix` function optimized for column-major data.

By using the query functions, the generated code for `addMatrixRouted` provides efficient memory access for either choice of array layout.

Query Array Layout of a Variable

Consider the function `bar`:

```
function bar
    coder.columnMajor;
```

```
x = magic(3);  
if coder.isColumnMajor(x)  
    fprintf('This will always be displayed in generated code.\n');  
else  
    fprintf('This will never be displayed in generated code.\n');  
end  
end
```

Generate code:

```
codegen bar
```

To run the MEX function, enter:

```
bar_mex
```

Input Arguments

arg — Variable name

array variable

Variable to query for array layout.

Example: `coder.isColumnMajor(x)`;

Limitations

- You cannot query the array layout of a structure field or property.

Tips

- The code generator uses column-major layout by default.
- Outside of code generation and simulation, `coder.isColumnMajor` is always true.
- If `coder.isColumnMajor` always resolves to true for your code, other branches in the `if` statement are ignored by the code generator. Otherwise, one instance of the current function is created for each array layout.

coder.isRowMajor

Determine whether the current function or variable uses row-major layout

Syntax

```
coder.isRowMajor
coder.isRowMajor(arg)
```

Description

`coder.isRowMajor` resolves as true in the generated code if the current function uses row-major array layout. Use the function as the expression in control flow (`if`, `else`, `switch`) statements.

`coder.isRowMajor(arg)` resolves as true if the current variable uses row-major array layout.

Examples

Query Array Layout of a Function

To query the array layout of a function at compile time, use `coder.isRowMajor` or `coder.isColumnMajor`. This query can be useful for specializing your generated code when it involves row-major and column-major functions. For example, consider this function:

```
function S = addMatrixRouted(A,B)
    if coder.isRowMajor
        %execute this code if row major
        S = addMatrix_OptimizedForRowMajor(A,B);
    elseif coder.isColumnMajor
        %execute this code if column major
        S = addMatrix_OptimizedForColumnMajor(A,B);
    end
```

The function `addMatrixRouted` behaves differently depending on whether it uses row-major layout or column-major layout. The layout that the function uses, for example, can depend on whether it is called from a function that contains `coder.rowMajor` or `coder.columnMajor`. When `addMatrixRouted` uses row-major layout, it calls the `addMatrix_OptimizedForRowMajor` function, which has efficient memory access for row-major data. When the function uses column-major layout, it calls a version of the `addMatrix` function optimized for column-major data.

By using the query functions, the generated code for `addMatrixRouted` provides efficient memory access for either choice of array layout.

Query Array Layout of a Variable

Consider the function `foo`:

```
function foo
    coder.rowMajor;
```

```
x = magic(3);
if coder.isRowMajor(x)
    fprintf('This will always be displayed in generated code.\n');
else
    fprintf('This will never be displayed in generated code.\n');
end
end
```

Generate code:

```
codegen foo
```

To run the MEX function, enter:

```
foo_mex
```

Input Arguments

arg — Variable name

array variable

Variable to query for array layout.

Example: `coder.isRowMajor(x)`;

Limitations

- You cannot query the array layout of a structure field or property.

Tips

- Outside of code generation and simulation, `coder.isRowMajor` is always false.
- If `coder.isRowMajor` always resolves to true for your code, other branches in the `if` statement are ignored by the code generator. Otherwise, one instance of the current function is created for each array layout.

coder.load

Load compile-time constants from MAT-file or ASCII file

Syntax

```
S = coder.load(filename)
S = coder.load(filename,var1,...,varN)
S = coder.load(filename,'-regex',expr1,...,exprN)
S = coder.load(filename,'-ascii')
S = coder.load(filename,'-mat')
S = coder.load(filename,'-mat',var1,...,varN)
S = coder.load(filename,'-mat','-regex', expr1,...,exprN)
```

Description

`S = coder.load(filename)` loads compile-time constants from `filename`.

- If `filename` is a MAT-file, then `coder.load` loads variables from the MAT-file into a structure array.
- If `filename` is an ASCII file, then `coder.load` loads data into a double-precision array.

`coder.load` loads data at code generation time, also referred to as *compile time*. If you change the content of `filename` after you generate code, the change is not reflected in the behavior of the generated code.

`S = coder.load(filename,var1,...,varN)` loads only the specified variables from the MAT-file `filename`.

`S = coder.load(filename,'-regex',expr1,...,exprN)` loads only the variables that match the specified regular expressions.

`S = coder.load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`S = coder.load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`S = coder.load(filename,'-mat',var1,...,varN)` treats `filename` as a MAT-file and loads only the specified variables from the file.

`S = coder.load(filename,'-mat','-regex', expr1,...,exprN)` treats `filename` as a MAT-file and loads only the variables that match the specified regular expressions.

Examples

Load compile-time constants from MAT-file

Generate code for a function `edgeDetect1` which given a normalized image, returns an image where the edges are detected with respect to the threshold value. `edgeDetect1` uses `coder.load` to load the edge detection kernel from a MAT-file at compile time.

Save the Sobel edge-detection kernel in a MAT-file.

```
k = [1 2 1; 0 0 0; -1 -2 -1];
```

```
save sobel.mat k
```

Write the function `edgeDetect1`.

```
function edgeImage = edgeDetect1(originalImage, threshold) %#codegen
assert(all(size(originalImage) <= [1024 1024]));
assert(isa(originalImage, 'double'));
assert(isa(threshold, 'double'));

S = coder.load('sobel.mat', 'k');
H = conv2(double(originalImage), S.k, 'same');
V = conv2(double(originalImage), S.k', 'same');
E = sqrt(H.*H + V.*V);
edgeImage = uint8((E > threshold) * 255);
```

Create a code generation configuration object for a static library.

```
cfg = coder.config('lib');
```

Generate a static library for `edgeDetect1`.

```
codegen -report -config cfg edgeDetect1
```

`codegen` generates C code in the `codegen\lib\edgeDetect1` folder.

Load compile-time constants from ASCII file

Generate code for a function `edgeDetect2` which given a normalized image, returns an image where the edges are detected with respect to the threshold value. `edgeDetect2` uses `coder.load` to load the edge detection kernel from an ASCII file at compile time.

Save the Sobel edge-detection kernel in an ASCII file.

```
k = [1 2 1; 0 0 0; -1 -2 -1];
```

```
save sobel.dat k -ascii
```

Write the function `edgeDetect2`.

```
function edgeImage = edgeDetect2(originalImage, threshold) %#codegen
assert(all(size(originalImage) <= [1024 1024]));
assert(isa(originalImage, 'double'));
assert(isa(threshold, 'double'));

k = coder.load('sobel.dat');
H = conv2(double(originalImage), k, 'same');
V = conv2(double(originalImage), k', 'same');
```

```
E = sqrt(H.*H + V.*V);
edgeImage = uint8((E > threshold) * 255);
```

Create a code generation configuration object for a static library.

```
cfg = coder.config('lib');
```

Generate a static library for `edgeDetect2`.

```
codegen -report -config cfg edgeDetect2
```

codegen generates C code in the `codegen\lib\edgeDetect2` folder.

Input Arguments

filename — Name of file

character vector | string scalar

Name of file. `filename` must be a compile-time constant.

`filename` can include a file extension and a full or partial path. If `filename` has no extension, `load` looks for a file named `filename.mat`. If `filename` has an extension other than `.mat`, `load` treats the file as ASCII data.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, %).

Example: `'myFile.mat'`

var1, ..., varN — Names of variables to load

character vector | string scalar

Names of variables, specified as one or more character vectors or string scalars. Each variable name must be a compile-time constant. Use the `*` wildcard to match patterns.

Example: `coder.load('myFile.mat', 'A*')` loads all variables in the file whose names start with `A`.

expr1, ..., exprN — Regular expressions indicating which variables to load

character vector | string scalar

Regular expressions indicating which variables to load specified as one or more character vectors or string scalars. Each regular expression must be a compile-time constant.

Example: `coder.load('myFile.mat', '-regexp', '^A')` loads only variables whose names begin with `A`.

Output Arguments

S — Loaded variables or data

structure array | m-by-n array

If `filename` is a MAT-file, `S` is a structure array.

If `filename` is an ASCII file, `S` is an `m`-by-`n` array of type `double`. `m` is the number of lines in the file and `n` is the number of values on a line.

Limitations

- Arguments to `coder.load` must be compile-time constants.
- The output `S` must be the name of a structure or array without any subscripting. For example, `S(i) = coder.load('myFile.mat')` is not allowed.
- You cannot use `save` to save workspace data to a file inside a function intended for code generation. The code generator does not support the `save` function. Furthermore, you cannot use `coder.extrinsic` with `save`. Prior to generating code, you can use `save` to save workspace data to a file.

Tips

- `coder.load(filename)` loads data at compile time, not at run time. If you change the content of `filename` after you generate code, the change is not reflected in the behavior of the generated code. If you are generating MEX code or code for Simulink simulation, you can use the MATLAB function `load` to load run-time values.
- If the MAT-file contains unsupported constructs, use `coder.load(filename,var1,...,varN)` to load only the supported constructs.
- If you generate code in a MATLAB Coder project, the code generator practices incremental code generation for the `coder.load` function. When the MAT-file or ASCII file used by `coder.load` changes, the software rebuilds the code.

coder.nullcopy

Package: coder

Declare uninitialized variables in code generation

Syntax

```
X = coder.nullcopy(A)
```

Description

`X = coder.nullcopy(A)` copies type, size, and complexity of `A` to `X`, but does not copy element values. The function preallocates memory for `X` without incurring the overhead of initializing memory. In code generation, the `coder.nullcopy` function declares uninitialized variables. In MATLAB, `coder.nullcopy` returns the input such that `X` is equal to `A`.

If `X` is a structure or a class containing variable-sized arrays, then you must assign the size of each array. `coder.nullcopy` does not copy sizes of arrays or nested arrays from its argument to its result.

Note Before you use `X` in a function or a program, ensure that the data in `X` is completely initialized. Declaring a variable through `coder.nullcopy` without assigning all the elements of the variable results in nondeterministic program behavior. For more information, see “How to Eliminate Redundant Copies by Defining Uninitialized Variables”.

Examples

Declare a Variable Without Initialization

This example shows how to declare an array type variable without initializing any value in the array.

To generate code for the following function, you must fully declare the output variable `outp` as a n -by- n array of real doubles before subscripting into `outp`. To perform this declaration without initializing all the values in the array, use `coder.nullcopy`.

```
function outp = foo(n) %#codegen

outp = coder.nullcopy(ones(n));
for idx = 1:n*n
    if mod(idx,2) == 0
        outp(idx) = idx;
    else
        outp(idx) = idx + 1;
    end
end
```

Run this `codegen` command to generate code and launch report.

```
codegen -config:lib -c foo -args {0} -launchreport
```

In the code generation report, click **Trace Code** to see the mapping between the MATLAB code and the generated code. To use the code traceability feature, you must have Embedded Coder.

The following figures show the comparison between the code generated with and without `coder.nullcopy`. Using `coder.nullcopy` with `ones` can specify the size of array `outp` without initializing each element to one.

```

1 function out = foo(inp)
2 out = coder.nullcopy(ones(inp));
3 for idx = 1:inp*inp
4     if mod(idx,2)==0
5         out(idx) = idx;
6     else
7         out(idx) = idx + 1;
8     end
9 end
10 end

```

```

22 void foo(double inp, emxArray_real_T *out)
23 {
24     double *out_data;
25     int i;
26     int idx;
27     i = out->size[0] * out->size[1];
28     out->size[0] = (int)inp;
29     out->size[1] = (int)inp;
30     emxEnsureCapacity_real_T(out, i);
31     out_data = out->data;
32     i = (int)(inp * inp);
33     for (idx = 0; idx < i; idx++) {
34         if (fmod((double)idx + 1.0, 2.0) == 0.0) {
35             out_data[idx] = (unsigned int)idx + 1U;
36         } else {
37             out_data[idx] = (unsigned int)idx + 2U;
38         }
39     }
40 }

```

If you do not use `coder.nullcopy`, the generated code explicitly initializes every element in `outp` to one (see lines 32 to 35).

```

1 function out = foo(inp)
2 out = ones(inp);
3 for idx = 1:inp*inp
4     if mod(idx,2)==0
5         out(idx) = idx;
6     else
7         out(idx) = idx + 1;
8     end
9 end
10 end

```

```

22 void foo(double inp, emxArray_real_T *out)
23 {
24     double *out_data;
25     int i;
26     int loop_ub;
27     i = out->size[0] * out->size[1];
28     out->size[0] = (int)inp;
29     out->size[1] = (int)inp;
30     emxEnsureCapacity_real_T(out, i);
31     out_data = out->data;
32     loop_ub = (int)inp * (int)inp;
33     for (i = 0; i < loop_ub; i++) {
34         out_data[i] = 1.0;
35     }
36     i = (int)(inp * inp);
37     for (loop_ub = 0; loop_ub < i; loop_ub++) {
38         if (fmod((double)loop_ub + 1.0, 2.0) == 0.0) {
39             out_data[loop_ub] = (unsigned int)loop_ub + 1U;
40         } else {
41             out_data[loop_ub] = (unsigned int)loop_ub + 2U;
42         }
43     }
44 }

```

Note In some situations, the code generator automatically performs the optimization corresponding to `coder.nullcopy`, even if you do not explicitly include the `coder.nullcopy` directive in your MATLAB code.

Input Arguments

A — Variable to copy

scalar | vector | matrix | class | multidimensional array

Variable to copy, specified as a scalar, vector, matrix, or multidimensional array.

Example: `coder.nullcopy(A);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `class`

Complex Number Support: Yes

Limitations

- You cannot use `coder.nullcopy` on sparse matrices.
- You cannot use `coder.nullcopy` with classes that support overloaded parentheses or require indexing methods to access their data, such as `table`.

“Eliminate Redundant Copies of Variables in Generated Code”

coder.opaque

Declare variable in generated code

Syntax

```
y = coder.opaque(type)
y = coder.opaque(type,value)
y = coder.opaque( ____, 'Size',Size)
y = coder.opaque( ____, 'HeaderFile',HeaderFile)
```

Description

`y = coder.opaque(type)` declares a variable `y` with the specified type and no initial value in the generated code.

- `y` can be a variable or a structure field.
- MATLAB code cannot set or access `y`, but external C functions can accept `y` as an argument.
- `y` can be an:
 - Argument to `coder.rref`, `coder.wref`, or `coder.ref`
 - Input or output argument to `coder.ceval`
 - Input or output argument to a user-written MATLAB function
 - Input to a subset of MATLAB toolbox functions supported for code generation
- Assignment from `y` declares another variable with the same type in the generated code. For example:

```
y = coder.opaque('int');
z = y;
```

declares a variable `z` of type `int` in the generated code.

- You can assign `y` from another variable declared using either `coder.opaque` or assignment from a variable declared using `coder.opaque`. The variables must have identical types.
- You can compare `y` to another variable declared using either `coder.opaque` or assignment from a variable declared using `coder.opaque`. The variables must have identical types.

`y = coder.opaque(type,value)` specifies the type and initial value of `y`.

`y = coder.opaque(____, 'Size',Size)` specifies the size, in bytes, of `y`. You can specify the size with any of the previous syntaxes.

`y = coder.opaque(____, 'HeaderFile',HeaderFile)` specifies the header file that contains the type definition. The code generator produces the `#include` statement for the header file where the statement is required in the generated code. You can specify the header file with any of the previous syntaxes.

Examples

Declare Variable Specifying Initial Value

Generate code for a function `valtest` which returns 1 if the call to `myfun` is successful. This function uses `coder.opaque` to declare a variable `x1` with type `int` and initial value 0. The assignment `x2 = x1` declares `x2` to be a variable with the type and initial value of `x1`.

Write a function `valtest`.

```
function y = valtest
%codegen
%declare x1 to be an integer with initial value '0'
x1 = coder.opaque('int','0');
%Declare x2 to have same type and initial value as x1
x2 = x1;
x2 = coder.ceval('myfun');
%test the result of call to 'myfun' by comparing to value of x1
if x2 == x1
    y = 0;
else
    y = 1;
end
end
```

Declare Variable Specifying Initial Value and Header File

Generate code for a MATLAB function `filetest` which returns its own source code using `fopen/fread/fclose`. This function uses `coder.opaque` to declare the variable that stores the file pointer used by `fopen/fread/fclose`. The call to `coder.opaque` declares the variable `f` with type `FILE *`, initial value `NULL`, and header file `<stdio.h>`.

Write a MATLAB function `filetest`.

```
function buffer = filetest
%#codegen

% Declare 'f' as an opaque type 'FILE *' with initial value 'NULL'
%Specify the header file that contains the type definition of 'FILE *';

f = coder.opaque('FILE *', 'NULL', 'HeaderFile', '<stdio.h>');
% Open file in binary mode
f = coder.ceval('fopen', cstring('filetest.m'), cstring('rb'));

% Read from file until end of file is reached and put
% contents into buffer
n = int32(1);
i = int32(1);
buffer = char(zeros(1,8192));
while n > 0
    % By default, MATLAB converts constant values
    % to doubles in generated code
    % so explicit type conversion to int32 is inserted.
    n = coder.ceval('fread', coder.ref(buffer(i)), int32(1), ...
        int32(numel(buffer)), f);
    i = i + n;
end
coder.ceval('fclose', f);

buffer = strip_cr(buffer);

% Put a C termination character '\0' at the end of MATLAB character vector
```

```

function y = cstring(x)
    y = [x char(0)];

% Remove all character 13 (CR) but keep character 10 (LF)
function buffer = strip_cr(buffer)
    j = 1;
    for i = 1:numel(buffer)
        if buffer(i) ~= char(13)
            buffer(j) = buffer(i);
            j = j + 1;
        end
    end
    buffer(i) = 0;

```

Compare Variables Declared Using `coder.opaque`

Compare variables declared using `coder.opaque` to test for successfully opening a file.

Use `coder.opaque` to declare a variable `null` with type `FILE *` and initial value `NULL`.

```
null = coder.opaque('FILE *', 'NULL', 'HeaderFile', '<stdio.h>');
```

Use assignment to declare another variable `ftmp` with the same type and value as `null`.

```
ftmp = null;
ftmp = coder.ceval('fopen', ['testfile.txt', char(0)], ['r', char(0)]);
```

Compare the variables.

```
if ftmp == null
    %error condition
end
```

Cast to and from Types of Variables Declared Using `coder.opaque`

This example shows how to cast to and from types of variables that are declared using `coder.opaque`. The function `castopaque` calls the C run-time function `strncmp` to compare at most `n` characters of the strings `s1` and `s2`. `n` is the number of characters in the shorter of the strings. To generate the correct C type for the `strncmp` input `nsizet`, the function casts `n` to the C type `size_t` and assigns the result to `nsizet`. The function uses `coder.opaque` to declare `nsizet`. Before using the output `retval` from `strncmp`, the function casts `retval` to the MATLAB type `int32` and stores the results in `y`.

Write this MATLAB function:

```

function y = castopaque(s1,s2)

% <0 - the first character that does not match has a lower value in s1 than in s2
%  0 - the contents of both strings are equal
% >0 - the first character that does not match has a greater value in s1 than in s2
%
%#codegen

coder.cinclude('<string.h>');
n = min(numel(s1), numel(s2));

% Convert the number of characters to compare to a size_t
nsizet = cast(n,'like',coder.opaque('size_t','0'));

```

```

% The return value is an int
retval = coder.opaque('int');
retval = coder.ceval('strncmp', cstr(s1), cstr(s2), nsizet);

% Convert the opaque return value to a MATLAB value
y = cast(retval, 'int32');

%-----
function sc = cstr(s)
% NULL terminate a MATLAB character vector for C
sc = [s, char(0)];

```

Generate the MEX function.

```
codegen castopaque -args {blanks(3), blanks(3)} -report
```

Call the MEX function with inputs 'abc' and 'abc'.

```
castopaque_mex('abc', 'abc')
```

ans =

0

The output is 0 because the strings are equal.

Call the MEX function with inputs 'abc' and 'abd'.

```
castopaque_mex('abc', 'abd')
```

ans =

-1

The output is -1 because the third character d in the second string is greater than the third character c in the first string.

Call the MEX function with inputs 'abd' and 'abc'.

```
castopaque_mex('abd', 'abc')
```

ans =

1

The output is 1 because the third character d in the first string is greater than the third character c in the second string.

In the MATLAB workspace, you can see that the type of y is int32.

Declare Variable Specifying Initial Value and Size

Declare y to be a 4-byte integer with initial value 0.

```
y = coder.opaque('int', '0', 'Size', 4);
```

Input Arguments

type — Type of variable

character vector | string scalar

Type of variable in generated code. `type` must be a compile-time constant. The type must be a:

- Built-in C data type or a type defined in a header file
- C type that supports copy by assignment
- Legal prefix in a C declaration

Example: `'FILE *'`

value — Initial value of variable

character vector | string scalar

Initial value of variable in generated code. `value` must be a compile-time constant. Specify a C expression not dependent on MATLAB variables or functions.

If you do not provide the initial value in `value`, initialize the value of the variable before using it. To initialize a variable declared using `coder.opaque`:

- Assign a value from another variable with the same type declared using either `coder.opaque` or assignment from a variable declared using `coder.opaque`.
- Assign a value from an external C function.
- Pass the address of the variable to an external function using `coder.wref`.

Specify a `value` that has the type that `type` specifies. Otherwise, the generated code can produce unexpected results.

Example: `'NULL'`

Size — Size of variable

integer

Number of bytes for the variable in the generated code, specified as an integer. If you do not specify the size, the size of the variable is 8 bytes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

HeaderFile — Name of header file

character vector | string scalar

Name of header file that contains the definition of `type`. `HeaderFile` must be a compile-time constant.

For a system header file, use angle brackets.

Example: `'<stdio.h>'` generates `#include <stdio.h>`

For an application header file, use double quotes.

Example: `'"foo.h"'` generates `#include "foo.h"`

If you omit the angle brackets or double quotes, the code generator produces double quotes.

Example: 'foo.h' generates #include "foo.h"

Specify the include path in the build configuration parameters.

Example: `cfg.CustomInclude = 'c:\myincludes'`

Tips

- Specify a value that has the type that type specifies. Otherwise, the generated code can produce unexpected results. For example, the following `coder.opaque` declaration can produce unexpected results.

```
y = coder.opaque('int', '0.2')
```

- `coder.opaque` declares the type of a variable. It does not instantiate the variable. You can instantiate a variable by using it later in the MATLAB code. In the following example, assignment of `fp1` from `coder.ceval` instantiates `fp1`.

```
% Declare fp1 of type FILE *
fp1 = coder.opaque('FILE *');
%Create the variable fp1
fp1 = coder.ceval('fopen', ['testfile.txt', char(0)], ['r', char(0)]);
```

- In the MATLAB environment, `coder.opaque` returns the value specified in `value`. If `value` is not provided, it returns an empty character vector.
- You can compare variables declared using either `coder.opaque` or assignment from a variable declared using `coder.opaque`. The variables must have identical types. The following example demonstrates how to compare these variables. “Compare Variables Declared Using `coder.opaque`” on page 2-114
- To avoid multiple inclusions of the same header file in generated code, enclose the header file in the conditional preprocessor statements `#ifndef` and `#endif`. For example:

```
#ifndef MyHeader_h
#define MyHeader_h
<body of header file>
#endif
```

- You can use the MATLAB `cast` function to cast a variable to or from a variable that is declared using `coder.opaque`. Use `cast` with `coder.opaque` only for numeric types.

To cast a variable declared by `coder.opaque` to a MATLAB type, you can use the `B = cast(A, type)` syntax. For example:

```
x = coder.opaque('size_t', '0');
x1 = cast(x, 'int32');
```

You can also use the `B = cast(A, 'like', p)` syntax. For example:

```
x = coder.opaque('size_t', '0');
x1 = cast(x, 'like', int32(0));
```

To cast a MATLAB variable to the type of a variable declared by `coder.opaque`, you must use the `B = cast(A, 'like', p)` syntax. For example:

```
x = int32(12);
x1 = coder.opaque('size_t', '0');
x2 = cast(x, 'like', x1);
```

Use `cast` with `coder.opaque` to generate the correct data types for:

- Inputs to C/C++ functions that you call using `coder.ceval`.
- Variables that you assign to outputs from C/C++ functions that you call using `coder.ceval`.

Without this casting, it is possible to receive compiler warnings during code generation.

Topics

“Integrate C Code by Using the MATLAB Function Block”

coder.ref

Indicate data to pass by reference

Syntax

```
coder.ref(arg)
coder.ref(arg, 'gpu')
```

Description

`coder.ref(arg)` indicates that `arg` is an expression or variable to pass by reference to an external C/C++ function. Use `coder.ref` inside a `coder.ceval` call only. The C/C++ function can read from or write to the variable passed by reference. Use a separate `coder.ref` construct for each argument that you pass by reference to the function.

See also `coder.rref` and `coder.wref`.

`coder.ref(arg, 'gpu')` indicates that `arg` is a GPU argument. This option requires a valid GPU Coder license. If the `coder.ceval` calls a CUDA GPU `__device__` function, the code generator ignores the 'gpu' specification.

Examples

Pass Scalar Variable by Reference

Consider the C function `addone` that returns the value of an input plus one:

```
double addone(double* p) {
    return *p + 1;
}
```

The C function defines the input variable `p` as a pointer to a double.

Pass the input by reference to `addone`:

```
...
y = 0;
u = 42;
y = coder.ceval('addone', coder.ref(u));
...
```

Pass Multiple Arguments by Reference

```
...
u = 1;
v = 2;
y = coder.ceval('my_fcn', coder.ref(u), coder.ref(v));
...
```

Pass Class Property by Reference

```
...
x = myClass;
```

```
x.prop = 1;
coder.ceval('foo', coder.ref(x.prop));
...
```

Pass a Structure by Reference

To indicate that the structure type is defined in a C header file, use `coder.cstructname`.

Suppose that you have the C function `incr_struct`. This function reads from and writes to the input argument.

```
#include "MyStruct.h"

void incr_struct(struct MyStruct *my_struct)
{
    my_struct->f1 = my_struct->f1 + 1;
    my_struct->f2 = my_struct->f2 + 1;
}
```

The C header file, `MyStruct.h`, defines a structure type named `MyStruct`:

```
#ifndef MYSTRUCT
#define MYSTRUCT

typedef struct MyStruct
{
    double f1;
    double f2;
} MyStruct;

void incr_struct(struct MyStruct *my_struct);

#endif
```

In your MATLAB function, pass a structure by reference to `incr_struct`. To indicate that the structure type for `s` has the name `MyStruct` that is defined in the C header file `MyStruct.h`, use `coder.cstructname`.

```
function y = foo
%#codegen
y = 0;
coder.updateBuildInfo('addSourceFiles','incr_struct.c');

s = struct('f1',1,'f2',2);
coder.cstructname(s,'MyStruct','extern','HeaderFile','MyStruct.h');
coder.ceval('incr_struct', coder.ref(s));
```

To generate standalone library code, enter:

```
codegen -config:lib foo -report
```

Pass Structure Field by Reference

```
...
s = struct('s1', struct('a', [0 1]));
coder.ceval('foo', coder.ref(s.s1.a));
...
```

You can also pass an element of an array of structures:

```

...
c = repmat(struct('u',magic(2)),1,10);
b = repmat(struct('c',c),3,6);
a = struct('b',b);
coder.ceval('foo', coder.ref(a.b(3,4).c(2).u));
...

```

Input Arguments

arg — Argument to pass by reference

scalar variable | array | element of an array | structure | structure field | object property

Argument to pass by reference to an external C/C++ function. The argument cannot be a class, a System object, a cell array, or an index into a cell array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct
Complex Number Support: Yes

Limitations

- You cannot pass these data types by reference:
 - Class or System object
 - Cell array or index into a cell array
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties”.

Tips

- If arg is an array, then `coder.ref(arg)` provides the address of the first element of the array. The `coder.ref(arg)` function does not contain information about the size of the array. If the C function must know the number of elements of your data, pass that information as a separate argument. For example:

```
coder.ceval('myFun',coder.ref(arg),int32(numel(arg)));
```
- When you pass a structure by reference to an external C/C++ function, use `coder.cstructname` to provide the name of a C structure type that is defined in a C header file.
- In MATLAB, `coder.ref` results in an error. To parameterize your MATLAB code so that it can run in MATLAB and in generated code, use `coder.target`.
- You can use `coder.opaque` to declare variables that you pass to and from an external C/C++ function.

coder.rowMajor

Specify row-major array layout for a function or class

Syntax

```
coder.rowMajor
```

Description

`coder.rowMajor` specifies row-major array layout for the data used by the current function in generated code. When placed in a class constructor, `coder.rowMajor` specifies row-major layout for data used by the class.

Note By default, code generation uses column-major array layout.

Examples

Specify Row-Major Array Layout for a Function

Specify row-major array layout for a function by inserting `coder.rowMajor` into the function body.

Suppose that `myFunction` is the top-level function of your code. Your application requires you to perform matrix addition with row-major array layout and matrix multiplication with column-major layout.

```
function S = myFunction(A,B)
%#codegen
% check to make sure inputs are valid
if size(A,1) ~= size(B,1) || size(A,2) ~= size(B,2)
    disp('Matrices must be same size.');
```

return;

```
end
% make both matrices symmetric
B = B*B';
A = A*A';
% add matrices
S = addMatrix(A,B);
end
```

Write a function for matrix addition called `addMatrix`. Specify row-major layout for `addMatrix` by using `coder.rowMajor`.

```
function S = addMatrix(A,B)
%#codegen
S = zeros(size(A));
coder.rowMajor; % specify row-major array layout
S = A + B;
end
```

Generate code for `myFunction`. Use the `codegen` command.

```
codegen myFunction -args {ones(10,20),ones(10,20)} -config:lib -launchreport
```

The code generator produces code for `addMatrix` that uses row-major array layout. However, the matrix multiplication from the top-level function uses the default layout, column-major.

Tips

- To specify row-major array layout for all the functions in your generated code, use the `codegen -rowmajor` option.
- Other functions called from within a row-major function inherit the row-major specification. However, if one of the called functions has its own distinct `coder.columnMajor` call, the code generator changes the array layout accordingly. If a row-major function and a column-major function call the same function, which does not have its own array layout specification, the code generator produces a row-major version and column-major version of the function.
- `coder.rowMajor` is ignored outside of code generation and simulation.

coder.rref

Indicate read-only data to pass by reference

Syntax

```
coder.rref(arg)
coder.rref(arg, 'gpu')
```

Description

`coder.rref(arg)` indicates that `arg` is a read-only expression or variable to pass by reference to an external C/C++ function. Use `coder.rref` only inside a `coder.ceval` call.

The `coder.rref` function can enable the code generator to optimize the generated code. Because the external function is assumed to not write to `coder.rref(arg)`, the code generator can perform optimizations such as expression folding on assignments to `arg` that occur before and after the `coder.ceval` call. Expression folding is the combining of multiple operations into one statement to avoid the use of temporary variables and improve code performance.

Note The code generator assumes that the memory that you pass with `coder.rref(arg)` is read-only. To avoid unpredictable results, the C/C++ function must not write to this variable.

See also `coder.ref` and `coder.wref`.

`coder.rref(arg, 'gpu')` indicates that `arg` is a GPU argument. This option requires a valid GPU Coder license. If the `coder.ceval` calls a CUDA GPU `__device__` function, the code generator ignores the 'gpu' specification.

Examples

Pass Scalar Variable as a Read-Only Reference

Consider the C function `addone` that returns the value of a constant input plus one:

```
double addone(const double* p) {
    return *p + 1;
}
```

The C function defines the input variable `p` as a pointer to a constant double.

Pass the input by reference to `addone`:

```
...
y = 0;
u = 42;
```

```
y = coder.ceval('addone', coder.rref(u));
...
```

Pass Multiple Arguments as a Read-Only Reference

```
...
u = 1;
v = 2;
y = coder.ceval('my_fcn', coder.rref(u), coder.rref(v));
...
```

Pass Class Property as a Read-Only Reference

```
...
x = myClass;
x.prop = 1;
y = coder.ceval('foo', coder.rref(x.prop));
...
```

Pass Structure as a Read-Only Reference

To indicate that the structure type is defined in a C header file, use `coder.cstructname`.

Suppose that you have the C function `use_struct`. This function reads from the input argument but does not write to it.

```
#include "MyStruct.h"

double use_struct(const struct MyStruct *my_struct)
{
    return my_struct->f1 + my_struct->f2;
}
```

The C header file, `MyStruct.h`, defines a structure type named `MyStruct`:

```
#ifndef MYSTRUCT
#define MYSTRUCT

typedef struct MyStruct
{
    double f1;
    double f2;
} MyStruct;

double use_struct(const struct MyStruct *my_struct);

#endif
```

In your MATLAB function, pass a structure as a read-only reference to `use_struct`. To indicate that the structure type for `s` has the name `MyStruct` that is defined in the C header file `MyStruct.h`, use `coder.cstructname`.

```
function y = foo
%#codegen
y = 0;
coder.updateBuildInfo('addSourceFiles','use_struct.c');

s = struct('f1',1,'f2',2);
```

```
coder.cstructname(s, 'MyStruct', 'extern', 'HeaderFile', 'MyStruct.h');
y = coder.ceval('use_struct', coder.rref(s));
```

To generate standalone library code, enter:

```
codegen -config:lib foo -report
```

Pass Structure Field as a Read-Only Reference

```
...
s = struct('s1', struct('a', [0 1]));
y = coder.ceval('foo', coder.rref(s.s1.a));
...
```

You can also pass an element of an array of structures:

```
...
c = repmat(struct('u', magic(2)), 1, 10);
b = repmat(struct('c', c), 3, 6);
a = struct('b', b);
coder.ceval('foo', coder.rref(a.b(3,4).c(2).u));
...
```

Input Arguments

arg — Argument to pass by reference

scalar variable | array | element of an array | structure | structure field | object property

Argument to pass by reference to an external C/C++ function. The argument cannot be a class, a System object, a cell array, or an index into a cell array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct`

Complex Number Support: Yes

Limitations

- You cannot pass these data types by reference:
 - Class or System object
 - Cell array or index into a cell array
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties”.

Tips

- If `arg` is an array, then `coder.rref(arg)` provides the address of the first element of the array. The `coder.rref(arg)` function does not contain information about the size of the array. If the C function must know the number of elements of your data, pass that information as a separate argument. For example:

```
coder.ceval('myFun', coder.rref(arg), int32(numel(arg)));
```

- When you pass a structure by reference to an external C/C++ function, use `coder.cstructname` to provide the name of a C structure type that is defined in a C header file.
- In MATLAB, `coder.rref` results in an error. To parametrize your MATLAB code so that it can run in MATLAB and in generated code, use `coder.target`.
- You can use `coder.opaque` to declare variables that you pass to and from an external C/C++ function.

coder.screener

Package: coder

Determine if function is suitable for code generation

Syntax

```
coder.screener(fcn)
coder.screener(fcn, '-gpu')
coder.screener(fcn_1, ..., fcn_n)
info = coder.screener( ___ )
```

Description

`coder.screener(fcn)` analyzes the entry-point MATLAB function `fcn` to identify unsupported functions and language features as code generation compliance issues. The code generation compliance issues are displayed in the readiness report.

If `fcn` calls other functions directly or indirectly that are not MathWorks functions (MATLAB built-in functions and toolbox functions), `coder.screener` analyzes these functions. It does not analyze the MathWorks functions.

It is possible that `coder.screener` does not detect all code generation issues. Under certain circumstances, it is possible that `coder.screener` reports false errors.

To avoid undetected code generation issues and false errors, before generating code, verify that your MATLAB code is suitable for code generation by performing these additional checks:

- Before using `coder.screener`, fix issues that the Code Analyzer identifies.
- After using `coder.screener`, and before generating C/C++ code, verify that your MATLAB code is suitable for code generation by generating and verifying a MEX function.

The `coder.screener` function does not report functions that the code generator treats as extrinsic. Examples of such functions are `plot`, `disp`, and `figure`. See “Use MATLAB Engine to Execute a Function Call in Generated Code”.

`coder.screener(fcn, '-gpu')` analyzes the entry-point MATLAB function `fcn` to identify unsupported functions and language features for GPU code generation.

`coder.screener(fcn_1, ..., fcn_n)` analyzes multiple entry-point MATLAB functions.

`info = coder.screener(___)` returns a `coder.ScreenerInfo` object. The properties of this object contain the code generation readiness analysis results. Use `info` to access the code generation readiness results programmatically. For a list of properties, see `coder.ScreenerInfo` Properties.

Examples

Identify Unsupported Functions

The `coder.screener` function identifies calls to functions that are not supported for code generation. It checks the entry-point function, `foo1`, and the function, `foo2`, that `foo1` calls.

Write the function `foo2` and save it in the file `foo2.m`.

```
function [tf1,tf2] = foo2(source,target)
G = digraph(source,target);
tf1 = hascycles(G);
tf2 = isdag(G);
end
```

Write the function `foo1` that calls `foo2`. Save `foo1` in the file `foo1.m`.

```
function [tf1,tf2] = foo1(source,target)
assert(numel(source)==numel(target))
[tf1,tf2] = foo2(source,target);
end
```

Analyze `foo1`.

```
coder.screener('foo1')
```

The Code Generation Readiness report displays a summary of the unsupported MATLAB function calls. The report **Issues** tab indicates that `foo2.m` contains one call to the `isdag` function and one call to the `hascycles`, which are not supported for code generation.

2 Code generation readiness issues - Code might require changes Language C/C++ (MATLAB Coder) [Refresh](#) [Edit](#)

2 Unsupported functions
2 Files analyzed

Issues Files Group by: Issue  

- Unsupported function: `hascycles` (1)
- Unsupported function: `isdag` (1)

Unsupported function: `hascycles`

foo2.m

```

1 function [tf1,tf2] = foo2(source,target)
2 G = digraph(source,target);
3 tf1 = hascycles(G);
4 tf2 = isdag(G);
5 end
6

```

The function `foo2` calls two unsupported MATLAB functions. To generate a MEX function, modify the code to make the calls to `hascycles` and `isdag` extrinsic by using the `coder.extrinsic` directive, and then rerun the code generation readiness tool.

```

function [tf1,tf2] = foo2(source,target)
coder.extrinsic('hascycles','isdag');
G = digraph(source,target);
tf1 = hascycles(G);
tf2 = isdag(G);
end

```

Rerun `coder.screener` on the entry-point function `foo1`.

```
coder.screener('foo1')
```

The report no longer flags that code generation does not support the `hascycles` and `isdag` functions. When you generate a MEX function for `foo1`, the code generator dispatches these two functions to MATLAB for execution.

Access Code Generation Readiness Results Programmatically

You can call the `coder.screener` function with an optional output argument. If you use this syntax, the `coder.screener` function returns a `coder.ScreenerInfo` object that contains the results of

the code generation readiness analysis for your MATLAB code base. See `coder.ScreenerInfo` Properties.

This example uses the files `foo1.m` and `foo2.m` defined in the previous example. Call the `coder.screener` function:

```
info = coder.screener('foo1.m')
```

```
info =
```

```
  ScreenerInfo with properties:
```

```
      Files: [2×1 coder.CodeFile]
      Messages: [2×1 coder.Message]
      UnsupportedCalls: [2×1 coder.CallSite]
```

```
  View Screener Report
```

To access information about the first unsupported call, index into the `UnsupportedCalls` property,

```
firstCall = info.UnsupportedCalls(1)
```

```
firstCall =
```

```
  CallSite with properties:
```

```
      CalleeName: 'hascycles'
      File: [1×1 coder.CodeFile]
      StartIndex: 78
      EndIndex: 86
```

View the text of the file that contains this unsupported call to `hascycles`.

```
firstCall.File.Text
```

```
ans =
```

```
'function [tf1,tf2] = foo2(source,target)
      G = digraph(source,target);
      tf1 = hascycles(G);
      tf2 = isdag(G);
      end
      '
```

To export the entire code generation readiness report to a MATLAB string, use the `textReport` function.

```
reportString = textReport(info)
```

```
reportString =
```

```
'Code Generation Readiness (Text Report)
=====

2 Code generation readiness issues
2 Unsupported functions
2 Files analyzed

Configuration
```

```

=====
Language: C/C++ (MATLAB Coder)

Code Generation Issues
=====

Unsupported function: digraph (2)
  - foo2.m (Line 3)
  - foo2.m (Line 4)

```

Identify Unsupported Data Types

The `coder.screener` function identifies MATLAB data types that code generation does not support.

Write the function `myfun1` that contains a MATLAB calendar duration array data type.

```

function out = myfun1(A)
out = calyears(A);
end

```

Analyze `myfun1`.

```

coder.screener('myfun1');

```

The code generation readiness report indicates that the `calyears` data type is not supported for code generation. Before generating code, fix the reported issue.

Input Arguments

fcn — Name of entry-point function

character vector | string scalar

Name of entry-point MATLAB function for analysis. Specify as a character vector or a string scalar.

Example: `coder.screener('myfun');`

Data Types: `char` | `string`

fcn_1, ..., fcn_n — List of entry-point function names

character vector | string scalar

Comma-separated list of entry-point MATLAB function names for analysis. Specify as character vectors or string scalars.

Example: `coder.screener('myfun1','myfun2');`

Data Types: `char` | `string`

coder.target

Determine if code generation target is specified target

Syntax

```
tf = coder.target(target)
```

Description

`tf = coder.target(target)` returns true (1) if the code generation target is `target`. Otherwise, it returns false (0).

If you generate code for MATLAB classes, MATLAB computes class initial values at class loading time before code generation. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns true.

Examples

Use coder.target to Parametrize a MATLAB Function

Parametrize a MATLAB function so that it works in MATLAB or in generated code. When the function runs in MATLAB, it calls the MATLAB function `myabsval`. The generated code, however, calls a C library function `myabsval`.

Write a MATLAB function `myabsval`.

```
function y = myabsval(u)
%#codegen
y = abs(u);
```

Generate a C static library for `myabsval`, using the `-args` option to specify the size, type, and complexity of the input parameter.

```
codegen -config:lib myabsval -args {0.0}
```

The `codegen` function creates the library file `myabsval.lib` and header file `myabsval.h` in the folder `\codegen\lib\myabsval`. (The library file extension can change depending on your platform.) It generates the functions `myabsval_initialize` and `myabsval_terminate` in the same folder.

Write a MATLAB function to call the generated C library function using `coder.ceval`.

```
function y = callmyabsval(y)
%#codegen
% Check the target. Do not use coder.ceval if callmyabsval is
% executing in MATLAB
if coder.target('MATLAB')
    % Executing in MATLAB, call function myabsval
    y = myabsval(y);
else
```

```

% add the required include statements to generated function code
coder.updateBuildInfo('addIncludePaths','$(START_DIR)\codegen\lib\myabsval');
coder.cinclude('myabsval_initialize.h');
coder.cinclude('myabsval.h');
coder.cinclude('myabsval_terminate.h');

% Executing in the generated code.
% Call the initialize function before calling the
% C function for the first time
coder.ceval('myabsval_initialize');

% Call the generated C library function myabsval
y = coder.ceval('myabsval',y);

% Call the terminate function after
% calling the C function for the last time
coder.ceval('myabsval_terminate');
end

```

Generate the MEX function `callmyabsval_mex`. Provide the generated library file at the command line.

```
codegen -config:mex callmyabsval codegen\lib\myabsval\myabsval.lib -args {-2.75}
```

Rather than providing the library at the command line, you can use `coder.updateBuildInfo` to specify the library within the function. Use this option to preconfigure the build. Add this line to the `else` block:

```
coder.updateBuildInfo('addLinkObjects','myabsval.lib','$(START_DIR)\codegen\lib\myabsval',100,tru
```

Note The `START_DIR` macro is only supported for generating code with MATLAB Coder.

Run the MEX function `callmyabsval_mex` which calls the library function `myabsval`.

```
callmyabsval_mex(-2.75)
```

```
ans =
```

```
2.7500
```

Call the MATLAB function `callmyabsval`.

```
callmyabsval(-2.75)
```

```
ans =
```

```
2.7500
```

The `callmyabsval` function exhibits the desired behavior for execution in MATLAB and in code generation.

Input Arguments

target — code generation target

'MATLAB' | 'C' | 'C++' | 'CUDA' | 'OpenCL' | 'SystemC' | 'SystemVerilog' | 'Verilog' | 'VHDL' | 'MEX' | 'Sfun' | 'Rtw' | 'HDL' | 'Custom'

Code generation target, specified as a character vector or a string scalar. Specify one of these targets.

'MATLAB'	Running in MATLAB (not generating code)
'C', 'C++', 'CUDA', 'OpenCL', 'SystemC', 'SystemVerilog', 'Verilog', 'VHDL'	Supported target languages for code generation
'MEX'	Generating a MEX function
'Sfun'	Simulating a Simulink model. Also used for running in Accelerator mode.
'Rtw'	Generating a LIB, DLL, or EXE target. Also used for running in Simulink Coder and Rapid Accelerator mode.
'HDL'	Generating an HDL target
'Custom'	Generating a custom target

Example: `tf = coder.target('MATLAB')`

Example: `tf = coder.target("MATLAB")`

Note In case of CUDA or SystemC code generation, `coder.target('C++')` is always true.

coder.unroll

Unroll for-loop by making a copy of the loop body for each loop iteration

Syntax

```
coder.unroll()  
coder.unroll(flag)
```

Description

`coder.unroll()` unrolls a for-loop. The `coder.unroll` call must be on a line by itself immediately preceding the for-loop that it unrolls.

Instead of producing a for-loop in the generated code, loop unrolling produces a copy of the for-loop body for each loop iteration. In each iteration, the loop index becomes constant. To unroll a loop, the code generator must be able to determine the bounds of the for-loop.

For small, tight loops, unrolling can improve performance. However, for large loops, unrolling can increase code generation time significantly and generate inefficient code.

`coder.unroll` is ignored outside of code generation.

`coder.unroll(flag)` unrolls a for-loop if `flag` is `true`. `flag` is evaluated at code generation time. The `coder.unroll` call must be on a line by itself immediately preceding the for-loop that it unrolls.

Examples

Unroll a for-loop

To produce copies of a for-loop body in the generated code, use `coder.unroll`.

In one file, write the entry-point function `call_getrand` and a local function `getrand`. `getrand` unrolls a for-loop that assigns random numbers to an n-by-1 array. `call_getrand` calls `getrand` with the value 3.

```
function z = call_getrand  
%#codegen  
z = getrand(3);  
end  
  
function y = getrand(n)  
coder.inline('never');  
y = zeros(n, 1);  
coder.unroll();  
for i = 1:n  
    y(i) = rand();  
end  
end
```

Generate a static library.

```
codegen -config:lib call_getrand -report
```

In the generated code, the code generator produces a copy of the for-loop body for each of the three loop iterations.

```
static void getrand(double y[3])
{
    y[0] = b_rand();
    y[1] = b_rand();
    y[2] = b_rand();
}
```

Control for-loop Unrolling with Flag

Control loop unrolling by using `coder.unroll` with the `flag` argument.

In one file, write the entry-point function `call_getrand_unrollflag` and a local function `getrand_unrollflag`. When the number of loop iterations is less than 10, `getrand_unrollflag` unrolls the for-loop. `call_getrand` calls `getrand` with the value 50.

```
function z = call_getrand_unrollflag
    %#codegen
    z = getrand_unrollflag(50);
end

function y = getrand_unrollflag(n)
    coder.inline('never');
    unrollflag = n < 10;
    y = zeros(n, 1);
    coder.unroll(unrollflag)
    for i = 1:n
        y(i) = rand();
    end
end
```

Generate a static library.

```
codegen -config:lib call_getrand_unrollflag -report
```

```
static void getrand_unrollflag(double y[50])
{
    int i;
    for (i = 0; i < 50; i++) {
        y[i] = b_rand();
    }
}
```

The number of iterations is not less than 10. Therefore, the code generator does not unroll the for-loop. It produces a for-loop in the generated code.

Use Legacy Syntax to Unroll for-Loop

- ```
function z = call_getrand
 %#codegen
 z = getrand(3);
end

function y = getrand(n)
 coder.inline('never');
 y = zeros(n, 1);
 for i = coder.unroll(1:n)
 y(i) = rand();
 end
end
```

### Use Legacy Syntax to Control for-Loop Unrolling

- ```
function z = call_getrand_unrollflag
    %#codegen
    z = getrand_unrollflag(50);
end

function y = getrand_unrollflag(n)
    coder.inline('never');
    unrollflag = n < 10;
    y = zeros(n, 1);
    for i = coder.unroll(1:n, unrollflag)
        y(i) = rand();
    end
end
```

Input Arguments

flag — Indicates whether to unroll the for-loop

true (default) | false

When flag is true, the code generator unrolls the for-loop. When flag is false, the code generator produces a for-loop in the generated code. flag is evaluated at code generation time.

Tips

- Sometimes, the code generator unrolls a for-loop even though you do not use `coder.unroll`. For example, if a for-loop indexes into a heterogeneous cell array or into `varargin` or `varargout`, the code generator unrolls the loop. By unrolling the loop, the code generator can determine the value of the index for each loop iteration. The code generator uses heuristics to determine when to unroll a for-loop. If the heuristics fail to identify that unrolling is warranted, or if the number of loop iterations exceeds a limit, code generation fails. In these cases, you can force loop unrolling by using `coder.unroll`. See “Nonconstant Index into `varargin` or `varargout` in a for-Loop”.

Version History

coder.updateBuildInfo

Update build information object RTW.BuildInfo

Syntax

```
coder.updateBuildInfo('addCompileFlags',options)
coder.updateBuildInfo('addLinkFlags',options)
coder.updateBuildInfo('addDefines',options)
coder.updateBuildInfo( __ ,group)
```

```
coder.updateBuildInfo('addLinkObjects',filename,path)
coder.updateBuildInfo('addLinkObjects',filename,path,priority,precompiled)
coder.updateBuildInfo('addLinkObjects',filename,path,priority,precompiled,
linkonly)
coder.updateBuildInfo( __ ,group)
```

```
coder.updateBuildInfo('addNonBuildFiles',filename)
coder.updateBuildInfo('addSourceFiles',filename)
coder.updateBuildInfo('addIncludeFiles',filename)
coder.updateBuildInfo( __ ,path)
coder.updateBuildInfo( __ ,path,group)
```

```
coder.updateBuildInfo('addSourcePaths',path)
coder.updateBuildInfo('addIncludePaths',path)
coder.updateBuildInfo( __ ,group)
```

Description

`coder.updateBuildInfo('addCompileFlags',options)` adds compiler options to the build information object.

`coder.updateBuildInfo('addLinkFlags',options)` adds link options to the build information object.

`coder.updateBuildInfo('addDefines',options)` adds preprocessor macro definitions to the build information object.

`coder.updateBuildInfo(__ ,group)` assigns a group name to options for later reference.

`coder.updateBuildInfo('addLinkObjects',filename,path)` adds a link object from a file to the build information object.

`coder.updateBuildInfo('addLinkObjects',filename,path,priority,precompiled)` specifies if the link object is precompiled.

`coder.updateBuildInfo('addLinkObjects',filename,path,priority,precompiled,linkonly)` specifies if the object is to be built before being linked or used for linking alone. If the object is to be built, it specifies if the object is precompiled.

`coder.updateBuildInfo(__ ,group)` assigns a group name to the link object for later reference.

`coder.updateBuildInfo('addNonBuildFiles', filename)` adds a nonbuild-related file to the build information object.

`coder.updateBuildInfo('addSourceFiles', filename)` adds a source file to the build information object.

`coder.updateBuildInfo('addIncludeFiles', filename)` adds an include file to the build information object.

`coder.updateBuildInfo(____, path)` adds the file from specified path.

`coder.updateBuildInfo(____, path, group)` assigns a group name to the file for later reference.

`coder.updateBuildInfo('addSourcePaths', path)` adds a source file path to the build information object.

`coder.updateBuildInfo('addIncludePaths', path)` adds an include file path to the build information object.

`coder.updateBuildInfo(____, group)` assigns a group name to the path for later reference.

Examples

Add Multiple Compiler Options

Add the compiler options `-Zi` and `-Wall` during code generation for function, `func`.

Anywhere in the MATLAB code for `func`, add the following line:

```
coder.updateBuildInfo('addCompileFlags', '-Zi -Wall');
```

Generate code for `func` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport func
```

Add Source File Name

Add a source file to the project build information while generating code for a function, `calc_factorial`.

- 1 Write a header file `fact.h` that declares a C function `factorial`.

```
double factorial(double x);
```

`fact.h` will be included as a header file in generated code. This inclusion ensures that the function is declared before it is called.

Save the file in the current folder.

- 2 Write a C file `fact.c` that contains the definition of `factorial`. `factorial` calculates the factorial of its input.

```
#include "fact.h"
```

```

double factorial(double x)
{
    int i;
    double fact = 1.0;
    if (x == 0 || x == 1) {
        return 1.0;
    } else {
        for (i = 1; i <= x; i++) {
            fact *= (double)i;
        }
        return fact;
    }
}

```

`fact.c` is used as a source file during code generation.

Save the file in the current folder.

- 3 Write a MATLAB function `calc_factorial` that uses `coder.ceval` to call the external C function `factorial`.

Use `coder.updateBuildInfo` with option `'addSourceFiles'` to add the source file `fact.c` to the build information. Use `coder.cinclude` to include the header file `fact.h` in the generated code.

```

function y = calc_factorial(x) %#codegen

    coder.cinclude('fact.h');
    coder.updateBuildInfo('addSourceFiles', 'fact.c');

    y = 0;
    y = coder.ceval('factorial', x);

```

- 4 Generate code for `calc_factorial` using the `codegen` command.

```

codegen -config:dll -launchreport calc_factorial -args 0

```

Add Link Object

Add a link object `LinkObj.lib` to the build information while generating code for a function `func`. For this example, you must have a link object `LinkObj.lib` saved in a local folder, for example, `c:\Link_Objects`.

Anywhere in the MATLAB code for `func`, add the following lines:

```

libPriority = '';
libPreCompiled = true;
libLinkOnly = true;
libName = 'LinkObj.lib';
libPath = 'c:\Link_Objects';
coder.updateBuildInfo('addLinkObjects', libName, libPath, ...
    libPriority, libPreCompiled, libLinkOnly);

```

Generate a MEX function for `func` using the `codegen` command. Open the Code Generation Report.

```
codegen -launchreport func
```

Add Include Paths

Add an include path to the build information while generating code for a function, `adder`. Include a header file, `adder.h`, existing on the path.

When header files do not reside in the current folder, to include them, use this method:

- 1 Write a header file `mysum.h` that contains the declaration for a C function `mysum`.

```
double mysum(double, double);
```

Save it in a local folder, for example `c:\coder\myheaders`.

- 2 Write a C file `mysum.c` that contains the definition of the function `mysum`.

```
#include "mysum.h"

double mysum(double x, double y)
{
    return(x+y);
}
```

Save it in the current folder.

- 3 Write a MATLAB function `adder` that adds the path `c:\coder\myheaders` to the build information.

Use `coder.cinclude` to include the header file `mysum.h` in the generated code.

```
function y = adder(x1, x2) %#codegen
    coder.updateBuildInfo('addIncludePaths','c:\coder\myheaders');
    coder.updateBuildInfo('addSourceFiles','mysum.c');
    %Include the source file containing C function definition
    coder.cinclude('mysum.h');
    y = 0;
    if coder.target('MATLAB')
        % This line ensures that the function works in MATLAB
        y = x1 + x2;
    else
        y = coder.ceval('mysum', x1, x2);
    end
end
```

- 4 Generate code for `adder` using the `codegen` command.

```
codegen -config:lib -launchreport adder -args {0,0}
```

Input Arguments

options — Build options

character vector | string scalar

Build options, specified as a character vector or string scalar. The value must be a compile-time constant.

Depending on the leading argument, `options` specifies the relevant build options to be added to the project's build information.

Leading Argument	Values in options
'addCompileFlags'	Compiler options
'addLinkFlags'	Link options
'addDefines'	Preprocessor macro definitions

The function adds the options to the end of an option vector.

Example: `coder.updateBuildInfo('addCompileFlags', '-Zi -Wall')`

group – Group name

character vector | string scalar

Name of user-defined group, specified as a character vector or string scalar. The value must be a compile-time constant.

The group option assigns a group name to the parameters in the second argument.

Leading Argument	Second Argument	Parameters Named by group
'addCompileFlags'	options	Compiler options
'addLinkFlags'	options	Link options
'addLinkObjects'	filename	Name of file containing linkable objects
'addNonBuildFiles'	filename	Name of nonbuild-related file
'addSourceFiles'	filename	Name of source file
'addSourcePaths'	path	Name of source file path

You can use `group` to:

- Document the use of specific parameters.
- Retrieve or apply multiple parameters together as one group.

filename – File name

character vector | string scalar

File name, specified as a character vector or string scalar. The value must be a compile-time constant.

Depending on the leading argument, `filename` specifies the relevant file to be added to the project's build information.

Leading Argument	File Specified by filename
'addLinkObjects'	File containing linkable objects
'addNonBuildFiles'	Nonbuild-related file
'addSourceFiles'	Source file

The function adds the file name to the end of a file name vector.

Example: `coder.updateBuildInfo('addSourceFiles', 'fact.c')`

path — Path name

character vector | string scalar

Relative path name, specified as a character vector or string scalar. The value must be a compile-time constant.

Depending on the leading argument, `path` specifies the relevant path name to be added to the project's build information. The function adds the path to the end of a path name vector.

Leading Argument	Path Specified by path
'addLinkObjects'	Path to linkable objects
'addNonBuildFiles'	Path to nonbuild-related files
'addSourceFiles', 'addSourcePaths'	Path to source files

The relative path starts from the *current working folder* in which you generate code. In the relative path name, reference the current working folder by using the `START_DIR` macro. For example, suppose that your source file `fact.c` is contained in `C:\myCode\mySrcDir`, and you generate code from `C:\myCode`. Write the path as in this example:

```
Example: coder.updateBuildInfo('addSourceFiles', 'fact.c', '$(START_DIR)\mySrcDir')
```

Note The `START_DIR` macro is only supported for generating code with MATLAB Coder.

priority — Relative priority of link object

Priority of link objects.

This feature applies only when several link objects are added. Currently, only a single link object file can be added for every `coder.updateBuildInfo` statement. Therefore, this feature is not available for use.

To use the succeeding arguments, include `' '` as a placeholder argument.

precompiled — Variable indicating if link objects are precompiled

logical value

Variable indicating if the link objects are precompiled, specified as a logical value. The value must be a compile-time constant.

If the link object has been prebuilt for faster compiling and linking and exists in a specified location, specify `true`. Otherwise, the MATLAB Coder build process creates the link object in the build folder.

If `linkonly` is set to `true`, this argument is ignored.

Data Types: `logical`

linkonly — Variable indicating if objects must be used for linking only

logical value

Variable indicating if objects must be used for linking only, specified as a logical value. The value must be a compile-time constant.

If you want that the MATLAB Coder build process must not build or generate rules in the makefile for building the specified link object, specify `true`. Instead, when linking the final executable, the process should just include the object. Otherwise, rules for building the link object are added to the makefile.

You can use this argument to incorporate link objects for which source files are not available.

If `linkonly` is set to `true`, the value of `precompiled` is ignored.

Data Types: `logical`

coder.varsize

Package: coder

Declare variable-size data

Syntax

```
coder.varsize(varName1,...,varNameN)
coder.varsize(varName1,...,varNameN,ubounds)
coder.varsize(varName1,...,varNameN,ubounds,dims)
```

Description

`coder.varsize(varName1,...,varNameN)` declares that the variables named `varName1,...,varNameN` have a variable size. The declaration instructs the code generator to allow the variables to change size during execution of the generated code. With this syntax, you do not specify the upper bounds of the dimensions of the variables or which dimensions can change size. The code generator computes the upper bounds. All dimensions, except singleton dimensions on page 2-154, are allowed to change size.

Use `coder.varsize` according to these restrictions and guidelines:

- Use `coder.varsize` inside a MATLAB function intended for code generation.
- The `coder.varsize` declaration must precede the first use of a variable. For example:

```
...
x = 1;
coder.varsize('x');
disp(size(x));
...
```

- Use `coder.varsize` to declare that an output argument has a variable size or to address size mismatch errors. Otherwise, to define variable-size data, use the methods described in “Define Variable-Size Data for Code Generation”.

Note For MATLAB Function blocks, to declare variable-size output variables, use the **Symbols** pane and Property Inspector. See “Declare Variable-Size MATLAB Function Block Variables”. If you provide upper bounds in a `coder.varsize` declaration, the upper bounds must match the upper bounds in the Property Inspector.

For more restrictions and guidelines, see “Limitations” on page 2-153 and “Tips” on page 2-154.

`coder.varsize(varName1,...,varNameN,ubounds)` also specifies an upper bound for each dimension of the variables. All variables must have the same number of dimensions. All dimensions, except singleton dimensions on page 2-154, are allowed to change size.

`coder.varsize(varName1,...,varNameN,ubounds,dims)` also specifies an upper bound for each dimension of the variables and whether each dimension has a fixed size or a variable size. If a dimension has a fixed size, then the corresponding `ubound` element specifies the fixed size of the dimension. All variables have the same fixed-size dimensions and the same variable-size dimensions.

The code generator uses a colon prefix to denote a variable-size dimension. For example, if the size of an array *A* is denoted as `3x:5x:Inf`, then:

- The first dimension has a fixed size 3
- The second dimension is variable-size with an upper bound 5
- The third dimension is variable-size and unbounded

Examples

Address Size Mismatch Error by Using `coder. varsize`

After a variable is used (read), changing the size of the variable can cause a size mismatch error. Use `coder. varsize` to specify that the size of the variable can change.

Code generation for the following function produces a size mismatch error because `x = 1:10` changes the size of the second dimension of `x` after the line `y = size(x)` that uses `x`.

```
function [x,y] = usevarsize(n)
%#codegen
x = 1;
y = size(x);
if n > 10
    x = 1:10;
end
```

To declare that `x` can change size, use `coder. varsize`.

```
function [x,y] = usevarsize(n)
%#codegen
x = 1;
coder. varsize('x');
y = size(x);
if n > 10
    x = 1:10;
end
```

If you remove the line `y = size(x)`, you no longer need the `coder. varsize` declaration because `x` is not used before its size changes.

Declare Variable-Size Array with Upper Bounds

Specify that *A* is a row vector of size `1x:20`. This denotes that the second dimension of *A* has a variable size with an upper bound of 20.

```
function fcn()
...
coder. varsize('A',[1 20]);
...
end
```

When you do not provide `dims`, all dimensions, except singleton dimensions, have a variable size.

Declare Variable-Size Array with a Mix of Fixed and Variable Dimensions

Specify that A is an array with size 3×20 . This denotes that the first dimension has a fixed size of three and whose second dimension has a variable size with an upper bound of 20.

```
function fcn()
...
coder.versize('A',[3 20], [0 1] );
...
end
```

Declare Variable-Size Structure Fields

In this function, the statement `coder.versize('data.values')` declares that the field `values` inside each element of `data` has a variable size.

```
function y = varsize_field()
%#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.versize('data.values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end
end
```

Declare Variable-Size Cell Array

Specify that cell array C has a fixed-size first dimension and variable-size second dimension with an upper bound of three. The `coder.versize` declaration must precede the first use of C.

```
...
C = {1 [1 2]};
coder.versize('C', [1 3], [0 1]);
y = C{1};
...
end
```

Without the `coder.versize` declaration, C is a heterogeneous cell array whose elements have the same class and different sizes. With the `coder.versize` declaration, C is a homogeneous cell array whose elements have the same class and maximum size.

- The cell array C is of size 1×3 . The colon denotes that the second dimension of C is variable-size with an upper bound of 3.

- Each element of `C` is a `1x:2` array.

Declare That a Cell Array Has Variable-Size Elements

Specify that the elements of cell array `C` are `1x:5` vectors. This denotes that the elements each have a fixed-size first dimension and variable-size second dimension with an upper bound of 5.

```
...
C = {1 2 3};
coder.varsize('C{:}', [1 5], [0 1]);
C = {1, 1:5, 2:3};
...
```

You can also specify a specific element of a cell array to be variable-size. For example, in a 1-by-3 cell array `x`, declare the first element `x{1}` to be a `1x:10` row vector.

```
...
x = {1,2,3};
coder.varsize('x{1}', [1 10]);
...
```

Input Arguments

varName1, ..., varNameN — Names of variables to declare as having a variable size
character vectors | string scalars

Names of variables to declare as having a variable size, specified as one or more character vectors or string scalars.

Example: `coder.varsize('x','y')`

ubounds — Upper bounds for array dimensions
[] (default) | vector of integer constants

Upper bounds for array dimensions, specified as a vector of integer constants.

When you do not specify `ubounds`, the code generator computes the upper bound for each variable. If the `ubounds` element corresponds to a fixed-size dimension, the value is the fixed size of the dimension.

Example: `coder.varsize('x','y',[1 2])`

dims — Indication of whether each dimension has a fixed size or a variable size
logical vector

Indication of whether each dimension has a fixed size or a variable size, specified as a logical vector. Dimensions that correspond to 0 or `false` in `dims` have a fixed size. Dimensions that correspond to 1 or `true` have a variable size.

When you do not specify `dims`, the dimensions have a variable size, except for the singleton dimensions.

Example: `coder.varsize('x','y',[1 2], [0 1])`

Limitations

- The `coder.varsize` declaration instructs the code generator to allow the size of a variable to change. It does not change the size of the variable. Consider this code:

```
...
x = 7;
coder.varsize('x', [1,5]);
disp(size(x));
...
```

After the `coder.varsize` declaration, `x` is still a 1-by-1 array. You cannot assign a value to an element beyond the current size of `x`. For example, this code produces a run-time error because the index 3 exceeds the dimensions of `x`.

```
...
x = 7;
coder.varsize('x', [1,5]);
x(3) = 1;
...
```

- `coder.varsize` is not supported for a function input argument. Instead:
 - If the function is an entry-point function, specify that an input argument has a variable size by using `coder.typeof` at the command line. Alternatively, specify that an entry-point function input argument has a variable size by using the **Define Input Types** step of the app.
 - If the function is not an entry-point function, use `coder.varsize` in the calling function with the variable that is the input to the called function.
- For sparse matrices, `coder.varsize` drops upper bounds for variable-size dimensions.
- Limitations for using `coder.varsize` with cell arrays:
 - A cell array can have a variable size only if it is homogeneous. When you use `coder.varsize` with a heterogeneous cell array, the code generator tries to make the cell array homogeneous. The code generator tries to find a class and maximum size that apply to all elements of the cell array. For example, consider the cell array `c = {1, [2 3]}`. Both elements can be represented by a double type whose first dimension has a fixed size of 1 and whose second dimension has a variable size with an upper bound of 2. If the code generator cannot find a common class and a maximum size, code generation fails. For example, consider the cell array `c = {'a', [2 3]}`. The code generator cannot find a class that can represent both elements because the first element is `char` and the second element is `double`.
 - If you use the `cell` function to define a fixed-size cell array, you cannot use `coder.varsize` to specify that the cell array has a variable size. For example, this code causes a code generation error because `x = cell(1,3)` makes `x` a fixed-size,1-by-3 cell array.

```
...
x = cell(1,3);
coder.varsize('x',[1 5])
...
```

You can use `coder.varsize` with a cell array that you define by using curly braces. For example:

```
...
x = {1 2 3};
coder.varsize('x',[1 5])
...
```

- To create a variable-size cell array by using the `cell` function, use this code pattern:

```
function mycell(n)
%#codegen
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
end
```

See “Definition of Variable-Size Cell Array by Using `cell`”.

To specify upper bounds for the cell array, use `coder.versize`.

```
function mycell(n)
%#codegen
x = cell(1,n);
for i = 1:n
    x{i} = i;
coder.versize('x',[1,20]);
end
end
```

More About

Singleton Dimension

Dimension for which `size(A,dim) = 1`.

Tips

- In a code generation report or a MATLAB Function report, a colon (:) indicates that a dimension has a variable size. For example, a size of `1x:2` indicates that the first dimension has a fixed size of one and the second dimension has a variable size with an upper bound of two.
- If you use `coder.versize` to specify that the upper bound of a dimension is 1, by default, the dimension has a fixed size of 1. To specify that the dimension can be 0 (empty array) or 1, set the corresponding element of the `dims` argument to `true`. For example, this code specifies that the first dimension of `x` has a fixed size of 1 and the other dimensions have a variable size of 5.

```
coder.versize('x',[1,5,5])
```

In contrast, this code specifies that the first dimension of `x` has an upper bound of 1 and has a variable size (can be 0 or 1).

```
coder.versize('x',[1,5,5],[1,1,1])
```

- If you use input variables or the result of a computation using input variables to specify the size of an array, it is declared as variable-size in the generated code. Do not re-use `coder.versize` on the array, unless you also want to specify an upper bound for its size.
- If you do not specify upper bounds with a `coder.versize` declaration and the code generator is unable to determine the upper bounds, the generated code uses dynamic memory allocation. Dynamic memory allocation can reduce the speed of generated code. To avoid dynamic memory allocation, specify the upper bounds by providing the `ubounds` argument.

coder.wref

Indicate write-only data to pass by reference

Syntax

```
coder.wref(arg)
coder.wref(arg, 'gpu')
```

Description

`coder.wref(arg)` indicates that `arg` is a write-only expression or variable to pass by reference to an external C/C++ function. Use `coder.wref` only inside a `coder.ceval` call. This function enables the code generator to optimize the generated code by ignoring prior assignments to `arg` in your MATLAB code, because the external function is assumed to not read from the data. Write to all the elements of `arg` in your external code to fully initialize the memory.

Note The C/C++ function must fully initialize the memory referenced by `coder.wref(arg)`. Initialize the memory by assigning values to every element of `arg` in your C/C++ code. If the generated code tries to read from uninitialized memory, it can cause undefined run-time behavior.

See also `coder.ref` and `coder.rref`.

`coder.wref(arg, 'gpu')` indicates that `arg` is a GPU argument. This option requires a valid GPU Coder license. If the `coder.ceval` calls a CUDA GPU `__device__` function, the code generator ignores the 'gpu' specification.

Examples

Pass Array by Reference as Write-Only

Suppose that you have a C function `init_array`.

```
void init_array(double* array, int numel) {
    for(int i = 0; i < numel; i++) {
        array[i] = 42;
    }
}
```

The C function defines the input variable `array` as a pointer to a double.

Call the C function `init_array` to initialize all elements of `y` to 42:

```
...
Y = zeros(5, 10);
coder.ceval('init_array', coder.wref(Y), int32(numel(Y)));
...
```

Pass Multiple Arguments as a Write-Only Reference

```
...
U = zeros(5, 10);
```

```
V = zeros(5, 10);
coder.ceval('my_fcn', coder.wref(U), int32(numel(U)), coder.wref(V), int32(numel(V)));
...
```

Pass Class Property as a Write-Only Reference

```
...
x = myClass;
x.prop = 1;
coder.ceval('foo', coder.wref(x.prop));
...
```

Pass Structure as a Write-Only Reference

To indicate that the structure type is defined in a C header file, use `coder.cstructname`.

Suppose that you have the C function `init_struct`. This function writes to the input argument but does not read from it.

```
#include "MyStruct.h"

void init_struct(struct MyStruct *my_struct)
{
    my_struct->f1 = 1;
    my_struct->f2 = 2;
}
```

The C header file, `MyStruct.h`, defines a structure type named `MyStruct`:

```
#ifndef MYSTRUCT
#define MYSTRUCT

typedef struct MyStruct
{
    double f1;
    double f2;
} MyStruct;

void init_struct(struct MyStruct *my_struct);

#endif
```

In your MATLAB function, pass a structure as a write-only reference to `init_struct`. Use `coder.cstructname` to indicate that the structure type for `s` has the name `MyStruct` that is defined in the C header file `MyStruct.h`.

```
function y = foo
%#codegen
y = 0;
coder.updateBuildInfo('addSourceFiles','init_struct.c');

s = struct('f1',1,'f2',2);
coder.cstructname(s,'MyStruct','extern','HeaderFile','MyStruct.h');
coder.ceval('init_struct', coder.wref(s));
```

To generate standalone library code, enter:

```
codegen -config:lib foo -report
```

Pass Structure Field as a Write-Only Reference

```
...
s = struct('s1', struct('a', [0 1]));
coder.ceval('foo', coder.wref(s.s1.a));
...
```

You can also pass an element of an array of structures:

```
...
c = repmat(struct('u', magic(2)), 1, 10);
b = repmat(struct('c', c), 3, 6);
a = struct('b', b);
coder.ceval('foo', coder.wref(a.b(3,4).c(2).u));
...
```

Input Arguments

arg — Argument to pass by reference

scalar variable | array | element of an array | structure | structure field | object property

Argument to pass by reference to an external C/C++ function. The argument cannot be a class, a System object, a cell array, or an index into a cell array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct

Complex Number Support: Yes

Limitations

- You cannot pass these data types by reference:
 - Class or System object
 - Cell array or index into a cell array
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties”.

Tips

- If `arg` is an array, then `coder.wref(arg)` provides the address of the first element of the array. The `coder.wref(arg)` function does not contain information about the size of the array. If the C function must know the number of elements of your data, pass that information as a separate argument. For example:

```
coder.ceval('myFun', coder.wref(arg), int32(numel(arg)));
```

- When you pass a structure by reference to an external C/C++ function, use `coder.cstructname` to provide the name of a C structure type that is defined in a C header file.
- In MATLAB, `coder.wref` results in an error. To parametrize your MATLAB code so that it can run in MATLAB and in generated code, use `coder.target`.

- You can use `coder.opaque` to declare variables that you pass to and from an external C/C++ function.

Version History

configset.reference.getOverriddenParameters

Parameters that are overridden in a configuration reference

Syntax

```
parameters = configset.reference.getOverriddenParameters(model)
```

Description

`parameters = configset.reference.getOverriddenParameters(model)` returns the parameters that are overridden in the configuration reference that is active for the model.

Examples

Override Parameters in a Configuration Reference

Programmatically override a parameter in a configuration reference and set a value that is different from the referenced configuration set.

Open the model `slexConfigSetRefExample`, which uses a configuration reference as the active configuration.

```
model = 'slexConfigSetRefExample';  
open(model)
```

Check if the model has any overridden parameters.

```
configset.reference.hasOverriddenParameters(model)
```

```
ans = logical  
     0
```

The model does not have any overridden parameters. For this example, override the parameter `ModelReferenceNumInstancesAllowed`. This parameter controls the number of times that the model can be referenced directly or indirectly by another model. In the referenced configuration set, the value is `Multi`. For the model `slexConfigSetRefExample`, override the parameter and set the value to `Single` so that it can be referenced only once by another model.

```
configset.reference.overrideParameter(model, "ModelReferenceNumInstancesAllowed", "Single");
```

Verify that the parameter `ModelReferenceNumInstancesAllowed` is overridden and check its value for the model.

```
configset.reference.isParameterOverridden(model, "ModelReferenceNumInstancesAllowed")
```

```
ans = logical  
     1
```

```
get_param(model, "ModelReferenceNumInstancesAllowed")
```

```
ans =
'Single'
```

Restore the parameter to the value in the referenced configuration set. Restoring the parameter makes it read-only again.

```
configset.reference.restoreOverriddenParameter(model, "ModelReferenceNumInstancesAllowed");
```

If multiple parameters are overridden for the model, you can interact with all of them at once. For example, override the parameters `StartTime`, `StopTime`, and `SolverType`. Then, use the function `configset.reference.getOverriddenParameters` to see a list of the overridden parameters.

```
configset.reference.overrideParameter(model, "StartTime");
configset.reference.overrideParameter(model, "StopTime");
configset.reference.overrideParameter(model, "Solver");
configset.reference.getOverriddenParameters(model)
```

```
ans = 3x1 string
    "StartTime"
    "StopTime"
    "Solver"
```

Now, restore all of the overridden parameters for the model. The parameters reset to the values in the referenced configuration set and become read-only again.

```
configset.reference.restoreAllOverriddenParameters(model)
```

Input Arguments

model — Model that uses configuration reference

character vector | string scalar

Model that uses configuration reference, specified as a character vector or string scalar.

Example: 'mymodel'

Output Arguments

parameters — Overridden parameters

string array

Overridden parameters, returned as a string array.

```
configset.reference.overrideParameter(model, "StartTime");  
configset.reference.overrideParameter(model, "StopTime");  
configset.reference.overrideParameter(model, "Solver");  
configset.reference.getOverriddenParameters(model)
```

```
ans = 3x1 string  
    "StartTime"  
    "StopTime"  
    "Solver"
```

Now, restore all of the overridden parameters for the model. The parameters reset to the values in the referenced configuration set and become read-only again.

```
configset.reference.restoreAllOverriddenParameters(model)
```

Input Arguments

model — Model that uses configuration reference

character vector | string scalar

Model that uses configuration reference, specified as a character vector or string scalar.

Example: 'vdp'

Output Arguments

tf — True or false result

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

Topics

“Change Parameter Value in a Configuration Reference”

configset.reference.overrideParameter

Change value of parameter in configuration reference

Syntax

```
configset.reference.overrideParameter(model, parameter)
configset.reference.overrideParameter(model, parameter, value)
```

Description

`configset.reference.overrideParameter(model, parameter)` overrides the parameter `parameter` in the active configuration reference that `model` uses. By default, a configuration reference uses the parameter values from the configuration set that it references and does not enable editing. Overriding a parameter enables editing in the configuration reference so that you can change the value for the parameter in the reference without changing the referenced configuration set. Changing the value in the referenced configuration set does not affect the value of the overridden parameter. Some parameters cannot be overridden.

`configset.reference.overrideParameter(model, parameter, value)` overrides the parameter and sets the value in the configuration reference to `value`.

Examples

Override Parameters in a Configuration Reference

Programmatically override a parameter in a configuration reference and set a value that is different from the referenced configuration set.

Open the model `slexConfigSetRefExample`, which uses a configuration reference as the active configuration.

```
model = 'slexConfigSetRefExample';
open(model)
```

Check if the model has any overridden parameters.

```
configset.reference.hasOverriddenParameters(model)
```

```
ans = logical
      0
```

The model does not have any overridden parameters. For this example, override the parameter `ModelReferenceNumInstancesAllowed`. This parameter controls the number of times that the model can be referenced directly or indirectly by another model. In the referenced configuration set, the value is `Multi`. For the model `slexConfigSetRefExample`, override the parameter and set the value to `Single` so that it can be referenced only once by another model.

```
configset.reference.overrideParameter(model, "ModelReferenceNumInstancesAllowed", "Single");
```

Verify that the parameter `ModelReferenceNumInstancesAllowed` is overridden and check its value for the model.

```
configset.reference.isParameterOverridden(model, "ModelReferenceNumInstancesAllowed")
```

```
ans = logical  
     1
```

```
get_param(model, "ModelReferenceNumInstancesAllowed")
```

```
ans =  
'Single'
```

Restore the parameter to the value in the referenced configuration set. Restoring the parameter makes it read-only again.

```
configset.reference.restoreOverriddenParameter(model, "ModelReferenceNumInstancesAllowed");
```

If multiple parameters are overridden for the model, you can interact with all of them at once. For example, override the parameters `StartTime`, `StopTime`, and `SolverType`. Then, use the function `configset.reference.getOverriddenParameters` to see a list of the overridden parameters.

```
configset.reference.overrideParameter(model, "StartTime");  
configset.reference.overrideParameter(model, "StopTime");  
configset.reference.overrideParameter(model, "Solver");

```

```
ans = 3x1 string  
     "StartTime"  
     "StopTime"  
     "Solver"
```

Now, restore all of the overridden parameters for the model. The parameters reset to the values in the referenced configuration set and become read-only again.

```
configset.reference.restoreAllOverriddenParameters(model)
```

Input Arguments

model — Model that uses configuration reference

character vector | string scalar

Model that uses the configuration reference, specified as a character vector or string scalar.

Example: `'vdp'`

parameter — Parameter to override

character vector | string scalar

Parameter to override, specified as a character vector or string scalar.

Example: `'ModelReferenceNumInstancesAllowed'`

value — Value to set

character vector | string scalar

Value to set for the overridden parameter, specified as a character vector or string scalar.

Example: 'Multi'

createCustomDBFromExcel

Create custom units database file from Microsoft Excel spreadsheet

Syntax

```
createCustomDBFromExcel(units_db.xlsx)
```

Description

`createCustomDBFromExcel(units_db.xlsx)` creates a custom units database file from an Excel spreadsheet that contains custom units. On all supported platforms, the `createCustomDBFromExcel` function supports: `.xls` and `.xlsx` files.

To see the supported spreadsheet format, see “Custom Units Spreadsheet Format”.

Examples

Create Custom Units Database File from Excel Spreadsheet

Create a custom units database file from custom Excel spreadsheet file, `unitsDB.xlsx`.

Create a Excel spreadsheet containing these columns and data in any order:

- **name**, containing `ounce_force`
- **symbol**, containing `ozf`
- **asciiSymbol**, containing `ozf`
- **displayName**, containing $\{\rm\{oz_{force}\}}$
- **definitionExpression**, containing `oz*gn`
- **conversionFactor**, containing `1`
- **conversionOffset**, containing `0`
- **physicalQuantity**, containing `force`

Enter your custom unit specifications.

Save the database file, for example `unitsDB.xlsx`.

Create the database.

```
createCustomDBFromExcel('unitsDB.xlsx')
```

The function creates `unitsDB.slunitdb.mldatx` in the current folder.

Add the current folder to the MATLAB path.

```
addpath C:\work\custom_units
```

Load the new units database into memory.

rehashUnitDBs

Input Arguments

units_db.xlsx — Custom unit database

Excel units database file name

Custom unit database, specified as the file name of an Excel units database file. Create this file as an Excel spreadsheet with columns that contain custom unit information.

The function creates a unit database file, *units_db.slunitdb.mldatx*, in the current folder, where *units_db* is the name of the Excel file. If the unit entry is empty for the **symbol**, **asciiSymbol**, or **displayName** columns, the function uses the unit name for the missing **symbol**, **asciiSymbol**, or **displayName** entries.

To see the supported spreadsheet format, see “Custom Units Spreadsheet Format”.

Example: *custom_units.xlsx*

Data Types: char | string

Version History

Introduced in R2020a

createInputDataset

Generate dataset object for root-level Inport or bus element ports in model

Syntax

```
[inports_dataset] = createInputDataset(model)
[inports_dataset] = createInputDataset(model, 'DatasetSignalFormat', value)
```

Description

[inports_dataset] = createInputDataset(model) generates a Simulink.SimulationData.Dataset object from the root-level Inport blocks or bus element ports in a model. Signals in the generated dataset have the properties of the root inports and the corresponding ground values at model start and stop times. You can create timetable or timeseries objects for the time and values for signals for which you want to load data for simulation. The other signals use ground values.

[inports_dataset] = createInputDataset(model, 'DatasetSignalFormat', value) generates a Simulink.SimulationData.Dataset object whose signal dataset signal elements are either timeseries or timetable.

Examples

Generate and Populate Dataset for Root-Level Inport Blocks

This example shows how to create a timeseries dataset with elements for the four root-level Inport blocks in a model. Use that dataset as a basis for creating a dataset to load signal data into the model.

The In1 block outputs a double, In2 and In3 each output a nonvirtual bus, and In4 outputs an int16.

```
mdl = 'ex_dataset_for_inports';
open_system(mdl)
```

Create a Dataset object for the root-level Inport blocks.

```
ds = createInputDataset mdl
```

```
Exporting logged dataset prior to deleting run...done.
```

```
ds =
```

```
Simulink.SimulationData.Dataset '' with 4 elements
```

		Name	BlockPath
1	[1x1 timeseries]	In1	''
2	[1x1 struct]	In2	''
3	[1x1 struct]	In3	''
4	[1x1 timeseries]	In4	''

- Use braces { } to access, modify, or add elements using index.

Replace the placeholder value for the first signal in the Dataset with actual signal values that you want to load into the model.

```
ds{1} = ds{1}.delsample('Index',[1,2]);
ds{1} = ds{1}.addsample('time',[1 3 3 10]','data',[1 1 5 5]');
```

Examine the In2 signal.

```
ds{2}
```

```
ans =
```

```
struct with fields:
```

```
a: [1x1 timeseries]
b: [1x1 timeseries]
```

For In2 , create data for bus elements a and b.

```
ds{2}.a = ds{2}.a.delsample('Index',[1,2]);
ds{2}.a = addsample(ds{2}.a,'time',[1:10]','data',[1:10]');
ds{2}.b = timeseries((1:10)',0.1:.1:1,'Name','sig2_b');
```

For In3, specify data for element a of the bus, and use ground values for element b.

```
ds{3}.a = timeseries((1:10)',0.1:.1:1,'Name','sig3_a');
```

Plot ds.

```
plot(ds)
```

Set the **Input** configuration parameter to ds. Alternatively, you can use the Root Inport Mapper tool to set the **Input** parameter.

```
set_param mdl, 'LoadExternalInput', 'on');
set_param mdl, 'ExternalInput', 'ds');
```

Run the simulation. The Inport blocks use the signal data specified in ds or ground values for elements that do not have specified signal data.

```
sim mdl)
```

Input Arguments

model — Model for which to generate dataset for root-level Inport blocks or bus element ports

string | character vector | model handle

Model for which to generate a dataset with an element for each root-level Inport block, specified as a string, character vector, or model handle.

'DatasetSignalFormat', value — Signal format for dataset signal elements

'timeseries' (default) | 'timetable'

Signal format for dataset signal elements, specified as 'timetable' or 'timeseries'.

Output Arguments

inports_dataset — Dataset with element for each root-level Inport block

Simulink.SimulationData.Dataset object

Dataset with an element for each root-level Inport block, returned as a Simulink.SimulationData.Dataset object.

Version History

Introduced in R2017a

R2023a: createInputDataset Function Allows Signal Format Specification

The `createInputDataset` function allows specification of the signal formats for the signal elements in the dataset.

getHardwareImplementation

Class: `coder.BuildConfig`

Package: `coder`

Get handle of copy of hardware implementation object

Syntax

```
hw = getHardwareImplementation(bldcfg)
```

Description

`hw = getHardwareImplementation(bldcfg)` returns the handle of a copy of the hardware implementation object.

Input Arguments

bldcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

hw — Hardware implementation

handle

Hardware implementation, returned as a handle of a copy of the `coder.HardwareImplementation` object.

Version History

Introduced in R2013b

`coder.HardwareImplementation`

getStdLibInfo

Class: `coder.BuildConfig`

Package: `coder`

Get standard library information

Syntax

```
[linkLibPath,linkLibExt,execLibExt,libPrefix] = getStdLibInfo(bldcfg)
```

Description

`[linkLibPath,linkLibExt,execLibExt,libPrefix] = getStdLibInfo(bldcfg)` returns standard library information associated with the build context, `bldcfg`.

Input Arguments

bldcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

linkLibPath — Architecture-specific library path

character vector

Standard MATLAB architecture-specific library path returned as a character vector. The character vector can be empty.

Data Types: `char`

linkLibExt — Library file extension used at link time

`'.lib' | '.dylib' | '.so' | ''`

Platform-specific library file extension for use at link time, returned as `'.lib'`, `'.dylib'`, `'.so'`, or `''`.

Data Types: `enumerated`

execLibExt — Library file extension used at run time

`'.lib' | '.dylib' | '.so' | ''`

Platform-specific library file extension for use at run time, returned as `'.lib'`, `'.dylib'`, `'.so'`, or `''`.

Data Types: `enumerated`

libPrefix — Architecture-specific library name prefix

character vector

Standard architecture-specific library name prefix, specified as a character vector. The character vector can be empty.

Data Types: char

getTargetLang

Class: `coder.BuildConfig`

Package: `coder`

Get target code generation language

Syntax

```
lang = getTargetLang(bldcfg)
```

Description

`lang = getTargetLang(bldcfg)` returns the target code generation language of the build context, `bldcfg`.

Input Arguments

bldcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

lang — Target code generation language

'C' | 'C++'

Target code generation language, returned as either 'C' or 'C++'.

Version History

Introduced in R2013b

getToolchainInfo

Class: `coder.BuildConfig`

Package: `coder`

Returns handle of copy of toolchain information object

Syntax

```
tc = getToolchainInfo(blcfg)
```

Description

`tc = getToolchainInfo(blcfg)` returns the toolchain information associated with the build context, `blcfg`.

Input Arguments

blcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

tc — Toolchain information

`coder.make.ToolchainInfo` handle

Toolchain information, returned as a handle of a copy of the `coder.make.ToolchainInfo` object.

Version History

`coder.BuildConfig`

isCodeGenTarget

Class: `coder.BuildConfig`

Package: `coder`

Determine if build context represents specified target

Syntax

```
tf = isCodeGenTarget(blldcfg, target)
```

Description

`tf = isCodeGenTarget(blldcfg, target)` checks if the code generation target of the build context `blldcfg` represents the code generation target specified by `target`.

Input Arguments

blldcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

target — Code generation target

character vector | cell array of character vectors

Code generation target, specified as a character vector or a cell array of character vectors with one or more of the following values:

Value	Description
'rtw'	C/C++ dynamic Library, C/C++ static library, or C/C++ executable
'sfun'	S-function (Simulation)
'mex'	MEX-function

Example: `blldcfg.isCodeGenTarget({'sfun', 'mex'})` checks whether the build context represents an S-function target or a MEX-function target.

Data Types: `char` | `cell`

Output Arguments

tf — Whether build context represents code generation target

`true(1)` | `false(0)`

Whether the build context represents the code generation target, returned as either `true(1)` or `false(0)`. If you specify more than one value for `target`, the function returns `true(1)` if the build context represents any of the code generation targets.

Data Types: `logical`

Determine if hardware implementation object target is MATLAB host computer

Syntax

```
tf = isMatlabHostTarget(blcfg)
```

Description

`tf = isMatlabHostTarget(blcfg)` returns if the current hardware implementation targets the MATLAB host computer.

Input Arguments

blcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

tf — Whether current hardware implementation targets host computer

`true(1) | false(0)`

Whether the current hardware implementation object targets the MATLAB host computer, returned as either `true(1)` or `false(0)`.

Data Types: `logical`

`coder.BuildConfig`

coder.ExternalDependency.getDescriptiveName

Class: coder.ExternalDependency

Package: coder

Return descriptive name for external dependency

Syntax

```
extname = coder.ExternalDependency.getDescriptiveName(blcfg)
```

Description

`extname = coder.ExternalDependency.getDescriptiveName(blcfg)` returns the name that you want to associate with an “external dependency” on page 2-192. The code generator uses the external dependency name for error messages.

You must implement this method in a subclass of `coder.ExternalDependency`.

Input Arguments

blcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the “build context” on page 2-192.

Output Arguments

extname — External dependency name

character vector

External dependency name, returned as a character vector.

Data Types: char

Examples

Return external dependency name

Define a method that always returns the same name.

```
function myextname = getDescriptiveName(~)
    myextname = 'MyLibrary';
end
```

Return external library name based on the code generation target

Define a method that uses the build context to determine the name.

```
function myextname = getDescriptiveName(context)
    if context.isMatlabHostTarget()
        myextname = 'MyLibrary_MatlabHost';
    else
        myextname = 'MyLibrary_Local';
    end
end
```

More About

external dependency

External code interface represented by a class derived from a `coder.ExternalDependency` class. The external code can be a library, object files, or C/C++ source.

build context

Information used by the build process including:

- Target language
- Code generation target
- Target hardware
- Build toolchain

Version History

Introduced in R2013b

See Also

`coder.updateBuildInfo` | `coder.BuildConfig` | `coder.ceval` | `coder.ExternalDependency`

Topics

coder.ExternalDependency.isSupportedContext

Class: coder.ExternalDependency

Package: coder

Determine if build context supports external dependency

Syntax

```
tf = coder.ExternalDependency.isSupportedContext(blcfg)
```

Description

`tf = coder.ExternalDependency.isSupportedContext(blcfg)` returns if you can use the “external dependency” on page 2-194 in the “build context” on page 2-194, `blcfg`.

If you cannot use the external dependency in the current build context, display an error message and stop code generation. The error message must describe why you cannot use the external dependency in this build context. If the method returns `false (0)`, the code generator uses a default error message. The default error message uses the name returned by the `getDescriptiveName` method of the `coder.ExternalDependency` class.

You must implement this method in a subclass of `coder.ExternalDependency`.

Input Arguments

blcfg — Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the build context.

Output Arguments

tf — Whether build context supports external dependency

`true (1) | false (0)`

Whether the build context supports the external dependency, returned as either `true (1)` or `false (0)`.

Data Types: `logical`

Examples

Report error when build context does not support external library

This method returns `true (1)` if the code generation target is a MATLAB host target. Otherwise, the method reports an error and stops code generation.

Write `isSupportedContext` method.

```
function tf = isSupportedContext(ctx)
    if ctx.isMatlabHostTarget()
        tf = true;
    else
        error('adder library not available for this target');
    end
end
```

More About

external dependency

External code interface represented by a class derived from `coder.ExternalDependency` class. The external code can be a library, object file, or C/C++ source.

coder.ExternalDependency.updateBuildInfo

Class: `coder.ExternalDependency`

Package: `coder`

Update build information

Syntax

```
coder.ExternalDependency.updateBuildInfo(buildInfo,bldcfg)
```

Description

`coder.ExternalDependency.updateBuildInfo(buildInfo,bldcfg)` updates the build information, `buildInfo` with the build context, `bldcfg`. After code generation, the build information object has standard information. Use this method to provide additional information required to link to external code.

You must implement this method in a subclass of `coder.ExternalDependency`.

Input Arguments

buildInfo – Build information

`handle`

Build information, specified as a handle.

bldcfg – Build context during code generation

`coder.BuildConfig` object

Build context during code generation, specified as a `coder.BuildConfig` object. Use `coder.BuildConfig` methods to get information about the “build context” on page 2-195.

Limitations

- The build information method `AddIncludeFiles` has no effect in a `coder.ExternalDependency.updateBuildInfo` method.

More About

coder.read

Package: coder

Read data files at run time in generated code

Syntax

```
dataFromFile = coder.read(fileName)
dataFromFile = coder.read(fileName,TypeHeaderFrom=typeHeaderFilename)
[dataFromFile,errID] = coder.read( ___ )
```

Description

`dataFromFile = coder.read(fileName)` reads from the `fileName.coderdata` storage file and returns the data stored within the file. This syntax works for a constant `fileName` input only. Use this function in your MATLAB code for which you want to generate C/C++ code. The generated code performs the data read at run time.

To store your workspace variables in a `.coderdata` file, use the `coder.write` function in MATLAB.

`dataFromFile = coder.read(fileName,TypeHeaderFrom=typeHeaderFilename)` uses the information contained in `typeHeaderFilename` to determine the type and size of the data to be read from `fileName`. Both `fileName` and `typeHeaderFilename` must be `.coderdata` files. The `typeHeaderFilename` argument must be a compile-time constant and the file that this name represents must exist in your current directory during code generation.

Each `.coderdata` file contains a type header that specifies the type and size of the data stored in the file. The code generated for the `coder.read` function can read any `.coderdata` file at run-time, while the file type and size is consistent with the type and size information that you supply using the `typeHeaderFilename` file during code generation.

To create a `.coderdata` file to use with the `TypeHeaderFrom` argument, use the `coder.write` function in MATLAB.

`[dataFromFile,errID] = coder.read(___)` suppresses run-time errors during a read operation. `errID` is a `coder.ReadStatus` enumeration object. If any errors occur, `coder.read` returns the first error through `errID` and `dataFromFile` returns unusable content. Use this option to test the generated code for targets for which run-time errors are disabled.

Examples

Read Data from a Fixed `.coderdata` File at Run Time

In this example, you use `coder.write` to create a `.coderdata` file that stores a single array from your MATLAB workspace. You then generate code for a `coder.read` function call that reads this file at run time.

Create a 20-by-20 array of double type in your workspace.

```
c = rand(20);
```

Store this variable in a file named `exampleData.coderdata` in your current directory.

```
coder.write("exampleData.coderdata",c);
```

To read from a `.coderdata` file with the constant file name `exampleData`, use the `coder.read` function as shown in your MATLAB entry-point function.

```
function data = readSingleFile %#codegen
data = coder.read("exampleData.coderdata");
end
```

Generate a MEX function for `readSingleFile`.

```
codegen readSingleFile -report
```

Read the data stored in `exampleData.coderdata` at run time by running the generated MEX.

```
readSingleFile_mex
```

Read Data from Multiple `.coderdata` Files at Run Time

This example shows how to generate code for a `coder.read` command that can read multiple `.coderdata` files at run time. These files contain array data that have the same type, but different sizes. To enable a single `coder.read` call to read all these files, pass a type header file that is consistent with all your individual data files to the `coder.read` function call.

To start, create a storage file that you want the generated code to read. The following `coder.write` command creates the storage file `file_a.coderdata`, which contains two variables with array data of type `double`. Variables `a` and `b` are of different sizes.

```
a = rand(10,20);
b = rand(5,30);
coder.write("file_a.coderdata",a);
```

A `coder.Type` object that is consistent with both variables `a` and `b` must have variable-size dimensions. The upper bounds of the two array dimensions must be at least 10 and 30 respectively. Create a `coder.Type` object that represents a variable-size `double` type with these bounds.

```
t = coder.typeof(a,[10 30],[1 1])
```

```
t =
```

```
coder.PrimitiveType
:10x:30 double
```

You can modify the header information of `file_a.coderdata` and use the modified file as the source of the type header information.

```
coder.write("file_a.coderdata",a,TypeHeader=t);
```

You can also create the `file_b.coderdata` file with the required type header information by running this command.

```
coder.write("file_b.coderdata",b,TypeHeader=t);
```

Create a MATLAB entry-point function, `readMultipleFiles`, that can read `file_a.coderdata` and `file_b.coderdata`.

```
function data = readMultipleFiles(filename) %#codegen
data = coder.read(filename,TypeHeaderFrom="file_b.coderdata");
end
```

Generate a MEX for `readMultipleFiles`. Specify the input argument type as an unbounded variable-size character vector.

```
codegen readMultipleFiles -args {coder.typeof('a',[1 inf])} -report
```

Run the generated MEX with inputs `'file_a.coderdata'` and `'file_b.coderdata'`.

```
readMultipleFiles_mex('file_a.coderdata')
readMultipleFiles_mex('file_b.coderdata')
```

Input Arguments

fileName — Name of .coderdata storage file

string scalar (default) | character vector

Name of the `.coderdata` storage file from which you want to read data, specified as a string scalar or character vector.

To store your workspace variables in a `.coderdata` file, use the `coder.write` function in MATLAB.

typeHeaderFilename — Constant name of .coderdata file that stores type and size information

string scalar | character vector

Constant file name of a `.coderdata` file that stores type and size information about the files to read at run time, specified as a string scalar or character vector.

Each `.coderdata` file contains a type header that specifies the type and size of the data stored in the file. The code generated for the `coder.read` function can read any `.coderdata` file at run time while the file type and size is consistent with the type and size information that you supply using the `typeHeaderFilename` file during code generation. This file is also referred to as the type header file.

To create a type header file, use the `coder.write` function in MATLAB.

Output Arguments

dataFromFile — Data read from .coderdata storage file

array | structure | cell array | enumeration | categorical | sparse array

Data read from the `.coderdata` storage file, returned as an array or multiple arrays stored within a structure or cell array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `cell` | `categorical` | `sparse`

errID — Read error enumeration object

`coder.ReadStatus` object

Read error enumeration object, specified as one of these values.

Enumeration Member	Enumeration Value	Error Reference
Success	0	Read operation success.
CoderReadCouldNotOpen	1	Unable to open specified <code>.coderdata</code> file.
CoderReadProblemReading	2	Issue while reading <code>.coderdata</code> file.
CoderReadUnexpectedValue	3	Unexpected value in <code>.coderdata</code> file.
CoderReadWrongHeader	4	<code>.coderdata</code> file does not contain expected metadata. The input file might be corrupted or is not a <code>.coderdata</code> file. Use <code>coder.write</code> to create <code>.coderdata</code> files.
CoderReadWrongVersion	5	<code>.coderdata</code> file is not compatible with this release of MATLAB Coder. Create a new <code>.coderdata</code> file with this version of the product to generate a compatible file.
CoderReadStructArray	6	Expected to read a scalar structure, but <code>.coderdata</code> file contains a structure array. Use a compatible <code>TypeHeader</code> to read this file or a constant file name.
MATFile	7	<code>coder.read</code> cannot read MAT file. Convert your MAT file to a <code>.coderdata</code> files by running these commands in the command window: <pre>s = load('MATFileName'); coder.write('fileName.coderdata',s);</pre> Read the new <code>.coderdata</code> file by using <code>coder.read</code> .
WrongType	8	The type information of the <code>.coderdata</code> file does not match the type information in the specified by the <code>TypeHeaderFrom</code> argument.

Topics

“Data Read and Write Considerations” (MATLAB Coder)

coder.write

Package: coder

Create data files that the generated code reads at run time

Syntax

```
coder.write(fileName,data)
coder.write(fileName,data,Name=Value)
```

Description

`coder.write(fileName,data)` stores the argument `data` in a file with the name `fileName.coderdata` in your current directory. Use this function in MATLAB execution only and not the MATLAB code you intend to use for C/C++ code generation.

Use the `coder.read` function to read data from a `.coderdata` file in MATLAB and in the generated code.

A `.coderdata` file contains a type header that specifies the type and size of the data stored in the file. The code generated for the `coder.read` function can read any `.coderdata` file at run-time, whose type and size is consistent with the type and size information that you supply to `coder.read` during code generation.

`coder.write(fileName,data,Name=Value)` creates a type header file, which is a `.coderdata` file that you use to specify the type and size of data to the `coder.read` function. Use the name-value arguments to:

- Specify a custom type header for the `.coderdata` file that is consistent with the variable `data`.
- Omit the actual data and create a `.coderdata` file with a type header only.

Examples

Store Variable in .coderdata File

This example shows how to create a storage file for a single variable. This storage file can be read at run-time by using the `coder.read` function.

Create a 20-by-20 array of double type in your workspace.

```
c = rand(20);
```

Store this variable in a file named `storageFile.coderdata` in your current directory.

```
coder.write("storageFile.coderdata",c);
```

Store Multiple Variables in .coderdata File

This example shows how to create a storage file for multiple variables.

Create two arrays of double type in your workspace. Array `a` is of size 10-by-10 and array `b` is 20-by-20.

```
a = rand(10);
b = rand(20);
```

Create structure `s` that contains arrays `a` and `b` in its fields.

```
s = struct('a',a,'b',b);
```

Store the structure `s` in a `.coderdata` file.

```
coder.write("storageFile.coderdata",s);
```

Alternatively, you can use a cell array to store multiple variables in a `.coderdata` file.

Create Type Header File Compatible with Multiple Data Files

In this example, you generate code for a `coder.read` command that can read multiple `.coderdata` files at run time. These files contain array data that have the same type, but different sizes. To generate code, you must pass a type header file that is consistent with all your individual data files to the `coder.read` function call.

Create the storage file `file_a.coderdata`, which contains two variables with array data of type double. Variables `a` and `b` are of different sizes.

```
a = rand(10,20);
b = rand(5,30);
coder.write("file_a.coderdata",a);
```

A `coder.Type` object that is consistent with both variables `a` and `b` must have variable-size dimensions. The upper bounds of the two array dimensions must be at least 10 and 30 respectively. Create a `coder.Type` object that represents a variable-size double type with these bounds.

```
t = coder.typeof(a,[10 30],[1 1])
t =
```

```
coder.PrimitiveType
:10x:30 double
```

You can modify the header information of `file_a.coderdata` and use the modified file as the source of the type header information.

```
coder.write("file_a.coderdata",a,TypeHeader=t);
```

You can also create the `file_b.coderdata` file with the required type header information by running this command.

```
coder.write("file_b.coderdata",b,TypeHeader=t);
```

Alternatively, you can create a separate type header file, `myTypeHeader.coderdata`, that contains only the type header compatible with all the existing storage files and does not contain any actual data.

```
coder.write("file_b.coderdata",b,TypeHeader=t,TypeHeaderOnly=true);
```

Such a type header file is useful if you are working with large data files, and want to use the generated file as a type header file only.

Input Arguments

fileName — Name or full file path of new or existing storage file

string scalar | character vector

Name or full file path of a new or existing storage file, specified as a string scalar or character vector. The generated storage file has the name `fileName.coderdata`, or just `fileName` if the value you supplied already has the extension.

data — Data source to save in storage file

array | structure | cell array | enumeration | categorical | sparse array

Data source to save in the storage file, specified as an array or multiple arrays stored within a structure or cell array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `cell` | `categorical` | `sparse`
Complex Number Support: Yes

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

```
Example: coder.write('example.coderdata',rand(1000),TypeHeader=coder.typeof(1,[1000 1000],1 1),TypeHeaderOnly=true)
```

TypeHeader — Type information for storage data

`coder.typeof(data)` (default) | `coder.Type` object

Type information for storage data, specified as a `coder.Type` object. This type object must be compatible with the input argument `data`.

To create a type object, use the `coder.typeof` or `coder.newtype` function. You can also create and edit `coder.Type` objects interactively by using the `Coder Type Editor`. See “Create and Edit Input Types by Using the Coder Type Editor” (MATLAB Coder).

```
Example: coder.write('example.coderdata',rand(10),TypeHeader=coder.typeof(1,[10 10],1 1))
```

TypeHeaderOnly — Whether to create .coderdata file with type header only

`false` (default) | `true`

Option to specify whether to omit the data and create a `.coderdata` file with the type header only, specified as `true` or `false`. If `data` is a large array and you want to use the `.coderdata` file as a type header file only, set this argument to `true`.

Example: `coder.write('example.coderdata', rand(1000), TypeHeaderOnly=true)`

Verbose — Whether to report when writing a file

`true` (default) | `false`

Option to specify whether to report when writing a `.coderdata` file at the MATLAB command line, specified as `true` or `false`.

Version History

Introduced in R2023a

`coder.read` | `coder.load` | `fread` | `fwrite` | `fscanf` | `fprintf`

Topics

“Data Read and Write Considerations” (MATLAB Coder)

convertToSLDataset

Convert contents of MAT-file to `Simulink.SimulationData.Dataset` object

Syntax

```
success=convertToSLDataset(source,destination)
success=convertToSLDataset(source,destination,datasetname)
```

Description

`success=convertToSLDataset(source,destination)` converts the contents of a MAT-file (`source`) to a destination MAT-file (`destination`).

`success=convertToSLDataset(source,destination,datasetname)` names the dataset `datasetname`.

When converting structure signal data, the function names the signal using the value contained in the `label` field of the structure signal field, such as: `mySignal.signal(1).label`.

This function ignores time expressions in `source`.

Examples

Save Signals to Dataset in file2.mat

Save signals from `file1.mat` to a dataset named `file1` in `file2.mat`.

```
success=convertToSLDataset('file1.mat','file2.mat')
```

Save Signals to Dataset Named myDataset in file2.mat

Save signals from `file1.mat` to a dataset named `myDataset` in `file2.mat`.

```
success=convertToSLDataset('file1.mat','file2.mat','myDataset')
```

Input Arguments

source — MAT-file

character vector

MAT-file that contains Simulink inputs.

destination — MAT-file

character vector

MAT-file to contain `Simulink.SimulationData.Dataset` converted from contents of `source`.

datasetname — Data set name

character vector

Data set name for new `Simulink.SimulationData.Dataset` object.

Output Arguments**success — Outcome of conversion**

binary

Outcome of conversion, specified as binary:

- 1

Conversion is successful.

- 0

Conversion is not successful.

Version History**Introduced in R2016a**

delete_block

Delete blocks from Simulink system

Syntax

```
delete_block(blockArg)
```

Description

`delete_block(blockArg)` deletes the specified blocks from a system. Open the system before you delete blocks.

Examples

Delete Block Using Full Path Name

Delete the block Mu from the vdp system.

```
open_system('vdp')  
delete_block('vdp/Mu')
```

Delete Block Using Block Handle

Delete the block Out2 from the vdp system using the block handle.

Open the vdp system.

```
open_system('vdp')
```

Interactively select the block Out1. Get the block's handle and assign it to the variable `Out1_handle`. Delete the block using the handle.

```
Out1_handle = get_param(gcf, 'Handle');  
delete_block(Out1_handle)
```

Delete Blocks Using Vector of Handles

Delete three blocks from the vdp system.

Open the vdp system. Add three blocks and assign their handles to variables.

```
open_system('vdp')  
Constant_handle = add_block('built-in/Constant', 'vdp/MyConstant');  
Gain_handle = add_block('built-in/Gain', 'vdp/MyGain');  
Outputport_handle = add_block('built-in/Outputport', 'vdp/MyOutputport');
```

Delete the blocks you added using a vector of handles.

```
delete_block([Constant_handle Gain_handle Outport_handle])
```

Input Arguments

blockArg — Blocks to delete

full path name | handle | vector of handles | 1-D cell array or string array of handles or block path names

Blocks to delete, specified as the full block path name, a handle, a vector of handles, or a 1-D cell array or string array of handles or block path names.

Example: 'vdp/Mu'

Example: [handle1 handle2]

Example: {'vdp/Mu' 'vdp/Out1' 'vdp/Out2'}

Example: "vdp/Out" + (1:2)

Version History

Introduced before R2006a

See Also

add_block

delete_line

Delete line from Simulink model

Syntax

```
delete_line(sys,out,in)
delete_line(sys,point)
delete_line(lineHandle)
```

Description

`delete_line(sys,out,in)` deletes the line from the model or subsystem `sys` that connects the output port `out` to the input port `in`.

`delete_line(sys,point)` deletes the line that includes the point `point`.

`delete_line(lineHandle)` deletes the line using the line handle.

Examples

Remove Line Using Block Port Names

For the model `vdp`, remove the line connecting the Product block with the Gain block.

```
load_system('vdp');
delete_line('vdp','Product/1','Mu/1');
```

Remove Line Using Line Handle

For the model `vdp`, remove a line using the line handle. You can get the line handle using different techniques.

```
load_system('vdp');
h = get_param('vdp/Mu','LineHandles');
delete_line(h.Outputport(1));
```

Get a line handle when you create the line. Delete the line using that handle.

```
a = add_line('vdp','Mu/1','Sum/2');
delete_line(a)
```

Delete a Line Using a Point

You can use a point on the line to delete the whole line.

Find the port coordinates for the block `Mu` in the model `vdp`.

```
open_system('vdp');
mu = get_param('vdp/Mu', 'PortConnectivity');
mu.Position
```

```
ans = 1×2
    190    150
```

```
ans = 1×2
    225    150
```

The line that connects the Mu block to the Sum block starts at the output port, which is at (225,150). You can use any point to the right of that point along the same x-axis to delete the line.

```
delete_line('vdp',[230,150]);
```

Delete Segments of Branched Lines

Use `delete_line` with branched lines to remove the segment for any connection.

Open the model `vdp`.

```
open_system('vdp');
```

Delete the signal line segment that connects the `x1` block to the `Out1` block.

```
delete_line('vdp','x1/1','Out1/1')
```

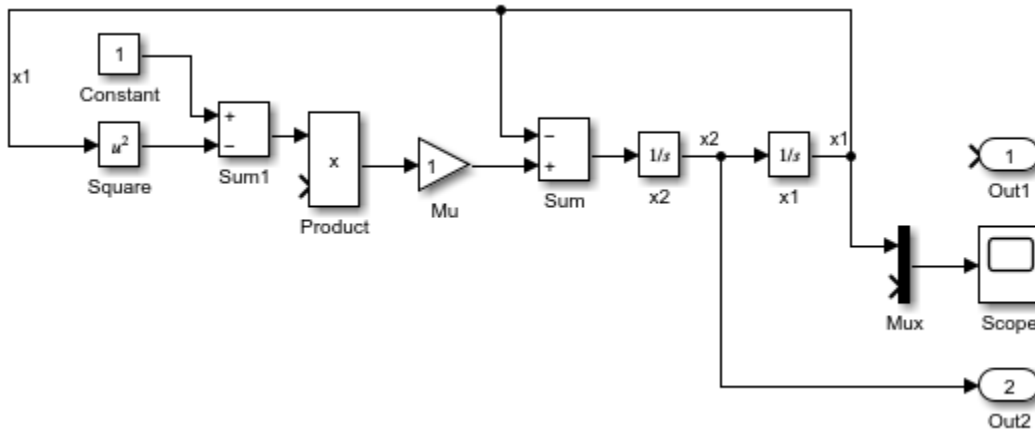

Delete the signal line segment that connects the `x2` block to the Mux block.

```
delete_line('vdp','x2/1','Mux/2')
```

Delete the line segment that connects the x2 block to the Product block.

```
delete_line('vdp', 'x2/1', 'Product/2')
```

Input Arguments

sys – Model or subsystem to delete line from
character vector

Model or subsystem to delete the line from, specified as a character vector.

Example: 'vdp', 'f14/Controller'

out – Block output port to delete line from
block/port name or number character vector | port handle

Block output port to delete line from, specified as either:

- The block name, a slash, and the port name or number. Most block ports are numbered from top to bottom or from left to right. For a state port, use the port name State instead of a port number.
- The port handle that you want to delete the line from.

Use 'PortHandles' with get_param to get the handles.

Example: 'Mu/1', 'Subsystem/2'

in — Block input port to delete line from

block/port name or number character vector | port handle

Block input port to delete line from, specified as either:

- The block name, a slash, and the port name or number. The port name on:
 - An enabled subsystem is Enable.
 - A triggered subsystem is Trigger.
 - If Action and Switch Case Action subsystems is Action.
- The port handle that you want to delete the line from.

Use 'PortHandles' with get_param to get handles.

Example: 'Mu/1', 'Subsystem/2'

point — Point on the line you want to delete

1-by-2 matrix

Point that falls on the line you want to delete, specified as a 1-by-2 matrix.

Example: [150 200]

lineHandle — Handle of the line you want to delete

handle

Handle of the line you want to delete. You can get the line handle by using get_param with the 'LineHandles' option or by assigning the line to a handle when you create it programmatically.

Version History

Introduced before R2006a

See Also

add_line | get_param

delete_param

Delete system parameter added with add_param function

Syntax

```
delete_param(sys,param1,...,paramN)
```

Description

delete_param(sys,param1,...,paramN) deletes parameters that were added to the system using the add_param function. If a specified parameter was not added with the add_param function, you receive an error.

Examples

Delete Added Parameter

Add parameters to a system, then delete one of the parameters from the system.

Load the vdp system.

```
load_system('vdp')
```

Add the DemoName and EquationOrder parameters to the vdp system.

```
add_param('vdp','DemoName','VanDerPolEquation','EquationOrder','2')
```

Delete the DemoName parameter from the vdp system.

```
delete_param('vdp','DemoName')
```

Input Arguments

sys — System name

character vector | string scalar

System name, specified as a character vector or string scalar.

Data Types: char | string

param1,...,paramN — One or more parameters to delete from system

character vector | string scalar

One or more parameters to delete from system, each specified as a character vector or string scalar.

Data Types: char | string

Version History

Introduced before R2006a

See Also

add_param

dependencies.fileDependencyAnalysis

Find model file dependencies

Syntax

```
files = dependencies.fileDependencyAnalysis('modelname')
[files,missing] = dependencies.fileDependencyAnalysis('modelname')
[files,missing,depfile] = dependencies.fileDependencyAnalysis('modelname')
[files,missing,depfile,manifestfile] = dependencies.fileDependencyAnalysis('modelname','manifestfile')
```

Description

`files = dependencies.fileDependencyAnalysis('modelname')` returns the full paths of all existing files referenced by the model `modelname`.

`[files,missing] = dependencies.fileDependencyAnalysis('modelname')` also returns `missing`, any referenced files that cannot be found.

`[files,missing,depfile] = dependencies.fileDependencyAnalysis('modelname')` also returns `depfile`, the full path of the user dependencies (.smd) file, if it exists, that stores the names of any files the user manually added or excluded.

`[files,missing,depfile,manifestfile] = dependencies.fileDependencyAnalysis('modelname','manifestfile')` also creates a manifest file specified in `manifestfile`.

Examples

Find Model File Dependencies

Programmatically find all the file dependencies of the model `sldemo_mdref_depgraph`.

```
files = dependencies.fileDependencyAnalysis('sldemo_mdref_depgraph')
```

```
files = 7x1 cell
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_F2C...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_depgraph...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_heating...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_heating...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_housing...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_outdoor...'
    {'C:\TEMP\Bdoc23a_2213998_3568\ib570499\14\tp74e06091\simulink-ex05898741\sldemo_mdref_thermal...'}}
```

Input Arguments

modelname — Model, library, or subsystem name or path

character vector | string

Full name or path of a model, library, or subsystem to analyze, specified as a character vector or string.

Data Types: `char` | `string`

manifestfile — Manifest file name or path

character vector | string

(Optional) Full name or path of the manifest file to create, specified as a character vector or string. The function adds the suffix `.smf` to the user-specified name.

Data Types: `char` | `string`

Output Arguments

files — Full paths of referenced files

character vector | cell array of character vectors

Full paths of all existing files referenced by the model or library `modelName`, returned as a character vector or a cell array of character vectors.

missing — Full paths of missing files

character vector | cell array of character vectors

Full paths of files referenced by the model or library `modelName` that cannot be found, returned as a character vector or a cell array of character vectors.

depfile — Full path of user dependencies file

character vector

Full path of user dependencies (`.smd`) file, if it exists, that stores the names of any files the user manually added or excluded, returned as a character vector.

manifestfile — Full path of created manifest file

character vector

Full path of new manifest (`.smf`) file, returned as a character vector.

Tips

- Interactively generate a dependency graph and a report summarizing the list of required files and products. For more details, see “Analyze Model Dependencies”.
- If your model is in a project, use `listRequiredFiles` instead.
- To programmatically check which add-ons are required, use `dependencies.toolboxDependencyAnalysis` instead.

Version History

Introduced in R2012a

R2020b: Output arguments `manifestfile` and `depfile` will be removed

Not recommended starting in R2020b

Output arguments `manifestfile` and `depfile` will be removed in a future release.

Starting in R2020b, you can only generate the manifest file programmatically. You can open manifest files created prior to R2020b using the Dependency Analyzer. To interactively generate a dependency graph and report, perform a dependency analysis. For more details, see “Analyze Model Dependencies”.

Starting in R2020b, you can no longer generate a user dependencies file (.smd file). The function only returns a .smd file if it already exists. To manually add or exclude dependencies, create a project from your model. For more details, see “Create a Project from a Model” and “Add Files to the Project”.

See Also

`listRequiredFiles` | `listImpactedFiles` | `dependencies.toolboxDependencyAnalysis` | **Dependency Analyzer**

dependencies.toolboxDependencyAnalysis

Find add-on dependencies

Syntax

```
names = dependencies.toolboxDependencyAnalysis(files)
[names, folders] = dependencies.toolboxDependencyAnalysis(files)
```

Description

`names = dependencies.toolboxDependencyAnalysis(files)` returns `names`, a cell array of the add-on names required by the files in `files`.

`[names, folders] = dependencies.toolboxDependencyAnalysis(files)` also returns `folders`, a cell array of the add-on folders.

Examples

Find Required Add-Ons

Find all the required add-ons for the opened model `vdp`.

```
openExample("vdp.slx");
names = dependencies.toolboxDependencyAnalysis(bdroot)

names =

    1×1 cell array

    {'Simulink'}
```

Tip You can interactively run a dependency analysis. You can find the required add-ons for the entire project, for selected files, or for a model. You can see which products a new team member requires to use the design, or find which file is introducing a product dependency. See “Find Required Products and Add-Ons”.

To programmatically check which files are required, see [dependencies.fileDependencyAnalysis](#).

To view long product names, examine the `names` cell array as follows:

```
names{:}

ans =

    'Simulink'
```

Find Names and Folders of Required Add-Ons

Find the names and folders of the required add-ons for the opened model vdp.

```
openExample("vdp.slx");  
[names, folders] = dependencies.toolboxDependencyAnalysis(bdroot)  
  
names =  
  
    1×1 cell array  
  
    {'Simulink'}  
  
folders =  
  
    1×1 cell array  
  
    {'simulink'}
```

Input Arguments

files — Files names or paths

" " (default) | cell array of strings

Names of files on the MATLAB path or full paths to files, specified as a cell array of strings.

Output Arguments

names — Add-on names

cell array of character vectors

Add-on names required by the files in `files`, returned as a cell array of character vectors.

folders — Add-on folders

cell array of character vectors

(Optional) Required add-on folders, returned as a cell array of character vectors.

Version History

Introduced in R2012a

`dependencies.fileDependencyAnalysis` | **Dependency Analyzer**

depview

Analyze and visualize model referencing dependencies with or without library dependencies

Syntax

```
depview(sys)
depview(sys, Name, Value)
```

Description

depview opens the Dependency Analyzer. While `view_mdhrefs` also opens the Dependency Analyzer, `depview` provides programmatic options that allow you to open a specific configuration of the dependency graph.

`depview(sys)` opens the Dependency Analyzer and displays a graph of dependencies for the model or library specified by `sys`.

`depview(sys, Name, Value)` opens the Dependency Analyzer and displays a graph of dependencies as specified by one or more `Name, Value` pair arguments.

Examples

Open Dependency Analyzer with Default Settings

Open the Dependency Analyzer for the `sldemo_mdhref_depgraph` model.

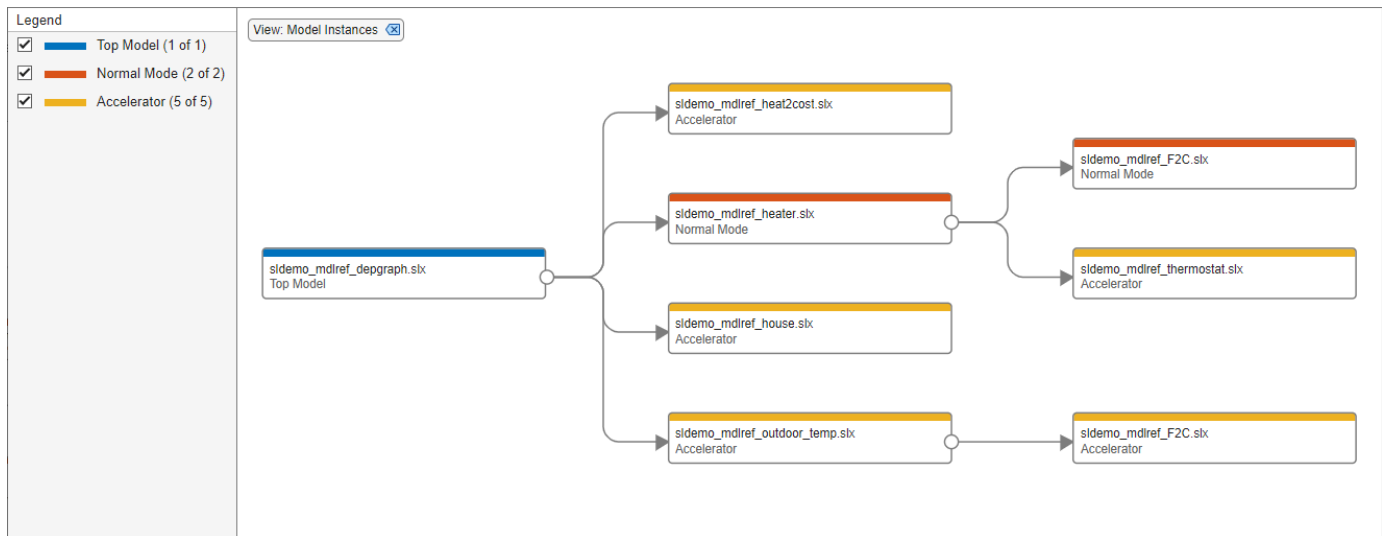

```
depview('sldemo_mdhref_depgraph');
```

Open Dependency Analyzer with Custom Settings

Open the Dependency Analyzer for the `sldemo_mdhref_depgraph` model in **Model Instances** view with a **Horizontal** layout.

```
depview('sldemo_mdhref_depgraph', 'ModelReferenceInstance', true, 'ShowHorizontal', true);
```

In **Model Instances** view, node appearance corresponds to simulation mode.

Input Arguments

`sys` — Name or path of model or library

' ' (default) | character vector

Name or path of model or library, specified as a character vector.

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify two name and value pair arguments in any order as `Name1`, `Value1`, `Name2`, `Value2`.

Example:

```
depview('sldemo_mdhref_depgraph', 'ModelReferenceInstance', true, 'ShowHorizontal', true)
```

`FileDependenciesExcludingLibraries` — Graph with only models

false (default) | true

To open the dependency graph with only models, set this parameter to `true`. In this view, node appearance corresponds to file type.

Dependencies

You can only set one of 'FileDependenciesExcludingLibraries', 'FileDependenciesIncludingLibraries', and 'ModelReferenceInstance' to true.

FileDependenciesIncludingLibraries — Graph with models and user-defined libraries

true (default) | false

To open the dependency graph with models and user-defined libraries, use the default setting. In this view, node appearance corresponds to file type.

Dependencies

You can only set one of 'FileDependenciesExcludingLibraries', 'FileDependenciesIncludingLibraries', and 'ModelReferenceInstance' to true.

ModelReferenceInstance — Graph with only models that shows each model instance separately

false (default) | true

To open the dependency graph with each instance of a model as a separate node in the graph, set this parameter to true. In this view, node appearance corresponds to simulation mode.

Dependencies

You can only set one of 'FileDependenciesExcludingLibraries', 'FileDependenciesIncludingLibraries', and 'ModelReferenceInstance' to true.

ShowHorizontal — Horizontal dependency display

false (default) | true

To open the dependency graph with referenced models and libraries to the right of their parents, set this parameter to true. By default, the Dependency Analyzer shows referenced models and libraries below their parents.

Version History

Introduced in R2006b

Functions

find_mdrefs

Topics

“Model Reference Basics”

“Analyze Model Dependencies”

detachConfigSet

Dissociate configuration set or configuration reference from model

Syntax

```
configObj = detachConfigSet(model, configObjName)
```

Description

`configObj = detachConfigSet(model, configObjName)` dissociates the configuration set or configuration reference with the name `configObjName` from the model. The function returns the detached configuration as a `Simulink.ConfigSet` object or a `Simulink.ConfigSetRef` object. You cannot detach the active configuration from a model. When you want to detach the active configuration, first activate a different configuration for the model.

Examples

Detach Configuration Set From Model

Create, attach, and activate a configuration set for a model. Then, detach the default configuration set from the model.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`. Create a configuration set named 'MyConfig' and attach it to the model.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
configObj = Simulink.ConfigSet;
set_param(configObj, 'Name', 'MyConfig')
attachConfigSet('sldemo_fuelsys', configObj)
```

The active configuration for `sldemo_fuelsys` is the default configuration set, `Configuration`. To detach `Configuration`, activate another configuration for the model. For this example, set `MyConfig` as the active configuration set for `sldemo_fuelsys`.

```
setActiveConfigSet('sldemo_fuelsys', 'MyConfig')
```

Detach the default configuration set `Configuration` from the model.

```
detachConfigSet('sldemo_fuelsys', 'Configuration');
```

Input Arguments

model — Model from which to detach configuration set

character vector | string scalar

Model from which to disassociate a configuration set, specified as a character vector or string scalar. The model must be open.

Example: 'my_model'

configObjName — Configuration object name

character vector | string scalar

Name of the configuration object to detach from the model, specified as a character vector or string scalar.

Example: 'Configuration'

Version History

Introduced in R2006a

Topics

"Manage Configuration Sets for a Model"

disableimplicitsignalresolution

Convert model to use only explicit signal resolution

Syntax

```
retVal = disableimplicitsignalresolution('model')
retVal = disableimplicitsignalresolution('model', displayOnly)
```

Description

`retVal = disableimplicitsignalresolution('model')` inputs a model, reports all signals and states that implicitly resolve to signal objects, and converts the model to resolve only signals and states that explicitly require it. The report and any changes are limited to the model itself; they do not include blocks that are library links.

Before executing this function, ensure that all relevant Simulink data objects are defined in the base workspace or a data dictionary to which the model is linked. The function ignores any data objects that are defined elsewhere.

The function scans `model`, returns a structure of handles to signals and states that resolve implicitly to signal objects, and performs the following operations on `model`:

- Search the model for all output ports and block states that resolve to Simulink signal objects.
- Modify these ports and blocks to enforce signal object resolution in the future.
- Set the model's `SignalResolutionControl` parameter to 'UseLocalSettings' (GUI: **Explicit Only**).

If `SignalResolutionControl` is already set to 'UseLocalSettings' or to 'None', the function takes no action and returns a warning.

- If any Stateflow output data resolves to a Simulink signal object:
 - Turn off hierarchical scoping of signal objects from within the Stateflow chart.
 - Explicitly label the output signal of the Stateflow chart.
 - Enforce signal object resolution for this signal in the future.

Any changes made by `disableimplicitsignalresolution` permanently change the model. Be sure to back up the model before calling the function with `displayOnly` defaulted to or specified as `false`.

`retVal = disableimplicitsignalresolution('model', displayOnly)` is equivalent to `disableimplicitsignalresolution(model)` if `displayOnly` is `false`.

If `displayOnly` is `true`, the function returns a structure of handles to signals and states that resolve implicitly to signal objects, but leaves the model unchanged.

Input Arguments

displayOnly

Boolean specifying whether to change the model.

- `false` — Changes the model.
- `true` — The function returns a structure of handles to signals and states that resolve implicitly to signal objects, but leaves the model unchanged.

Default: `false`

model

Model name or handle

Output Arguments

retVal

A MATLAB structure containing:

Signals	Handles to ports with signal names that resolve to signal objects
States	Handles to blocks with states that resolve to signal objects

Version History

Introduced in R2007a

docblock

Get or set editor invoked by Simulink DocBlock block

Syntax

```
docblock(setEditorType,command)
```

```
editCommand = docblock(getEditorType)
```

Description

`docblock(setEditorType,command)` uses the specified command to set the editor opened by double-clicking a DocBlock block.

By default, a DocBlock block opens Microsoft Word to edit HTML or RTF files. If Word is not available on your system, the block opens these file types using the text editor specified on the **Editor/Debugger Preferences** pane of the MATLAB Preferences dialog box. For text files, the default editor is the text editor specified in the MATLAB preferences.

The editor specifications persist between MATLAB sessions.

`editCommand = docblock(getEditorType)` returns the current command to open the specified editor from a DocBlock block.

Examples

Set DocBlock Text Editor

Specify Notepad as the DocBlock editor for text files.

```
docblock('setEditorTXT','system(''notepad "%<FileName>"'');')
```

Set and Get Current HTML Editor

You can use the `docblock` command to get the current editor.

Set your HTML editor for the DocBlock block to Mozilla Composer. The ampersand executes the command in the background.

```
docblock('setEditorHTML',...  
        'system(''/usr/local/bin/mozilla -edit "%<FileName>" &'');')
```

Get the current HTML editor.

```
htmlEd = docblock('getEditorHTML')
```

```
htmlEd =
    'system('/usr/local/bin/mozilla -edit "%<FileName>" &');'
```

Reset Text Editor to Default

Specify Notepad as the DocBlock editor for text files.

```
docblock('setEditorTXT','system('notepad "%<FileName>"');')
```

Get the current text editor.

```
txtEd = docblock('getEditorTXT')
txtEd =
    'system('notepad "%<FileName>"');
```

Reset the editor to the default editor.

```
docblock('setEditorTXT','')
```

Input Arguments

setEditorType — File type for which to set editor command

```
'setEditorHTML' | 'setEditorDOC' | 'setEditorTXT'
```

File type for which to set editor command, specified as 'setEditorHTML', 'setEditorDOC', or 'setEditorTXT'.

command — Command to open file type in editor

```
character vector | ''
```

Command to open file type in editor from the MATLAB Command Window, specified as a character vector. Use '' to reset to the default editor for that file type.

In the command, use the "%<FileName>" token to represent the full pathname to the document.

getEditorType — File type of editor command to return

```
'getEditorHTML' | 'getEditorDOC' | 'getEditorTXT'
```

File type of editor command to return, specified as 'getEditorHTML', 'getEditorDOC', or 'getEditorTXT'.

Output Arguments

editCommand — Command to open editor

```
character vector
```

Command to open editor, returned as a character vector.

Version History

Introduced in R2007a

R2021b: Editor specification does not persist between previous releases and R2021b or later

Behavior changed in R2021b

If you used `docblock` to specify the editors that a DocBlock block uses for HTML, RTF, or text documents before R2021b, you must specify the editors again in R2021b or a later release. Otherwise, a DocBlock block uses the default editor for the document type.

DocBlock

Topics

“Use a Simulink DocBlock to Add a Comment” (Embedded Coder)

edittime.getDisplayIssues

Check whether model design warnings and errors is on

Syntax

```
val = edittime.getDisplayIssues
```

Description

Use the `val = edittime.getDisplayIssues` function to check whether model design errors and warnings is on.

Examples

Enable model design errors and warnings via the command-line

By default, model design errors and warnings are visible while you edit a model. You can turn them off by entering this command at the MATLAB command line.

```
edittime.setDisplayIssues('off')
```

You can turn them on by entering this command at the MATLAB command line.

```
edittime.setDisplayIssues('on')
```

You can check whether they are on by entering this command at the MATLAB command line.

```
val = edittime.getDisplayIssues
```

Output Arguments

val — Returns on or off

char

If edit-time checking is on, this function returns on. If edit-time checking is off, this function returns off.

Version History

Introduced in R2019a

See Also

`edittime.setDisplayIssues` | **Simulink Editor**

edittime.setDisplayIssues

Detect model design errors and warnings

Syntax

```
edittime.setDisplayIssues(value)
```

Description

`edittime.setDisplayIssues(value)` function sets whether to display model design errors and warnings while you design your model. This function is equivalent to selecting **Diagnostics > Edit-Time Errors & Warnings**. This setting persists for all models.

Examples

Enable model design errors and warnings through the command-line

By default, model design errors and warnings are visible while you edit a model. You can turn them off. At the MATLAB command line, enter:

```
edittime.setDisplayIssues('off')
```

To turn on errors and warnings, at the MATLAB command line, enter:

```
edittime.setDisplayIssues('on')
```

Input Arguments

value — Enable model design warning and error detection

character vector

To enable warnings and errors while you edit your model, set value to `on`. To disable warnings and errors while you edit, set value to `off`.

Data Types: `char`

Version History

Introduced in R2019a

find_mdhrefs

Find referenced models and Model blocks in model hierarchy

Syntax

```
[models,blocks] = find_mdhrefs(system)
[models,blocks] = find_mdhrefs(system,Name,Value)
```

Description

`[models,blocks] = find_mdhrefs(system)` finds all referenced models and Model blocks in the model hierarchy below the specified system. The `find_mdhrefs` function temporarily loads the models.

`[models,blocks] = find_mdhrefs(system,Name,Value)` provides additional search options using one or more name-value pairs. For example, to keep the models loaded instead of temporarily loading them, set `KeepModelsLoaded` to `true`.

Examples

Find Referenced Models in Model Hierarchy

Find referenced models and Model blocks for all models referenced by the specified model.

```
load_system('sldemo_mdhref_basic');
[myModels,myModelBlks] = find_mdhrefs('sldemo_mdhref_basic')

myModels = 2x1 cell
    {'sldemo_mdhref_counter'}
    {'sldemo_mdhref_basic' }

myModelBlks = 3x1 cell
    {'sldemo_mdhref_basic/CounterA'}
    {'sldemo_mdhref_basic/CounterB'}
    {'sldemo_mdhref_basic/CounterC'}
```

Find and Load All Models in Model Hierarchy

By default, the `find_mdhrefs` function loads and then closes the models that were not already loaded. To identify what models are loaded, use the `find_system` function.

```
find_mdhrefs('sldemo_mdhref_depgraph');
find_system('type','block_diagram')

ans =

    0x1 empty cell array
```

To find and load all models in the model hierarchy, set `KeepModelsLoaded` to `true`.

```
find_mdrefs('sldemo_mdhref_depgraph', 'KeepModelsLoaded', true);
find_system('type', 'block_diagram')

ans = 8x1 cell
    {'sldemo_mdhref_thermostat' }
    {'sldemo_mdhref_heater'     }
    {'sldemo_mdhref_F2C'       }
    {'sldemo_mdhref_outdoor_temp'}
    {'sldemo_mdhref_house'     }
    {'sldemo_mdhref_heat2cost' }
    {'simulink_extras'        }
    {'sldemo_mdhref_depgraph'  }
```

The top model and all referenced models remain loaded. If you open `sldemo_mdhref_depgraph`, you can navigate the model hierarchy without waiting for the referenced models to load as you open them.

Input Arguments

system — System name, block path, or handle

character vector | string scalar | numeric scalar

System name, block path, or handle, specified as a character vector, string scalar, or numeric scalar.

The system must be an SLX file, MDL file, Model block, or Subsystem block.

If you specify a file name, do not include the file extension.

Data Types: `double` | `char` | `string`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

```
Example: refModels =
find_mdrefs(topmodel, 'KeepModelsLoaded', true, 'ReturnTopModelAsLastElement', false)
```

KeepModelsLoaded — Option to keep models loaded

`false` or `0` (default) | `true` or `1`

Option to keep models loaded, specified as the comma-separated pair consisting of `'KeepModelsLoaded'` and a numeric or logical `1` (`true`) or `0` (`false`).

By default the function loads and then closes the models that were not already loaded. To keep the models loaded, set this argument to `true`. Keeping the models loaded can be useful if you plan on interacting with the models after finding them.

Data Types: `logical`

AllLevels — Levels to search

true or 1 (default) | false or 0

Levels to search, specified as the comma-separated pair consisting of 'AllLevels' and a numeric or logical 1 (true) or 0 (false).

- true — Search all Model blocks in the model hierarchy of the specified system.
- false — Search only the top-level system.

Data Types: logical

IncludeProtectedModels — Option to include protected models

false or 0 (default) | true or 1

Option to include protected models in the search results, specified as the comma-separated pair consisting of 'IncludeProtectedModels' and a numeric or logical 1 (true) or 0 (false).

This setting only affects the returned list of referenced models; It does not affect the returned list of Model blocks.

Data Types: logical

IncludeCommented — Option to include commented blocks

false or 0 (default) | true or 1

Option to include commented blocks in the search results, specified as the comma-separated pair consisting of 'IncludeCommented' and a numeric or logical 1 (true) or 0 (false).

Data Types: logical

CaseSensitive — Option to match case when searching

true (default) | false

Option to match case when searching, specified as true for case-sensitive search or false for case-insensitive search.

Data Types: logical

FollowLinks — Option for search to follow library links

true (default) | false

Option for the search to follow library links, specified as true or false. If true, search follows links into library blocks.

Data Types: logical

LookUnderMasks — Options to search masked blocks

'all' (default) | 'none' | 'functional' | 'graphical'

Options to search masked blocks, specified as:

- 'all' — Search in all masked blocks.
- 'none' — Prevent searching in masked systems.
- 'functional' — Include masked subsystems that do not have dialogs.
- 'graphical' — Include masked subsystems that do not have workspaces or dialogs.

Data Types: `char` | `string`

MatchFilter — Option to match and filter elements in search

function handle

Option to match and filter elements such as blocks, system, lines, ports, and annotations in a search, specified as function handle. Use `MatchFilter` to determine whether elements should be included or skipped in the search.

The argument:

- Allows you to filter elements with custom filter functions
- Avoids processing elements when filters do not match
- Applies complex filters on blocks, lines, or annotations, to filter the results internally

The named function must be defined within a MATLAB program file. The function takes the handle of the element as input and returns two outputs.

```
function [match, prune] = func(element)
```

- The input `element` is the handle of the block being processed.
- The first output, `match`, is a logical value. If `false`, search skips the element.
- The second output, `prune`, is an optional logical value that only applies when `element` is a subsystem. The default value is `false`. If this value is set to `true`, the entire subsystem is omitted from the search.

For example, use `MatchFilter` to find all `Model` blocks in a model for which the `InitFcn` callback is defined, using the filter function `initFcnMdlBlocks`:

```
function match = initFcnMdlBlocks(handle)
    match = ~isempty(get_param(handle, 'InitFcn'));
end

openExample('simulink_variants/SimulinkVariantsExample');
model='slexVariantMdlRefCondProp';
load_system(model);
[models,blocks] = find_mdrefs(model, 'MatchFilter', @initFcnMdlBlocks)
```

Variants: Simulink provides these built-in match filter functions to find variant blocks that are active in simulation or part of the generated code.

- `Simulink.match.activeVariants` — Filter function to find blocks that are active in simulation after model compilation.
- `Simulink.match.codeCompileVariants` — Filter function to find blocks that are part of generated code after model compilation.
- `Simulink.match.allVariants` — Filter function to find all blocks irrespective of whether the block is active or inactive due to variants.

Note To get correct results, you must **compile the model** before using `Simulink.match.activeVariants` and `Simulink.match.codeCompileVariants` filters. If the model is not compiled, these filters return all blocks in the model.

For example, use the `Simulink.match.activeVariants` option to find active variants in a model.

```
openExample('simulink_variants/SimulinkVariantsExample');
model='slexVariantMdlRefCondProp';
load_system(model);
set_param(model,'SimulationCommand','update');
[models,blocks] = find_mdrefs(model,'MatchFilter',@Simulink.match.activeVariants);
```

For example, use the `Simulink.match.codeCompileVariants` option to find variant choices that are part of the generated C code.

```
openExample('simulink_variants/SimulinkVariantsExample');
load_system('slexVariantMdlRefCondProp');
assignin('base','VSS_MODE',2);
slexVariantMdlRefCondProp([],[],[],'compileForCodegen');
[models,blocks] = find_mdrefs('slexVariantMdlRefCondProp',...
    'MatchFilter',@Simulink.match.codeCompileVariants);
slexVariantMdlRefCondProp([],[],[],'term');
```

Example: Use the `Simulink.match.allVariants()` filter to find all blocks in a model.

```
openExample('simulink_variants/SimulinkVariantsExample');
model='slexVariantMdlRefCondProp';
load_system(model);
[models,blocks]=find_mdrefs(model,'MatchFilter',@Simulink.match.allVariants);
```

Variants — Option to include variant models

'ActivePlusCodeVariants' (default) | 'ActiveVariants' | 'AllVariants'

Note The Variants argument will be removed. Use MatchFilter instead. For more information, see “Compatibility Considerations” on page 2-238.

Option to include variant models in the search results, specified as the comma-separated pair consisting of 'Variants' and 'ActivePlusCodeVariants', 'ActiveVariants', or 'AllVariants'.

- 'ActivePlusCodeVariants' — Include all variant models in the Variant Subsystem that are active in simulation and is part of the generated code.
- 'ActiveVariants' — Include the active variant models in the Variant Subsystem block.
- 'AllVariants' — Include all variant models in the Variant Subsystem block.

This search constraint applies only to Variant Subsystem blocks that have the **Variant control mode** set to expression or label. Use the `find_mdrefs` function with the `MatchFilter` option to operate on all types of variant blocks.

Data Types: char | string

ReturnTopModelAsLastElement — Option to include specified system

true or 1 (default) | false or 0

Option to include the specified system in the search results, specified as the comma-separated pair consisting of 'ReturnTopModelAsLastElement' and a numeric or logical 1 (true) or 0 (false).

By default, the last element in the returned list of referenced models is the name of the model, library, or subsystem file that you specified with the `system` argument. If you specify a block, the last element is the name of the file that contains it.

Data Types: logical

Output Arguments

models — Names of models

cell array of character vectors

Names of models, returned as a cell array of character vectors.

By default, the last element is the name of the model, library, or subsystem file that you specified with the `system` argument. If you specify a block, the last element is the model, library, or subsystem file that contains it.

blocks — Names of Model blocks

cell array of character vectors

Names of Model blocks, returned as a cell array of character vectors.

Version History

Introduced before R2006a

R2022b: Warnings for removal of Variants argument

Warns starting in R2022b

As part of the removal of the `Variants` argument in a future release, these warnings have been introduced:

- When you use the `find_mdhrefs` function without the `Variants` argument, the function generates a warning if it skips the inactive choice of a Variant Subsystem block during the search.

Consider a model with a Variant Model block that has two variant choices, `Mdl_Linear_Controller` and `Mdl_NonLinear_Controller`. The `Mdl_NonLinear_Controller` block is the active choice.

This command skips the inactive `Mdl_Linear_Controller` block and generates a warning.

```
[myModels,myModelBlks] = find_mdhrefs...
('sldemo_variant_subsystems_modelblocks')
```

Warning: Using `find_mdhrefs` without the `'Variants'` argument skips inactive Variant Subsystem blocks in the search. This behavior will change in a future release to look at all choices of the Variant Subsystem. To find blocks that are active in simulation or code generation, compile the model and use the built-in variant filters with the `'MatchFilter'` option.

myModels =

2x1 cell array

```
{'mdlref_nonlinear_controller'      }
{'sldemo_variant_subsystems_modelblocks'}
```

myModelBlks =

1x1 cell array

```
{'sldemo_variant_subsystems_modelblocks/Controller/Mdl_NonLinear_Controller'}
```

- When you use the `Variants` argument with its value set to `'AllVariants'`, the function generates a warning.

```
[myModels,myModelBlks] = find_mdhrefs...
('sldemo_variant_subsystems_modelblocks','Variants','AllVariants')
```

Warning: 'Variants' will be removed. Instead of using 'Variants' with value set to 'AllVariants', use 'MatchFilter' with value set to @Simulink.match.allVariants.

```
myModels =
    3x1 cell array

    {'Linear_Controller'          }
    {'Nonlinear_Controller'      }
    {'sldemo_variant_subsystems_modelblocks'}
```

```
myModelBlks =
    2x1 cell array

    {'sldemo_variant_subsystems_modelblocks/Controller/Linear Controller' }
    {'sldemo_variant_subsystems_modelblocks/Controller/Nonlinear Controller'}
```

R2022a: New built-in match filter to find all variant blocks

You can use the built-in match filter, `Simulink.match.allVariants`, to find all the blocks in a variant model regardless of whether the block is active or inactive due to variants. This filter is the recommended replacement for the `AllVariants` option.

To be removed	Recommended Replacement
<code>find_mdhrefs(model, 'Variants', 'AllVariants')</code>	<code>find_mdhrefs(model, 'MatchFilter', ... @Simulink.match.allVariants);</code>

R2021a: Default behavior has changed for Variants and MatchFilter arguments in model with variant blocks

Behavior changed in R2021a

- **Variants:** When you use the `find_mdhrefs` function without the `Variants` argument, for Variant Subsystem blocks, the function currently includes only those choices that are active during simulation or code generation in the search by default.

For other variant blocks such as Variant Source, Variant Sink, or Variant Subsystem blocks with the **Propagate conditions outside of variant subsystem** parameter set to on, the function includes all choices in the search.

Consider a model with a Variant Model block that has two variant choices, `Mdl_Linear_Controller` and `Mdl_NonLinear_Controller`.

This command returns only the active Model blocks in the model.

```
[myModels,myModelBlks] = find_mdhrefs...
('sldemo_variant_subsystems_modelblocks')
```

```
myModels =
    2x1 cell array

    {'mdlref_nonlinear_controller' }
    {'sldemo_variant_subsystems_modelblocks'}
```

```
myModelBlks =
    1x1 cell array

    {'sldemo_variant_subsystems_modelblocks/Controller/Mdl_NonLinear_Controller'}
```

- **MatchFilter:** When you use the `find_mdhrefs` function with the `MatchFilter` argument, the function applies the filters on the active and inactive variant choices by default.

Consider a model with a Variant Model block that has two variant choices, `Mdl_Linear_Controller` and `Mdl_NonLinear_Controller`. The filter function `initFcnMdlBlocks` finds all the Model blocks for which the `InitFcn` callback is set.

```
function match = initFcnMdlBlocks(handle)
match = ~isempty(get_param(handle, 'InitFcn'));
end
```

This command returns the active and inactive Model blocks in the model.

```
[myModels,myModelBlks] = find_mdhrefs('sldemo_variant_subsystems_modelblocks',...
'MatchFilter', @initFcnMdlBlocks)

myModels =

3x1 cell array

    'mdlref_linear_controller'
    'mdlref_nonlinear_controller'
    'sldemo_variant_subsystems_modelblocks'

myModelBlks =

2x1 cell array

    'sldemo_variant_subsystems_modelblocks/Controller/Mdl_Linear_Controller'
    'sldemo_variant_subsystems_modelblocks/Controller/Mdl_NonLinear_Controller'
```

R2021a: Variants argument will be removed

Warns starting in R2021a

The `Variants` argument will be removed from `find_mdhrefs` in a future release. Function calls that use the `Variants` argument continue to work with a warning.

Using the `find_mdhrefs` function with the `Variants` argument produces inconsistent search results. The `find_mdhrefs` function is an edit-time operation, but to determine whether a block is active in a model with all types of variant blocks, you need to compile the model.

To find Model blocks that are active during simulation or code generation, compile the model and use the `find_mdhrefs` function with the `MatchFilter` argument.

This table lists the recommended replacement for different values of the `Variants` argument.

To Be Removed	Recommended Replacement
<code>find_mdhrefs(model, 'Variants', ... 'ActiveVariants');</code>	<code>set_param(model, 'SimulationCommand', 'update');</code> <code>find_mdhrefs(model, 'MatchFilter', ... @Simulink.match.activeVariants);</code>
<code>find_mdhrefs(model, 'Variants', ... 'ActivePlusCodeVariants');</code>	<code>model([],[],[], 'compileForCodegen');</code> <code>[models, blocks] = find_mdhrefs(model, 'MatchFilter', ... @Simulink.match.codeCompileVariants);</code> <code>model([],[],[], 'term');</code>

When you use the `find_system` function, you cannot specify both of the `MatchFilter` and `Variants` arguments.

This command produces an error.

```
find_mdrefs(bdroot, 'MatchFilter', @Simulink.match.activeVariants, ...  
            'Variants', 'ActiveVariants');
```

R2020b: Filter elements during search with MatchFilter

To match and filter model elements during a search, you can define a custom filter function and pass the function handle as value to the `MatchFilter` name-value argument.

To find variant blocks that are active in a simulation or part of the generated code, you can use the built-in match filter functions, `Simulink.match.activeVariants`, `Simulink.match.codeCompileVariants`, and `Simulink.match.allVariants`, after compiling the model.

R2020b: Specifying a logical value as the second argument of find_mdrefs is discouraged *Not recommended starting in R2020b*

The `find_mdrefs` function provides two ways to specify whether to search all levels of the model hierarchy. Both techniques give the same results, but only the name-value pair technique allows you to specify additional options.

Instead of specifying whether to search all levels of the model hierarchy with a logical as the second argument, use the `AllLevels` name-value pair.

Blocks

Model

Functions

`find_system`

Topics

“Model Reference Basics”

“Inspect Model Hierarchies”

find_system

Find systems, blocks, lines, ports, and annotations

Syntax

```
Objects = find_system
Objects = find_system(System)
Objects = find_system(Name,Value)
Objects = find_system(System,Name,Value)
```

Description

`Objects = find_system` returns loaded systems and their blocks, including subsystems.

`Objects = find_system(System)` returns the specified system and its blocks.

`Objects = find_system(Name,Value)` returns loaded systems and the objects in those systems that meet the criteria specified by one or more `Name, Value` pair arguments. You can use this syntax to specify search constraints and to search for specific parameter values. Specify the search constraints before the parameter and value pairs.

`Objects = find_system(System,Name,Value)` returns the objects in the specified system that meet the specified criteria.

Examples

Find Loaded Systems and Their Blocks

Return the names of all loaded systems and their blocks.

```
load_system('vdp')
find_system

ans = 15x1 cell
    {'vdp' }
    {'vdp/Constant' }
    {'vdp/More Info' }
    {'vdp/More Info/Model Info'}
    {'vdp/Mu' }
    {'vdp/Mux' }
    {'vdp/Product' }
    {'vdp/Scope' }
    {'vdp/Square' }
    {'vdp/Sum' }
    {'vdp/Sum1' }
    {'vdp/x1' }
    {'vdp/x2' }
    {'vdp/Out1' }
    {'vdp/Out2' }
```

Returns loaded systems and libraries, including vdp.

Find Specific System and Its Blocks

Return vdp system and its blocks.

```
load_system({'vdp','ex_sl-demo-clutch'})
find_system('vdp')
```

```
ans = 15x1 cell
    {'vdp' }
    {'vdp/Constant' }
    {'vdp/More Info' }
    {'vdp/More Info/Model Info' }
    {'vdp/Mu' }
    {'vdp/Mux' }
    {'vdp/Product' }
    {'vdp/Scope' }
    {'vdp/Square' }
    {'vdp/Sum' }
    {'vdp/Sum1' }
    {'vdp/x1' }
    {'vdp/x2' }
    {'vdp/Out1' }
    {'vdp/Out2' }
```

Return Names of Loaded Models, Subsystems, and Libraries

Return the names of the loaded models, subsystems, and libraries. A subsystem name is returned only if the subsystem can be loaded independently.

```
load_system('vdp');
find_system('type','block-diagram')
```

```
ans = 1x1 cell array
    {'vdp'}
```

Search Children of Subsystem

Return the names of all Goto blocks that are children of the Unlocked subsystem in the ex_sl-demo-clutch system.

```
load_system('ex_sl-demo-clutch');
find_system('ex_sl-demo-clutch/Unlocked','SearchDepth',1,'BlockType','Goto')
```

```
ans = 2x1 cell
    {'ex_sl-demo-clutch/Unlocked/Goto' }
    {'ex_sl-demo-clutch/Unlocked/Goto1' }
```

Copyright 2020 The MathWorks, Inc.

Search Using Multiple Criteria

Search in the vdp system and return the names of all Gain blocks whose **Gain** value is set to 1.

```
load_system('vdp');  
find_system('vdp', 'BlockType', 'Gain', 'Gain', '1')
```

```
ans = 1x1 cell array  
    {'vdp/Mu'}
```

Return Lines and Annotations as Handles

Get the handles of all lines and annotations in the vdp system. With 'FindAll', the function returns handles regardless of how you specify the system to search.

```
load_system('vdp');  
L = find_system('vdp', 'FindAll', 'on', 'type', 'line')
```

```
L = 19x1  
  
    35.0023  
    34.0023  
    33.0031  
    32.0027  
    30.0027  
    29.0027  
    28.0031  
    27.0026  
    26.0027  
    25.0027  
    :
```

```
A = find_system('vdp', 'FindAll', 'on', 'type', 'annotation')
```

```
A = 2x1  
  
    37.0022  
    36.0023
```

Search for Specific Block Parameter Value

Find any block dialog box parameters with a value of 0 in the vdp and ex_slldemo_clutch systems.

```
load_system({'vdp', 'f14'})  
find_system({'vdp', 'f14'}, 'BlockDialogParams', '0')
```

```
ans =
    32x1 cell array

    {'vdp/More Info' }
    {'vdp/More Info/Model Info' }
    {'vdp/Scope' }
    {'vdp/x2' }
    {'vdp/Out1' }
    {'vdp/Out1' }
    {'vdp/Out2' }
    {'vdp/Out2' }
    {'f14/AircraftDynamicsModel' }
    {'f14/AircraftDynamicsModel/Vertical Velocity-w (ft//sec)'}
    {'f14/AircraftDynamicsModel/Vertical Velocity-w (ft//sec)'}
    {'f14/AircraftDynamicsModel/Pitch Rate-q (rad//sec)'}
    {'f14/AircraftDynamicsModel/Pitch Rate-q (rad//sec)'}
    .
    .
    .
```

Search Using Regular Expressions

Find all blocks in the top level of the currently loaded systems with a block dialog parameter value that starts with 3.

```
load_system({'ex_sl-demo-clutch','vdp'});
find_system('SearchDepth','1','regexp','on','BlockDialogParams','^3')
```

```
ans = 4x1 cell
    {'vdp/Scope' }
    {'vdp/Scope' }
    {'vdp/Square' }
    {'ex_sl-demo-clutch/w'}
```

Regular Expression Search for Partial Match

When you search using regular expressions, you can specify a part of the character vector you want to match to return all objects that contain that character vector. Find all the inport and outport blocks in the ex_sl-demo-clutch model.

```
load_system('ex_sl-demo-clutch');
find_system('ex_sl-demo-clutch','regexp','on','blocktype','port')
```

```
ans = 39x1 cell
    {'ex_sl-demo-clutch/Friction...' }
    {'ex_sl-demo-clutch/Friction...' }
    {'ex_sl-demo-clutch/Friction...' }
    {'ex_sl-demo-clutch/Friction Mode Logic/Tin' }
    {'ex_sl-demo-clutch/Friction Mode Logic/Tfmaxs' }
    {'ex_sl-demo-clutch/Friction Mode Logic/Break Apart...' }
    {'ex_sl-demo-clutch/Friction Mode Logic/Break Apart...' }
```

```

{'ex_sl-demo_clutch/Friction Mode Logic/Break Apart...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup...'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup FSM/lock'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup FSM/unlock'}
{'ex_sl-demo_clutch/Friction Mode Logic/Lockup FSM/locked'}
{'ex_sl-demo_clutch/Friction Mode Logic/Requisite Friction/Tin'}
{'ex_sl-demo_clutch/Friction Mode Logic/Requisite Friction/Tf'}
{'ex_sl-demo_clutch/Friction Mode Logic/locked'}
{'ex_sl-demo_clutch/Friction Mode Logic/lock'}
{'ex_sl-demo_clutch/Friction Mode Logic/unlock'}
{'ex_sl-demo_clutch/Friction Mode Logic/Tf'}
{'ex_sl-demo_clutch/Locked/Tin'}
{'ex_sl-demo_clutch/Locked/w'}
{'ex_sl-demo_clutch/Unlocked/Tfmaxk'}
{'ex_sl-demo_clutch/Unlocked/Tin'}
{'ex_sl-demo_clutch/Unlocked/we'}
:

```

Update Library Links in a Subsystem

In this example, `myModel` contains a single subsystem, which is a library link. After the model was last opened, a Gain block was added to the corresponding subsystem in the library.

Open the model. Use `find_system` with `'FollowLinks'` set to `'off'`. The command does not follow the library links into the subsystem and returns only the subsystem at the top level.

```

open_system('myModel')
find_system(bdroot,'LookUnderMasks','on','FollowLinks','off')

```

ans =

```

' myModel'
' myModel/Subsystem'

```

Use `find_system` with `'FollowLinks'` set to `'on'`. `find_system` updates the library links and returns the block in the subsystem.

```

find_system(bdroot,'LookUnderMasks','on','FollowLinks','on')

```

```

Updating Link: myModel/Subsystem/Gain
Updating Link: myModel/Subsystem/Gain

```

ans =

```

' myModel'

```

```
'myModel/Subsystem'
'myModel/Subsystem/Gain'
```

Return Values as Handles

Provide the system to `find_system` as a handle. Search for block dialog box parameters with a value of 0. If you make multiple calls to `get_param` for the same block, then using the block handle is more efficient than specifying the full block path as a character vector.

```
load_system('vdp');
sys = get_param('vdp','Handle');
find_system(sys,'BlockDialogParams','0')
```

```
ans = 8×1
```

```
3.0032

Input Arguments

System — System to search

path name | cell array of path names | handle | vector of handles

System to search, specified as the full system path name, a cell array of system path names, a handle, or a vector of handles.

Example: 'MyModel/Subsystem1'

Example: {'vdp','ex_sl-demo_clutch'}

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

When you use the `find_system` function, `Name, Value` pair arguments can include search constraints and parameter name and value pairs. You can specify search constraints in any order, but they must precede the parameter name and value pairs.

See “Block-Specific Parameters” on page 6-24 for the list of block parameters.

Example: 'SearchDepth','0','LookUnderMasks','none','BlockType','Goto' searches in loaded systems, excluding masked subsystems, for Goto blocks.

BlockDialogParams — Option to search block dialog box parameters for the specified value
character vector | string scalar

Option to search block dialog box parameters for the specified value, specified as the comma-separated pair consisting of 'BlockDialogParams' and a character vector or string scalar. This pair must follow the other search constraint pairs.

CaseSensitive — Option to consider case when matching
'on' (default) | 'off'

Option to consider case when matching, specified as the comma-separated pair consisting of 'CaseSensitive' and 'on' for case-sensitive searching or 'off'.

FindAll — Option to include lines, ports, and annotations within systems
'off' (default) | 'on'

Option to include lines, ports, and annotations in systems in the search, specified as the comma-separated pair consisting of 'FindAll' and 'on' or 'off'. When this option is set to 'on', `find_system` returns a vector of handles regardless of how you specify the `System` argument.

FirstResultOnly — Option to return only the first result
'off' (default) | 'on'

Option to return only the first result and then stop the search, specified as the comma-separated pair consisting of 'FirstResultOnly' and 'on' or 'off'.

LookInsideSubsystemReference — Option to look inside a referenced subsystem
'on' (default) | 'off'

Option to look inside a referenced subsystem in a model and list child blocks specified as the comma-separated pair consisting of 'LookInsideSubsystemReference' and 'on' or 'off'.

FollowLinks — Option to follow links into library blocks
'off' (default) | 'on'

Option to follow links into library blocks, specified as the comma-separated pair consisting of 'FollowLinks' and 'on' or 'off'. If you do not specify a system to search, `find_system` includes loaded libraries in the results, whether you set 'FollowLinks' to 'on' or 'off'. You can use 'FollowLinks' with 'LookUnderMasks' to update library links in subsystems. See "Update Library Links in a Subsystem" on page 2-246.

IncludeCommented — Option to include commented blocks
'off' (default) | 'on'

Option to include commented blocks in the search, specified as the comma-separated pair consisting of 'IncludeCommented' and 'on' or 'off'.

LoadFullyIfNeeded — Option to load any partially loaded models
'on' (default) | 'off'

Option to load any partially loaded models, specified as the comma-separated pair of 'LoadFullyIfNeeded' and 'on' to load models or 'off' to disable loading. Use this option, for example, to prevent load warnings.

LookUnderMasks — Options for searching under masks

'graphical' (default) | 'none' | 'functional' | 'all' | 'on' | 'off'

Options for searching under masks, specified as the comma-separated pair consisting of 'LookUnderMasks' and one of these options:

- 'graphical' — Search includes masked subsystems that have no workspaces and no dialogs.
- 'none' — Search skips masked subsystems.
- 'functional' — Search includes masked subsystems that do not have dialogs.
- 'all' — Search includes all masked subsystems.
- 'on' — Search includes all masked subsystems.
- 'off' — Search skips masked subsystem.

RegExp — Option to treat search expressions as regular expressions

'off' (default) | 'on'

Option to treat search expressions as regular expressions specified as the comma-separated pair consisting of 'RegExp' and 'on' to treat search expressions as regular expressions or 'off'. To learn more about MATLAB regular expressions, see “Regular Expressions”.

SearchDepth — Option to restrict the search depth

positive integer character vector or string scalar

Option to restrict the search depth to the specified level, specified as the comma-separated pair consisting of 'SearchDepth' and a positive integer character vector or string scalar. For example, specify '0' to search loaded systems only, '1' for blocks and subsystems of the top-level system, '2' for the top-level system and its children, etc. The default is to search all levels.

Variants — Options for searching variants

'ActiveVariants' (default) | 'AllVariants' | 'ActivePlusCodeVariants'

Note The Variants argument will be removed. Use MatchFilter instead. For more information, see “Compatibility Considerations” on page 2-251.

Options for searching variants, specified as the comma-separated pair consisting of 'Variants' and one of these options:

- 'ActiveVariants' — Search only the active variant choice in the Variant Subsystem.
- 'AllVariants' — Search all variant choices in the Variant Subsystem.
- 'ActivePlusCodeVariants' — Search all variant choices in the Variant Subsystem that are active in simulation and is part of the generated code.

This search constraint applies only to Variant Subsystem blocks that have the **Variant control mode** set to expression or label. Use the find_system function with the MatchFilter option to operate on all types of variant blocks.

MatchFilter — Option to match and filter elements in search

function handle

Option to match and filter elements such as blocks, system, lines, ports, and annotations in a search, specified as function handle. Use `MatchFilter` to determine whether elements should be included or skipped in a search.

The argument:

- Allows you to filter elements with custom filter functions
- Avoids processing elements when filters do not match
- Applies complex filters on blocks, lines, or annotations, to filter the results internally

The named function must be defined within a MATLAB program file. The function takes the handle of the element as input and returns two outputs.

```
function [match, prune] = func(element)
```

- The input `element` is the handle of the block being processed.
- The first output, `match`, is a logical value. If `false`, search skips the element.
- The second output, `prune`, is an optional logical value that only applies when `element` is a subsystem. The default value is `false`. If this value is set to `true`, the entire subsystem is omitted from the search.

Example: Use `MatchFilter` to find all non Inport and Outport blocks in a model using your own defined filter function, `nonInOutBlocks`.

```
function match = nonInOutBlocks(handle)
match = true;
if strcmp(get_param(handle, 'Type'), 'block')
    blockType = get_param(handle, 'BlockType');
    if strcmp(blockType, 'Inport') || ...
        strcmp(blockType, 'Outport')
        match = false;
    end
end
end

load_system('vdp');
blks = find_system('vdp', 'MatchFilter', @nonInOutBlocks)
```

Variants: Simulink provides these built-in match filter functions to find variant blocks that are active in simulation or part of the generated code.

- `Simulink.match.activeVariants` — Filter function to find blocks that are active in simulation after model compilation.
- `Simulink.match.codeCompileVariants` — Filter function to find blocks that are part of generated code after model compilation.
- `Simulink.match.allVariants` — Filter function to find all blocks irrespective of whether the block is active or inactive due to variants.
- `Simulink.match.variantAssemblySubsystems` — Filter function to find all the Variant Assembly Subsystem blocks.

Note To get correct results, you must **compile the model** before using `Simulink.match.activeVariants` and `Simulink.match.codeCompileVariants` filters. If the model is not compiled, these filters return all blocks in the model.

For an example that compares the pre-compile and post-compile time results for these filters, see “Use `find_system` with Built-In MatchFilter Options for Variant Blocks”.

Example: Use the `Simulink.match.activeVariants` filter to find active variants in a model.

```
openExample('simulink_variants/BuiltInMatchFiltersWithfindsystemForVariantBlocksExample');
model='sldemo_variant_subsystems';
load_system(model);
assignin('base','VSS_MODE',2);
set_param(model, 'SimulationCommand', 'update');
activeBlks = find_system(model, 'MatchFilter', @Simulink.match.activeVariants);
```

Example: Use the `Simulink.match.codeCompileVariants` filter to find variant choices that are part of the generated C code.

```
openExample('simulink_variants/BuiltInMatchFiltersWithfindsystemForVariantBlocksExample');
load_system('sldemo_variant_subsystems');
assignin('base','VSS_MODE',2);
sldemo_variant_subsystems([], [], [], 'compileForCodegen');
activeBlks= find_system('sldemo_variant_subsystems', 'MatchFilter', @Simulink.match.codeCompileVariants);
sldemo_variant_subsystems([], [], [], 'term');
```

Example: Use the `Simulink.match.allVariants()` filter to find all blocks in a model.

```
find_system('sldemo_variant_subsystems', 'MatchFilter', @Simulink.match.allVariants);
```

Example: Use the `Simulink.match.variantAssemblySubsystems()` filter to find all the Variant Assembly Subsystem blocks in a model.

```
openExample('simulink_variants/ChoicesMaskVariantAssemblySubsystemMaskParamObjectExample');
load_system('slexVariantAssemblySubsystemWithMask')
find_system('slexVariantAssemblySubsystemWithMask', 'MatchFilter', @Simulink.match.variantAssemblySubsystems);
```

Output Arguments

Objects — Matching objects

cell array of path names | vector of handles

Matching objects found, returned as:

- A cell array of path names if you specified `System` as a path name or cell array of path names, or if you did not specify a system
- A vector of handles if you specified `System` as a handle or vector of handles

Version History

Introduced before R2006a

R2022b: Warnings for removal of Variants argument

Warns starting in R2022b

As part of the removal of the `Variants` argument in a future release, these warnings have been introduced:

- When you use the `find_system` function without the `Variants` argument, the function generates a warning if it skips the inactive choice of a Variant Subsystem block during the search.

Consider a model with a Variant Subsystem block that has two variant choices, `Linear Controller` and `Nonlinear Controller`. The `Nonlinear Controller` block is the active choice.

This command skips the inactive `Linear Controller` block and generates a warning.

```
blocks = find_system('sldemo_variant_subsystems/Controller')
```

Warning: Using `find_system` without the 'Variants' argument skips inactive Variant Subsystem blocks in the search. This behavior will change in a future release to look at all choices of the Variant Subsystem. To find blocks that are active in simulation or code generation, compile the model and use the built-in variant filters with the 'MatchFilter' option.

```
blocks =
```

```
12x1 cell array
```

```
{'sldemo_variant_subsystems/Controller' }
{'sldemo_variant_subsystems/Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Out1' }
```

- When you use the `Variants` argument with its value set to `'AllVariants'`, the function generates a warning.

```
blocks = find_system('sldemo_variant_subsystems/Controller','Variants','AllVariants')
```

Warning: 'Variants' will be removed. Instead of using 'Variants' with value set to 'AllVariants' use 'MatchFilter' with value set to `@Simulink.match.allVariants`.

```
blocks =
```

```
19x1 cell array
```

```
{'sldemo_variant_subsystems/Controller' }
{'sldemo_variant_subsystems/Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Linear Controller' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Discrete-Transfer Fcn' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Out1' }
```

R2022a: New built-in match filter to find all variant blocks

You can use the built-in match filter, `Simulink.match.allVariants`, to find all the blocks in a variant model regardless of whether the block is active or inactive due to variants. This filter is the recommended replacement for the `AllVariants` option.

To be removed	Recommended Replacement
<code>find_system(model, 'Variants', ... 'AllVariants');</code>	<code>find_system(model, 'MatchFilter', ... @Simulink.match.allVariants);</code>

R2021a: Default behavior has changed for Variants and MatchFilter arguments in model with variant blocks

Behavior changed in R2021a

- **Variants:** When you use the `find_system` function without specifying the `Variants` argument, the function currently includes only the active variant choice for Variant Subsystem blocks in the search by default.

For other variant blocks such as Variant Source, Variant Sink, or Variant Subsystem blocks with the **Propagate conditions outside of variant subsystem** parameter set to on, the function includes all choices in the search.

Consider a model with a Variant Subsystem that has two variant choices, Linear Controller and Nonlinear Controller.

This command returns only the active Add blocks in the model.

```
add_blocks = find_system('sldemo_variant_subsystems/Controller', ...  
'BlockType', 'Sum')
```

```
add_blocks =
```

```
    1x1 cell array
```

```
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add'}
```

- **MatchFilter:** When you use the `find_system` function with the `MatchFilter` argument, the function applies the filters on the active and inactive variant choices by default.

Consider a model with a Variant Subsystem that has two variant choices, Linear Controller and Nonlinear Controller. The filter function `findAddBlocks` finds all the Add blocks in the model.

```
function match = findAddBlocks(handle)  
match = strcmp(get_param(handle, 'Type'), 'block') &&...  
strcmp(get_param(handle, 'BlockType'), 'Sum');  
end
```

This command returns the active and inactive Add blocks in the model.

```
add_blocks = find_system('sldemo_variant_subsystems', 'MatchFilter', ...  
@findAddBlocks)
```

```
add_blocks =
```

```
    2x1 cell array
```

```
{'sldemo_variant_subsystems/Controller/Linear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add'}
```

R2021a: Variants argument will be removed

Warns starting in R2021a

The Variants argument will be removed from `find_system` in a future release. Function calls that use the Variants argument continue to work with a warning.

Using the `find_system` function with the Variants argument produces inconsistent search results. The `find_system` function is an edit-time operation, but to determine whether a block is active in a model with all types of variant blocks, you need to compile the model.

To find variant blocks that are active during simulation or code generation, **compile the model** and use the `find_system` function with the `MatchFilter` argument.

This table lists the recommended replacement for different values of the Variants argument.

To Be Removed	Recommended Replacement
<code>find_system(model, 'Variants', ... 'ActiveVariants');</code>	<code>set_param(model, 'SimulationCommand', 'update'); find_system(model, 'MatchFilter', ... @Simulink.match.activeVariants);</code>
<code>find_system(model, 'Variants', ... 'ActivePlusCodeVariants');</code>	<code>model([], [], [], 'compileForCodegen'); activeBlks= find_system(model, 'MatchFilter', ... @Simulink.match.codeCompileVariants); model([], [], [], 'term');</code>

When you use the `find_system` function, you cannot specify both of the `MatchFilter` and `Variants` arguments.

This command produces an error.

```
find_system(bdroot, 'MatchFilter', @Simulink.match.activeVariants, ...  
'Variants', 'ActiveVariants');
```

R2020b: Filter elements during search with MatchFilter

To match and filter model elements during a search, you can define a custom filter function and pass the function handle as value to the `MatchFilter` name-value argument.

To find variant blocks that are active in a simulation or part of the generated code, you can use the built-in match filter functions, `Simulink.match.activeVariants`, `Simulink.match.codeCompileVariants`, and `Simulink.match.allVariants`, after compiling the model.

fixdt

Package: Simulink

Create `Simulink.NumericType` object describing a fixed-point or floating-point data type

Syntax

```
a = fixdt(Signed,WordLength)
a = fixdt(Signed,WordLength,FractionLength)
a = fixdt(Signed,WordLength>TotalSlope,Bias)
a = fixdt(Signed,WordLength,SlopeAdjustmentFactor,FixedExponent,Bias)
a = fixdt(DataTypeNameString)
a = fixdt(____,'DataTypeOverride','Off')
[a,IsScaledDouble] = fixdt(____)
```

Description

`a = fixdt(Signed,WordLength)` returns a `Simulink.NumericType` object that describes a fixed-point data type with the specified signedness and word length, and unspecified scaling.

`a = fixdt(Signed,WordLength,FractionLength)` returns a `Simulink.NumericType` object that describes a fixed-point data type with binary point scaling.

`a = fixdt(Signed,WordLength>TotalSlope,Bias)` returns a `Simulink.NumericType` object that describes a fixed-point data type with slope and bias scaling.

`a = fixdt(Signed,WordLength,SlopeAdjustmentFactor,FixedExponent,Bias)` returns a `Simulink.NumericType` object that describes a fixed-point data type with slope and bias scaling.

`a = fixdt(DataTypeNameString)` returns a `Simulink.NumericType` object that describes an integer, fixed-point, or floating-point data type specified by the name of a data type.

`a = fixdt(____,'DataTypeOverride','Off')` returns a `Simulink.NumericType` object with its `DataTypeOverride` parameter set to `Off`. The default value for this property is `Inherit`. You can specify the `DataTypeOverride` parameter after any combination of other input parameters.

`[a,IsScaledDouble] = fixdt(____)` returns a `Simulink.NumericType` object that describes a fixed-point or floating-point data type and a flag that indicates whether the specified data type is of a scaled double data type.

Examples

Create a `Simulink.NumericType` Object with Unspecified Scaling

Create a signed `Simulink.NumericType` object with a word length of 16 bits and unspecified scaling.

```
a = fixdt(1,16)
```

```

a =
  NumericType with properties:

    DataTypeMode: 'Fixed-point: unspecified scaling'
    Signedness: 'Signed'
    WordLength: 16
    IsAlias: 0
    DataScope: 'Auto'
    HeaderFile: ''
    Description: ''

```

Create a Simulink.NumericType Object with Binary Point Scaling

Create a `Simulink.NumericType` object that describes a signed fixed-point data types with a word length of 16 bits and fraction length of 2 bits.

```

a = fixdt(1,16,2)

a =
  NumericType with properties:

    DataTypeMode: 'Fixed-point: binary point scaling'
    Signedness: 'Signed'
    WordLength: 16
    FractionLength: 2
    IsAlias: 0
    DataScope: 'Auto'
    HeaderFile: ''
    Description: ''

```

Create a Simulink.NumericType Object with Slope and Bias Scaling

The real-world value of a slope bias scaled number is represented by:

$$\text{real world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

Create a `Simulink.NumericType` object that describes a signed fixed-point data type with a word length of 16 bits, slope of 2^{-2} , and bias of 4.

```

a = fixdt(1,16,2^-2,4)

a =
  NumericType with properties:

    DataTypeMode: 'Fixed-point: slope and bias scaling'
    Signedness: 'Signed'
    WordLength: 16
    Slope: 0.2500
    Bias: 4
    IsAlias: 0
    DataScope: 'Auto'

```

```
HeaderFile: ''
Description: ''
```

Alternatively, the slope can be represented by:

$$\text{slope} = \text{slopeadjustmentfactor} \times 2^{\text{fixedexponent}}$$

```
a = fixdt(1,16,1,-2,4)
```

```
a =
```

```
NumericType with properties:
```

```
DataTypeMode: 'Fixed-point: slope and bias scaling'
Signedness: 'Signed'
WordLength: 16
    Slope: 0.2500
    Bias: 4
    IsAlias: 0
    DataScope: 'Auto'
HeaderFile: ''
Description: ''
```

The `DataTypeMode` property of the `Simulink.NumericType` object, `a`, is slope and bias scaling.

Create a `Simulink.NumericType` Object Using a Data Type Name

Use a data type name to create a `Simulink.NumericType` object that describes an 8-bit, unsigned, fixed-point data type and return a flag that indicates whether the object is of a scaled double data type.

```
[a,IsScaledDouble] = fixdt('ufix8')
```

```
a =
```

```
NumericType with properties:
```

```
DataTypeMode: 'Fixed-point: binary point scaling'
Signedness: 'Unsigned'
WordLength: 8
FractionLength: 0
    IsAlias: 0
    DataScope: 'Auto'
HeaderFile: ''
Description: ''
```

```
IsScaledDouble = logical
    0
```

The `IsScaledDouble` output returns `0`, which indicates that the data type of `a` is not a scaled double data type.

Create a Simulink.NumericType Object with DataTypeOverride Set to Off

Create a Simulink.NumericType object with its DataTypeOverride property set to Off.

```
a = fixdt(0,8,2,'DataTypeOverride','Off')

a =
  NumericType with properties:
      DataTypeMode: 'Fixed-point: binary point scaling'
      Signedness: 'Unsigned'
      WordLength: 8
      FractionLength: 2
      DataTypeOverride: 'Off'
      IsAlias: 0
      DataScope: 'Auto'
      HeaderFile: ''
      Description: ''
```

Input Arguments

Signed — Signedness

true or 1 | false or 0

Signedness of the Simulink.NumericType object, specified as a numeric or logical 1 (true) or 0 (false). A value of 1, or true, indicates a signed data type. A value of 0, or false, indicates an unsigned data type.

Data Types: logical

WordLength — Word length

positive scalar

Word length, in bits, of the Simulink.NumericType object, specified as a positive scalar.

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

FractionLength — Fraction length

0 (default) | scalar

Fraction length, in bits, of the Simulink.NumericType object, specified as a scalar.

FractionLength can be greater than WordLength. For more information, see “Binary Point Interpretation” (Fixed-Point Designer).

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TotalSlope — Slope of the scaling

1 (default) | scalar

Slope of the scaling, specified as a scalar.

The following equation represents the real-world value of a slope bias scaled number:

$$realworldvalue = (slope \times integer) + bias$$

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Bias — Bias of the scaling

0 (default) | scalar

Bias of the scaling, specified as a scalar.

The following equation represents the real-world value of a slope bias scaled number:

$$realworldvalue = (slope \times integer) + bias$$

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SlopeAdjustmentFactor — Slope adjustment factor of slope and bias scaled number

1 (default) | positive scalar

Slope adjustment factor of a slope bias scaled number, specified as a positive scalar.

The slope adjustment factor must be greater than or equal to 1 and less than 2. If you input a `SlopeAdjustmentFactor` outside this range, `fixdt` automatically applies a scaling normalization to the values of `SlopeAdjustmentFactor` and `FixedExponent` so that the revised slope adjustment factor is greater than or equal to 1 and less than 2, and maintains the value of the slope.

The following equation demonstrates the relationship between the slope, fixed exponent, and slope adjustment factor:

$$slope = slopeadjustmentfactor \times 2^{fixedexponent}$$

Data Types: half | single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

FixedExponent — Fixed exponent of slope and bias scaled number

0 (default) | scalar

Fixed exponent of a slope bias scaled number, specified as a scalar.

The following equation demonstrates the relationship between the slope, fixed exponent, and slope adjustment factor:

$$slope = slopeadjustmentfactor \times 2^{fixedexponent}$$

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

DataTypeNameString — Data type name

character vector

Data type name, specified as a character vector.

The data type name can be either the name of a built-in Simulink data type or the name of a fixed-point data type that conforms to the naming convention for fixed-point names established by the

Fixed-Point Designer product. For more information, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).

Data Types: char

Output Arguments

a — Data type

Simulink.NumericType object

Data type, returned as a Simulink.NumericType object.

IsScaledDouble — Scaled double flag

logical

Scaled double flag, returned as a logical that indicates whether the specified data type name is the name of a scaled double data type.

fixpt_evenspace_cleanup

Modify breakpoints of lookup table to have even spacing

Syntax

```
xdata_modified = fixpt_evenspace_cleanup(xdata,xdt,xscale)
```

Description

xdata_modified = fixpt_evenspace_cleanup(*xdata*,*xdt*,*xscale*) modifies breakpoints of a lookup table to have even spacing after quantization. By adjusting breakpoints to have even spacing after quantization, Simulink Coder generated code can exclude breakpoints from memory.

xdata is the breakpoint vector of a lookup table to make evenly spaced, such as 0:0.005:1. *xdt* is the data type of the breakpoints, such as sfix(16). *xscale* is the scaling of the breakpoints, such as 2⁻¹². Using these three inputs, fixpt_evenspace_cleanup returns the modified breakpoints in *xdata_modified*.

This function works only with nontunable data and considers data to have even spacing relative to the scaling slope. For example, the breakpoint vector [0 2 5], which has spacing value 2 and 3, appears to have uneven spacing. However, the difference between the maximum spacing 3 and the minimum spacing 2 equals 1. If the scaling slope is 1 or greater, a spacing variation of 1 represents a 1-bit change or less. In this case, the fixpt_evenspace_cleanup function considers a spacing variation of 1 bit or less to be even.

Modifications to breakpoints can change the numerical behavior of a lookup table. To check for changes, test the model using simulation, rapid prototyping, or other appropriate methods.

Examples

Modify breakpoints of a lookup table to have even spacing after quantization:

```
xdata = 0:0.005:1;  
xdt = sfix(16);  
xscale = 2^-12;  
xdata_modified = fixpt_evenspace_cleanup(xdata,xdt,xscale)
```

fixpt_look1_func_approx

Optimize fixed-point approximation of nonlinear function by interpolating lookup table data points

Syntax

```
[xdata,ydata,errworst] = fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,nptsmax)
[xdata,ydata,errworst] = fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,[])
[xdata,ydata,errworst] = fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,[],nptsmax)
[xdata,ydata,errworst] = fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydtydt,yscale,rndmeth,errmax,nptsmax,spacing)
```

Description

[*xdata,ydata,errworst*] = `fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,nptsmax)` returns the optimal breakpoints of a lookup table, an ideal function applied to the breakpoints, and the worst-case approximation error. The lookup table satisfies the maximum acceptable error and maximum number of points that you specify.

[*xdata,ydata,errworst*] = `fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,[])` returns the optimal breakpoints of a lookup table, an ideal function applied to the breakpoints, and the worst-case approximation error. The lookup table satisfies the maximum acceptable error that you specify.

[*xdata,ydata,errworst*] = `fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,[],nptsmax)` returns the optimal breakpoints of a lookup table, an ideal function applied to the breakpoints, and the worst-case approximation error. The lookup table satisfies the maximum number of points that you specify.

[*xdata,ydata,errworst*] = `fixpt_look1_func_approx('func',...
xmin,xmax,xdt,xscale,ydtydt,yscale,rndmeth,errmax,nptsmax,spacing)` returns the optimal breakpoints of a lookup table, an ideal function applied to the breakpoints, and the worst-case approximation error. The lookup table satisfies the maximum acceptable error, maximum number of points, and breakpoint spacing that you specify.

In each case, `fixpt_look1_func_approx` interpolates between lookup table data points to optimize the fixed-point approximation. The inputs *xmin* and *xmax* specify the range over which to approximate the breakpoints. The inputs *xdt*, *xscale*, *ydt*, *yscale*, and *rndmeth* follow conventions used by fixed-point Simulink blocks.

The inputs *errmax*, *nptsmax*, and *spacing* are optional. Of these inputs, you must specify at least *errmax* or *nptsmax*. If you omit one of those two inputs, you must use brackets, [], in place of the omitted input. `fixpt_look1_func_approx` ignores that requirement for the lookup table.

If you do not specify spacing, and more than one spacing satisfies *errmax* and *nptsmax*, `fixpt_look1_func_approx` chooses in this order: power-of-2 spacing, even spacing, uneven

spacing. This behavior applies when you specify both *errmax* and *nptsmax*, but not when you specify just one of the two.

Input Arguments

func

Function of x for which to approximate breakpoints. Enclose this expression in single quotes, for example, `'sin(2*pi*x)'`.

xmin

Minimum value of x .

xmax

Maximum value of x .

xdt

Data type of x .

xscale

Scaling for the x values.

ydt

Data type of y .

yscale

Scaling for the y values.

rndmeth

Rounding mode supported by fixed-point Simulink blocks:

'Ceiling'	Round to the nearest representable number in the direction of positive infinity.
'Floor' (default)	Round to the nearest representable number in the direction of negative infinity.
'Nearest'	Round to the nearest representable number.
'Toward Zero'	Round to the nearest representable number in the direction of zero.

errmax

Maximum acceptable error between the ideal function and the approximation given by the lookup table.

nptsmax

Maximum number of points for the lookup table.

spacing

Spacing of breakpoints for the lookup table:

'even'	Even spacing
'pow2'	Even, power-of-2 spacing
'unrestricted' (default)	Uneven spacing

If you specify...	The breakpoints of the lookup table...
<i>errmax</i> and <i>nptsmax</i>	Meet both criteria, if possible. The <i>errmax</i> requirement has higher priority than <i>nptsmax</i> . If the breakpoints cannot meet both criteria with the specified spacing, <i>nptsmax</i> does not apply.
<i>errmax</i> only	Meet the error criteria, and <code>fixpt_look1_func_approx</code> returns the fewest number of points.
<i>nptsmax</i> only	Meet the points criteria, and <code>fixpt_look1_func_approx</code> returns the smallest worst-case error.

Output Arguments**xdata**

Vector of breakpoints for the lookup table.

ydata

Vector of values from applying the ideal function to the breakpoints.

errworst

Worst-case error, which is the maximum absolute error between the ideal function and the approximation given by the lookup table.

Examples

Approximate a fixed-point sine function using a lookup table:

```
func = 'sin(2*pi*x)';
% Define the range over which to optimize breakpoints
xmin = 0;
xmax = 0.25;
% Define the data type and scaling for the inputs
xdt = ufix(16);
xscale = 2^-16;
% Define the data type and scaling for the outputs
ydt = sfix(16);
yscale = 2^-14;
% Specify the rounding method
rndmeth = 'Floor';
```

```
% Define the maximum acceptable error
errmax = 2^-10;
% Choose even, power-of-2 spacing for breakpoints
spacing = 'pow2';
% Create the lookup table
[xdata,ydata,errworst] = fixpt_look1_func_approx(func,...
    xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,[],spacing);
```

fixpt_look1_func_plot

Plot fixed-point approximation function for lookup table

Syntax

```
fixpt_look1_func_plot(xdata,ydata,'func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth)
errworst = fixpt_look1_func_plot(xdata,ydata,'func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth)
```

Description

`fixpt_look1_func_plot(xdata,ydata,'func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth)` plots a lookup table approximation function and the error from the ideal function.

`errworst = fixpt_look1_func_plot(xdata,ydata,'func',...
xmin,xmax,xdt,xscale,ydt,yscale,rndmeth)` plots a lookup table approximation function and the error from the ideal function. The output `errworst` is the maximum absolute error.

You can use `fixpt_look1_func_approx` to generate `xdata` and `ydata`, the breakpoints and table data for the lookup table, respectively. `fixpt_look1_func_approx` applies the ideal function to the breakpoints in `xdata` to produce `ydata`. While this method is the easiest way to generate `ydata`, you can choose other values for `ydata` as input for `fixpt_look1_func_plot`. Choosing different values for `ydata` can, in some cases, produce a lookup table with a smaller maximum absolute error.

Input Arguments

xdata

Vector of breakpoints for the lookup table.

ydata

Vector of values from applying the ideal function to the breakpoints.

func

Function of `x` for which to approximate breakpoints. Enclose this expression in single quotes, for example, `'sin(2*pi*x)'`.

xmin

Minimum value of `x`.

xmax

Maximum value of `x`.

xdt

Data type of x.

xscale

Scaling for the x values.

ydt

Data type of y.

yscale

Scaling for the y values.

rndmeth

Rounding mode supported by fixed-point Simulink blocks:

'Ceiling'	Round to the nearest representable number in the direction of positive infinity.
'Floor' (default)	Round to the nearest representable number in the direction of negative infinity.
'Nearest'	Round to the nearest representable number.
'Toward Zero'	Round to the nearest representable number in the direction of zero.

Examples

Plot a fixed-point approximation of the sine function using data points generated by `fixpt_look1_func_approx`:

```
func = 'sin(2*pi*x)';
% Define the range over which to optimize breakpoints
xmin = 0;
xmax = 0.25;
% Define the data type and scaling for the inputs
xdt = ufix(16);
xscale = 2^-16;
% Define the data type and scaling for the outputs
ydt = sfix(16);
yscale = 2^-14;
% Specify the rounding method
rndmeth = 'Floor';
% Define the maximum acceptable error
errmax = 2^-10;
% Choose even, power-of-2 spacing for breakpoints
spacing = 'pow2';
% Generate data points for the lookup table
[xdata,ydata,errworst]=fixpt_look1_func_approx(func,...
    xmin,xmax,xdt,xscale,ydt,yscale,rndmeth,errmax,[],spacing);
% Plot the sine function (ideal and fixed-point) & errors
fixpt_look1_func_plot(xdata,ydata,func,xmin,xmax,...
    xdt,xscale,ydt,yscale,rndmeth);
```

`fixpt_look1_func_plot` plots the fixed-point sine function, using generated data points, and plots the error between the ideal function and the fixed-point function. The maximum absolute error and the number of points required appear on the plot. The error drops to zero at a breakpoint, but increases between breakpoints due to curvature differences between the ideal function and the line drawn between breakpoints.

The lookup table requires 33 points to achieve a maximum absolute error of $2^{-11.3922}$.

fixpt_set_all

Set property for each fixed-point block in subsystem

Syntax

```
fixpt_set_all(SystemName, fixptPropertyName, fixptPropertyValue)
```

Description

`fixpt_set_all(SystemName, fixptPropertyName, fixptPropertyValue)` sets the property `fixptPropertyName` of every applicable block in the model or subsystem `SystemName` to the value `fixptPropertyValue`

Examples

Set each fixed-point block in a model `Filter_1` to round towards the floor and saturate upon overflow:

```
% Round towards the floor  
fixpt_set_all('Filter_1', 'RndMeth', 'Floor')
```

```
% Saturate upon overflow  
fixpt_set_all('Filter_1', 'DoSatur', 'on')
```

Version History

Introduced before R2006a

fixptbestexp

Exponent that gives best precision for fixed-point representation of value

Syntax

```
out = fixptbestexp(RealWorldValue, TotalBits, IsSigned)
out = fixptbestexp(RealWorldValue, FixPtDataType)
```

Description

`out = fixptbestexp(RealWorldValue, TotalBits, IsSigned)` returns the exponent that gives the best precision for the fixed-point representation of *RealWorldValue*. *TotalBits* specifies the number of bits for the fixed-point number. *IsSigned* specifies whether the fixed-point number is signed: 1 indicates the number is signed and 0 indicates the number is not signed.

`out = fixptbestexp(RealWorldValue, FixPtDataType)` returns the exponent that gives the best precision based on the data type *FixPtDataType*.

Examples

Get the exponent that gives the best precision for the real-world value 4/3 using a signed, 16-bit number:

```
out = fixptbestexp(4/3,16,1)
out =
    -14
```

Alternatively, specify the fixed-point data type:

```
out = fixptbestexp(4/3,sfix(16))
out =
    -14
```

This shows that the maximum precision representation of 4/3 is obtained by placing 14 bits to the right of the binary point:

```
01.01010101010101
```

You can specify the precision of this representation in fixed-point blocks by setting the scaling to 2^{-14} or `2^fixptbestexp(4/3,16,1)`.

Version History

Introduced before R2006a

See Also

fixptbestprec

fixptbestprec

Determine maximum precision available for fixed-point representation of value

Syntax

```
out = fixptbestprec(RealWorldValue,TotalBits,IsSigned)
out = fixptbestprec(RealWorldValue,FixPtDataType)
```

Description

`out = fixptbestprec(RealWorldValue,TotalBits,IsSigned)` determines the maximum precision for the fixed-point representation of the real-world value specified by `RealWorldValue`. You specify the number of bits for the fixed-point number with `TotalBits`, and you specify whether the fixed-point number is signed with `IsSigned`. If `IsSigned` is 1, the number is signed. If `IsSigned` is 0, the number is not signed. The maximum precision is returned to `out`.

`out = fixptbestprec(RealWorldValue,FixPtDataType)` determines the maximum precision based on the data type specified by `FixPtDataType`.

Examples

Example 1

The following command returns the maximum precision available for the real-world value 4/3 using a signed, 8-bit number:

```
out = fixptbestprec(4/3,8,1)

out =
    0.015625
```

Alternatively, you can specify the fixed-point data type:

```
out = fixptbestprec(4/3,sfix(8))

out =
    0.015625
```

This value means that the maximum precision available for 4/3 is obtained by placing six bits to the right of the binary point since 2^{-6} equals 0.015625:

```
01.010101
```

Example 2

You can use the maximum precision as the scaling in fixed-point blocks. This enables you to use `fixptbestprec` to perform a type of autoscaling if you would like to designate a known range of your simulation. For example, if your known range is -13 to 22, and you are using a safety margin of 30%:

```
knownMax = 22;
knownMin = -13;
```

```
localSafetyMargin = 30;  
slope = max( fixptbestprec( (1+localSafetyMargin/100)* ...  
    [knownMax,knownMin], sfix(16) ) );
```

The variable `slope` can then be used in the expression that you specify for the **Output data type** parameter in a block mask. Be sure to select the **Lock output data type setting against changes by the fixed-point tools** check box in the same block to prevent the Fixed-Point Tool from overriding the scaling. If you know the range, you can use this technique in place of relying on a model simulation to provide the range to the autoscaling tool, as described in `autofixexp`.

`fixptbestexp`

fmudialog.createBusType

Create all FMU bus objects required for structured input or output ports in workspace

Syntax

```
fmudialog.createBusType(currentBlock)
```

Description

`fmudialog.createBusType(currentBlock)` creates all the FMU bus objects required for structured input or output ports in the workspace.

Examples

Create FMU Bus Object in Current Workspace

Create FMU bus object in current workspace.

```
fmudialog.createBusType(gcb)
```

Input Arguments

currentBlock — Current block

current block

Current block for which to create all required FMU bus objects.

Data Types: char | string

Version History

Introduced in R2020b

FMU

Topics

“Import FMUs”

“Implement an FMU Block”

frameedit

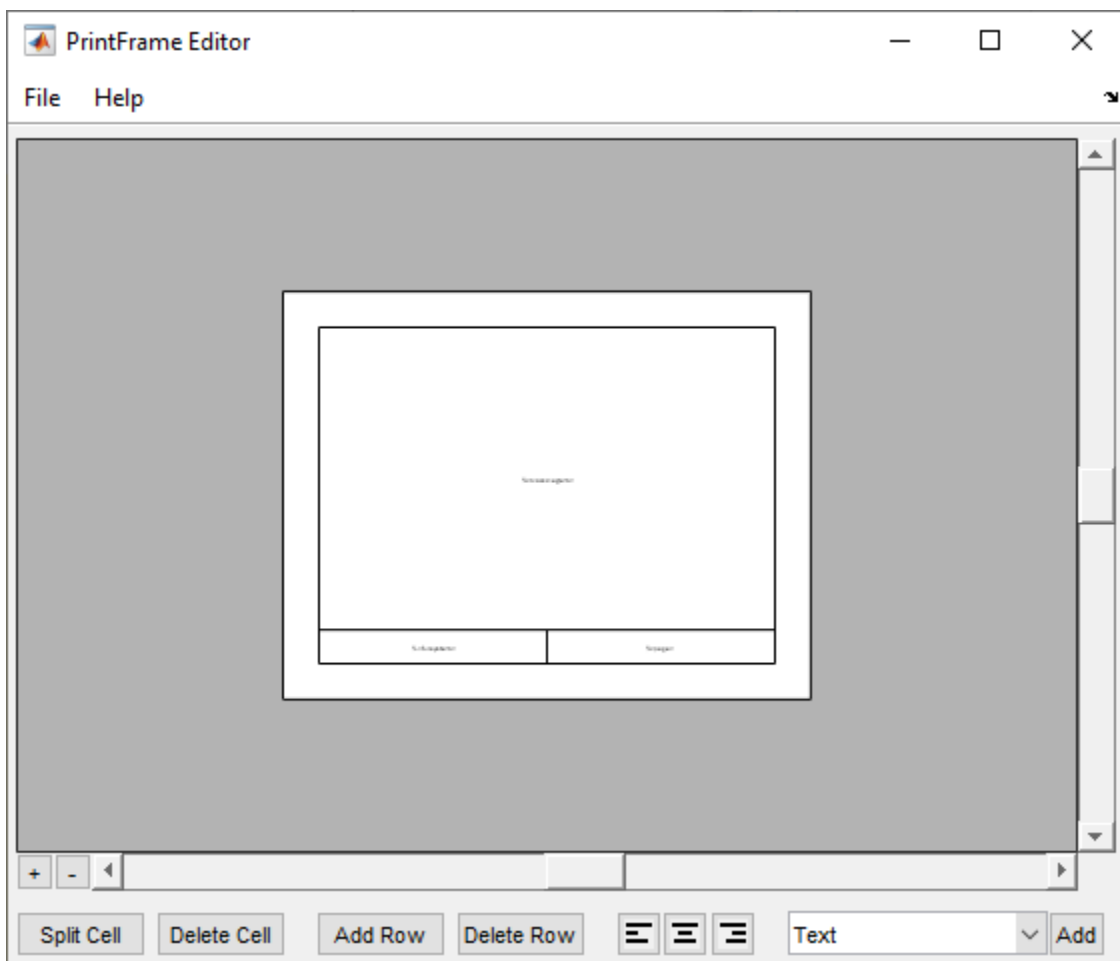

Open PrintFrame Editor to edit print frames for Simulink and Stateflow block diagrams

Syntax

```
frameedit  
frameedit(filename)
```

Description

frameedit opens a new file in the **PrintFrame Editor**, which is a graphical interface you use to create borders for Simulink and Stateflow block diagrams.

frameedit(filename) opens the specified file in the **PrintFrame Editor**.

Examples

Open Existing Print Frame for Editing

Suppose you have a print frame named `myFrame.fig`. You can open it directly in the **PrintFrame Editor** from the MATLAB Command Window.

```
frameedit('myFrame.fig')
```

The **PrintFrame Editor** opens the print frame named `myFrame.fig`.

Input Arguments

filename — Print frame file name

character vector | string scalar

Print frame file name, specified as a character vector or string scalar.

The specified file must be a figure file (`.fig`) previously created and saved with the **PrintFrame Editor**.

Example: `frameedit('myFrame.fig')`

Data Types: `char` | `string`

gcb

Get path name of current block

Syntax

```
b1 = gcb  
b1 = gcb(sys)
```

Description

`b1 = gcb` returns the full block path name of the current block in the current system. The current block is:

- The most recently clicked block
- The S-Function block currently executing its corresponding MATLAB function
- The block whose callback routine is being executed
- The block whose mask is being evaluated as part of the `MaskInitialization` parameter evaluation
- The last block loaded after opening a model

`b1 = gcb(sys)` returns the full block path name of the current block in the specified system. Load the system first.

Examples

Get Path Name of Most Recently Selected Block

Open a model.

```
vdp
```

In the model, select a block. For example, select the Gain block. Then, enter `gcb` at the command prompt.

```
gcb
```

```
ans =
```

```
vdp/Mu
```

Get Parameters of Current Block

Open a model.

```
vdp
```

Select the Gain block.

Use the value of `gcb` with `get_param` to get the value of the Gain parameter.

```
x = get_param(gcb, 'Gain')
```

```
x =
```

```
1
```

Get Current Block in Specified System

Load the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')  
load_system('sldemo_fuelsys');
```

Get the current block in the `fuel_rate_control` subsystem.

```
bl = gcb('sldemo_fuelsys/fuel_rate_control')
```

```
bl =
```

```
sldemo_fuelsys/fuel_rate_control/validate_sample_time
```

Input Arguments

sys – System that contains the block

character vector

System that contains the block, specified as a character vector.

Example: `'vdp' 'sldemo_fuelsys/fuel_rate_control'`

Version History

Introduced before R2006a

See Also

`gcbh` | `gcbp` | `gcs` | `get_param`

Topics

“Mask Callback Code”

gcbh

Get handle of current block

Syntax

```
handle = gcbh
```

Description

handle = gcbh returns the handle of the current block in the current system.

Examples

Get Handle of Current Block

Get the handle of the most recently selected block.

```
handle = gcbh
```

```
handle =
```

```
    281.0001
```

Version History

Introduced before R2006a

gcb | gcbp | gcs | getSimulinkBlockHandle

gcbp

Get `Simulink.BlockPath` object for current block

Syntax

```
path = gcbp
```

Description

`path = gcbp` returns the `Simulink.BlockPath` object of the current block in the current system. The current block is:

- The most recently clicked block
- The last block loaded after opening a model

The returned `Simulink.BlockPath` object is context sensitive to model hierarchy.

Examples

Create `Simulink.BlockPath` Object for Selected Block

Open `sldemo_mdref_basic`.

```
openExample('sldemo_mdref_basic')
```

Click a block in the model hierarchy. For example, click the block labeled `ScopeA` in the `CounterA` instance of `sldemo_mdref_counter`. Then, use `gcbp` in the Command Window.

```
path = gcbp
```

```
path =
```

```
Simulink.BlockPath  
Package: Simulink
```

```
Block Path:  
  sldemo_mdref_basic/CounterA  
  sldemo_mdref_counter/ScopeA
```

Use the `getBlock` method to access block path strings from this object.

```
Methods
```

Version History

Introduced in R2019a

Objects

Simulink.BlockPath

Functions

gcb | gcbh | gcs | get_param | open (BlockPath)

gcs

Get path name of current system

Syntax

`gcs`

Description

`gcs` returns the path name of the current system. The current system is one of these:

- During editing, the system or subsystem most recently clicked or that contains the block most recently clicked
- During simulation of a system that contains an S-Function block, the system or subsystem containing the S-Function block currently being evaluated
- When a callback is invoked, the system executing the callback
- During evaluation of `MaskInitialization`, the system containing the block whose mask is being evaluated
- The system most recently loaded into memory with `load_system`; only the first use of `load_system` makes the model the current system

The current system is the current model or a subsystem of the current model. Use `bdroot` to get the current model.

If you close the model that contains the current system, another open or loaded system becomes the current one. Use `gcs` to find out the new current system.

To explicitly set the current system, you can either:

- Use `set_param` with the 'CurrentSystem' parameter on the root Simulink model, for example:

```
set_param(0, 'CurrentSystem', 'mymodel')
```
- Open the model by using `open_system` or the model name at the MATLAB command prompt.

Examples

Get Current System That Contains a Block

Return the path of the system that contains the most recently selected block.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`. Open the subsystem To Controller.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
open_system('sldemo_fuelsys/To Controller')
```

Click the Rate Transition block. Get the current system.

```
gcs
ans =
    'sldemo_fuelsys/To Controller'
```

Get Current System After Loading a Model

Open the model f14 and get the current system.

```
f14
gcs
ans =
    'f14'
```

Load the model vdp using `load_system`. Then get the current system.

```
load_system('vdp');
gcs
ans =
    'vdp'
```

To remove vdp from memory, close it. In this example, the current system becomes the open model, f14.

```
close_system('vdp');
gcs
ans =
    'f14'
```

Version History

Introduced before R2006a

bdroot | gcb | gcbp

get_param

Get parameter names and values

Syntax

```
value = get_param(object,parameter)
```

Description

`value = get_param(object,parameter)` returns the value value of the specified parameter parameter for the target object specified by object. The target object can be a model, subsystem, library, block, line, port, or bus element port element.

Open or load the related Simulink model, subsystem, or library before calling this function.

Examples

Get Block Parameter Value and Model Parameter Value

Load the vdp model.

```
load_system('vdp');
```

Get the value for the Expression block parameter.

```
BlockParameterValue = get_param('vdp/Mu','Multiplication')
```

```
BlockParameterValue =
```

```
    'Element-wise(K.*u)'
```

Get the value for the SolverType model parameter.

```
SolverType = get_param('vdp','SolverType')
```

```
SolverType =
```

```
    'Variable-step'
```

Get Root Parameter Names and Values

Get a list of global parameter names by finding the difference between the Simulink root parameter names and the model parameter names.

```
RootParameterNames = fieldnames(get_param(0,'ObjectParameters'));
```

```
load_system('vdp')
```

```
ModelParameterNames = fieldnames(get_param('vdp','ObjectParameters'));
```

```
GlobalParameterNames = setdiff(RootParameterNames,ModelParameterNames)
```

```
GlobalParameterNames =
```

```

79x1 cell array

    {'AccelNoncompliantBlocksRatioLimit'      }
    {'AutoAccelerationStepsPerBlockLimit'     }
    {'AutoAccelerationStepsPerCodegenLimit'   }
    .
    .
    .
    {'CurrentSystem'                          }

```

Get the value of a global parameter.

```
GlobalParameterValue = get_param(0, 'CurrentSystem')
```

```
GlobalParameterValue =
```

```
    'vdp'
```

Get Model Parameter Names and Values

Get a list of model parameters for the vdp model .

```
load_system('vdp')
ModelParameterNames = get_param('vdp', 'ObjectParameters')
```

```
ModelParameterNames =
```

```
    struct with fields:
```

```

                                Name: [1x1 struct]
                                Tag: [1x1 struct]
    Description: [1x1 struct]
                                Type: [1x1 struct]
                                Parent: [1x1 struct]
                                Handle: [1x1 struct]
                                .
                                .
                                .
    ZeroInternalMemoryAtStartup: [1x1 struct]

```

Get the current value of the ModelVersion model parameter for the vdp model.

```
ModelParameterValue = get_param('vdp', 'ModelVersion')
```

```
ModelParameterValue =
```

```
    '7.0'
```

Get List of Blocks and Parameter Value

Get a list of block paths and names for the blocks in the sldemo_fuelsys model. For one of the blocks, get a list of block dialog parameters and the value of a block dialog parameter.

Open the Model a Fault-Tolerant Fuel Control System example.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample');
```

Get a list of block paths and names for all blocks in the top level of the sldemo_fuelsys model.

```
BlockPaths = get_param(gcs, 'blocks')
```

```
BlockPaths =
```

```
21x1 cell array
```

```

{'Throttle↔Command'         }
{'Throttle Angle↔Fault Switch'}
{'Throttle_Angle_Selector'  }
{'To Controller'           }
{'To Plant'                 }
{'fuel_rate_control'        }
```

The command outputs a list of block paths and names for all blocks in the top hierarchical level of the current system. If the current system is a subsystem, the command outputs a list of block paths and names for all blocks in the top hierarchical level of the subsystem.

In this example, the current system is `sldemo_fuelsys`, so the command outputs a list of block paths and names for all blocks in the top hierarchical level of the `sldemo_fuelsys` system.

Get a list of block paths and names for all blocks in all levels of the `sldemo_fuelsys` model.

```
BlockPaths = find_system(gcs, 'Type', 'Block')
```

```
BlockPaths =
```

```
188x1 cell array
```

```
{'sldemo_fuelsys/Callback Button'
{'sldemo_fuelsys/Constant2'
{'sldemo_fuelsys/Constant3'
...
{'sldemo_fuelsys/fuel_rate_control/fuel_rate'
```

The command outputs a list of block paths and names for all blocks in the top hierarchical level of the current system and in all lower levels of model hierarchy that the current system contains. In this example, the current system is `sldemo_fuelsys`, so the output is a list of block paths and names for all blocks in the `sldemo_fuelsys` model.

Get a list of block dialog parameters for the Gain block named RT/Vm. The first argument in the `get_param` function is the block path and name. Get the block path and name from the `BlockPaths` cell array.

```
BlockDialogParameters = get_param(BlockPaths{44}, 'DialogParameters')
```

```
BlockDialogParameters =
```

```
struct with fields:
```

```

    Gain: [1x1 struct]
    Multiplication: [1x1 struct]
    ParamMin: [1x1 struct]
    ParamMax: [1x1 struct]
    ParamDataTypeStr: [1x1 struct]
    OutMin: [1x1 struct]
    OutMax: [1x1 struct]
    OutDataTypeStr: [1x1 struct]
    LockScale: [1x1 struct]
    RndMeth: [1x1 struct]
    SaturateOnIntegerOverflow: [1x1 struct]
    SampleTime: [1x1 struct]

```

Get the value for the `Multiplication` block parameter.

```
BlockParameterValue = get_param(BlockPaths{44}, 'Multiplication')
```

```
BlockParameterValue =
```

```
'Element-wise(K.*u)'
```

Get Block Parameter Value Using Block Handle

Get the value of the `Multiplication` block parameter of the Gain block named `Mu` in the `vdp` model.

Get the handle of the Gain block named `Mu` in the `vdp` model using the `getSimulinkBlockHandle` function. Specify the model and block names by entering `'vdp/Mu'` as the input argument. If the `vdp` model is not loaded, load the model by specifying `true` as the second input argument to the `getSimulinkBlockHandle` function.

```
mublockhandle = getSimulinkBlockHandle('vdp/Mu', true)
```

```
mublockhandle =
```

```
5.0001
```

The handle contains a double, for example, `5.0001`. If you display a handle number in the MATLAB Command Window, the display might not show all digits of the number. Do not try to use this handle number by manually entering what you see in the display. Instead, assign the handle to a variable and use that variable name to specify the block.

Tip If you make multiple calls to `get_param` for the same block, use the block handle instead of repeatedly specifying the full block path as a character vector such as `'vdp/Mu'`. You can use the block handle in subsequent calls to `get_param` or `set_param`.

To get the value of the `Multiplication` block parameter, use the `get_param` function. Specify the block handle as the first input argument and the name of the block parameter as the second input argument.

```
BlockParameterValue = get_param(mublockhandle, 'Multiplication')  
  
BlockParameterValue =  
  
    'Element-wise(K.*u)'
```

Display Block Types for All Blocks in Model

Get a list of block paths and names for the `vdp` model.

```
load_system('vdp')  
BlockPaths = find_system('vdp', 'Type', 'Block')  
  
BlockPaths =  
  
    14x1 cell array  
  
    {'vdp/Constant'           }  
    {'vdp/More Info'         }  
    {'vdp/More Info/Model Info'}  
    {'vdp/Mu'                 }  
    {'vdp/Mux'                }  
    {'vdp/Product'           }  
    {'vdp/Scope'             }  
    {'vdp/Square'            }  
    {'vdp/Sum'               }  
    {'vdp/Sum1'              }  
    {'vdp/x1'                 }  
    {'vdp/x2'                 }  
    {'vdp/Out1'              }  
    {'vdp/Out2'              }
```

Get the value for the `BlockType` parameter for each of the blocks in the `vdp` model.

```
BlockTypes = get_param(BlockPaths, 'BlockType')  
  
BlockTypes =  
  
    14x1 cell array  
  
    {'Constant' }  
    {'SubSystem' }  
    {'SubSystem' }  
    {'Gain'      }  
    {'Mux'       }  
    {'Product'   }  
    {'Scope'     }  
    {'Math'      }  
    {'Sum'       }  
    {'Sum'       }  
    {'Integrator'}  
    {'Integrator'}
```

```
{'Outport' }
{'Outport' }
```

Get List of Options for Masked Parameter, Simulink Object, Block Diagram, or Annotation

You can retrieve the list of options for a parameter, Simulink object, block diagram, or annotation using the `get_param` function with the keyword `options`.

Get the list of options for a masked parameter. For example, consider the masked Subsystem block in the `ACSystem` model. Get the list of options for the Subsystem block parameter `Show port labels`.

```
openExample('simulink_masking/DesignAMaskDialogBoxExample')
get_param('ACSystem/AC System','options@showportlabels')
```

```
ans =
```

```
1x4 cell array
```

```
{'none'} {'FromPortIcon'} {'FromPortBlockName'} {'SignalName'}
```

Get the list of options for a block parameter. For example, get the list of options for the `Icon display` parameter of an `Inport` block.

```
get_param('ACSystem/In1','options@icondisplay')
```

```
ans =
```

```
1x3 cell array
```

```
{'Signal name'} {'Port number'} {'Port number and si...'}
```

Get Evaluated Value of Mask Parameter

You can access the evaluated value of a masked block parameter using the `get_param` function with the keyword `value`.

For example, consider the masked Subsystem block in the `ACSystem` model. Get the evaluated value of the `edit` parameter on the mask called `Room Width (W)`.

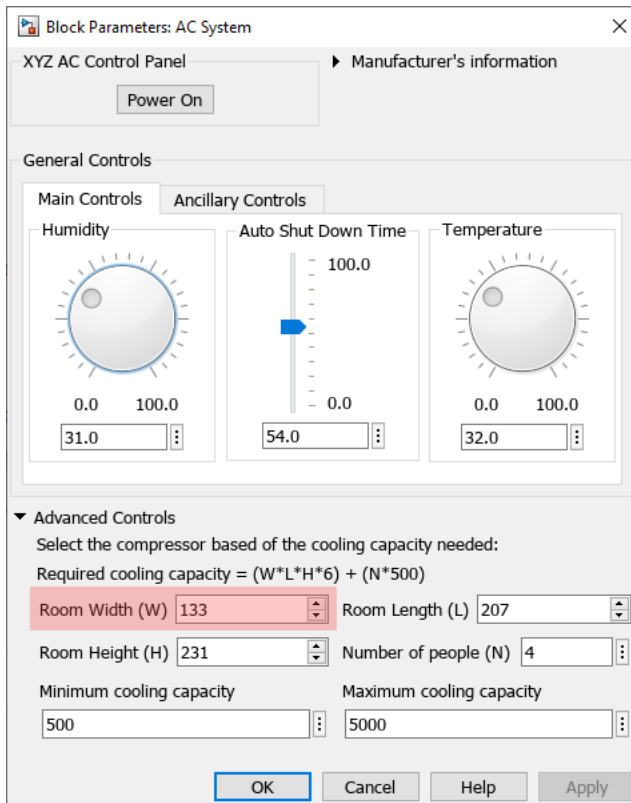

```
openExample('simulink_masking/DesignAMaskDialogBoxExample')
get_param('ACSystem/AC System','value@W')
```

```
ans =
```

```
133
```

The option to retrieve the evaluated value is limited to mask parameters.

Open the mask of the `AC System` block by double-clicking the block. The value of the `Room Width (W)` parameter is the same as the value you get using the `get_param` function.

Input Arguments

object — Name, path, or handle of object or root

character vector | cell array of character vectors | string array | numeric scalar | 0

Name, path, or handle of object or root, specified as a character vector, cell array of character vectors, string array, numeric scalar, or 0.

How you specify the target object depends on its type.

- Model — Model name or handle.
- Subsystem — Subsystem name or handle.
- Library — Library name or handle.
- Block — Block path or handle.
- Line — Line handle.
- Port — Port handle.
- Bus element port element — Block path of model component with element label. The element can be any element of the port, such as a top-level bus, nested bus, signal, or message.

To specify multiple objects with a common parameter, use a cell array of character vectors, a string array, or an array of handles. All the specified objects must have the specified parameter; otherwise, the function returns an error.

Specify 0 to get root parameter names, including global parameters and model parameters for the current Simulink session.

- Global parameters include Editor preferences and Simulink Coder parameters.
- Model parameters include configuration parameters, Simulink Coder parameters, and Simulink Code Inspector parameters.

Example: 'vdp/Mu'

Example: 'mymodel/Subsystem1/Out1.nonsinusoidal.saw'

Tips

- If you make multiple calls to `get_param` for the same block, specify the block with a numeric handle. This method is more efficient than using the full block path with `get_param`. Use `getSimulinkBlockHandle` to get a block handle.
- Do not try to manually specify the number of a handle, for example, `5.007`, because you usually need to specify more digits than MATLAB displays. Assign the handle to a variable and use that variable name.

Data Types: char | string | double

parameter — Parameter, property, or attribute name

character vector | string scalar

Parameter, property, or attribute name, specified as a character vector or string scalar. Some names are case sensitive.

This table shows special cases.

Specified Parameter	Result
'ObjectParameters'	Parameter names of the specified object as separate fields in a structure array.
'DialogParameters'	Block dialog box parameter names as separate fields in a structure array. If the block has a mask, the function instead returns the mask parameters.

For information about parameters, properties, or attributes, see the programmatic use information on the corresponding reference pages. For example:

- Models — See the configuration parameter reference pages.
- Blocks — See “Common Block Properties” on page 6-12 and block reference pages.
- Ports — See the **Signal Properties** tool reference page.
- Bus element port elements — See the In Bus Element and Out Bus Element block reference pages.

Example: 'ObjectParameters'

Example: 'Solver'

Example: 'SimulationCommand'

Example: 'Position'

Example: 'NameLocation'

Data Types: char | string

Output Arguments

value — Parameter value

format determined by parameter type

Parameter value, returned in the format determined by the parameter type. If you specify multiple objects, the output is a cell array.

This table shows special cases.

Specified Parameter	Result
'ObjectParameters'	Parameter names of the specified object as separate fields in a structure array.
'DialogParameters'	Block dialog box parameter names as separate fields in a structure array. If the block has a mask, the function instead returns the mask parameters.

If you get the root parameters by specifying `get_param(0, 'ObjectParameters')`, then the output value is a structure array with the root parameter names as separate fields in the structure. Each parameter field is a structure containing these fields:

- Type — Parameter type values are 'boolean', 'string', 'int', 'real', 'point', 'rectangle', 'matrix', 'enum', 'ports', or 'list'.
- Enum — Cell array of enumeration character vector values that applies only to 'enum' parameter types.
- Attributes — Cell array of character vectors defining the attributes of the parameter. Values are 'read-write', 'read-only', 'read-only-if-compiled', 'write-only', 'dont-eval', 'always-save', 'never-save', 'nondirty', or 'simulation'.

getActiveConfigSet

Get active configuration set or configuration reference of model

Syntax

```
myConfigObj = getActiveConfigSet(model)
```

Description

`myConfigObj = getActiveConfigSet(model)` returns the active configuration object of the model as a `ConfigSet` object or a `Simulink.ConfigSetRef` object.

Examples

Get Active Configuration Set

Get the active configuration set for a model that is open.

Open the model `vdp` and get the active configuration set.

```
vdp  
vdpConfig = getActiveConfigSet('vdp');
```

Input Arguments

model — Name of model

character vector | string scalar

Name of model, specified as a character vector or string scalar. The model must be open.

Example: `'vdp'`

Output Arguments

myConfigObj — Configuration object

`ConfigSet` object | `ConfigSetRef` object

The configuration object, returned as a `ConfigSet` object or a `Simulink.ConfigSetRef` object.

Version History

Introduced before R2006a

getCallbackAnnotation

Get annotation executing callback

Syntax

```
ann = getCallbackAnnotation
```

Description

`ann = getCallbackAnnotation` gets the annotation from which a callback was invoked. Invoke a callback from an annotation click function. After you get the annotation, you can, for example, get text or parameters from the annotation to use someplace else in your model.

For information on click functions, see “Add Hyperlinks to Annotations”.

Examples

Click Annotation to Change Parameter Value

Invoke a callback by way of an annotation click function. This example shows how to change a parameter value on a block to the value shown on an annotation.

Open `vdp`. Add and position two annotations. Each annotation displays a different value.

```
open_system('vdp');  
an1 = Simulink.Annotation('vdp/1');  
an1.position = [100,300];  
an2 = Simulink.Annotation('vdp/3');  
an2.position = [150,300];
```

Assign a click function to each annotation. The click function uses `getAnnotationCallback` to get the annotation instance. Get the text from each annotation and use it to set the parameter on the Gain block (Mu).

```
an1.ClickFcn = 'ann = getCallbackAnnotation; v = ann.Text; set_param(''vdp/Mu'', ''Gain'',v)';  
an2.ClickFcn = 'ann = getCallbackAnnotation; v = ann.Text; set_param(''vdp/Mu'', ''Gain'',v)';
```

Click each annotation. When you click, the gain value on the Mu block changes to the number shown on the annotation.

Output Arguments

ann — Annotation

`Simulink.Annotation` instance

Annotation, returned as a `Simulink.Annotation` instance.

Version History

Introduced before R2006a

getConfigSet

Get configuration set or configuration reference from model

Syntax

```
myConfigObj = getConfigSet(model, configObjName)
```

Description

`myConfigObj = getConfigSet(model, configObjName)` returns the configuration set or configuration reference that is attached to `model` and is named `configObjName`.

Examples

Get a Configuration Set

Get a configuration set for a model that is open.

Open the model `vdp` and get the configuration set `Configuration`.

```
vdp  
vdpConfig = getConfigSet('vdp','Configuration');
```

Input Arguments

model — Name of model

character vector | string scalar

Name of model, specified as a character vector or string scalar. The model must be open.

Example: `'vdp'`

configObjName — Configuration object

character vector | string scalar

Name of the configuration object, specified as a character vector or string scalar.

Example: `'Configuration'`

Output Arguments

myConfigObj — Configuration object

ConfigSet object | ConfigSetRef object

The configuration object, returned as a `ConfigSet` object or a `Simulink.ConfigSetRef` object. If no such object exists, the function returns an empty object.

Version History

Introduced before R2006a

getConfigSets

Get names of all of model's configuration sets or configuration references

Syntax

```
myConfigObjNames = getConfigSets(model)
```

Description

`myConfigObjNames = getConfigSets(model)` returns the names of the configuration objects that are attached to the model. You can use the returned name of a configuration set from `myConfigObjNames` to activate it for the model.

Examples

Get Names of Configurations for a Model

Get the names of the configuration sets and configuration references that are attached to a model.

Open the “Using a Data Dictionary to Manage the Data for a Fuel Control System” on page 13-139 example model `sldemo_fuelsys_dd` and the referenced model `sldemo_fuelsys_dd_controller`. Get the configuration object names.

```
openExample('simulink_automotive/UseDDForFuelContSysExample')
sldemo_fuelsys_dd
sldemo_fuelsys_dd_controller
configObjNames = getConfigSets('sldemo_fuelsys_dd_controller')

configObjNames =

    1×1 cell array

    {'ModelReferencing'}
```

The model has one configuration set with the name `ModelReferencing`.

Input Arguments

model — Name of model

character vector | string scalar

Name of model, specified as a character vector or string scalar. The model must be open.

Example: `'vdp'`

Output Arguments

myConfigObjNames — Names of configuration objects

cell array of character vectors

Names of the configuration objects that are attached to the model, returned as a cell array of character vectors. The configuration objects include configuration sets and configuration references.

Version History

Introduced before R2006a

getCurrentAnnotation

Get current annotation object

Syntax

```
getCurrentAnnotation
```

Description

`getCurrentAnnotation` gets the current annotation as a `Simulink.Annotation` object.

Examples

Get Current Annotation Object

Open the model `vdp`.

```
vdp
```

Select the annotation at the top of the diagram. To get the annotation object, use the function `getCurrentAnnotation`.

```
title = getCurrentAnnotation
```

```
title =
```

```
    Annotation with properties:
```

```
        Name: 'van der Pol Equation'
```

Version History

getfullname

Get path that identifies block or line

Syntax

```
path = getfullname(handle)
```

Description

`path = getfullname(handle)` returns the full path that identifies the block or line specified by `handle`. If you specify multiple block or line handles, the function returns a cell array of paths.

Examples

Get Path That Identifies Block

Open the vdp model.

```
vdp
```

Interactively, select the block named Mu.

Get the path that identifies the currently selected block.

```
blkpath = getfullname(gcf)
```

```
blkpath =
```

```
    'vdp/Mu'
```

Get Path That Identifies Line

Open the vdp model.

```
vdp
```

Interactively, select the output line from the block named Mu.

Get the handle associated with the currently selected line.

```
line = find_system(gcf, 'SearchDepth', 1, 'FindAll', 'on', ...  
    'Type', 'line', 'Selected', 'on');
```

Get the path that identifies the currently selected line.

```
linepath = getfullname(line)
```

```
linepath =
```

```
    'vdp/Mu/1'
```

The path describes the source port of the line.

Input Arguments

handle — Block or line

handle | cell array of handles

Block or line, specified as a handle or cell array of handles.

Example: `getfullname(gcf)`

Example: `getfullname({handle1,handle2})`

Data Types: double | cell

Version History

Introduced in R2007a

`gcb` | `find_system`

getInputString

Create comma-separated list of variables to map

Syntax

```
externalInputString = getInputString(inputmap, 'base')
```

```
externalInputString = getInputString(inputmap, filename)
```

```
externalInputString = getInputString(inputmap)
```

Description

`externalInputString = getInputString(inputmap, 'base')` creates an input character vector using the supplied mapping `inputmap` and the variables loaded in the base workspace ('base').

This function generates a comma-separated list of variables (input character vector) to be mapped. You can then use this list:

- As input to the `sim` command. Load the variables in the base workspace first.
- As input for the **Configuration Parameters > Data Import/Export > Input** parameter. Copy the contents of the input character vector into the text field.

This function is most useful if you have created a custom mapping.

`externalInputString = getInputString(inputmap, filename)` creates an input character vector using the supplied mapping `inputmap` and the variables defined in `filename`.

`externalInputString = getInputString(inputmap)` creates an input character vector using the signals from the most recently created mapping.

Examples

Create an input character vector from the base workspace

Create an input character vector from the base workspace and simulate a model.

Open the model.

```
openExample('slexAutotransRootInportsExample');
```

Create signal variables in the base workspace

```
Throttle = timeseries(ones(10,1)*10);
Brake     = timeseries(zeros(10,1));
```

Create a mapping (`inputMap`) for the model.

```
inputMap = getRootInportMap('model', ...
    'slexAutotransRootInportsExample', ...
```

```
'signalName', {'Throttle', 'Brake'}, ...  
'blockName', {'Throttle', 'Brake'});
```

Call `getInputString` with `inputMap` and `'base'` as inputs.

```
externalInputString = getInputString(inputMap, 'base')  
externalInputString =
```

```
Throttle, Brake
```

Simulate the model with the input character vector.

```
sim('slexAutotransRootInportsExample', 'ExternalInput', ...  
externalInputString);
```

Create an external input character vector from variables in a MAT-file

Create an external input character vector from variables in a MAT-file named `input.mat`.

In a writable folder, create a MAT-file with input variables.

```
Throttle = timeseries(ones(10,1)*10);  
Brake = timeseries(zeros(10,1));  
save('input.mat', 'Throttle', 'Brake');
```

Open the model.

```
openExample('slexAutotransRootInportsExample');
```

Create map object.

```
inputMap = getRootInportMap('model', ...  
'slexAutotransRootInportsExample', ...  
'signalName', {'Throttle', 'Brake'}, ...  
'blockName', {'Throttle', 'Brake'});
```

Get the resulting input character vector.

```
externalInputString = getInputString(inputMap, 'input.mat')  
externalInputString =
```

```
Throttle, Brake
```

Load variables from the base workspace for the simulation.

```
load('input.mat');
```

Simulate the model.

```
sim('slexAutotransRootInportsExample', 'ExternalInput', ...  
externalInputString);
```

Create an external input character vector from only an input map

Create an input character vector from only an input map vector and simulate the model.

Open the model.

```
openExample('slexAutotransRootInportsExample');
```

Create signal variables in the base workspace

```
Throttle = timeseries(ones(10,1)*10);
Brake     = timeseries(zeros(10,1));
```

Create a mapping vector for the model.

```
inputMap = getSIRootInportMap('model', 'slexAutotransRootInportsExample', ...
'MappingMode', 'BlockName', ...
'signalName', {'Throttle', 'Brake'}, ...
'signalValue', {Throttle, Brake});
```

Get the resulting input character vector.

```
externalInputString = getInputString(inputMap)
```

Simulate the model with the input character vector.

```
sim('slexAutotransRootInportsExample', 'ExternalInput', ...
externalInputString);
```

Alternatively, if you want to input the list of variables through the Configuration Parameters dialog, copy the contents of `externalInputString` (Throttle, Brake) into the **Data Import/Export > Input** parameter. Apply the changes, and then simulate the model.

Input Arguments

inputmap — Map object

character vector

Map object, as returned from the `getRootInportMap` or `getSIRootInportMap` functions.

filename — Input variables

MAT-file name as character vector

Input variables, contained in a MAT-file. The file contains variables to map.

Example: 'data.mat'

Data Types: char

Output Arguments

externalInputString — External input

comma-separated character vector

External input, returned as a comma-separated character vector. The character vector contains root inport information that you can specify to the `sim` command or the **Configuration Parameters > Data Import/Export > Input** parameter.

Version History

Introduced in R2013a

`getRootInportMap` | `getS1RootInportMap`

Topics

“Map Root Inport Signal Data”

getRootInportMap

Create custom object to map signals to root-level inports

Syntax

```
map = getRootInportMap('Empty');
map = getRootInportMap(model,mdl,Name,Value);
map = getRootInportMap(inputmap,map,Name,Value);
```

Description

`map = getRootInportMap('Empty');` creates an empty map object, *map*. Use this map object to set up an empty custom mapping object. Load the model before using this function. If you do not load the model first, the function loads the model to make the mapping and then closes the model afterwards.

`map = getRootInportMap(model,mdl,Name,Value);` creates a map object for `model`, `mdl`, with block names and signal names specified. Load the model before using this function. If you do not load the model first, the function loads the model to make the mapping and then closes the model afterwards. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

`map = getRootInportMap(inputmap,map,Name,Value);` overrides the mapping object with the specified property. You can override only the properties `model`, `blockName`, and `signalName`. Load the model before using this function. If you do not load the model first, the function loads the model to make the mapping and then closes the model afterwards. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

Use the `getRootInportMap` function when creating a custom mapping mode to map data to root-level inports. For more information, see “Create and Use Custom Map Modes”.

Input Arguments

Empty

Create an empty map object.

Default: none

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

model

Name of model to associate with the root inport map.

Default: None

blockName

Block names of root-level input ports. The tool assigns data to ports according to the name of the root-inport block. If the tool finds a data element whose name matches the name of a root-inport block, it maps the data to the corresponding port.

The value for this argument can be:

Block name of root-level input ports.

Cell array containing multiple block names of root-level input ports.

Default: None

blockPath

Block paths of root-level input ports. The tool assigns data to ports according to the block path of the root-inport block. If the tool finds a data element whose name matches the block path of a root-inport block, it maps the data to the corresponding port.

The value for this argument can be:

Block path of root-level input ports.

Cell array containing multiple block paths of root-level input ports.

Default: None

signalName

Signal names to be mapped. The tool assigns data to ports according to the name of the signal on the port. If the tool finds a data element whose name matches the name of a signal at a port, it maps the data to the corresponding port.

The value for this argument can be:

Signal name to be mapped.

Cell array containing multiple signal names of signals to be mapped.

Default: None

inputmap

Name of mapping object to override.

Default: None

Output Arguments

map

Custom object that you can use to map data to root-level input port. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

Examples

Create Empty Mapping Object

Create an empty mapping object.

```
map = getRootInportMap('Empty')
map =
    1x0 InputMap array with properties:
        Type
        DataSourceName
        Destination
        Status
        BlockName
        BlockPath
        SignalName
        PortNumber
```

Create Simple Mapping Object

Create a simple mapping object using a MATLAB® time series object.

Create a time series object, `signalIn1`.

```
signalIn1 = timeseries((1:10)')
timeseries
Common Properties:
    Name: 'unnamed'
    Time: [10x1 double]
    TimeInfo: tsdata.timemetadata
    Data: [10x1 double]
    DataInfo: tsdata.datametadata
```

Create a mapping object for the time series object for the model,

```
model = 'ex_three_inports'
model =
'ex_three_inports'
open_system(model);
map = getRootInportMap('model','ex_three_inports',...
'blockName','In1','signalname','signalIn1')
map =
    InputMap with properties:
        Type: 'Inport'
        DataSourceName: 'signalIn1'
        Destination: [1x1 Simulink.iospecification.Destination]
        Status: -1
        BlockName: 'In1'
        BlockPath: 'ex_three_inports/In1'
```

```
SignalName: 'signalGain5'  
PortNumber: 1
```

Mapping Object with Vectors

Create a mapping object using vectors of block names and signal names for the model

Create a mapping object of vectors.

```
model = 'ex_three_inports';  
open_system(model);  
map = getRootInportMap('model','ex_three_inports',...  
'blockName',{ 'In1' 'In2'}, ...  
'signalname',{ 'signalIn1' 'signalIn2'})
```

```
map=1x2 object  
  1x2 InputMap array with properties:
```

```
    Type  
    DataSourceName  
    Destination  
    Status  
    BlockName  
    BlockPath  
    SignalName  
    PortNumber
```

Override Maps

Create a mapping object that contains the signal *var2*, then override *var2* with *var1*.

Load the model and define variables

```
model = 'ex_three_inports';  
open_system(model);  
blockNameValue = 'In1';  
signalNameValue = 'var2';  
portType = 'Inport';
```

Define *var1* and override *var2* with *var1*.

```
signalNameToOverload = 'var1';  
mapToOverload = getRootInportMap('model',model,...  
'blockName',blockNameValue,...  
'signalName',signalNameToOverload)
```

```
mapToOverload =  
  InputMap with properties:
```

```
    Type: 'Inport'  
    DataSourceName: 'var1'
```

```
Destination: [1x1 Simulink.iospecification.Destination]
  Status: -1
  BlockName: 'In1'
  BlockPath: 'ex_three_inports/In1'
  SignalName: 'signalGain5'
  PortNumber: 1
```

Tips

- Load the model before running this function.
- If your custom mapping mode is similar to an existing Simulink mapping mode, consider using the `getSlRootInportMap` function instead.

Version History

Introduced in R2012b

getSimulinkBlockHandle

Get block handle from block path

Syntax

```
handle = getSimulinkBlockHandle(path)
handle = getSimulinkBlockHandle(path,true)
```

Description

`handle = getSimulinkBlockHandle(path)` returns the numeric handle of the block specified by `path`, if it exists in a loaded model or library. Returns -1 if the block is not found. Library links are resolved where necessary.

Use the numeric handle returned by `getSimulinkBlockHandle` to manipulate the block in subsequent calls to `get_param` or `set_param`. This approach is more efficient than making multiple calls to these functions using the full block path. Do not try to use the number of a handle alone (e.g., 5.007) because you usually need to specify many more digits than MATLAB displays. Assign the handle to a variable and use that variable name to specify a block. The handle applies only to the current MATLAB session.

Use `getSimulinkBlockHandle` to check whether a block path is valid. This approach is more efficient than calling `get_param` inside a `try` statement.

`handle = getSimulinkBlockHandle(path,true)` attempts to load the model or library containing the specified block path, and then checks if the block exists. No error is returned if the model or library is not found. Any models or libraries loaded this way remain in memory even if the function does not find a block with the specified path.

Examples

Get the Handle of a Block

Get the handle of the Pilot block.

```
load_system('f14')
handle = getSimulinkBlockHandle('f14/Pilot')
```

```
handle =
    562.0004
```

You can use the handle in subsequent calls to `get_param` or `set_param`.

Load the Model and Get the Block Handle

Load the model `f14` if necessary (by specifying `true`), and get the handle of the `Pilot` block.

```
handle = getSimulinkBlockHandle('f14/Pilot',true)

handle =

    562.0004
```

You can use the handle in subsequent calls to `get_param` or `set_param`.

Check If a Model Contains a Specific Block

Check whether the model `f14` is loaded and contains a block named `Pilot`. Valid handles are always greater than zero. If the function does not find the block, it returns `-1`.

```
valid_block_path = getSimulinkBlockHandle('f14/Pilot') > 0

valid_block_path =

    0
```

The model contains the block but the model is not loaded, so this command returns `0` because it cannot find the block.

Using `getSimulinkBlockHandle` to check whether a block path is valid is more efficient than calling `get_param` inside a `try` statement.

Input Arguments

path — Block path name

character vector | cell array of character vectors

Block path name, specified as a character vector or a cell array of character vectors.

Example: `'f14/Pilot'`

Data Types: `char`

Output Arguments

handle — Numeric handle of a block

double | array of doubles

Numeric handle of a block, returned as a double or an array of doubles. Valid handles are always greater than zero. If the function does not find the block, it returns `-1`. If the `path` input is a cell array of character vectors, then the output is a numeric array of handles.

Data Types: `double`

getSlRootInportMap

Create custom object to map signals to root-level inports using Simulink mapping mode

Syntax

```
inputMap = getSlRootInportMap('model',modelname,'MappingMode',
mappingmode,'SignalName',signalname,'SignalValue',signalvalue)
[inputMap, hasASignal] = getSlRootInportMap('model',modelname,'MappingMode',
mappingmode,'SignalName',signalname,'SignalValue',signalvalue)
```

```
inputMap = getSlRootInportMap('model',
modelname,'MappingMode','Custom','CustomFunction',
customfunction,'SignalName',signalname,'SignalValue',signalvalue)
[inputMap,hasASignal] = getSlRootInportMap('model',
modelname,'MappingMode','Custom','CustomFunction',
customfunction,'SignalName',signalname,'SignalValue',signalvalue)
```

Description

`inputMap = getSlRootInportMap('model',modelname,'MappingMode', mappingmode,'SignalName',signalname,'SignalValue',signalvalue)` creates a root inport map using one of the Simulink mapping modes. Load the model before using this function. If you do not load the model first, the function loads the model to make the mapping and then closes the model afterwards. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

`[inputMap, hasASignal] = getSlRootInportMap('model',modelname,'MappingMode', mappingmode,'SignalName',signalname,'SignalValue',signalvalue)` returns a vector of logical values specifying whether or not the root inport map has a signal associated with it. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

`inputMap = getSlRootInportMap('model', modelname,'MappingMode','Custom','CustomFunction', customfunction,'SignalName',signalname,'SignalValue',signalvalue)` creates a root inport map using a custom mapping mode specified in `customfunction`. Load the model before using this function. If you do not load the model first, the function loads the model to make the mapping and then closes the model afterwards. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

`[inputMap,hasASignal] = getSlRootInportMap('model', modelname,'MappingMode','Custom','CustomFunction', customfunction,'SignalName',signalname,'SignalValue',signalvalue)` returns a vector of logical values specifying whether or not the root inport map has a signal associated with it. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

To map signals to root-level inports using custom mapping modes, you can use `getSlRootInport` with the Root Inport Mapper dialog box custom mapping capability.

Examples

Create inport map using Simulink mapping mode

Create a vector of inport maps using a built-in mapping mode.

```
openExample('slexAutotransRootInportsExample');
Throttle = timeseries(ones(10,1)*10);
Brake    = timeseries(zeros(10,1));
inputMap = getSIRootInportMap('model','slexAutotransRootInportsExample',...
    'MappingMode','BlockName', ...
    'SignalName',{'Throttle' 'Brake'},...
    'SignalValue',{Throttle Brake});
```

Create inport map using custom function

Create a vector of inport maps using a custom function

```
openExample('slexAutotransRootInportsExample');
port1 = timeseries(ones(10,1)*10);
port2 = timeseries(zeros(10,1));
inputMap = getSIRootInportMap('model','slexAutotransRootInportsExample',...
    'MappingMode','Custom', ...
    'CustomFunction','slexCustomMappingMyCustomMap',...
    'SignalName',{'port1' 'port2'},...
    'SignalValue',{port1 port2});
```

Input Arguments

modelName — Model name

character vector

Specify the model to associate with the root inport map.

Data Types: char

mappingmode — Simulink mapping mode

character vector

Specify the mapping mode to use with model name and data source. Possible values are:

'Index'	Assign sequential index numbers, starting at 1, to the data in the MAT-file, and map this data to the corresponding inport.
'BlockName'	Assign data to ports according to the name of the root-inport block. If the block name of a data element matches the name of a root-inport block, map the data to the corresponding port.
'SignalName'	Assign data to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, map the data to the corresponding port.
'BlockPath'	Assign data to ports according to the block path of the root-inport block. If the block path of a data element matches the block path of a root-inport block, map the data to the corresponding port.
'Custom'	Apply mappings according to the definitions in a custom file.

Data Types: char

customfunction — Custom function file name

character vector

Specify name of file that implements a custom method to map signals to root-level ports. This function must be on the MATLAB path.

Data Types: char

signalname — signal name

scalar | cell array of character vectors

Specify the signal name(s) of the signal to associate with the root inport map.

Data Types: char | cell

signalvalue — signal value

scalar | cell arrays

Specify the values of the signals to map to the root inport map. For the list of supported data types for the values, see “Choose a Base Workspace and MAT-File Format”.

Output Arguments

inputMap — input map

scalar | vector

Mapping object that defines the mapping of input signals to root-level ports. To create a comma-separated list of variables to map from this object, use the `getInputString` function.

hasASignal — signal presence indicator

scalar | vector

A vector of logical values with the same length as `inputMap`. If the value is true the `inputMap` has a signal associated with it. If the value is false the `inputMap` does not have a signal associated with it and will use a ground value as an input.

Data Types: logical

Tips

- Load the model before running this function.
- If your custom mapping mode is not similar to an existing Simulink mapping mode, consider using the `getRootInportMap` function instead.

hdlLib

Display blocks that are compatible with HDL code generation

Syntax

```
hdlLib
hdlLib('off')
hdlLib('html')
hdlLib('librarymodel')
```

Description

`hdlLib` displays the blocks that are supported for HDL code generation, and for which you have a license, in the Library Browser. To build models that are compatible with the HDL Coder software, use blocks from this Library Browser view.

If you close and reopen the Library Browser in the same MATLAB session, the Library Browser continues to show only the blocks supported for HDL code generation. To show all blocks, regardless of HDL code generation compatibility, at the command prompt, enter `hdlLib('off')`.

`hdlLib('off')` displays all the blocks for which you have a license in the Library Browser, regardless of HDL code generation compatibility.

`hdlLib('html')` creates a library of blocks that are compatible with HDL code generation. It generates two additional HTML reports: a categorized list of blocks (`hdlblklist.html`) and a table of blocks and their HDL code generation parameters (`hdlsupported.html`).

To run `hdlLib('html')`, you must have an HDL Coder license.

`hdlLib('librarymodel')` displays blocks that are compatible with HDL code generation in the Library Browser. To build models that are compatible with the HDL Coder software, use blocks from this library.

The default library name is `hdlsupported`. After you generate the library, you can save it to a folder of your choice.

To keep the library current, you must regenerate it each time that you install a new software release.

To run `hdlLib('librarymodel')`, you must have an HDL Coder license.

Examples

Display Supported Blocks in the Library Browser

To display blocks that are compatible with HDL code generation in the Library Browser:

```
hdlLib
### Generating view of HDL Coder compatible blocks in Library Browser.
### To restore the Library Browser to the default Simulink view, enter "hdlLib off".
```

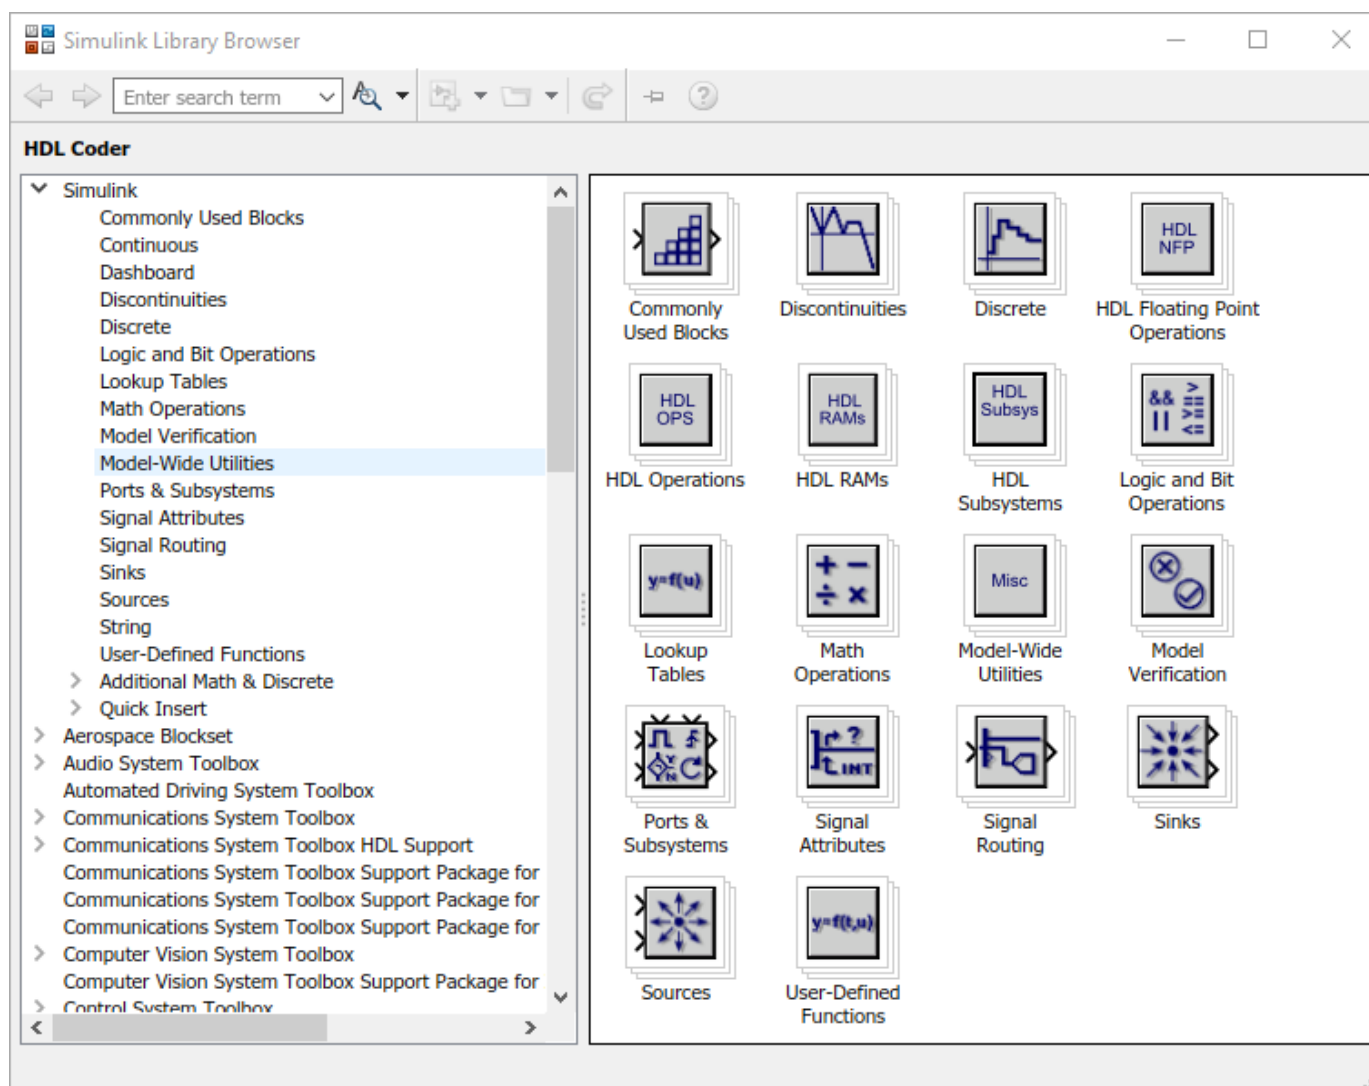

Display All Blocks in the Library Browser

To restore the Library Browser to the default view, in the Library Browser, click the  button. Alternatively, at the command line, enter:

```
hdllib('off')
```

Restoring Library Browser to default view; removing the HDL Coder compatibility filter.

Create a Supported Blocks Library and HTML Reports

To create a library and HTML reports showing the blocks that are compatible with HDL code generation:

```
hdlLib('html')
```

```
### HDL supported block list hdlblklist.html
### HDL implementation list hdl-supported.html
```

The `hdl-supported` library opens. To view the reports, click the `hdlblklist.html` and `hdl-supported.html` links.

Create a Supported Blocks Library

To create a library that contains blocks that are compatible with HDL code generation:

```
hdllib('librarymodel')
```

The `hdlsupported` block library opens.

Version History

Introduced in R2006b

hilite_system

Highlight block, signal line, port, or annotation

Syntax

```
hilite_system(obj)  
hilite_system(obj,style)
```

Description

`hilite_system(obj)` highlights a block, line, port, or annotation in an open model using the default highlight style. Use `hilite_system` with a port to highlight the signal line attached to the port. Each use of `hilite_system` adds to the highlighting. Highlighting is not saved with the model.

`hilite_system(obj,style)` uses the specified highlighting style.

Examples

Highlight Block Using Default Highlight Style

Open the model `slexAircraftExample`.

```
openExample('slexAircraftExample')
```

Highlight the Controller block. When you use the default highlight style, the block appears highlighted with a red outline and yellow fill.

```
hilite_system('slexAircraftExample/Controller')
```

Highlight a Block Using a Highlight Style

Open the model `vdp`.

```
vdp
```

Highlight the Mu block using the style 'fade'.

```
hilite_system('vdp/Mu','fade')
```

Use Block Highlighting to Trace Generated Code

If you have a Simulink Coder license, you can trace generated code to the corresponding source block in a model.

Open the model `f14`.

```
f14
```

In the model configuration parameters, in the **Solver** pane, set **Type** to Fixed-step.

Generate code for the model. In the **Apps** tab, under **Code Generation**, click **Embedded Coder**. The **C Code** tab appears. Click **Build**.

In an editor or in the code generation report, open a generated source or header file. As you review lines of code, note traceability tags that correspond to code of interest.

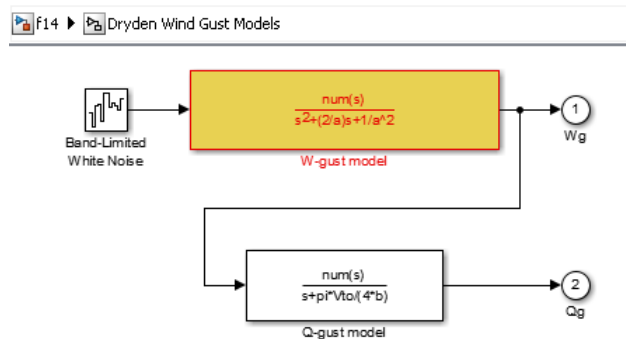

Highlight a block using a traceability tag.

```
hilite_system('<Root>/Stick Input')
```

Highlight a block in a subsystem.

```
hilite_system('<S3>/W-gust model')
```

Customize a Highlighting Style

You can customize a highlighting style by setting the 'HiliteAncestorsData' parameter on the root-level model using `set_param` in this form:

```
set_param(0, 'HiliteAncestorsData', hiliteData)
```

Specify `hiliteData` as a structure array that has these fields:

- 'HiliteType' — Highlighting style to customize, such as 'user1', 'debug', or 'error'.
- 'ForegroundColor' — Color for block fill.
- 'BackgroundColor' — Color for block outline.

The supported values for 'ForegroundColor' and 'BackgroundColor' are:

- 'black'
- 'white'
- 'gray'
- 'red'
- 'orange'
- 'yellow'
- 'green'
- 'darkGreen'
- 'blue'
- 'lightBlue'
- 'cyan'
- 'magenta'

Define a highlight style for 'user1', and customize the style for 'debug'.

```
set_param(0, 'HiliteAncestorsData', ...
    struct('HiliteType', 'user1', ...
        'ForegroundColor', 'darkGreen', ...
        'BackgroundColor', 'lightBlue'));
set_param(0, 'HiliteAncestorsData', ...
    struct('HiliteType', 'debug', ...
        'ForegroundColor', 'red', ...
        'BackgroundColor', 'black'));
```

Use the defined style to highlight a block.

```
f14
hilite_system('f14/Controller/Alpha-sensor Low-pass Filter', 'user1')
```

Input Arguments

obj — Block, port, line, or annotation to highlight

block path name | Simulink.BlockPath object | numeric handle | Simulink identifier | traceability tag

Block, port, line, or annotation to highlight, specified as:

- The full block path name
- A Simulink.BlockPath object

- A numeric handle for lines, ports, or annotations
- Simulink identifier
- A traceability tag from the comments of Simulink Coder generated code.

Using a traceability tag requires a Simulink Coder license.

The format for a traceability tag is `<system>/block`, where `system` is either:

- Root
- A unique system number assigned by Simulink during code generation

Example: `'vdp/Mu'`, `'sldemo_fuelsys/fuel_rate_control/airflow_calc'`, `'vdp:3'`, `'<Root>/Mu'`

style — Highlighting style

'default' (default) | character vector

Highlighting style, specified as one of these values. You can customize the appearance of any of the styles. See “Customize a Highlighting Style” on page 2-327.

- 'default' — Default color scheme: red outline, yellow fill.
- 'none' — Clears the highlight.

To clear all highlighting, in the Simulink Editor, in the **Signal** tab, click **Remove Trace**.

- 'debug' — Uses default color scheme.
- 'different' — Applies red outline, white fill.
- 'error' — Uses default color scheme.
- 'fade' — Applies gray outline, white fill.
- 'find' — Applies dark blue outline, blue fill.
- 'lineTrace' — Applies red outline, blue fill.
- 'unique' — Dark blue outline, white fill.
- 'user1', 'user2', 'user3', 'user4', 'user5' — Applies custom highlight: black outline, white fill by default (i.e., no highlight).

In addition, you can use these color schemes. The first word is the outline and the second is the fill color.

- 'orangeWhite'
- 'blackWhite'
- 'redWhite'
- 'blueWhite'
- 'greenWhite'

Version History

Introduced before R2006a

rtwtrace | find_system

isSimulinkStarted

Check whether Simulink is started

Syntax

```
tf = isSimulinkStarted
```

Description

`tf = isSimulinkStarted` returns whether Simulink is started.

Examples

Check Whether Simulink Is Started

```
isSimulinkStarted
```

```
ans =  
  
    logical  
  
     0
```

The returned value 0 indicates that Simulink is not started.

Start Simulink.

```
simulink
```

Confirm that Simulink is started.

```
isSimulinkStarted
```

```
ans =  
  
    logical  
  
     1
```

The returned value 1 indicates that Simulink is started.

Output Arguments

tf — True or false result

```
1 | 0
```

True or false result, returned as a 1 or 0 of data type `logical`.

- 1 (`true`) — Simulink is started.
- 0 (`false`) — Simulink is not started.

Version History

Introduced in R2020b

learning.simulink.launchOnramp

Open self-paced, interactive trainings

Syntax

```
learning.simulink.launchOnramp(id)
```

Description

`learning.simulink.launchOnramp(id)` opens the training that corresponds to the specified `id` argument.

Examples

Open Simulink Onramp

To open Simulink Onramp, in the MATLAB Command Window, enter this command.

```
learning.simulink.launchOnramp('simulink')
```

Input Arguments

`id` — Identifier for training

```
"simulink" | "slbe" | "stateflow" | "controls" | "simscape" | "circuits" |  
"powerelectronics"
```

Identifier for training, specified as one of these values:

- "simulink" — **Simulink Onramp**
- "slbe" — **Simulink Fundamentals**
- "stateflow" — **Stateflow Onramp**
- "controls" — **Control Design Onramp with Simulink**
- "simscape" — **Simscape Onramp**
- "circuits" — **Circuit Simulation Onramp**
- "powerelectronics" — **Power Electronics Simulation Onramp**

Version History

Introduced in R2019a

legacy_code

Integrate existing C/C++ code by using the Legacy Code Tool

Syntax

```
legacy_code('help')
specs = legacy_code('initialize')
legacy_code('sfcn_cmex_generate', specs)
legacy_code('compile', specs, compilerOptions)
legacy_code('generate_for_sim', specs, modelname)
legacy_code('slblock_generate', specs, modelname)
legacy_code('sfcn_tlc_generate', specs)
legacy_code('sfcn_makecfg_generate', specs)
legacy_code('rtwmakecfg_generate', specs)
legacy_code('backward_compatibility')
```

Description

`legacy_code('help')` displays instructions for using Legacy Code Tool.

`specs = legacy_code('initialize')` initializes the Legacy Code Tool data structure, `specs`, which registers characteristics of existing C or C++ code and properties of the S-function that the Legacy Code Tool generates.

`legacy_code('sfcn_cmex_generate', specs)` generates an S-function source file as specified by the Legacy Code Tool data structure, `specs`.

`legacy_code('compile', specs, compilerOptions)` compiles and links the S-function generated by the Legacy Code Tool based on the data structure, `specs`, and compiler options that you might specify. The compiler options must be supported by the mex function.

`legacy_code('generate_for_sim', specs, modelname)` generates, compiles, and links the S-function in a single step. If the `Options.useTlcWithAccel` field of the Legacy Code Tool data structure is set to logical 1 (true), the function also generates a TLC file for accelerated simulations.

`legacy_code('slblock_generate', specs, modelname)` generates a masked S-Function block for the S-function generated by the Legacy Code Tool based on the data structure, `specs`. The block appears in the Simulink model specified by `modelname`. If you omit `modelname`, the block appears in an empty model editor window.

`legacy_code('sfcn_tlc_generate', specs)` generates a TLC file for the S-function generated by the Legacy Code Tool based on the data structure, `specs`. This option is relevant if you want to:

- Force Accelerator mode in Simulink software to use the TLC inlining code of the generated S-function. See the description of the `ssSetOptions SimStruct` function and `SS_OPTION_USE_TLC_WITH_ACCELERATOR` S-function option for more information.
- Use Simulink Coder software to generate code from your Simulink model. For more information, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).

`legacy_code('sfcn_makecfg_generate', specs)` generates an `sFunction_makecfg.m` file for the S-function generated by the Legacy Code Tool based on the data structure, `specs`. If you use

Simulink Coder to generate code from your Simulink model, you can use this option to specify additional items for the S-function build process such as source folders, preprocessor macros, and link objects. For example, you can specify source files that the S-function depends on that are in folders other than the folder containing the generated S-function executable. For more information, see “Use makecfg to Customize Generated Makefiles for S-Functions” (Simulink Coder) and “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).

`legacy_code('rtwmakecfg_generate', specs)` generates an `rtwmakecfg.m` file for the S-function generated by the Legacy Code Tool based on the data structure, `specs`. If you use Simulink Coder to generate code from your Simulink model, you can use this option to specify additional items for the S-function build process such as source folders, preprocessor macros, and link objects. For example, you can specify source files that the S-function depends on that are in folders other than the folder containing the generated S-function executable. For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder) and “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).

`legacy_code('backward_compatibility')` automatically updates syntax for using Legacy Code Tool to the supported syntax described in this reference page and in “Integrate C Functions Using Legacy Code Tool”.

Examples

Inputs Passed by Value or Address to Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)`
- `FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)`

where `FLT` is a typedef to `float`. The legacy source code is found in the files `your_types.h`, `myfilter.h`, `filterV1.c`, and `filterV2.c`.

Note the difference in the `OutputFcnSpec` defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```
defs = [];
```

```

% sldemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles    = {'myfilter.h'};
def.SourceFiles    = {'filterV1.c'};
def.IncPaths       = {'sldemo_lct_src'};
def.SrcPaths       = {'sldemo_lct_src'};
defs = [defs; def];

% sldemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles    = {'myfilter.h'};
def.SourceFiles    = {'filterV2.c'};
def.IncPaths       = {'sldemo_lct_src'};
def.SrcPaths       = {'sldemo_lct_src'};
defs = [defs; def];

```

Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to `'generate_for_sim'` in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument `'defs'`. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the files `sldemo_sfun_filterV1.c` and `sldemo_sfun_filterV2.c`.

```
legacy_code('generate_for_sim', defs);
```

```

### Start Compiling sldemo_sfun_filterV1
    mex('-IC:\TEMP\Bdoc23a_2213998_3568\ib570499\30\tpc5797ca3\simulink_features-ex08075368\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
    mex('sldemo_sfun_filterV1.c', '-IC:\TEMP\Bdoc23a_2213998_3568\ib570499\30\tpc5797ca3\simulink
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
### Finish Compiling sldemo_sfun_filterV1
### Exit

### Start Compiling sldemo_sfun_filterV2
    mex('-IC:\TEMP\Bdoc23a_2213998_3568\ib570499\30\tpc5797ca3\simulink_features-ex08075368\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
    mex('sldemo_sfun_filterV2.c', '-IC:\TEMP\Bdoc23a_2213998_3568\ib570499\30\tpc5797ca3\simulink
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
### Finish Compiling sldemo_sfun_filterV2
### Exit

```

Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

Generating Masked S-Function Blocks for Calling the Generated S-Functions

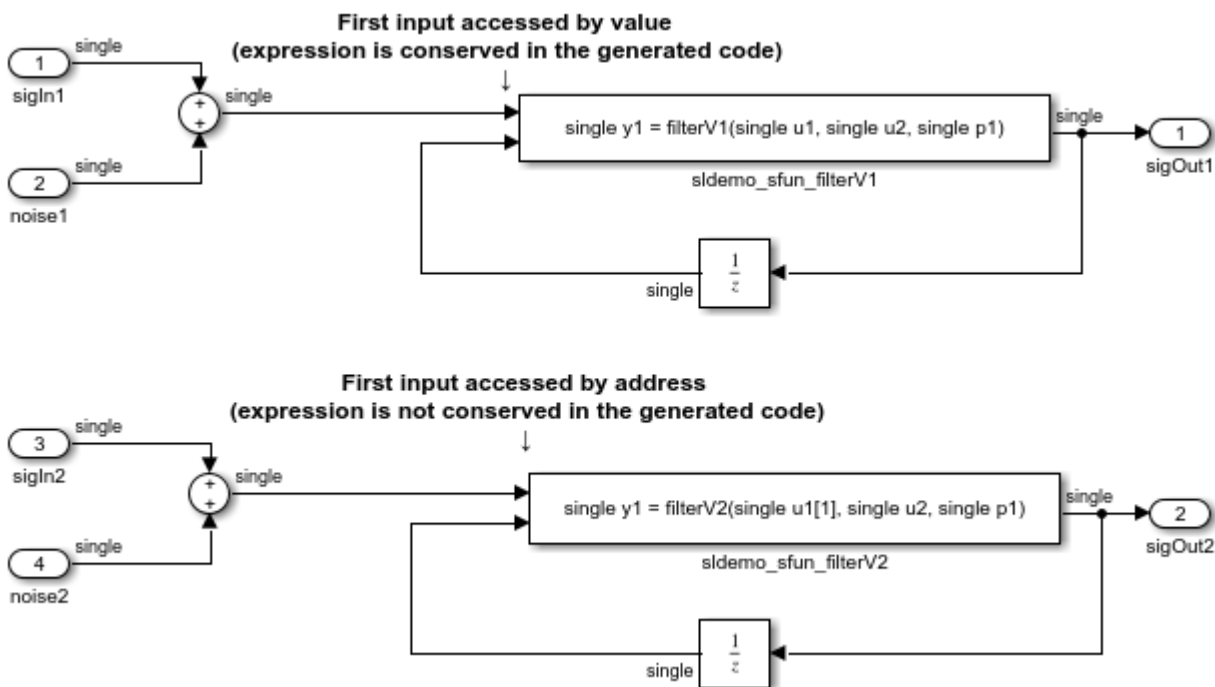

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate masked S-function blocks which are configured to call those S-functions. The blocks are placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', defs);
```

Integrate the Legacy Code

The model `sldemo_lct_filter` shows integration with the legacy code. The subsystem `TestFilter` serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('sldemo_lct_filter')
open_system('sldemo_lct_filter/TestFilter')
sim('sldemo_lct_filter');
```

Input Arguments

specs — Specification for existing C or C++ code and S-function

structure

Specification for existing C or C++ code and the S-function being generated, specified as a `struct` with these fields:

Name the S-function

`SFunctionName` (required) — Name for the S-function to be generated by the Legacy Code Tool, specified as a character vector or string.

Define Legacy Code Tool Function Specifications

- `InitializeConditionsFcnSpec` — Function that the S-function calls to initialize and reset states, specified as a nonempty character vector or string. You must declare this function by using tokens that Simulink software can interpret as explained in “Declaring Legacy Code Tool Function Specifications”.
- `OutputFcnSpec` — Function that the S-function calls at each time step, specified as a nonempty character vector or string. You must declare this function by using tokens that Simulink software can interpret as explained in “Declaring Legacy Code Tool Function Specifications”.
- `StartFcnSpec` — Function that the S-function calls when it begins execution, specified as a character vector or string. This function can access S-function parameter arguments and work data. You must declare this function by using tokens that Simulink software can interpret as explained in “Declaring Legacy Code Tool Function Specifications”.
- `TerminateFcnSpec` — Function that the S-function calls when it terminates execution, specified as a character vector or string. This function can access S-function parameter arguments and work data. You must declare this function by using tokens that Simulink software can interpret as explained in “Declaring Legacy Code Tool Function Specifications”.

Define Compilation Resources

- `HeaderFiles` — File names of header files required for compilation, specified as a cell array of character vectors or string array.
- `SourceFiles` — Source files required for compilation, specified as a cell array of character vectors or string array. You can specify the source files using absolute or relative path names.
- `HostLibFiles` — Library files required for host compilation, specified as a cell array of character vectors or string array. You can specify the library files using absolute or relative path names.
- `TargetLibFiles` — Library files required for target (that is, standalone) compilation, specified as a cell array of character vectors or string array. You can specify the library files using absolute or relative path names.
- `IncPaths` — Directories containing header files, specified as a cell array of character vectors or string array. You can specify the directories using absolute or relative path names.
- `SrcPaths` — Directories containing source files, specified as a cell array of character vectors or string array. You can specify the directories using absolute or relative path names.
- `LibPaths` — Directories containing host and target library files, specified as a cell array of character vectors or string array. You can specify the directories using absolute or relative path names.

Specify a Sample Time

`SampleTime` — One of the following:

- `'inherited'` (default) — Sample time is inherited from the source block.
- `'parameterized'` — Sample time is represented as a tunable parameter. Generated code can access the parameter by calling MEX API functions, such as `mxGetPr` or `mxGetData`.
- `Fixed` — Sample time that you explicitly specify. For information on how to specify sample time, see “Specify Sample Time”.

If you specify this field, you must specify it last.

Define S-Function Options

Options — S-function options, specified as a structure. The structure's fields include:

- `canBeCalledConditionally` — Setting of the S-function `SS_OPTION_CAN_BE_CALLED_CONDITIONALLY` option, specified as a logical. By default, the value is `true` (1).
- `convertNDArrayToRowMajor`— Automatic conversion of a matrix between a column-major format and a row-major format, specified as a logical. The column-major format is used by MATLAB, Simulink, and the generated code. The row-major format is used by C. By default, the value is `false` (0). If you currently specify the previous version of the option, `convert2DMatrixToRowMajor`, the function automatically specifies the new `convertNDArrayToRowMajor` option.

Note This option does not support a 2-D matrix of complex data.

- `isMacro` — Whether the legacy code is a C macro, specified as a logical. By default, the value is `false` (0).
- `isVolatile` — Setting of the S-function `SS_OPTION_NONVOLATILE` option, specified as a logical. By default, the value is `true` (1).
- `language` — Target language of the S-function that Legacy Code Tool will produce, specified as either 'C' or 'C++'. By default, the value is 'C'.

Note The Legacy Code Tool can interface with C++ functions, but not C++ objects. For a work around, see “Legacy Code Tool Limitations” in the Simulink documentation.

- `outputsConditionallyWritten`— Whether the legacy code conditionally writes the output ports, specified as a logical. If `true`, the generated S-function specifies that the memory associated with each output port cannot be overwritten and is global (`SS_NOT_REUSABLE_AND_GLOBAL`). If `false`, the memory associated with each output port is reusable and is local (`SS_REUSABLE_AND_LOCAL`). By default, the value is `false` (0). For more information, see `ssSetOutputPortOptimOpts`.
- `singleCPPMexFile` — Whether generated code:
 - Requires you to generate and manage an inlined S-function as only one file (.cpp) instead of two (.c and .tlc).
 - Maintains model code style (level of parentheses usage and preservation of operand order in expressions and condition expressions in if statements) as specified by model configuration parameters.

Specified as a logical. By default, the value is `false`.

Limitations You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
 - `Simulink.Bus`

- `Simulink.AliasType`
 - `Simulink.NumericType`
 - The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
 - `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files
-
- `supportsMultipleExecInstances`— Option to include a call to the `ssSupportsMultipleExecInstances` function, specified as a logical. By default, the value is `false` (0).
 - `supportCodeReuseAcrossModels`— Whether the generated S-function can be reused across the model reference hierarchy, specified as a logical. If `true`, the generated S-function includes the `ssSetSupportedForCodeReuseAcrossModels` function call. The code generator produces the code for the S-functions in the `slprj\ert_sharedutils` folder.
 - `supportCoverage`— Whether the generated S-function must be compatible with Model Coverage, specified as a logical. By default, the value is `false` (0).
 - `supportCoverageAndDesignVerifier`— Whether the generated S-function must be compatible with Model Coverage and Simulink Design Verifier, specified as a logical. By default, the value is `false` (0).
 - `useTlcWithAccel` — Setting of the S-function `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option, specified as a logical. By default, the value is `true` (1).

Data Types: `struct`

modelName — Model name

`string` | character vector

The name of a Simulink model, specified as a string or character vector. When you specify `legacy_code` with the action `'slblock_generate'`, Legacy Code Tool inserts the generated masked S-function block into the specified model. If you omit this argument, the block appears in an empty model editor window.

Data Types: `char` | `string`

compilerOptions — Compiler options

`string` | character vector

Compiler options to include when you specify `legacy_code` with the action `'compile'`, specified as a string or character vector. The compiler options must be supported by the `mex` function.

Data Types: `char` | `string`

Version History

Introduced in R2006b

libinfo

Get information about library blocks referenced by model

Syntax

```
libdata = libinfo('system')  
libdata = libinfo('system', constraint1, value1, ...)
```

Description

`libdata = libinfo('system')` returns information about library blocks referenced by `system` and all the systems underneath it.

`libdata = libinfo('system', constraint1, value1, ...)` restricts the search as indicated by the search constraint(s) `c1, v1, ...`

Input Arguments

system

The system to search recursively for library blocks.

constraint1, value1, ...

One or more pairs, each consisting of a search constraint followed by a constraint value. You can specify any of the search constraints that you can use with `find_system`.

Output Arguments

libdata

An array of structures that describes each library block referenced by `system`. Each structure has the following fields:

Block	Path of the link to the library block
Library	Name of the library containing the referenced block
ReferenceBlock	Path of the library block
LinkStatus	Value of the LinkStatus parameter for the link to the library block

Version History

Introduced before R2006a

`find_system`

Topics

“Create Custom Library”

LibraryBrowser.LibraryBrowser2

Get handle of Library Browser object

Syntax

```
libraryhandle = LibraryBrowser.LibraryBrowser2
```

Description

`libraryhandle = LibraryBrowser.LibraryBrowser2` creates the Library Browser object `LibraryBrowser.LBStandalone` and returns the object handle. When you have the object handle, you can use the object properties and functions to display, hide, size, position, and refresh the Library Browser in standalone mode. For more information, see [Library Browser in Standalone Mode](#), `LibraryBrowser.LBStandalone`, `show`, `hide`, `getPosition`, `setPosition`, and `refresh`.

Note You can also use `sLibraryBrowser` to create and get the handle of the Library Browser object.

When you use `sLibraryBrowser` to get the object handle:

- If the Library Browser is open in standalone mode, the Library Browser window moves in front of all other Simulink windows.
- If the Library Browser is not open in standalone mode, the Library Browser opens in standalone mode.

Examples

Keep Library Browser in Front of Other Windows

Create and get the handle of the `LibraryBrowser.LBStandalone` object that lets you programmatically access the Library Browser.

```
lb = LibraryBrowser.LibraryBrowser2;
```

Set the `IsOnTop` property of the Library Browser to 1 (`true`), using dot notation to access the property.

```
lb.IsOnTop = 1;
```

Limitations

The `LibraryBrowser.LibraryBrowser2` function does not act on a docked Library Browser. To use the `LibraryBrowser.LibraryBrowser2` function, open the Library Browser in standalone mode by clicking the Launch standalone library browser button .

Version History

Introduced in R2014b

R2016b: LibraryBrowser.LBStandalone object replaces LibraryBrowser.LibraryBrowser2 object

Behavior changed in R2016b

In previous releases, these two commands returned a LibraryBrowser.LibraryBrowser2 object:

```
lb = slLibraryBrowser  
lb = LibraryBrowser.LibraryBrowser2
```

Starting in R2016b, each command returns a LibraryBrowser.LBStandalone object. The functions to access Library Browser operations such as show and refresh support LibraryBrowser.LBStandalone objects.

linmod

Extract continuous-time linear state-space model around operating point

Syntax

```
argout = linmod('sys')
argout = linmod('sys',x,u)
argout = linmod('sys',x,u,para)
argout = linmod('sys',x,u,'v5')
argout = linmod('sys',x,u,para,'v5')
argout = linmod('sys',x,u,para,xpert,upert,'v5')
```

Arguments

<i>sys</i>	Name of the Simulink system from which the linear model is extracted.
<i>x</i> and <i>u</i>	State (<i>x</i>) and the input (<i>u</i>) vectors. If specified, they set the operating point at which the linear model is extracted. When a model has model references using the Model block, you must use the Simulink structure format to specify <i>x</i> . To extract the <i>x</i> structure from the model, use the following command: <pre>x = Simulink.BlockDiagram.getInitialState('sys');</pre> You can then change the operating point values within this structure by editing <code>x.signals.values</code> . If the state contains different data types (for example, 'double' and 'uint8'), then you cannot use a vector to specify this state. You must use a structure instead. In addition, you can only specify the state as a vector if the state data type is 'double'.
<i>Ts</i>	Sample time of the discrete-time linearized model
'v5'	An optional argument that invokes the perturbation algorithm created prior to MATLAB 5.3. Invoking this optional argument is equivalent to calling <code>linmodv5</code> .

- para** A three-element vector of optional arguments:
- `para(1)` — Perturbation value of delta, the value used to perform the perturbation of the states and the inputs of the model. This is valid for linearizations using the 'v5' flag. The default value is 1e-05.
 - `para(2)` — Linearization time. For blocks that are functions of time, you can set this parameter with a nonnegative value that gives the time (t) at which Simulink evaluates the blocks when linearizing a model. The default value is 0.
 - `para(3)` — Set `para(3)=1` to remove extra states associated with blocks that have no path from input to output. The default value is 0.
- xpert and upert** The perturbation values used to perform the perturbation of all the states and inputs of the model. The default values are
- $$\text{xpert} = \text{para}(1) + 1\text{e-}3*\text{para}(1)*\text{abs}(x)$$
- $$\text{upert} = \text{para}(1) + 1\text{e-}3*\text{para}(1)*\text{abs}(u)$$
- When a model has model references using the Model block, you must use the Simulink structure format to specify `xpert`. To extract the `xpert` structure, use the following command:
- ```
xpert = Simulink.BlockDiagram.getInitialState('sys');
```
- You can then change the perturbation values within this structure by editing `xpert.signals.values`.
- The perturbation input arguments are only available when invoking the perturbation algorithm created prior to MATLAB 5.3, either by calling `linmodv5` or specifying the 'v5' input argument to `linmod`.
- argout** `linmod`, `dlinmod`, and `linmod2` return state-space representations if you specify the output (left-hand) side of the equation as follows:
- `[A,B,C,D] = linmod('sys', x, u)` obtains the linearized model of `sys` around an operating point with the specified state variables `x` and the input `u`. If you omit `x` and `u`, the default values are zero.
- `linmod` and `dlinmod` both also return a transfer function and MATLAB data structure representations of the linearized system, depending on how you specify the output (left-hand) side of the equation. Using `linmod` as an example:
- `[num, den] = linmod('sys', x, u)` returns the linearized model in transfer function form.
  - `sys_struct = linmod('sys', x, u)` returns a structure that contains the linearized model, including state names, input and output names, and information about the operating point.

## Description

---

**Note** `linmod` provides only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

---

`linmod` compute a linear state-space model by linearizing each block in a model individually.

`linmod` obtains linear models from systems of ordinary differential equations described as Simulink models. Inputs and outputs are denoted in Simulink block diagrams using Inport and Outport blocks.

The default algorithm uses preprogrammed analytic block Jacobians for most blocks which should result in more accurate linearization than numerical perturbation of block inputs and states. A list of blocks that have preprogrammed analytic Jacobians is available in the Simulink Control Design documentation along with a discussion of the block-by-block analytic algorithm for linearization.

The default algorithm also allows for special treatment of problematic blocks such as the Transport Delay and the Quantizer. See the mask dialog of these blocks for more information and options.

## Notes

By default, the system time is set to zero. For systems that are dependent on time, you can set the variable `para` to a two-element vector, where the second element is used to set the value of `t` at which to obtain the linear model.

The ordering of the states from the nonlinear model to the linear model is maintained. For Simulink systems, a character vector variable that contains the block name associated with each state can be obtained using

```
[sizes,x0,xstring] = sys
```

where `xstring` is a vector of strings whose *i*th row is the block name associated with the *i*th state. Inputs and outputs are numbered sequentially on the diagram.

For single-input multi-output systems, you can convert to transfer function form using the routine `ss2tf` or to zero-pole form using `ss2zp`. You can also convert the linearized models to LTI objects using `ss`. This function produces an LTI object in state-space form that can be further converted to transfer function or zero-pole-gain form using `tf` or `zpk`.

The default algorithms in `linmod` handle Transport Delay blocks by replacing the linearization of the blocks with a Pade approximation. For the 'v5' algorithm, linearization of a model that contains Derivative or Transport Delay blocks can be troublesome. For more information, see “Linearizing Models”.

Linearization is not supported for models that contain one or more referenced models configured to use a local solver. For more information, see “Use Local Solvers in Referenced Models”.

## Examples

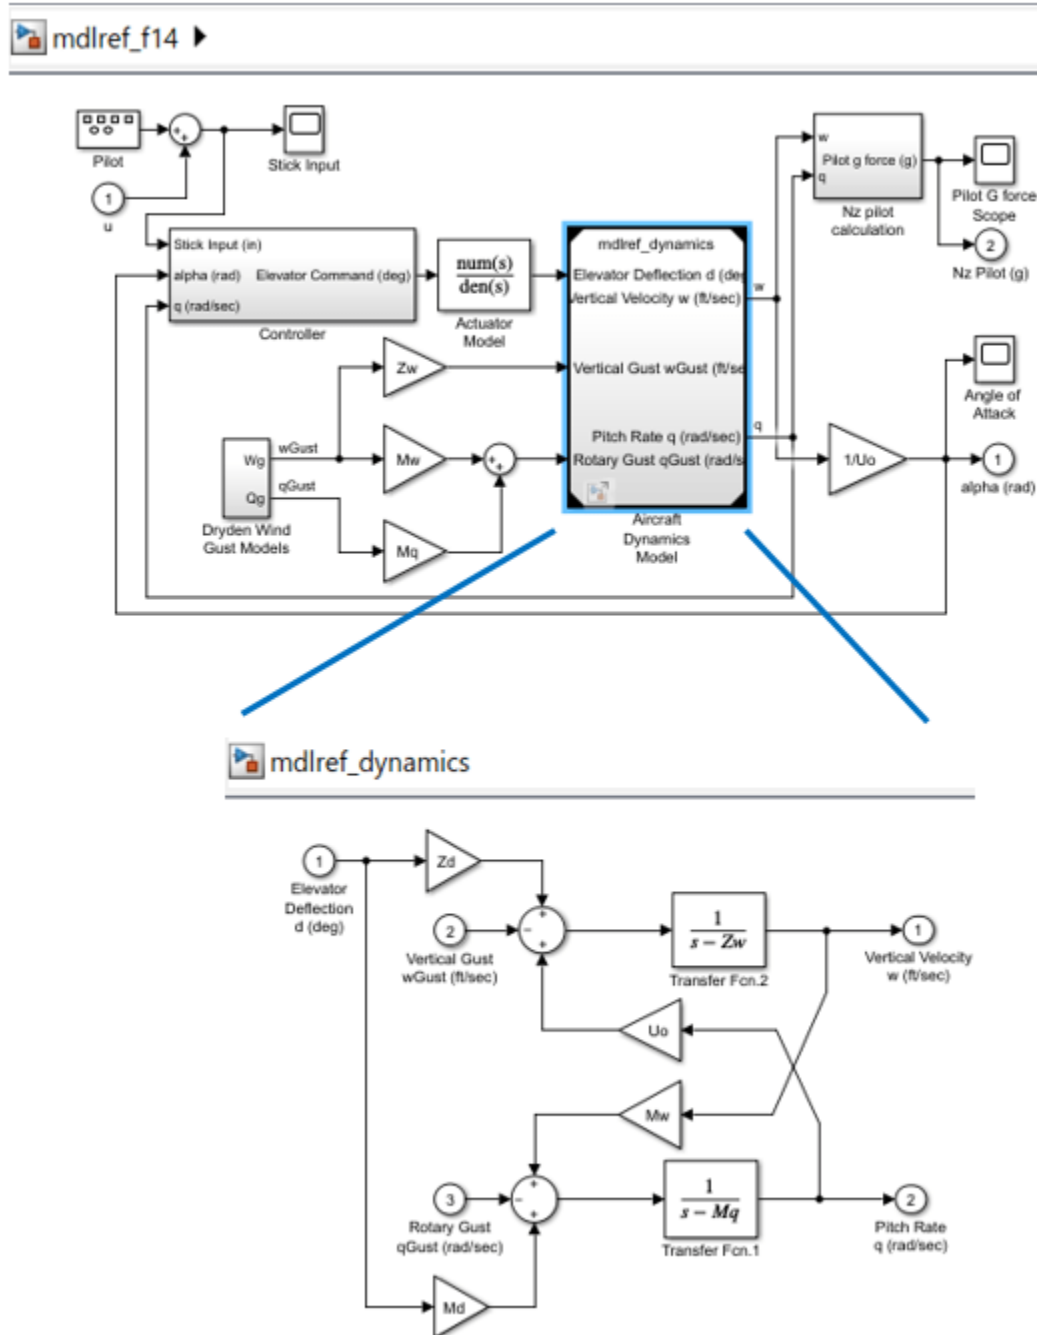

### Linearization with Referenced Models

You can use `linmod` to extract a linear model from a Simulink® environment that contains Model blocks. For example, open the referenced model `mdlref_dynamics` and the top model `mdlref_f14`.

```
open_system('mdlref_dynamics');
open_system('mdlref_f14');
```

In the `mdlref_f14` model, the Aircraft Dynamics Model block references the `mdlref_dynamics` model.

To linearize the `mdlref_f14` model, use the `linmod` command.

```
[A,B,C,D] = linmod('mdlref_f14');

Starting serial model reference simulation build.
Successfully updated the model reference simulation target for: mdlref_dynamics

Build Summary

Simulation targets built:

Model Action Rebuild Reason
=====
mdlref_dynamics Code generated and compiled. mdlref_dynamics_msf.mexw64 does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 39s
```

The resulting state-space model corresponds to the complete `mdlref_f14` model, including the referenced model.

You can call `linmod` with a state and input operating point for models that contain Model blocks. When using operating points, the state vector `x` refers to the total state vector for the top model and any referenced models. You must enter the state vector using the structure format. To get the complete state vector, use `getInitialState`.

```
x = Simulink.BlockDiagram.getInitialState(topmodelName)
```

### Tip

In Normal mode, the `linmod` command applies the block-by-block linearization algorithm on blocks inside the referenced model. If the Model block is in Accelerator mode, the `linmod` command uses numerical perturbation to linearize the referenced model. Due to limitations on linearizing multirate Model blocks in Accelerator mode, you should use Normal mode simulation for all models referenced by Model blocks when linearizing with referenced models.

### Linearization Using the 'v5' Algorithm

Calling the `linmod` command with the `'v5'` argument invokes the perturbation algorithm created prior to MATLAB software version 5.3. This algorithm also allows you to specify the perturbation values used to perform the perturbation of all the states and inputs of the model.

```
[A,B,C,D]=linmod('sys',x,u,para,xpert,upert,'v5')
```

Using `linmod` with the `'v5'` option to linearize a model that contains Derivative or Transport Delay blocks can be troublesome. Before linearizing, replace these blocks with specially designed blocks that avoid the problems. These blocks are in the Simulink Extras library in the Linearization sublibrary.

You access the Extras library by opening the Blocksets & Toolboxes icon:

- For the Derivative block, use the Switched derivative for linearization.

When using a Derivative block, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, it is better implemented (although this is not always possible) with a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

In this example, the blocks on the left of this figure can be replaced by the block on the right.

## linmod2

Extract continuous-time linear state-space model around operating point

### Syntax

```
argout = linmod2('sys',x,u)
```

```
argout = linmod2('sys',x,u,para)
```

### Arguments

*sys*

Name of the Simulink system from which the linear model is extracted.

*x, u*

State ( $x$ ) and the input ( $u$ ) vectors. If specified, they set the operating point at which the linear model is extracted. When a model has model references using the Model block, you must use the Simulink structure format to specify  $x$ . To extract the  $x$  structure from the model, use the following command:

```
x = Simulink.BlockDiagram.getInitialState('sys');
```

You can then change the operating point values within this structure by editing `x.signals.values`.

If the state contains different data types (for example, 'double' and 'uint8'), then you cannot use a vector to specify this state. You must use a structure instead. In addition, you can only specify the state as a vector if the state data type is 'double'.

*para*

A three-element vector of optional arguments:

- `para(1)` — Perturbation value of delta, the value used to perform the perturbation of the states and the inputs of the model. This is valid for linearizations using the 'v5' flag. The default value is 1e-05.
- `para(2)` — Linearization time. For blocks that are functions of time, you can set this parameter with a nonnegative value that gives the time ( $t$ ) at which Simulink evaluates the blocks when linearizing a model. The default value is 0.
- `para(3)` — Set `para(3)=1` to remove extra states associated with blocks that have no path from input to output. The default value is 0.

*argout*

`linmod`, `dlinmod`, and `linmod2` return state-space representations if you specify the output (left-hand) side of the equation as follows:

- `[A,B,C,D] = linmod('sys', x, u)` obtains the linearized model of `sys` around an operating point with the specified state variables `x` and the input `u`. If you omit `x` and `u`, the default values are zero.

`linmod` and `dlinmod` both also return a transfer function and MATLAB data structure representations of the linearized system, depending on how you specify the output (left-hand) side of the equation. Using `linmod` as an example:

- `[num, den] = linmod('sys', x, u)` returns the linearized model in transfer function form.
- `sys_struct = linmod('sys', x, u)` returns a structure that contains the linearized model, including state names, input and output names, and information about the operating point.

## Description

---

**Note** `linmod2` provides only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

---

`linmod2` computes a linear state-space model by perturbing the model inputs and model states, and uses an advanced algorithm to reduce truncation error.

`linmod2` obtains linear models from systems of ordinary differential equations described as Simulink models. Inputs and outputs are denoted in Simulink block diagrams using Inport and Outport blocks.

## Notes

By default, the system time is set to zero. For systems that are dependent on time, you can set the variable `para` to a two-element vector, where the second element is used to set the value of `t` at which to obtain the linear model.

The ordering of the states from the nonlinear model to the linear model is maintained. For Simulink systems, a character vector variable that contains the block name associated with each state can be obtained using

```
[sizes,x0,xstring] = sys
```

where `xstring` is a vector of strings whose *i*th row is the block name associated with the *i*th state. Inputs and outputs are numbered sequentially on the diagram.

For single-input multi-output systems, you can convert to transfer function form using the routine `ss2tf` or to zero-pole form using `ss2zp`. You can also convert the linearized models to LTI objects using `ss`. This function produces an LTI object in state-space form that can be further converted to transfer function or zero-pole-gain form using `tf` or `zpk`.

The default algorithms in `linmod` and `dlinmod` handle Transport Delay blocks by replacing the linearization of the blocks with a Pade approximation. For more information, see “Linearizing Models”.

Linearization is not supported for models that contain one or more referenced models configured to use a local solver. For more information, see “Use Local Solvers in Referenced Models”.

# linmodv5

Extract continuous-time linear state-space model around operating point

## Syntax

```
argout = linmodv5('sys')
argout = linmodv5('sys',x,u)
argout = linmodv5('sys',x,u,para)
argout = linmodv5('sys',x,u,para,xpert,upert)
```

## Arguments

*sys*

Name of the Simulink system from which the linear model is extracted.

*x, u*

State (*x*) and the input (*u*) vectors. If specified, they set the operating point at which the linear model is extracted. When a model has model references using the Model block, you must use the Simulink structure format to specify *x*. To extract the *x* structure from the model, use the following command:

```
x = Simulink.BlockDiagram.getInitialState('sys');
```

You can then change the operating point values within this structure by editing `x.signals.values`.

If the state contains different data types (for example, 'double' and 'uint8'), then you cannot use a vector to specify this state. You must use a structure instead. In addition, you can only specify the state as a vector if the state data type is 'double'.

*para*

A three-element vector of optional arguments:

- `para(1)` — Perturbation value of delta, the value used to perform the perturbation of the states and the inputs of the model. This is valid for linearizations using the 'v5' flag. The default value is 1e-05.
- `para(2)` — Linearization time. For blocks that are functions of time, you can set this parameter with a nonnegative value that gives the time (*t*) at which Simulink evaluates the blocks when linearizing a model. The default value is 0.
- `para(3)` — Set `para(3)=1` to remove extra states associated with blocks that have no path from input to output. The default value is 0.

*xpert, upert*

The perturbation values used to perform the perturbation of all the states and inputs of the model. The default values are

```
xpert = para(1) + 1e-3*para(1)*abs(x)
upert = para(1) + 1e-3*para(1)*abs(u)
```

When a model has model references using the Model block, you must use the Simulink structure format to specify *xpert*. To extract the *xpert* structure, use the following command:

```
xpert = Simulink.BlockDiagram.getInitialState('sys');
```

You can then change the perturbation values within this structure by editing `xpert.signals.values`.

The perturbation input arguments are only available when invoking the perturbation algorithm created prior to MATLAB 5.3, either by calling `linmodv5` or specifying the 'v5' input argument to `linmod`.

*argout*

`linmod`, `dlinmod`, and `linmod2` return state-space representations if you specify the output (left-hand) side of the equation as follows:

- `[A,B,C,D] = linmod('sys', x, u)` obtains the linearized model of *sys* around an operating point with the specified state variables *x* and the input *u*. If you omit *x* and *u*, the default values are zero.

`linmod` and `dlinmod` both also return a transfer function and MATLAB data structure representations of the linearized system, depending on how you specify the output (left-hand) side of the equation. Using `linmod` as an example:

- `[num, den] = linmod('sys', x, u)` returns the linearized model in transfer function form.
- `sys_struct = linmod('sys', x, u)` returns a structure that contains the linearized model, including state names, input and output names, and information about the operating point.

## Description

---

**Note** `linmodv5` provides only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

---

`linmodv5` computes a linear state space model using the full model perturbation algorithm created prior to MATLAB 5.3.

`linmodv5` obtains linear models from systems of ordinary differential equations described as Simulink models. Inputs and outputs are denoted in Simulink block diagrams using Inport and Outport blocks.

## Notes

By default, the system time is set to zero. For systems that are dependent on time, you can set the variable `para` to a two-element vector, where the second element is used to set the value of `t` at which to obtain the linear model.

The ordering of the states from the nonlinear model to the linear model is maintained. For Simulink systems, a character vector variable that contains the block name associated with each state can be obtained using

```
[sizes,x0,xstring] = sys
```

where `xstring` is a vector of strings whose *i*th row is the block name associated with the *i*th state. Inputs and outputs are numbered sequentially on the diagram.

For single-input multi-output systems, you can convert to transfer function form using the routine `ss2tf` or to zero-pole form using `ss2zp`. You can also convert the linearized models to LTI objects using `ss`. This function produces an LTI object in state-space form that can be further converted to transfer function or zero-pole-gain form using `tf` or `zpk`.

The default algorithms in `linmod` and `dlinmod` handle Transport Delay blocks by replacing the linearization of the blocks with a Pade approximation. For the 'v5' algorithm, linearization of a model that contains Derivative or Transport Delay blocks can be troublesome. For more information, see "Linearizing Models".

Linearization is not supported for models that contain one or more referenced models configured to use a local solver. For more information, see "Use Local Solvers in Referenced Models".

## Version History

Introduced in R2011b

### See Also

`linmod` | `dlinmod` | `linmod2`

## load\_system

Load Simulink model into memory

### Syntax

```
handle = load_system(sys)
```

### Description

`handle = load_system(sys)` loads the model `sys` into memory without opening the model in the Simulink Editor. After you load a model into memory, you can work with it using Simulink API commands. Save changes to the model using `save_system`.

### Examples

#### Load Model into Memory

Load the model `vdp` into memory and return the model handle.

```
h = load_system("vdp")
```

```
h =
```

```
172.0004
```

### Input Arguments

#### **sys** — System to search

character vector | string scalar

System to search, specified as the full system path name, a cell array of system path names, a handle, or a vector of handles.

Example: "vdp"

Example: 'MyModel/Subsystem1'

Example: {'vdp', 'fuelssystem'}

### Output Arguments

#### **handle** — Handle of loaded model

handle

Handle of loaded model.

### Version History

Introduced before R2006a

**See Also**

close\_system | open\_system | save\_system

# loadIntoMemory

Load logged data into memory

## Syntax

```
logs = loadIntoMemory(logs)
```

## Description

`logs = loadIntoMemory(logs)` loads the data in `logs` into memory. Data is logged to a repository and brought into memory on an as-needed basis. When you want to work with all elements of a large set of logged data, use `loadIntoMemory` to bring all of the elements into memory at once. Loading all the data at once, rather than element by element, is much faster.

## Examples

### Load Logged Data into Memory

This example shows how to load a set of logged data into memory all at once, rather than element by element.

```
% Simulate model to generate logged data
sim('sldemo_fuelsys')
```

The simulation logs all of the instrumented signals in the model to the `Simulink.SimulationData.Dataset` object `sldemo_fuelsys_output`. At the end of simulation, the signal data remains in the repository until used in the MATLAB workspace. When you work with small sets of data or only postprocess a subset, leaving signals in the repository improves performance. But when you have a large set of data and need to postprocess all of the signals, you should bring them all into memory at once.

```
% Load all logged signals into memory
loadIntoMemory(sldemo_fuelsys_output);
```

All of the data in `sldemo_fuelsys_output` is now available for efficient postprocessing.

## Input Arguments

### logs — Data to load into memory

'Simulink.SimulationData.Dataset' | 'Simulink.SimulationOutput'

Data to load into memory. The `loadIntoMemory` function can load `Simulink.SimulationData.Dataset` and `Simulink.SimulationOutput` data.

Example: `logout`

## Output Arguments

### Logs — Data

'Simulink.SimulationData.Dataset' | 'Simulink.SimulationOutput'

Data loaded into memory.

## Version History

Introduced in R2017b

### See Also

Simulink.SimulationData.Dataset | Simulink.SimulationOutput

# lookupTableEditor

Start Lookup Table Editor

## Syntax

```
lookupTableEditor
lookupTableEditor(path)
```

## Description

`lookupTableEditor` starts a stand-alone version of the Lookup Table Editor.

`lookupTableEditor(path)` starts the Lookup Table Editor for a model, subsystem, or lookup table block.

## Examples

### Start Lookup Table Editor for Model

Start the Lookup Table Editor for the `sldemo_fuelsys` model.

```
lookupTableEditor('sldemo_fuelsys')
```

## Input Arguments

### **path** — Path

character vector

Path to system containing lookup table, specified as a character vector or string.

Data Types: `char` | `string`

## Version History

Introduced in R2022a

## See Also

1-D Lookup Table | 2-D Lookup Table | Direct Lookup Table (n-D) | n-D Lookup Table | Interpolation Using Prelookup | Prelookup

# modeladvisor

Open Model Advisor

## Syntax

```
modeladvisor(model)
modeladvisor(model, 'configuration', configfile)
```

## Description

`modeladvisor(model)` opens the Model Advisor for the model or subsystem specified by `model`. If the specified model or subsystem is not open, this command opens it.

If you have a Simulink Check™ license, you can specify a name-value pair with `modeladvisor(model, 'configuration', configfile)` that opens the Model Advisor with a custom configuration. The configuration defines the organization of folders and checks in the Model Advisor. For more information, see “Create and Deploy a Model Advisor Custom Configuration” (Simulink Check).

## Examples

### Open Model Advisor for model

Open the Model Advisor for vdp example model:

```
modeladvisor('vdp')
```

### Open Model Advisor for subsystem

Open the Model Advisor for the Aircraft Dynamics Model subsystem of the f14 example model:

```
modeladvisor('f14/Aircraft Dynamics Model')
```

### Open Model Advisor for currently selected model

Open the Model Advisor on the currently selected model:

```
modeladvisor(bdroot)
```

### Open Model Advisor for currently selected subsystem

Open the Model Advisor on the currently selected subsystem:

modeladvisor(gcs)

## Input Arguments

### **model** — Model or subsystem name

character vector

Model or subsystem name or handle, specified as a character vector.

Data Types: char

### **configfile** — Custom configuration

character vector

File that contains a Model Advisor custom configuration of folders and checks (available with a Simulink Check license).

Data Types: char

## Version History

**Introduced before R2006a**

### **See Also**

“Run Model Advisor Checks”

# modelfinder

Search and open example models

## Syntax

```
modelfinder(str)
modelfinder(Name,Value)
```

## Description

`modelfinder(str)` finds models that match the specified search string. If there is more than one match, then all matching items are displayed as a list and you are prompted to select one.. Other options in the prompt include `q` to quit and `m` to see more results. If there are more than three words in the search term, then `modelfinder` treats the search as a natural language query and finds models that satisfy the natural language query.

`modelfinder(Name,Value)` specifies search options using one or more name-value arguments. For example, you can filter models based on the combination of specific search strings and blocks.

## Examples

### Models Matching Search String

Use this command to display models that has the word `autosar`.

```
modelfinder('autosar');
```

1. AUTOSARCounterExample
2. AuthorAUTOSARCompositionsInArchitectureModelExample
3. > autosar\_tpc\_actuator
4. > autosar\_tpc\_composition
5. > autosar\_tpc\_controller
6. > autosar\_tpc\_pedal\_sensor
7. > autosar\_tpc\_system
8. > autosar\_tpc\_throttle\_sensor1
9. > autosar\_tpc\_throttle\_sensor2
10. > autosar\_tpc\_throttle\_sensor\_monitor
11. ConfigureAndSimulateAUTOSARFiMServiceCallsExample
12. > autosar\_bsw\_fim
13. > autosar\_bsw\_fimmonitor
14. > autosar\_bsw\_fimoperationcycle
15. > autosar\_bsw\_fimsensor1
16. > autosar\_bsw\_fimsensor2
17. CreateAndConfigureAUTOSARAdaptiveSoftwareComponentExample
18. DesignAUTOSARComponentsExample
19. > autosar\_composition
20. > autosar\_swc\_actuator
21. > autosar\_swc\_controller
22. > autosar\_swc\_monitor
23. > autosar\_swc\_pedal\_sensor
24. > autosar\_swc\_throttle\_sensor
25. > autosar\_system

```
Showing 1-25 of 68 matches. Enter (m) for more results.
Enter the example number you want to open (choose number) OR
see more results (m) OR quit (q)
```

### Using Natural Language Query

Use this command to filter models that satisfies the query solar panel models in simulink.

```
modelfinder('solar panel models in simulink')
```

1. GenerateHDLFromMultipleSimscapeNetworksExample
2. > Solar\_Power\_Inverter\_Multiple\_Network\_HDL
3. > Solar\_Power\_Inverter\_Multiple\_Network\_StateSpace
4. HybridSolarPanelExample
5. > sscv\_hybrid\_solar\_panel
5. PartitionLargeNetworkIntoMultipleSmallerNetworksExample
6. > Solar\_Power\_Inverter\_Single\_Network\_HDL
6. ee\_mars\_helicopter\_system
7. ee\_solar\_boostconverter\_maxpowerpoint
8. ee\_solar\_generator
9. ee\_solar\_gridconnected\_singlephase
10. ee\_solar\_gridconnected\_threephase
11. ee\_solar\_inverter
12. ee\_solar\_panel
13. ee\_solar\_standalone\_acsystem\_withbatterybackup
14. ee\_solar\_standalone\_dcsystem\_withbatterybackup
15. power\_microgrid
16. sm\_solar\_tracker

Enter the example number you want to open (choose number) OR quit (q) :

### Models with Additional Filters

You can filter models that contains specific search string and blocks . For example, use this command to filter models that contains the word motor and the block gain.

```
modelfinder('fluid', 'blocks', {'condenser'}, 'verbose', 'off')
```

1. ssc\_rankine\_cycle
2. ssc\_refrigeration
3. sscfluids\_condenser\_evaporator
4. sscfluids\_ev\_thermal\_management
5. sscfluids\_liquid\_air\_energy\_storage
6. sscfluids\_refrigeration
7. sscfluids\_refrigeration\_step2
8. sscfluids\_refrigeration\_step3
9. sscfluids\_refrigeration\_step4
10. sscfluids\_refrigeration\_step5
11. sscfluids\_refrigeration\_step6
12. sscfluids\_refrigerator
13. sscfluids\_residential\_air\_source\_heat\_pump

Enter the example number you want to open (choose number) OR quit (q) :

### Input Arguments

**str** — Search string

(default) | ''

Search string specified as string. You can use wildcard (\*) characters in the search. If there are more than three words in the string modelfinder treats it as natural language query.

Example: `modelfinder('autosar')`

Data Types: `char | string`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `modelfinder('fluid', 'blocks', {'condenser'})` finds models with the search string `fluid` having block name `condenser`. “Models with Additional Filters” on page 2-366

### **blocks — Block names in search criteria**

(default) | ''

Block names in search criteria specified as string. This argument limits the models displayed in the search result based on blocks present in the models.

Example: `modelfinder('motor', 'blocks', 'gain')`

Data Types: `char | string`

### **verbose — Option to display path of matched model and matched character from search term**

(default) | off

If you specify this argument as on, search results are displayed with the path of the matched models and the matching characters from the search term. Additional information about the matched component, such as model name, annotations, and description is displayed. Search results that appear indented and prefixed with > are individual Simulink models that are part of a bigger example or project. You may open an individual model or an entire example, with the corresponding number.

Example: `modelfinder('pmsm models using discrete pulse generator', 'verbose', 'on')`

Data Types: `char | string`

### **resultsPerPage — Number of results displayed per page**

(default) | 20

Number of results per page specified as positive integer. By default, 20 results are displayed per page.

---

**Note** The number of results displayed may vary to preserve the model hierarchy in output.

---

Example: `modelfinder('pmsm models using discrete pulse generator', 'resultsPerPage', 5)`

Data Types: `char | string`

## **Version History**

### **Topics**

*"Use modelfinder to Index Simulink Models and Improve Their Discoverability"*

# modelfinder.registerFolder

Register folder path to search index of modelfinder

## Syntax

```
modelfinder.registerFolder(pathToFolder)
```

## Description

`modelfinder.registerFolder(pathToFolder)` registers all models from the path to modelfinder search result. The function searches for models recursively within the specified folder.

## Input Arguments

### **pathToFolder** — Path to folder

string

Path to folder specified as string. Specify the path of the models to be included for indexing.

Example: `modelfinder.registerFolder("~/Desktop/myFolder")`

Example: `modelfinder.registerFolder(["~/Desktop/myFolder1", "~/Desktop/myFolder2"])`

## Version History

**Introduced in R2022a**

## See Also

`modelfinder` | `modelfinder.unregisterFolder`

## Topics

"Use modelfinder to Index Simulink Models and Improve Their Discoverability"

## **modelfinder.unregisterFolder**

Unregister folder path from search path of `modelfinder`

### **Syntax**

```
modelfinder.unregisterFolder(pathToFolder)
```

### **Description**

`modelfinder.unregisterFolder(pathToFolder)` unregisters all model from the specified `pathToFolder` from `modelfinder` search index so that the models does not appear in search results. The function unregisters all models recursively within the specified folder.

### **Input Arguments**

#### **pathToFolder — Path to folder**

string

Path to folder specified as string. Specify path of the models to be excluded from indexing.

Example: `modelfinder.unregisterFolder("~/Desktop/myFolder")`

Example: `modelfinder.unregisterFolder(["~/Desktop/myFolder1", "~/Desktop/myFolder2"])`

### **Version History**

**Introduced in R2022a**

### **See Also**

`modelfinder` | `modelfinder.registerFolder` | “Use `modelfinder` to Index Simulink Models and Improve Their Discoverability”

## new\_system

Create Simulink model or library in memory

### Syntax

```
h = new_system
h = new_system(name)
h = new_system(name, 'FromTemplate', template)
h = new_system(name, 'FromFile', file)
h = new_system(___, 'ErrorIfShadowed')

h = new_system(name, 'Model')
h = new_system(name, 'Model', subsystem)
h = new_system(name, 'Subsystem')
h = new_system(name, 'Library')
h = new_system(___, 'ErrorIfShadowed')
```

### Description

`h = new_system` creates a model named `untitled` (and then `untitled1`, `untitled2`, and so on) based on your default model template and returns the new model's numeric handle. Select your default model template on the Simulink start page or by using the `Simulink.defaultModelTemplate` function.

The `new_system` function does not open the new model. This function creates the model in memory. To save the model, use `save_system`, or open the model with `open_system` and then save it using the Simulink Editor.

`h = new_system(name)` creates a model based on your default model template and gives the new model the specified name. This function returns the new model's numeric handle. Select your default model template on the Simulink start page or by using the `Simulink.defaultModelTemplate` function.

If `name` is empty, the function creates a model named `untitled`, `untitled1`, `untitled2`, and so on.

The `new_system` function does not open the new model. This function creates the model in memory. To save the model, use `save_system`, or open the model with `open_system` and then save it using the Simulink Editor.

`h = new_system(name, 'FromTemplate', template)` creates the model based on the specified template.

`h = new_system(name, 'FromFile', file)` creates the model based on the specified model or template.

`h = new_system( ___, 'ErrorIfShadowed' )` creates the model or returns an error if another model, MATLAB file, or variable with the same name is on the MATLAB path or in the workspace. It uses any of the input arguments in the previous syntaxes.

`h = new_system(name, 'Model')` creates an empty model based on the Simulink default model and returns the new model's numeric handle. The Simulink default model is also known as the root block diagram and has the numeric handle 0. If `name` is empty, the function creates a model or library named `untitled`, `untitled1`, `untitled2`, and so on.

The `new_system` function does not open the new model. This function creates the model in memory. To save the model, use `save_system`, or open the model with `open_system` and then save it using the Simulink Editor.

`h = new_system(name, 'Model', subsystem)` creates a model based on the subsystem `subsystem` in a currently loaded model.

`h = new_system(name, 'Subsystem')` creates an empty subsystem file that has the specified name.

`h = new_system(name, 'Library')` creates an empty library that has the specified name and returns a numeric handle.

`h = new_system( ____, 'ErrorIfShadowed')` returns an error if another model, MATLAB file, or variable with the same name is on the MATLAB path or in the workspace. This syntax uses any of the input arguments in the previous syntaxes.

## Examples

### Create a Model Based on Default Template

Create a model in memory called `untitled`.

```
h = new_system;
```

You can use `get_param` to get the name.

```
get_param(h, 'Name')
open_system(h)
open_system('untitled')
open_system(get_param(h, 'Name'))
```

```
ans =
```

```
untitled
```

Use the name, the handle, or `get_param` command as input to `open_system`. You can use any of these commands:

### Create a Model Based on Named Template

Before you use this syntax, create a template. In the Simulink Editor, create the model you want to use as the template, then in the **Simulation** tab, select **Save > Template**. For this example, name the template `mytemplate`.

By default, the template is on the MATLAB path, so if you change location, add the folder to the MATLAB path.

Create a model named `templateModel` based on the template `mytemplate`.

```
h = new_system('templateModel','FromTemplate','mytemplate');
```

Invoking template `\\myuserdir\Documents\MATLAB\mytemplate.sltx`

### Create a Model Based on Another Model

Create a model named `mynewmodel` based on `myoldmodel`, which is in the current folder.

```
h = new_system('mynewmodel','FromFile','myoldmodel.slx');
```

### Create Model from Subsystem

Load the model `f14`. Create a model based on the Controller subsystem.

```
load_system('f14');
new_system('mycontroller','Model','f14/Controller');
open_system('mycontroller');
```

### Create a Library

Create a library in memory and then open it.

```
new_system('mylib', 'Library')
open_system('mylib')
```

### Create a Subsystem File

Create a subsystem file in memory and then open it.

```
new_system('mysubsystem', 'Subsystem')
open_system('mysubsystem')
```

### Ensure Model Name Is Unique

Create a variable with the name myvar.

```
myvar = 17;
```

Try to create a model that uses the same name as the variable. When you use the 'ErrorIfShadowed' option, the new\_system function returns an error.

```
new_system('myvar', 'Model', 'ErrorIfShadowed')
```

The model 'myvar' cannot be created because this name is shadowing another name on the MATLAB path or in the workspace. Choose another name, or do not use the option 'ErrorIfShadowed'

## Input Arguments

### **name** — Name of new model or library

character vector

Name of new model or library, specified as a character vector that:

- Has 63 or fewer characters
- Is not a MATLAB keyword
- Is not 'simulink'
- Is unique among model names, variables, and MATLAB files on the MATLAB path and in the workspace

Example: 'mymodel', 'mylibrary'

### **subsys** — Subsystem to base new model on

subsystem block path name

Subsystem to base the new model on, specified as the subsystem block path name in a currently open model.

Example: 'f14/Controller'

### **template** — Name of template to base new model on

character vector

Name of the template to base the new model on, specified as a character vector of the name of a template on the MATLAB path. Create a template in the Simulink Editor. In the **Simulation** tab, select **Save > Template**.

Example: 'mytemplate', 'mytemplate.slx'

**file** — Path name of model or template to base new model on  
character vector

Path name of the model or template to base the new model on, specified as a character vector. You can use an .mdl, .slx, or .sltx file. Include the extension and use a full or relative path.

Example: 'Models/mymodel.slx', 'mytemplate.slx', 'model.mdl'

## Version History

Introduced before R2006a

### See Also

[open\\_system](#) | [save\\_system](#) | [Simulink.defaultModelTemplate](#)

## open\_system

Open model, library, subsystem, or block dialog box

### Syntax

```
open_system(obj)

open_system(sys, 'loadonly')

open_system(sbsys, 'window')
open_system(sbsys, 'tab')

open_system(blk, 'mask')
open_system(blk, 'force')
open_system(blk, 'parameter')
open_system(blk, 'OpenFcn')
```

### Description

`open_system(obj)` opens the specified model, library, subsystem, or block. This is equivalent to double-clicking the model or library in the Current Folder Browser, or the subsystem or block in the Simulink Editor.

A model or library opens in a new window. For a subsystem or block within a model, the behavior depends on the type of block and its properties.

- Any `OpenFcn` callback parameter is evaluated.
- If there is no `OpenFcn` callback, and a mask is defined, the mask parameter dialog box opens.
- Without an `OpenFcn` callback or a mask parameter, Simulink opens the object.
  - A referenced model opens in a new window.
  - A subsystem opens in a new tab in the same window.
  - For blocks, the parameters dialog box for the block opens.

To open a specific subsystem or block, you must load the model or library containing it. Otherwise Simulink returns an error.

You can override the default behavior by supplying a second input argument.

`open_system(sys, 'loadonly')` loads the specified model or library without opening the Simulink Editor. This is equivalent to using `load_system`.

`open_system(sbsys, 'window')` opens the subsystem `sbsys` in a new Simulink Editor window. Before opening a specific subsystem or block, load the model or library containing it. Otherwise Simulink returns an error.

`open_system(sbsys, 'tab')` opens the subsystem in a new Simulink Editor tab in the same window. Before opening a specific subsystem or block, load the model or library containing it. Otherwise Simulink returns an error.

`open_system(blk, 'mask')` opens the mask dialog box of the block or subsystem specified by `blk`. Load the model or library containing `blk` before opening it.

`open_system(blk, 'force')` looks under the mask of a masked block or subsystem. It opens the dialog box of the block under the mask or opens a masked subsystems in a new Simulink Editor tab. This is equivalent to the **Look Under Mask** menu item. Before opening a specific subsystem or block, load the model or library containing it. Otherwise Simulink returns an error.

`open_system(blk, 'parameter')` opens the block parameter dialog box.

`open_system(blk, 'OpenFcn')` runs the block callback `OpenFcn`.

## Examples

### Open a Model

Open the f14 model.

```
open_system('f14')
```

### Load a Model Without Opening it

Load the f14 model.

```
open_system('f14', 'loadonly')
```

### Open a Subsystem

Open the Controller subsystem of the f14 model.

```
load_system('f14')
open_system('f14/Controller')
```

### Open a Subsystem in New Tab in Existing Window

Open the f14 model and open the Controller subsystem in a new tab.

```
f14
open_system('f14/Controller', 'tab')
```

### Open a Subsystem in a Separate Window

Open a subsystem in its own Simulink Editor window.

```
open_system('f14')
open_system('f14/Controller', 'window')
```

### Open a Referenced Model

Open the model `sldemo_mdhref_counter`, which is referenced by the CounterA Model block in `sldemo_mdhref_basic`.

```
openExample('sldemo_mdhref_basic')
open_system('sldemo_mdhref_basic/CounterA')
```

The referenced model opens in its own Simulink Editor window as a top model. To open the referenced model in the context of a model hierarchy, use the `open` function with a `Simulink.BlockPath` object.

### Open Block Dialog Box

Open the block parameters dialog box for the first Gain block in the Controller subsystem.

```
load_system('f14')
open_system('f14/Controller/Gain')
```

### Run Block Open Callback Function

Define an `OpenFcn` callback for a block and execute the block callback.

```
f14
set_param('f14/Pilot','OpenFcn','disp(''Hello World!'')')
open_system('f14/Pilot','OpenFcn')
```

The words `Hello World` appear on the MATLAB Command Prompt.

### Open Masked Subsystem

Open the contents of the masked subsystem Pump in the model `sldemo_hydcyl`.

```
openExample('sldemo_hydcyl')
open_system('sldemo_hydcyl/Pump','force')
```

### Open Multiple Systems with One Command

Create a cell array of two model names, `f14` and `vdp`. Open both models using `open_system` with the cell array name.

```
models = {'f14','vdp'}
open_system(models)
```

## Input Arguments

**obj** — Model, referenced model, library, subsystem, or block path

character vector

Model, referenced model, library, subsystem, or block path, specified as a character vector. If the model is not on the MATLAB path, specify the full path to the model file. Specify the block or subsystem using its full name, e.g., `f14/Controller/Gain`, on an opened or loaded model. On UNIX systems, the fully qualified path name of a model can start with a tilde (~), signifying your home directory.

Data Types: char

### **sys — Model or library path**

character vector

The full name or path of a model or library, specified as a character vector.

Data Types: char

### **sbsys — Subsystem path**

character vector

The full name or path of a subsystem in an open or loaded model, specified as a character vector.

Data Types: char

### **blk — Block or subsystem path**

character vector

The full name or path of a block or subsystem in an open or loaded model, specified as a character vector.

Data Types: char

## **Tips**

To open a referenced model in the context of a model hierarchy, use the `open` function with a `Simulink.BlockPath` object.

## **Version History**

**Introduced before R2006a**

## **See Also**

`new_system` | `load_system` | `close_system` | `save_system` | `open` (BlockPath)

## openDialog

Open configuration parameters dialog

### Syntax

```
openDialog(configObj)
```

### Arguments

*configObj*

A configuration set (`Simulink.ConfigSet`) or configuration reference (`Simulink.ConfigSetRef`)

### Description

`openDialog` opens a configuration parameters dialog box. If *configObj* is a configuration set, the dialog box displays the configuration set. If *configObj* is a configuration reference, the dialog box displays the referenced configuration set, or generates an error if the reference does not specify a valid configuration set. If the dialog box is already open, its window becomes selected.

### Examples

The following example opens a configuration parameters dialog box that shows the current parameters for the current model. The parameter values derive from the active configuration set or configuration reference (configuration object). The code is the same in either case; the only difference is which type of configuration object is currently active.

```
myConfigObj = getActiveConfigSet(gcs);
openDialog(myConfigObj);
```

## Version History

**Introduced in R2006b**

# parsim

Simulate dynamic system multiple times in parallel or serial

## Syntax

```
simOut = parsim(in)
simOut = parsim(in, 'ShowSimulationManager', 'on')
simOut = parsim(in, Name, Value)
```

## Description

`simOut = parsim(in)` simulates a model using the inputs specified in the `SimulationInput` object, `in`. The `parsim` command uses an array of `SimulationInput` objects to run multiple simulations.

`simOut = parsim(in, 'ShowSimulationManager', 'on')` simulates a model in parallel using the inputs specified in the `SimulationInput` object and opens the Simulation Manager UI. For more information, see `Simulation Manager`.

`simOut = parsim(in, Name, Value)` simulates a model in parallel using the inputs specified in the `SimulationInput` object and the options specified as the `Name, Value` pair.

The `parsim` command uses the Parallel Computing Toolbox license to run the simulations in parallel. `parsim` runs the simulations in serial if a parallel pool cannot be created or if Parallel Computing Toolbox is not used.

## Examples

### Using `parsim` with Rapid Accelerator

Simulate the model, `vdp`, in rapid accelerator mode.

Load the model.

```
model = 'vdp';
load_system(model)
```

This step builds the Rapid Accelerator target

```
Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
```

Create a `SimulationInput` object and use `setModelParameter` method to set `RapidAcceleratorUpToDateCheck` to 'off'.

```
in = Simulink.SimulationInput(model);
in = in.setModelParameter('SimulationMode', 'rapid-accelerator');
in = in.setModelParameter('RapidAcceleratorUpToDateCheck', 'off');
```

Simulate the model.

```
out = parsim(in)
```

### **Simulate Model in Parallel with parsim**

Simulate the model, CSTR, in parallel by sweeping over a variable. An array of `SimulationInput` objects is used to perform the sweep.

Specify sweep values.

```
FeedTempSweep = 250:10:300;
```

Create an array of `SimulationInput` objects.

```
for i = length(FeedTempSweep):-1:1
in(i) = Simulink.SimulationInput('CSTR');
in(i) = in(i).setVariable('FeedTemp0',FeedTempSweep(i));
end
```

Simulate the model in parallel.

```
out = parsim(in, 'ShowSimulationManager', 'on')
```

```

```

```
out =
```

```
1x6 Simulink.SimulationOutput array
```

## **Input Arguments**

### **in — Simulink.SimulationInput object used to simulate the model**

object, array

A `Simulink.SimulationInput` object or an array of `Simulink.SimulationInput` objects that is used to specify changes to the model for a simulation.

Example: `in = Simulink.SimulationInput('vdp')`

Example: `for i = 10:-1:1 in(i) = Simulink.SimulationInput('vdp'); end`

## Name-Value Pair Arguments

---

**Note** All parameters passed to `parsim` command are unrelated to the parameters that are used with the `sim` command. To pass to the `parsim` command, use the list of following input arguments

---

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` and `Value` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ShowProgress', 'on'`

### AttachedFiles — Files to attach to parallel pool

cell array

Additional files to attach to the parallel pool, specified as a cell array. `parsim` does not support loading data from From File blocks that make reference to mat files in subdirectories.

### ShowProgress — Show the progress of the simulations

'on'(default) | 'off'

Set to `'on'`, to see the progress of the simulations in the command window. The progress is hidden when set to `'off'`.

---

**Note** When the progress is shown, a message `'Cleaning up parallel workers..'` may be displayed before the completion of the last few simulations. This message does not depend on the completion of the simulations. Simulations complete when the outputs are fetched from the future. For more information, see `Simulink.Simulation.Future`.

---

### RunInBackground — Run simulations in background

'off' (default) | 'on'

Set to `'on'` to run simulations asynchronously, keeping the MATLAB command prompt available for use. To terminate the simulations running in the background, use the `cancel` method on the `Simulink.Simulation.Future` objects.

### SetupFcn — Function handle to run once per worker

function handle

Specify a function handle to `'SetupFcn'` to run once per worker before the start of the simulations.

Example: `'SetupFcn',@( )currentProject('Modelex/Model_example.prj')`

---

**Note** When `buildRapidAcceleratorTarget` is used in the `SetupFcn` and the model has external inputs specified, either set `'LoadExternalInput'` to `'off'` or ensure that the specified external input is available on the workers to prevent compilation error.

---

### CleanupFcn — Function handle to run once per worker after running simulations

function handle

Specify a function handle to 'CleanupFcn' to run once per worker after the simulations are completed.

**ManageDependencies — Manage model dependencies**

'on' (default) | 'off'

When `ManageDependencies` is set to `on`, model dependencies are automatically sent to the parallel workers if required. If `ManageDependencies` is set to `off`, explicitly attach model dependencies to the parallel pool.

**UseFastRestart — Use fast restart**

'off' (default) | 'on'

When `UseFastRestart` is set to `on`, simulations run on the workers using fast restart.

When performing a parameter sweep varying properties of a Simscape component (e.g. mass and inertia of a Solid block in Simscape Multibody), specify the Simscape block parameter as run-time configurable. For more information, see “About Simscape Run-Time Parameters” (Simscape).

---

**Note** When using `parsim`, use the `UseFastRestart` option and not the `FastRestart` option. See “Get Started with Fast Restart” for more information.

`parsim` in fast restart mode does not support models with `ToFile` blocks.

---

**TransferBaseWorkspaceVariables — Transfer variables to the parallel workers**

'off' (default) | 'on'

When `TransferBaseWorkspaceVariables` is set to `on`, variables used in the model and everything defined in the base workspace are transferred to the parallel workers.

**ShowSimulationManager — Starts the Simulation Manager app**

'off' (default) | 'on'

When 'ShowSimulationManager' is set to 'on', you can use the Simulation Manager App to monitor simulations.

**StopOnError — Stop simulations on errors**

'off' (default) | 'on'

Setting 'StopOnError' to 'on' stops the execution of simulations if an error is encountered.

## Output Arguments

**simOut — Simulation object containing logged simulation results**

object

Array of `Simulink.SimulationOutput` objects that contains all of the logged simulation results. The size of the array is equal to the size of the array of `Simulink.SimulationInput` objects.

All simulation outputs (logged time, states, and signals) are returned in a single `Simulink.SimulationOutput` object. You define the model time, states, and output that is logged using the **Data Import/Export** pane of the Model Configuration Parameters dialog box. You can log

signals using blocks such as the To Workspace and Scope blocks. The **Signal & Scope Manager** can directly log signals.

## Version History

Introduced in R2017a

## Extended Capabilities

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

If you have Parallel Computing Toolbox installed, then when you use `parsim`, MATLAB automatically opens a parallel pool of workers on your local machine. MATLAB runs the simulations across the available workers. Control parallel behavior with the parallel preferences, including scaling up to a cluster.

For details, see “Running Multiple Simulations”.

## polyspacePackNGo

Generate and package options files to run Polyspace analysis on code generated from Simulink model

### Syntax

```
archivePath = polyspacePackNGo mdlName)
archivePath = polyspacePackNGo mdlName, psOpt)
archivePath = polyspacePackNGo mdlName, psOpt, asModelRef)
```

### Description

`archivePath = polyspacePackNGo mdlName)` examines the Simulink model `mdlName`, extracts Polyspace® options files from it, and packages the options files in the zip file located at `archivePath`. Before using `polyspacePackNGo`, generate code from your Simulink model. Then archive the generated code, for instance, by using `packNGo`. Generate the Polyspace options files from the Simulink model and include them in the code archive by using `polyspacePackNGo`. In a different development environment, when running a Polyspace analysis of the generated code, use the options files included in the code archive to preserve model-specific information, such as design range specifications. You must have Embedded Coder to use `slbuild`.

`archivePath = polyspacePackNGo mdlName, psOpt)` generates and packages the Polyspace options files that are generated according to the specification in `psOpt`. The object `psOpt` must be a Polyspace options object that is generated by using `pslinkoptions`. Using `psOpt`, modify the options for the Polyspace analysis.

`archivePath = polyspacePackNGo mdlName, psOpt, asModelRef)` generates and packages the Polyspace options files by using `asModelRef` to specify whether to generate option files for model reference code or standalone code.

### Examples

#### Generate and Package Polyspace Options Files

To generate and package Polyspace options files for a Simulink model, use `polyspacePackNGo`.

Open the Simulink model `rtwdemo_counter` and specify a folder for storing the generated code.

```
% Make temporary folders for code generation
[TEMPDIR, CGDIR] = rtwdemodir();
% Open the model
mdlName = 'rtwdemo_counter';
open_system(mdlName);
% Specify a folder for generated code
codegenFolder = 'rtwdemo_counter_ert_rtw';
```

To enable packing the generated code in an archive, set the option `PackageGeneratedCodeAndArtifacts` to `true`. Specify the name of the generated code archive as `genCodeArchive.zip`.

```
configSet = getActiveConfigSet mdlName);
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
```

To make the model compatible with Polyspace, set `SystemTargetFile` to `ert.tlc`.

```
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate code.

```
slbuild mdlName)
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

Generate and package Polyspace options files.

```
zipFile = polyspacePackNGo mdlName);
```

In the code archive `genCodeArchive.zip`, the Polyspace options files are packaged in the `polyspace` folder.

### Package Polyspace Options Files That Have Specific Polyspace Analysis Options

To specify the Polyspace analysis options when packaging and generating options files, use `pslinktoptions`.

Open the Simulink model `rtwdemo_counter` and configure the model for generating a code archive that is compatible with Polyspace.

```
% Make temporary folders for code generation
[TEMPDIR, CGDIR] = rtwdemodir();
% Open the model
mdlName = 'rtwdemo_counter';
open_system mdlName);
% Specify a folder for generated code
codegenFolder = 'rtwdemo_counter_ert_rtw';
configSet = getActiveConfigSet mdlName);
% Enable packing the generated code into an archive
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
% Specify a name for the code archive
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
% Configure the model to be Polyspace Compatible
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate code.

```
slbuild mdlName)
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

To specify the model configuration for the Polyspace analysis, use a `pslinktoptions` object. Create this object by using the function `pslinktoptions`.

```
psOpt = pslinktoptions mdlName);
```

The object `psOpt` is a structure where the fields are model configurations that you can specify.

Specify the model configuration by using `psOpt` object. For instance, set `InputRangeMode` to full range. For a full options list, see the input argument `psOpt`.

```
psOpt.InputRangeMode = 'FullRange';
```

Generate and package Polyspace options files. Use the `psOpt` object as the second argument in `polyspacePackNGo`.

```
zipFile = polyspacePackNGo mdlName, psOpt);
```

In the code archive `genCodeArchive.zip`, the Polyspace options files are packaged in the `polyspace` folder. The file `optionsFile.txt` contains the specified Polyspace analysis options.

### Package Polyspace Options Files for Code Generated as a Model Reference

To accelerate model simulations, invoke referenced Simulink models as simulation targets. To generate model reference simulation targets from a Simulink model, generate code from the model by using `slbuild` with the build process specified as `ModelReferenceCoderTarget`. Then, package the generated code by using `packNGo`. To generate and package Polyspace options files for analyzing such code, use the function `polyspacePackNGo` with the optional argument `asModelRef` set to `true`.

Open the Simulink model `rtwdemo_counter` and configure the model for generating a code archive that is compatible with Polyspace.

```
% Make temporary folders for code generation
[TEMPDIR, CGDIR] = rtwmoddir();
% Load model
mdlName = 'rtwdemo_counter';
load_system(mdlName);
configSet = getActiveConfigSet(mdlName);
% Enable packing the generated code into an archive
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', '');
% Configure the model to be Polyspace Compatible
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
```

After configuring the model, generate a model reference simulation target from it by using the function `slbuild`. Specify the option `ModelReferenceCoderTarget`. See `slbuild`.

```
slbuild(mdlName, 'ModelReferenceCoderTarget');
```

The code that is generated is stored in the folder `slprj`.

To package the code that is generated as a model reference, use the function `packNGo`. Locate the file `buildinfo.mat` in `<working folder>/slprj/ert/rtwdemo_counter` and use the full path to it as the input to `packNGo`. This command generates an archive containing the generated code and the object `buildinfo.mat`. See `packNGo`.

```
% Locate buildinfo and generate code archive
buildinfo = fullfile(pwd, 'slprj', 'ert', mdlName, 'buildinfo.mat');
packNGo(buildinfo)
```

Generate and package Polyspace options files. Omit the optional second argument. Set the third argument `asModelRef` to `true`.

```
zipFile = polyspacePackNGo mdlName, [], true);
```

In the code archive `rtwdemo_counter.zip`, the Polyspace options files are packaged in the `polyspace` folder.

## Input Arguments

### **mdlName** — Name of Simulink model for which to generate Polyspace options files

model name

A character array containing the name of the model for which you want to generate and package the Polyspace options files.

Example: `polyspacePackNGo('rtwdemo_roll')`

Data Types: `char`

### **psOpt** — Polyspace options object

options associated with `model` (default) | object created by using `pslinkoptions`

Specifies the model configuration for the Polyspace analysis by using a `pslinkoptions` object. You can modify certain analysis options by modifying `psOpt`, which is a structure where individual fields represent analysis options. For a full list of options that you can modify, see the table **Polyspace Analysis Options Supported by polyspacePackNGo**.

**Polyspace Analysis Options Supported by polyspacePacknGo**

| Property                                                                                                                                                                     | Value                          | Description                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EnableAdditionalFileList: Enable an additional file list to be analyzed, specified as true or false. Use with the AdditionalFileList option.                                 | true                           | Polyspace verifies additional files specified in the AdditionalFileList option.                                                                                                  |
|                                                                                                                                                                              | false (default)                | Polyspace does not verify additional files.                                                                                                                                      |
| AdditionalFileList: List of additional files to be analyzed specified as a cell array of files. To add these files to the analysis, use the EnableAdditionalFileList option. | cell array                     | Polyspace considers the listed files for verification.                                                                                                                           |
| InputRangeMode: Specifies the range of the input variables.                                                                                                                  | 'DesignMinMax' (default)       | Polyspace uses the input range defined in the workspace or a block.                                                                                                              |
|                                                                                                                                                                              | 'Fullrange'                    | Polyspace uses full range inputs.                                                                                                                                                |
| ParamRangeMode: Specifies the range of the constant parameters.                                                                                                              | 'DesignMinmax'                 | Polyspace uses the constant parameter range defined in the workspace or in a block.                                                                                              |
|                                                                                                                                                                              | 'None' (default)               | Polyspace uses the value of parameters specified in the code.                                                                                                                    |
| OutputRangeMode: Specifies the output assertions.                                                                                                                            | 'DesignMinMax'                 | Polyspace applies assertions to outputs by using a range defined in a block or the workspace.                                                                                    |
|                                                                                                                                                                              | 'None' (default)               | Polyspace does not apply assertions to the output variables.                                                                                                                     |
| ModelRefVerifDepth: Specify the depth for analyzing the models that are referenced by the current model.                                                                     | 'Current model Only' (default) | Polyspace analyzes only the top model without analyzing the referenced models. Use this option when you refer to models that do not need to be analyzed, such as library models. |

| Property                                                                                                               | Value              | Description                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                        | '1'   '2'   '3'    | Polyspace analyzes referenced models up to the specified depth in the reference hierarchy. To analyze the models that are referenced by the top model, specify the property <code>ModelRefVerifDepth</code> as '1'. To analyze models that are referenced by the first level of references, specify this property as '2'. |
|                                                                                                                        | 'All'              | Polyspace verifies all referenced models.                                                                                                                                                                                                                                                                                 |
| ModelRefByModelRefVerif:<br>Specify whether you want to analyze all referenced models together or individually.        | true               | Polyspace analyzes the top model and the referenced models together. Use this option to check for integration or scaling issues.                                                                                                                                                                                          |
|                                                                                                                        | false (default)    | Polyspace analyzes the top model and the referenced models individually.                                                                                                                                                                                                                                                  |
| AutoStubLUT: Specifies how lookup tables are used.                                                                     | true (default)     | Polyspace stubs the lookup tables and verifies the model without analyzing the lookup table code.                                                                                                                                                                                                                         |
|                                                                                                                        | false              | Polyspace includes the lookup table code in the analysis.                                                                                                                                                                                                                                                                 |
| CheckConfigBeforeAnalysis:<br>Specifies the level of configuration checking done before the Polyspace analysis starts. | 'Off'              | Polyspace checks only for errors. The analysis stops if errors are found.                                                                                                                                                                                                                                                 |
|                                                                                                                        | 'OnWarn' (default) | Polyspace stops the analysis when errors are found and displays a message when warnings are found.                                                                                                                                                                                                                        |
|                                                                                                                        | 'OnHalt'           | Polyspace stops the analysis when either errors or warnings are found.                                                                                                                                                                                                                                                    |

Example: `polyspacePackNGo('rtwdemo_roll', psOpt)`, where `ps_opt` is an options object created by calling `pslinkoptions`

**asModelRef – Indicator for model reference analysis**

false (default) | true

Indicator for model reference analysis, specified as true or false.

- If `asModelRef` is false (default), the function generates options files so that Polyspace analyzes the generated code as standalone code.

- If `asModelRef` is `true`, the function generates options files so that Polyspace analyzes the generated code as model reference code.

---

**Note** If you set `asModelRef` to `true`, use `slbuild` to generate code.

---

Example: `polyspacePackNGo('rtwdemo_roll', psOpt,true)`

Data Types: `logical`

## Output Arguments

**archivePath** — The full path to the archive containing the generated options files

path to archive

A character array containing the path to the generated archive. The options files are located in the `polyspace` folder in the archive. The `polyspace` folder contains these options files:

- `optionsFile.txt`: a text file containing the Polyspace options required to run a Polyspace analysis on the generated code without losing model-specific information, such as design range specification.
- `model_drs.xml`: A file containing the design range specification of the model.
- `linksData.xml`: A file that links the generated code to the components of the model.

To run a Polyspace analysis on the generated code in an environment that is different than the environment where the code was generated from the Simulink model, use these files.

Data Types: `char`

## Version History

Introduced in R2020b

### Topics

“Run Polyspace Analysis on Generated Code by Using Packaged Options Files” (Polyspace Bug Finder)

## pslinkoptions

Create an options object to customize configuration of a Simulink model, generated code or a S-Function block. Use the object to specify configuration options for these Simulink objects in a Polyspace run from the MATLAB command line

### Syntax

```
opts = pslinkoptions(codegen)
opts = pslinkoptions(model)
opts = pslinkoptions(sfunc)
```

### Description

`opts = pslinkoptions(codegen)` returns an options object with the configuration options for code generated by codegen.

`opts = pslinkoptions(model)` returns an options object with the configuration options for the Simulink model.

`opts = pslinkoptions(sfunc)` returns an options object with the configuration options for the S-Function.

---

**Note** Before you run Polyspace from MATLAB, you must link your Polyspace and MATLAB installations. See “Integrate Polyspace with MATLAB and Simulink” (Polyspace Bug Finder).

---

### Examples

#### Create generic options object for code generated by Embedded Coder

This example shows how you can create a generic Polyspace options object that is suitable for analyzing code generated by using Embedded Coder. This options object is prepopulated with appropriate Embedded Coder parameters. Edit the options object to modify the generic analysis.

Create a new Polyspace configuration object `new_opt` by calling the function `pslinkoptions` and specify `'ec'` as the input argument.

```
new_opt = pslinkoptions('ec')
new_opt =
 ResultDir: 'results_ $ModelName$'
 VerificationSettings: 'PrjConfig'
 OpenProjectManager: 0
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
```

```

 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 ModelRefVerifDepth: 'Current model only'
 ModelRefByModelRefVerif: 0
 AutoStubLUT: 1
 CxxVerificationSettings: 'PrjConfig'
 CheckConfigBeforeAnalysis: 'OnWarn'
 VerifAllSFcnInstances: 0

```

By default, this options object uses the same verification settings that you specify in the Polyspace project. To check MISRA C® 2012 coding rule violations in addition to the existing verifications specified in the project, run this code at the MATLAB command line:

```
new_opt.VerificationSettings = 'PrjConfigAndMisraC2012'
```

```
new_opt =
```

```

 ResultDir: 'results_ $ModelName$'
 VerificationSettings: 'PrjConfigAndMisraC2012'
 OpenProjectManager: 0
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 ModelRefVerifDepth: 'Current model only'
 ModelRefByModelRefVerif: 0
 AutoStubLUT: 1
 CxxVerificationSettings: 'PrjConfig'
 CheckConfigBeforeAnalysis: 'OnWarn'
 VerifAllSFcnInstances: 0

```

When you start the Polyspace analysis of the generated code, you might want to open the Polyspace User Interface to follow the progress of the and to review the results afterwards. To open the Polyspace interface when you start the analysis, run this code:

```
new_opt.OpenProjectManager = true
```

```
new_opt =
```

```

 ResultDir: 'results_ $ModelName$'
 VerificationSettings: 'PrjConfigAndMisraC2012'
 OpenProjectManager: 1
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0

```

```

 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 ModelRefVerifDepth: 'Current model only'
 ModelRefByModelRefVerif: 0
 AutoStubLUT: 1
 CxxVerificationSettings: 'PrjConfig'
 CheckConfigBeforeAnalysis: 'OnWarn'
 VerifAllSFcnInstances: 0

```

### Create and edit options object to modify Polyspace configuration

This example shows how you can store the Polyspace configurations of a Simulink model in to an object, and use the object to edit the configuration options.

Load the model `closed_loop_control`.

```
load_system('closed_loop_control');
```

To create an object containing the Polyspace configurations of the model, call `pslinkoptions`.

```
model_opt = pslinkoptions('closed_loop_control')
```

```
model_opt =
```

```

 ResultDir: 'results_ $ModelName$'
 VerificationSettings: 'PrjConfig'
 OpenProjectManager: 0
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 ModelRefVerifDepth: 'Current model only'
 ModelRefByModelRefVerif: 0
 AutoStubLUT: 1
 CxxVerificationSettings: 'PrjConfig'
 CheckConfigBeforeAnalysis: 'OnWarn'
 VerifAllSFcnInstances: 0

```

The model is already configured for Embedded Coder®, so only the Embedded Coder configuration options appear as the fields of the object `model_opt`.

To modify a Polyspace configuration option, set the corresponding field of `model_opt`. For instance, change the results directory and set the verification mode to `CodeProver` by modifying fields : `model_opt.ResultDir` and `model_opt.VerificationMode`, respectively.

```
model_opt.ResultDir = 'results_v1_ $ModelName$';
model_opt.VerificationMode = 'CodeProver'
```

```

model_opt =
 ResultDir: 'results_v1_$ModelName$'
 VerificationSettings: 'PrjConfig'
 OpenProjectManager: 0
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 ModelRefVerifDepth: 'Current model only'
 ModelRefByModelRefVerif: 0
 AutoStubLUT: 1
 CxxVerificationSettings: 'PrjConfig'
 CheckConfigBeforeAnalysis: 'OnWarn'
 VerifAllSFcnInstances: 0

```

### Create and edit an options object for TargetLink at the command line

Create a Polyspace® options object called `new_opt` with TargetLink® parameters:

```

new_opt = pslinkoptions('tl')
new_opt =

```

```

 ResultDir: 'results_$ModelName$'
 VerificationSettings: 'PrjConfig'
 OpenProjectManager: 0
 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 AutoStubLUT: 1

```

Set the `OpenProjectManager` option to true to follow the progress in the Polyspace interface. Also change the configuration to check for both run-time errors and MISRA C® coding rule violations:

```

new_opt.OpenProjectManager = true;
new_opt.VerificationSettings = 'PrjConfigAndMisra'
new_opt =
 ResultDir: 'results_$ModelName$'
 VerificationSettings: 'PrjConfigAndMisra'
 OpenProjectManager: 1

```

```

 AddSuffixToResultDir: 0
 EnableAdditionalFileList: 0
 AdditionalFileList: {}
 VerificationMode: 'CodeProver'
 EnablePrjConfigFile: 0
 PrjConfigFile: ''
 AddToSimulinkProject: 0
 InputRangeMode: 'DesignMinMax'
 ParamRangeMode: 'None'
 OutputRangeMode: 'None'
 AutoStubLUT: 1

```

## Input Arguments

### **codegen** — Code generator

'ec' | 'tl'

Code generator, specified as either 'ec' for Embedded Coder or 'tl' for TargetLink®. Each argument creates a Polyspace options object with properties specific to that code generator.

For a description of all configuration options and their values, see `pslinkoptions`.

Example: `ec_opt = pslinkoptions('ec')`

Example: `tl_opt = pslinkoptions('tl')`

Data Types: char

### **model** — Simulink model name

model name

Simulink model, specified by the model name. Creates a Polyspace options object with the configuration options of that model. If you have not set any options, the object has the default configuration options. If you have set a code generator, the object has the default options for that code generator.

For a description of all configuration options and their values, see `pslinkoptions`.

Example: `model_opt = pslinkoptions('my_model')`

Data Types: char

### **sfunc** — path to S-Function

character vector

Path to S-Function, specified as a character vector. Creates a Polyspace options object with the configuration options for the S-function. If you have not set any options, the object has the default configuration options.

For a description of all configuration options and their values, see `pslinkoptions`.

Example: `sfunc_opt = pslinkoptions('path/to/sfunction')`

Data Types: char

## Output Arguments

### **opts** — Polyspace configuration options

options object

Polyspace configuration options, returned as an options object. The object is used with `pslinkrun` to run Polyspace from the MATLAB command line.

For the list of object properties, see `pslinkoptions`.

```
Example: opts= pslinkoptions('ec')
opts.VerificationSettings = 'Misra'
```

## Version History

# rehashUnitDBs

Refresh unit database files on MATLAB path

## Syntax

rehashUnitDBs

## Description

rehashUnitDBs refreshes unit database files on the MATLAB path. To load a custom unit database, use this function in conjunction with the createCustomDBFromExcel function.

The rehashUnitDBs function:

- Clears all previously loaded custom units in memory.
- Resets the set of supported units to the built-in set of units.
- Looks for database files with the extension `.slunitdb.mldtax` on the MATLAB path and loads those databases.
- Issues warnings if units with the same names are loaded. If units have several definitions with the same name in different databases, by default the function tries to use the definition in a built-in units databases. If the unit is not defined in a built-in database, the function uses the definition in the database highest on the MATLAB path.

To see the supported spreadsheet format, see “Custom Units Spreadsheet Format”.

## Examples

### Create Custom Units Database File from Excel Spreadsheet

Create a custom units database file from custom Excel spreadsheet file, `unitsDB.xlsx`.

Create a Excel spreadsheet containing these columns and data in any order:

- **name**, containing `ounce_force`
- **symbol**, containing `oz f`
- **asciiSymbol**, containing `oz f`
- **displayName**, containing `{\rm{oz}_{force}}`
- **definitionExpression**, containing `oz*gn`
- **conversionFactor**, containing `1`
- **conversionOffset**, containing `0`
- **physicalQuantity**, containing `force`

Enter your custom unit specifications.

Save the database file, for example `unitsDB.xlsx`.

Create the database.

```
createCustomDBFromExcel('unitsDB.xlsx')
```

The function creates `unitsDB.slunitdb.mldatx` in the current folder.

Add the current folder to the MATLAB path.

```
addpath C:\work\custom_units
```

Load the new units database into memory.

```
rehashUnitDBs
```

## Version History

Introduced in R2020a

# replace\_block

Replace blocks in Simulink model

## Syntax

```
replBlks = replace_block(sys,current,new)
replBlks = replace_block(sys,Name,Value,new)
replBlks = replace_block(____, 'noprompt')
```

## Description

`replBlks = replace_block(sys,current,new)` replaces the blocks `current` in the model `sys` with blocks of type `new`.

You can use a block from a Simulink library or from another model as the replacement block.

The `replace_block` function prompts you to select the blocks you want to replace from a list of blocks that match the `current` argument.

Before using the `replace_block` function:

- Load the model `sys`. For more information on how to load a model, see `load_system` and `open_system`.
- If the library containing the new block with which you want to replace the current block is not loaded, load the library. For example, to replace the current block with a Message Triggered Subsystem block, load the **Simulink** library by entering this command in the MATLAB Command Window:

```
load_system('simulink.slx');
```

---

**Tip** Save the model before replacing blocks.

---

`replBlks = replace_block(sys,Name,Value,new)` replaces the blocks that match the block parameters specified by the `Name,Value` pair arguments. You can also use `find_system` `Name,Value` pairs to qualify the search for blocks to replace.

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

With the `replace_block` function, you can use block parameter and value pairs. For a list of all the block parameters, see “Common Block Properties” on page 6-12 and “Block-Specific Parameters” on page 6-24.

To specify additional information about the search for blocks to replace, you use `find_system` `Name,Value` pairs before the block parameters. For example, you can use

'CaseSensitive', 'off' to make the search for blocks case insensitive or 'FollowLinks', 'on' to follow links into library links. See `find_system` for that list of Name, Value pairs.

`replBlks = replace_block( ___, 'noprompt' )` replaces the blocks without prompting you to select them from a dialog box.

## Examples

### Replace Blocks in a Model

Replace blocks in the 'vdp' model.

Load the model 'vdp'.

```
load_system('vdp');
```

Replace Gain blocks with Integrator blocks.

```
RepNames = replace_block('vdp','Gain','Integrator');
```

A dialog box prompts you to select the blocks you want to replace.

With vdp/Mu selected in the dialog box, click **OK**.

Replace Scope blocks with To Workspace blocks.

```
RepNames = replace_block('vdp','Scope','simulink/Sinks/To Workspace');
```

A dialog box prompts you to select the blocks you want to replace.

With vdp/Scope selected in the dialog box, click **OK**.

To replace blocks in the model with blocks from the **Simulink Extras** library, load the **Simulink Extras** library.

```
load_system('simulink_extras.slx');
```

Replace Integrator blocks with Transfer Fcn (with initial states) blocks from the **Simulink Extras** library.

```
RepNames = replace_block('vdp','Integrator','simulink_extras/Additional Linear/Transfer Fcn (w/
```

A dialog box prompts you to select the blocks you want to replace.

With vdp/Mu, vdp/x1, and vdp/x2 selected in the dialog box, click **OK**.

### Replace Blocks in a Subsystem Using Parameter Values

Replace blocks in the Unlocked subsystem of the `sldemo_clutch` model. Replace blocks whose Gain parameter is set to `bv`.

Load the model `sldemo_clutch`.

```
openExample('sldemo_clutch');
```

In the 'Unlocked' subsystem, replace blocks whose Gain value is bv with Integrator blocks.

```
replace_block('sldemo_clutch/Unlocked','Gain','bv','Integrator');
```

A dialog box prompts you to select the blocks to replace.

With sldemo\_clutch/Unlocked/VehicleDamping selected in the dialog box, click **OK**.

### Replace Blocks Without Dialog Box

Load the model f14.

```
load_system('f14')
```

Replace Gain blocks with Integrator blocks. The command returns the blocks it found to replace and replaces the blocks.

```
repl = replace_block('f14','Gain','Integrator','noprompt')
```

```
repl = 13x1 cell
 {'f14/Aircraft...' }
 {'f14/Aircraft...' }
 {'f14/Aircraft...' }
 {'f14/Aircraft...' }
 {'f14/Controller/Gain' }
 {'f14/Controller/Gain2' }
 {'f14/Controller/Gain3' }
 {'f14/Gain' }
 {'f14/Gain1' }
 {'f14/Gain2' }
 {'f14/Gain5' }
 {'f14/Nz pilot...' }
 {'f14/Nz pilot...' }
```

### Use find\_system Pairs with replace\_block

Select a block that is a library link. Follow the library links and replace Gain blocks with Integrator blocks within them.

```
replace_block(gcb, 'FollowLinks', 'on', 'BlockType', 'Gain', 'Integrator', 'noprompt')
```

## Input Arguments

### sys — Model or subsystem whose blocks to replace

character vector

Name of model whose blocks to replace, specified as a character vector. If you specify a model, the command replaces all blocks that match in the model. If you specify a subsystem, the command replaces blocks in that subsystem and below.

Example: 'vdp', 'sldemo\_fuelsys/fuel\_rate\_control'

**current — Type of block to replace**

BlockType value | MaskType value

Type of block to replace, specified as a **BlockType** or **MaskType** value. To find out the block type, select the block and, at the command prompt, enter:

```
get_param(gcb, 'BlockType')
```

For masked blocks, to find out the mask type, select the block and enter:

```
get_param(gcb, 'MaskType')
```

**new — Block to replace current blocks**

BlockType value | MaskType value | library path | block path name from a model

Block to replace the current block, specified in one of these forms:

- **BlockType** value of the replacement block. Specifying this value uses a library block as the replacement block.
- **MaskType** value of the replacement block. Specifying this value uses a library block as the replacement block.
- Library path of the replacement block, for example, 'simulink/Sinks/To Workspace'. Hover over the block in the library to see the library path.
- Block path name of a block from a different model, for example, 'vdp/Mu'. Use this value to reuse an instance of a block from another model in your model.

**Output Arguments****replBlks — Blocks returned by the current argument**

cell array of character vectors

Blocks returned by the **current** argument, returned as a cell array of character vectors. The function returns the values regardless of whether you complete the replacement.

**Version History****Introduced before R2006a****See Also**

"Block-Specific Parameters" on page 6-24

# save\_system

Save Simulink model

## Syntax

```
filename = save_system
filename = save_system(sys)
filename = save_system(sys,newsys)
filename = save_system(sys,Name,Value)
filename = save_system(sys,newsys,Name,Value)
```

## Description

`filename = save_system` saves the current top-level model. If the model was not previously saved, `save_system` creates a file in the current folder.

To save a subsystem, instead use `Simulink.SubSystem.copyContentsToBlockDiagram` to copy the subsystem contents to a new model. You can then save that model using `save_system`. See `Simulink.SubSystem.copyContentsToBlockDiagram`.

`filename = save_system(sys)` saves the model `sys`. The model must be open or loaded.

`filename = save_system(sys,newsys)` saves the model to a new file `newsys`. If you do not specify an extension, then `save_system` uses the file format specified in your Simulink preferences.

`filename = save_system(sys,Name,Value)` saves the system with additional options specified by one or more `Name,Value` pair arguments.

`filename = save_system(sys,newsys,Name,Value)` saves the system to a new file with additional options specified by one or more `Name,Value` pair arguments. To use `Name,Value` pairs without saving to a new file, use `[]` for `newsys`.

## Examples

### Save Named Model

Create a model.

```
new_system('newmodel')
```

Save the model.

```
save_system('newmodel')
```

### Save Model with Another Name

Open the model `vdp`. Save it to a model named `myvdp` in the current folder. Without a file extension, the function saves the model using the format specified in your Simulink preferences.

```
open_system('vdp')
save_system('vdp','myvdp')
```

After you save the model by another name, the model is no longer open under its original name. Open `vdp` again and save it as an `.mdl` file in the current folder.

```
open_system('vdp')
save_system('vdp','mynewvdp.mdl')
```

### Return Error If Name Exists

Save a model with a new name and return an error if something with this name exists on the MATLAB path. In this case, `save_system` displays an error because `max` is the name of a MATLAB function. The model is not saved.

```
open_system('vdp')
save_system('vdp','max','ErrorIfShadowed',true)
```

```
Error using save_system (line 38)
The model 'vdp' cannot be saved with the new name 'max', because this name is
shadowing another name on the MATLAB path or in the workspace. Choose another
name, or do not use the option 'ErrorIfShadowed'
```

### Save Model with Options

Suppose that you have a model named `mymodel`. Open the model and save it to a model named `newmodel`. Also save the model workspace, break links to user-defined library blocks, and overwrite if the file has changed on disk,

```
open_system('mymodel')
save_system('mymodel','mynewmodel','SaveModelWorkspace',
true,'BreakUserLinks',true,'OverwriteIfChangedOnDisk',true)
```

### Save Model to Same Name and Use Options

Save the model `mymodel`, breaking links to user-defined library blocks in the model.

```
save_system('mymodel','BreakUserLinks',true)
```

## Input Arguments

### **sys** — Name of model to save

character vector | cell array of character vectors | string array | handle | array of handles

Name of model to save, specified as a character, cell array of character vectors, string array, handle, or array of handles. Do not use a file extension.

### **newsys** — File to save to

character vector | cell array of character vectors | string array | [ ]

File to save to, specified as a character vector, cell array of character vectors, string array, or, to use `Name, Value` pairs without changing the file name, [ ]. You can specify a model name in the current folder or the full path name, with or without an extension.

With no an extension, `save_system` saves to the file format specified in your Simulink preferences. Possible model extensions are `.slx` and `.mdl`. With the 'ExportToXML' option, use the extension `.xml`.

For information on rules for naming models, see “Choose Valid Model File Names”.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

```
save_system('mymodel', 'newmodel', 'SaveModelWorkspace', true, 'BreakUserLinks', true, 'OverwriteIfChangedOnDisk', true)
```

### AllowPrompt — Allow dialog box prompts

false (default) | true | 'on' | 'off'

Option to allow dialog box prompts, specified as `true`, `false`, `'on'`, or `'off'`. By default, warnings and error messages appear at the command line.

### BreakAllLinks — Replace links to library blocks

false (default) | true | 'on' | 'off'

Option to, in the saved file, replace links to library blocks with copies of the library blocks, specified as `true`, `false`, `'on'`, or `'off'`. This option affects user-defined blocks and Simulink library blocks.

---

**Caution** The 'BreakAllLinks' option can result in compatibility issues when upgrading to newer versions of Simulink. For example:

- Any masks on top of library links to Simulink S-functions do not upgrade to the new version of the S-function.
- Any library links to masked subsystems in a Simulink library do not upgrade to the new subsystem behavior.
- Any broken links prevent the library forwarding mechanism from upgrading the link. See “Maintain Compatibility of Library Blocks Using Forwarding Tables”.

If you saved a model with broken links to built-in libraries, use the Upgrade Advisor to scan the model for out-of-date blocks. Then upgrade the Simulink blocks to their current versions.

---

### BreakUserLinks — Replace links to user-defined blocks

false (default) | true | 'on' | 'off'

Option to, in the saved file, replace links to user-defined library blocks with copies of the library blocks, specified as `true`, `false`, `'on'`, or `'off'`.

### BreakToolboxLinks — Replace links to built-in library block

false (default) | true | 'on' | 'off'

Option to, in the saved file, replace links to built-in library blocks with copies of the library blocks, specified as `true`, `false`, `'on'`, or `'off'`. This option affects Simulink library blocks and blocks from libraries supplied with MathWorks toolboxes or blocksets.

#### **ErrorIfShadowed — Return an error if name exists**

`false` (default) | `true` | `'on'` | `'off'`

Option to return an error if the new name exists on the MATLAB path or workspace, specified as `true`, `false`, `'on'`, or `'off'`.

#### **ExportToXML — Export model to XML format**

`false` (default) | `true` | `'on'` | `'off'`

Option to export the model to a file in a simple XML format, specified as `true`, `false`, `'on'`, or `'off'`. Specify the full name of the file, including the `.xml` extension. The block diagram in memory does not change and no callbacks execute. Use this option without any other `Name, Value` pair arguments. This option warns and will be removed in a future release.

Example: `save_system('mymodel', 'exportfile.xml', 'ExportToXML', true)`

#### **ExportToVersion — MATLAB release name to export to**

character vector | string scalar

MATLAB release name to export to, specified in either of these forms (not case sensitive). You can export to seven years of previous releases.

- Release name, for example, `'R2013B'`, `'R2016B'`
- Release name, followed by an underscore and then the extension, for example, `'R2016A_SLX'`, `'R2014A_MDL'`. If you do not specify an extension, you export to the file format specified in your Simulink preferences.

`save_system` exports the system such that the specified Simulink version can load it. If the system contains functionality not supported by the specified Simulink version, the command removes the functionality in the exported file. It also replaces unsupported blocks with empty masked subsystem blocks colored yellow. As a result, the exported system might generate different results.

Alternatively, use `Simulink.exportToVersion` or, interactively, the Export to Previous Version dialog box.

To export a project to previous releases, see “Export a Project to a Previous Version” on page 2-607.

#### **OverwriteIfChangedOnDisk — Overwrite file**

`false` (default) | `true` | `'on'` | `'off'`

Option to overwrite the file on disk even if it has been modified since the system was loaded, specified as `true`, `false`, `'on'`, or `'off'`. By default, if the file changed on disk since the model was loaded, `save_system` displays an error to prevent the changes on disk from being overwritten.

You can control whether `save_system` displays an error if the file has changed on disk using a Simulink preference. In the **Model File** pane of the Simulink Preferences dialog box, under **Change Notification**, select **Saving the model**. This preference is on by default.

#### **SaveDirtyReferencedModels — Save referenced models with unsaved changes**

`false` (default) | `true` | `'on'` | `'off'`

Option to save referenced models that have unsaved changes while saving changes to their parent model, specified as `true`, `false`, `'on'`, or `'off'`. This option applies to models that are directly referenced by each model that is saved. If the parent model of a dirty referenced model is not saved, the dirty referenced model is not saved.

Suppose you have a model hierarchy in which model A references model B, and model B references model C. If models B and C both have unsaved changes, they are both saved. If model C has unsaved changes but model B does not have unsaved changes, neither model is saved.

By default, attempting to save a model that contains unsaved referenced models return an error.

### **SaveModelWorkspace — Save model workspace**

`false` (default) | `true` | `'on'` | `'off'`

Option to save the contents of the model workspace, specified as `true`, `false`, `'on'`, or `'off'`. The model workspace `DataSource` must be a MAT-file. If the data source is not a MAT-file, `save_system` does not save the workspace. See “Specify Source for Data in Model Workspace”.

## **Output Arguments**

### **filename — Name of saved file**

character vector | cell array of character vectors

Full name of saved file, returned as a character vector or a cell array of character vectors.

## **Version History**

**Introduced before R2006a**

### **See Also**

### **Topics**

“Save Models”

## set\_param

Set Simulink parameter value

### Syntax

```
set_param(object,parameter1,value1,...,parameterN,valueN)
```

### Description

`set_param(object,parameter1,value1,...,parameterN,valueN)` sets the specified Simulink parameter `parameter` to the specified value `value` for the target object specified by `object`. The target object can be a model, subsystem, library, block, line, port, or bus element port element.

To set multiple parameter values for the target object, call the `set_param` function once with multiple name-value arguments instead of separately calling the function for each parameter. Setting multiple parameters with one function call is efficient because one call evaluates the parameters only once. If any parameter names or values are invalid, then the function does not set any parameters.

### Examples

#### Set Configuration Parameters of Model

Open the `vdp` model and set the **Solver** and **StopTime** parameter values.

```
vdp
set_param('vdp','Solver','ode15s','StopTime','3000')
```

#### Set Configuration Parameters of Current Model

Open a model and set the **Solver** and **StopTime** parameters. Use the `bdroot` function to get the current top model.

```
vdp
set_param(bdroot,'Solver','ode15s','StopTime','3000')
```

#### Set Gain Block Parameter Value

Open `vdp` and set the **Gain** parameter value of the Gain block named `Mu`.

```
vdp
set_param('vdp/Mu','Gain','10')
```

## Set Position of Block

Open vdp and set the position of the Gain block named Mu.

```
vdp
set_param('vdp/Mu','Position',[50 100 110 120])
```

## Set Position of Block Using a Handle

Set the position of the Gain block named Mu in the vdp model using the block handle.

To get a handle to the Gain block named Mu, use the `getSimulinkBlockHandle` function. To load the vdp model, specify `true`.

```
mublockhandle = getSimulinkBlockHandle('vdp/Mu',true);
```

If you make multiple calls to `set_param` for the same block, use the block handle, which is more efficient than the full block path.

You can use the block handle in subsequent calls to `get_param` or `set_param`. The handle contains a double. Do not try to manually enter the number of a handle, for example `5.007`, because you usually need to specify more digits than MATLAB displays. Instead, assign the handle to a variable and use that variable name to specify the block.

Use the block handle with `set_param` to set the position.

```
set_param(mublockhandle,'Position',[50 100 110 120])
```

## Put Block Name on Top of Block

Open vdp and, for the Gain block named Mu, set the block name on top of the block.

```
vdp
set_param('vdp/Mu','NameLocation','top')
```

## Input Arguments

### object — Name, path, or handle of object

character vector | string scalar | numeric scalar

Name, path, or handle of object, specified as a character vector, string scalar, or numeric scalar.

How you specify the target object depends on its type.

- Model — Model name or handle.
- Subsystem — Subsystem name or handle.
- Library — Library name or handle.
- Block — Block path or handle.
- Line — Line handle.
- Port — Port handle.

- Bus element port element — Block path of model component with element label. The element can be any element of the port, such as a top-level bus, nested bus, signal, or message.

Example: 'vdp/Mu'

Example: 'myModel/Subsystem1/Out1.nonsinusoidal.saw'

### Tips

- If you make multiple calls to `set_param` for the same block, specify the block with a numeric handle. This method is more efficient than using the full block path with `set_param`. Use `getSimulinkBlockHandle` to get a block handle.
- Do not try to manually specify the number of a handle, for example, `5.007`, because you usually need to specify more digits than MATLAB displays. Assign the handle to a variable and use that variable name.

Data Types: char | string | double

### parameter — Parameter, property, or attribute name

character vector | string scalar

Parameter, property, or attribute name, specified as a character vector or string scalar. Some names are case sensitive.

For information about parameters, properties, or attributes, see the programmatic use information on the corresponding reference pages. For example:

- Models — See the configuration parameter reference pages.
- Blocks — See “Common Block Properties” on page 6-12 and block reference pages.
- Ports — See the **Signal Properties** tool reference page.
- Bus element port elements — See the In Bus Element and Out Bus Element block reference pages.

To get all parameters of a target object, use the `get_param` function with the 'ObjectParameters' option. Some of the returned parameters may be for internal use only.

Example: 'Solver'

Example: 'SimulationCommand'

Example: 'Position'

Example: 'NameLocation'

Data Types: char | string

### value — Parameter value

format determined by parameter type

Parameter value, specified in the format determined by the parameter type. Some parameter values are case sensitive. Values are often character vectors or string scalars, but they can also be numeric scalars, arrays, and other types.

Many block parameter values are specified as character vectors or string scalars. Two exceptions are `Position`, which is specified as a vector, and `UserData`, which can be any data type.

## Limitations

If you use `matlab -nodisplay` to start a session, you cannot use `set_param` to run a simulation. The `-nodisplay` mode does not support simulation using `set_param`. Use the `sim` function instead.

## Tips

After you set parameters in the MATLAB workspace, to see the changes in a model, update the diagram.

```
set_param(model, 'SimulationCommand', 'Update')
```

## Version History

Introduced before R2006a

## setActiveConfigSet

Specify active configuration set or configuration reference for model

### Syntax

```
setActiveConfigSet(model, configObjName)
```

### Description

`setActiveConfigSet(model, configObjName)` activates the configuration set or configuration reference that is attached to `model` and is named `configObjName`. Before you activate a configuration, attach the configuration to the model by using `attachConfigSet`.

### Examples

#### Activate Configuration Set

Create a configuration set, attach it to a model, and activate it.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

Create a configuration set named `Config1` and attach it to the model.

```
configObj = Simulink.ConfigSet;
set_param(configObj, 'Name', 'Config1')
attachConfigSet('sldemo_fuelsys', configObj)
```

Activate the `Config1` configuration set.

```
setActiveConfigSet('sldemo_fuelsys', 'Config1')
```

### Input Arguments

#### **model** — Model for which to activate configuration

character vector | string scalar

Name of model for which you want to activate a configuration set, specified as a character vector or string scalar. The model must be open.

Example: `'my_model'`

#### **configObjName** — Name of configuration object

character vector | string scalar

Name of the configuration object that you want to activate, specified as a character vector or string scalar.

Example: 'Configuration'

## shareMATLABForFMUCoSim

Share current MATLAB session for FMU tool-coupling co-simulation

### Syntax

```
shareMATLABForFMUCoSim
```

### Description

shareMATLABForFMUCoSim dedicates the current MATLAB session available for requests from the external tool to co-simulate an imported FMU. When an FMU is connected to this session, the Simulink editor and Simulink project are loaded, and co-simulation starts automatically. You can use this session to pause, resume co-simulation, tune parameters, and plot signals from the command window while co-simulation is running. If co-simulation is finished, stopped by you, or interrupted by a runtime error, MATLAB closes, unloads the Simulink editor and Simulink project, and discards changes to the model. If an error occurs, it displays in the simulation tool that imports this FMU. Each session can connect to one FMU instance at the same time.

### Examples

#### Dedicate Current MATLAB Session for Co-Simulation

Dedicate the current MATLAB session for requests from external tools to co-simulate an imported FMU.

```
shareMATLABForFMUCoSim
```

```
The current MATLAB session ('MATLAB_27284') is now dedicated
for tool-coupling co-simulation FMU usage. Make sure your work
is saved, and no other application is connecting to this MATLAB session.
```

# showblockdatatypetable

Display HTML page of Simulink block data type support

## Syntax

```
showblockdatatypetable
```

## Description

showblockdatatypetable displays an HTML page of the Simulink block data type support. This table lists the data types that Simulink blocks support.

## Examples

### Display Support of Simulink Block Data Types

Display an HTML page of the Simulink block data type support.

```
showblockdatatypetable
```

## Tips

To open the Block Support Table using a block, double-click the Block Support Table block in the block library or add it to a model and then double-click it.

## Version History

**Introduced before R2006a**

Block Support Table

## Topics

“Data Types Supported by Simulink”

## **showunitslist**

Show built-in units, physical quantities, and unit systems supported by Simulink

### **Syntax**

```
showunitslist
```

### **Description**

`showunitslist` opens a web browser that contains the list of built-in units, physical quantities, and unit systems supported by Simulink.

### **Examples**

#### **Show Built-in Units, Physical Quantities, and Unit Systems**

Show built-in units, physical quantities, and unit systems supported by Simulink.

```
showunitslist
```

This function opens a web browser displaying the allowed units.

# signalbuilder

(Not recommended) Create and access Signal Builder blocks

---

**Note** The `signalbuilder` function is not recommended. For more information on why you should migrate your models, see “Migrate from Signal Builder Block to Signal Editor Block”.

---

## Syntax

```
[time,data] = signalbuilder(block)
[time,data,signames] = signalbuilder(block)
[time,data,signames,groupnames] = signalbuilder(block)

block = signalbuilder(path,'create',time,data)
block = signalbuilder(path,'create',time,data,signames,groupnames)
block = signalbuilder(path,'create',time,data,signames,groupnames,vis)
block = signalbuilder(path,'create',time,data,signames,groupnames,vis,pos)
block = signalbuilder(path,'create',time,data,signames,groupnames,vis,pos,{
openui openmodel})

block = signalbuilder(block,'appendgroup',time,data,signames,groupnames)
signalbuilder(block,'appendgroup',ds)
signalbuilder(block,'appendgroup',[ds1 ...dsN])
signalbuilder(block,'appendsignal',time,data,signames)

signalbuilder(block,'showsignal',signal,group)
signalbuilder(block,'hidesignal',signal, group)

[time,data] = signalbuilder(block,'get',signal,group)
ds = signalbuilder(block,'get',group)
[ds, ...dsN] = signalbuilder(block,'get',group)
signalbuilder(block,'set',signal,group,time,data)
signalbuilder(block,'set',group,ds)
signalbuilder(block,'set',group,[ds1 ...dsN])

index = signalbuilder(block,'activegroup')
[index, activeGroupLabel] = signalbuilder(block,'activegroup')
signalbuilder(block,'activegroup',index)

signalbuilder(block,'annotategroup')

signalbuilder(block,'print',config,printArgs)
figh = signalbuilder(block,'print',config,'figure')
```

## Description

`[time,data] = signalbuilder(block)` returns the time and data of the Signal Builder block, `block`.

`[time,data,signames] = signalbuilder(block)` returns signal names, `signames`, and time and data.

`[time,data,signames,groupnames] = signalbuilder(block)` returns the signal names, `signames`, and group names, `groupnames`, and time and data.

`block = signalbuilder(path,'create',time,data)` creates a new Signal Builder block at `path` with specified time and data. Signal and group names are default.

`block = signalbuilder(path,'create',time,data,signames,groupnames)` creates a new Signal Builder block at `path` with specified time and data, signal names, and group names.

`block = signalbuilder(path,'create',time,data,signames,groupnames,vis)` creates a new Signal Builder block and sets the visible signals in each group based on the values of the matrix `vis`.

`block = signalbuilder(path,'create',time,data,signames,groupnames,vis,pos)` creates a new Signal Builder block and sets the block position to `pos`.

If you create signals that are smaller than the display range or do not start from 0, the Signal Builder block extrapolates the undefined signal data. It does so by holding the final value.

`block = signalbuilder(path,'create',time,data,signames,groupnames,vis,pos,{openui openmodel})` creates a new Signal Builder block and opens or invisibly loads the model and Signal Builder block window.

`block = signalbuilder(block,'appendgroup',time,data,signames,groupnames)` appends new groups (`groupnames`) containing `signames` to the Signal Builder block, `block`. The time and data arguments must have the same number of signals as the existing block.

`signalbuilder(block,'appendgroup',ds)` appends one dataset.

`signalbuilder(block,'appendgroup',[ds1 ...dsN])` appends  $N$  datasets.

`signalbuilder(block,'appendsignal',time,data,signames)` appends new signals to all signal groups in the Signal Builder block, `block`. You can append either the same signals to all groups, or append different signals to different groups. Regardless of which signals you append, append the same number of signals to all the groups. Append signals to all the groups in the block; you cannot append signals to a subset of the groups. Correspondingly, provide `time` and `data` arguments for either one group (append the same information to all groups) or different `time` and `data` arguments for different groups.

`signalbuilder(block,'showsignal',signal,group)` makes signals that are hidden from the Signal Builder block visible. By default, signals in the current active group are visible when created.

`signalbuilder(block,'hidesignal',signal,group)` makes signals, `signal`, hidden from the Signal Builder block. By default, all signals are visible when created.

`[time,data] = signalbuilder(block,'get',signal,group)` gets the time and data values for the specified signal(s) and group(s).

`ds = signalbuilder(block,'get',group)` gets one or more datasets for one requested Signal Builder group. `r` gets  $N$  datasets for  $N$  requested Signal Builder groups.

`[ds, ...dsN] = signalbuilder(block, 'get', group)` gets  $N$  datasets for  $N$  requested Signal Builder groups.

`signalbuilder(block, 'set', signal, group, time, data)` sets the time and data values for the specified signal and group. Use empty values of `time` and `data` to remove groups and signals. To remove a signal group, you must also remove all the signals in that group in the same command.

`signalbuilder(block, 'set', group, ds)` sets one dataset for the requested Signal Builder group. Specifying an empty dataset deletes the groups specified in `group`.

`signalbuilder(block, 'set', group, [ds1 ...dsN])` sets  $N$  datasets for  $N$  requested groups.

`index = signalbuilder(block, 'activegroup')` gets the index of the active group.

`[index, activeGroupLabel] = signalbuilder(block, 'activegroup')` gets the label value of the active group.

`signalbuilder(block, 'activegroup', index)` sets the active group to indexed active group.

`signalbuilder(block, 'annotategroup')` controls the display of the current group name on the mask of the Signal Builder block. 'annotategroup' takes one of these values:

- 'on' — Shows the current group name
- 'off' — Hides the current group name

`signalbuilder(block, 'print', config, printArgs)` prints the currently active signal group or the signal group that `config` specifies. Use the `config` to customize the printed appearance of a signal group.

`figh = signalbuilder(block, 'print', config, 'figure')` prints the currently active signal group or the signal group that `config` specifies to a new hidden figure handle, `figh`.

## Examples

### Create Signal Builder Block

Create a Signal Builder block in a new model editor window.

```
block = signalbuilder([], 'create', [0 5], {[2 2];[0 2]});
```

Get Signal Builder data from this block.

```
[time, data, signames, groupnames] = signalbuilder(block)
```

```
time =
```

```
2×1 cell array
```

```
 {1×2 double}
 {1×2 double}
```

```
data =
```

```
2×1 cell array
```

```
{1×2 double}
{1×2 double}

signames =

1×2 cell array

 {'Signal 1'} {'Signal 2'}

groupnames =

1×1 cell array

 {'Group 1'}
```

The Signal Builder block contains two signals in one group. Alter the second signal in the group.

```
signalbuilder(block, 'set', 2, 1, [0 5], [2 0]);
```

To make this same change using the signal name and group name:

```
signalbuilder(block, 'set', 'Signal 2', 'Group 1', [0 5], [2 0])
```

### **Create Signal Builder Block and Delete Group**

Create a Signal Builder block with two signal groups and delete one of the groups.

```
block = signalbuilder([], 'create', [0 2], {[0 1],[1 0]});
```

The Signal Builder block has two groups, each of which contains a signal.

To delete the second group, also delete its signal.

```
signalbuilder(block, 'set', 1, 2, [], [])
```

### **Create Signal Builder Block with Two Groups**

Create a Signal Builder block with two groups, each of which contains three signals.

```
block = signalbuilder([], 'create', [0 1], ...
 {[0 0],[1 1];[1 0],[0 1];[1 1],[0 0]});
```

### **Create Signal Builder Block and Append Signal Groups**

Create a Signal Builder block in a new model editor window.

```
block = signalbuilder([], 'create', {[0 10],[0 20]},{[6 -6],...
 [2 5]});
```

The Signal Builder block has two groups. Each group contains one signal.

Append a new signal group to the existing block.

```
block = signalbuilder(block, 'appendgroup', [0 30],[10 -10]);
```

Append a new signal, sig3, to all groups.

```
signalbuilder(block, 'appendsignal', [0 30], [0 10], 'sig3');
```

### Create Signal Builder Block and Delete Signal Group

Create a Signal Builder block in a new model editor window.

```
time = [0 1];
data = {[0 0], [1 1]; [1 0], [0 1]; [1 1], [0 0]};
block = signalbuilder([], 'create', time, data);
```

The Signal Builder block has two groups. Each group contains three signals.

Delete the second group. To delete a signal group, also delete all the signals in the group.

```
signalbuilder(block, 'set', [1,2,3], 'Group 2', []);
```

### Create Signal Builder Block and Hide Signal

Create a Signal Builder block in a new model editor window and hide signal.

```
block = signalbuilder([], 'create', [0 5], {[2 2]; [0 2]});
```

The Signal Builder block has one group that contains two signals.

Hide the signal, Signal 1.

```
signalbuilder(block, 'hidesignal', 'Signal 1', 'Group 1')
```

Signal 1 is no longer visible in the Signal Builder block.

Make Signal 1 visible again.

```
signalbuilder(block, 'showsignal', 'Signal 1', 'Group 1')
```

### Create Two Signal Builder Blocks

Create two Signal Builder blocks in new model editor windows.

```
block = signalbuilder([], 'create', [0 5], {[2 2]; [0 2]});
block1 = signalbuilder('untitled/Signal Builder1', 'create', [1 2], {[1 2]; [0 10]});
```

Get a dataset for group 1 of block.

```
ds=signalbuilder(block, 'get', 1);
```

Get a dataset for group 1 of block1.

```
ds1=signalbuilder(block1, 'get', 1);
```

Set the dataset for group 1 of block to ds1.

```
signalbuilder(block, 'set', 1, ds1);
```

Append the original dataset for group 1 of block (ds) to block.

```
signalbuilder(block, 'appendgroup', ds);
```

To create a third group in block, append ds1 to the end of the groups in block.

```
signalbuilder(block, 'appendgroup', ds1);
```

## Input Arguments

### block — Signal Builder block path or handle

[] (default) | block handle | block name

Signal Builder block handle or name. If you specify [] for this argument, the block has the path 'untitled/Signal Builder'.

Example: 'untitled/Signal Builder'

Example: block\_handle = gcbh

Data Types: char | string

### time — Time

row vector | column cell vector | row cell vector | cell matrix

Specify time format depending on the block configuration.

If data is a cell array and time is a vector, the time values are duplicated for each element of data. Each vector within time and data must be the same length and have at least two elements. If time is a cell array, all elements in a column must have the same initial and final value.

| Configuration       | Time Format                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 1 signal, 1 group   | Row vector of break points.                                                                                 |
| >1 signal, 1 group  | Column cell vector where each element corresponds to a separate signal and contains a row vector of points. |
| 1 signal, >1 group  | Row cell vector where each element corresponds to a separate group and contains a row vector of points.     |
| >1 signal, >1 group | Cell matrix where each element (i, j) corresponds to signal i and group j.                                  |

### Dependencies

If signalbuilder is called for an existing block, the time argument must have the same number of signals as the existing block.

Data Types: double

### data — Data

row vector | column cell vector | row cell vector | cell matrix

Specify data format depending on the block configuration.

If data is a cell array and time is a vector, the time values are duplicated for each element of data. Each vector within time and data must be the same length and have at least two elements. If time is a cell array, all elements in a column must have the same initial and final value.

| Configuration       | Time/Data Format                                                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 1 signal, 1 group   | Row vector of break points.                                                                                 |
| >1 signal, 1 group  | Column cell vector where each element corresponds to a separate signal and contains a row vector of points. |
| 1 signal, >1 group  | Row cell vector where each element corresponds to a separate group and contains a row vector of points.     |
| >1 signal, >1 group | Cell matrix where each element (i, j) corresponds to signal i and group j.                                  |

Data Types: double

### **config** – Configuration structure name

structure name

Configuration structure containing instructions to display signal group information on the block mask. Set up the structure with one or more of these fields before you print.

| Field          | Description                                                                                                                               | Example Value      |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| groupIndex     | Scalar specifying index of signal group to print                                                                                          | 2                  |
| timeRange      | Two-element vector specifying the time range to print (must not exceed the block's time range)                                            | [3 6]              |
| visibleSignals | Vector specifying index of signals to print                                                                                               | [1 2]              |
| yLimits        | Cell array specifying limits for each signal's y-axis                                                                                     | {[-1 1],<br>[0 1]} |
| extent         | Two-element vector of the form:<br>[width, height]<br><br>specifying the dimensions (in pixels) of the area in which to print the signals | [500 300]          |
| showTitle      | Logical value specifying whether to print a title:<br>true (1) prints the title                                                           | false              |

For example, to print just group 2 using a configuration structure, `configstruct`, set up the structure as follows. You do not need to specify any other fields.

```
configstruct.groupIndex=1
```

Example: `configstruct`

Data Types: char | string

### 'create' – Create directive

'create'

Create new Signal Builder block.

Data Types: char | string

### signames – Signal names

Signal 1 (default) | ' ' | {} | character vector | cell array of character vectors

Signal names, specified as ' ', {}, a character vector, or cell array of character vectors.

If you specify a value of ' ' or {}, the function uses existing signal names for the new groups.

Data Types: char | string

### **groupnames — Signal group names**

Group 1 (default) | character vector | cell array of character vectors

Group names, specified as a character vector or cell array of character vectors.

Data Types: char | string

### **path — Block path**

[] (default) | full block path

Block path, specified as full block path. To create a Signal Builder block in a new model, untitled, with the name Signal Builder, specify [].

Data Types: char | string

### **vis — Signal visibility**

matrix

Signal visibility, specified as a matrix. The Signal Builder block displays signals in each group based on the values of the matrix vis. This matrix must be the same size as the cell array, data. You cannot create Signal Builder blocks in which all signals are invisible. For example, if you set the vis parameter for all signals to 0, the first signal is still visible.

Data Types: double

### **pos — Block position in model**

[0 0] (default) | [x y right bottom]

Block position in model, specified as [x y right bottom].

Data Types: double

### **openui — Open Signal Builder block dialog box**

0 (default) | 1

Open Signal Builder block dialog upon creation by signalbuilder function, specified as 0 or 1.

Data Types: double

### **openmodel — Open model**

1 (default) | 0

Open model upon creation by signalbuilder function, specified as one of:

- 0 — Load the model but do not open it.
- 1 — Open the model.

Data Types: double

### **'appendsignal' — Append signals**

'appendsignal' (default)

Append new signals to all signal groups in the Signal Builder block. You can append either the same signals to all groups, or append different signals to different groups. Regardless of which signals you append, append the same number of signals to all the groups. Append signals to all the groups in the block. You cannot append signals to a subset of the groups.

Data Types: `char` | `string`

### **'appendgroup' — Append new signal group**

`'appendgroup'`

Append new signal groups whose number of time and signal elements are the same as existing signal groups in the Signal Builder block.

For the `showsignal` and `hidesignal` methods, if you do not specify a value for the `group` argument, `signalbuilder` applies the operation to all the signals and groups.

Data Types: `char`

### **'set' — Set values**

`'set'`

Set values based on input arguments.

- `time` and `data` — Return time and data values.
- `ds` — Return `Simulink.SimulationData.Dataset` object(s).

Data Types: `char`

### **'get' — Get values**

`'get'`

Get values based on output arguments.

- `[time, data]` — Return time and data values.
- `[ds, ...dsN]` — Return `Simulink.SimulationData.Dataset` object(s).

Data Types: `char` | `string`

### **'showsignal' — Make signal visible**

`'showsignal'`

Make one or more signals visible in a signal group. If no group is specified, all the signals and groups are visible.

Data Types: `char` | `string`

### **'hidesignal' — Hide signal**

`'hidesignal'`

Hide one or more signals in a signal group. If no group is specified, all the signals and groups are hidden.

Data Types: `char`

### **ds — Dataset**

`timeseries` data elements | 1-D scalar data value at each time | nonempty data and/or time | empty values

Dataset of timeseries elements, specified as a `Simulink.SimulationData.Dataset` object.

Data Types: `double`

### **ds1 ... dsN — Multiple datasets**

vectors of timeseries data elements | vectors of 1-D scalar data value at each time | nonempty data and/or time

One or more datasets of timeseries elements, specified as `Simulink.SimulationData.Dataset` objects.

Example: `[ds1 ds2 ds3]`

Data Types: `double`

### **signal — Signal**

signal name | scalar index | array of signal indices

Signal, specified as a signal name, scalar index, or array of signal indices.

Data Types: `char` | `double` | `string`

### **group — Signal group**

group name | scalar index | array of group indices

Signal group, specified as a group name, scalar index, or array of group indices.

Data Types: `char` | `double` | `string`

### **index — Group index**

active group index

Active signal group index.

Data Types: `double`

### **'activegroup' — Get active group**

`'activegroup'`

Get currently active signal group.

Data Types: `char` | `string`

### **'annotategroup' — Display active signal group name**

`'on'` (default) | `'off'`

Display active signal group name on Signal Builder block mask:

- `'on'` — Display active signal group names on block mask.
- `'off'` — Do not display active signal group names on block mask.

Data Types: `char` | `string`

### **'print' — Print signal group**

`'print'`

Print signal group.

Data Types: `char` | `string`

**printArgs — Configure print options**

[] | print function arguments

Configure print options (see `print`).

To print the entire contents of the Signal Builder block, specify [].

Data Types: `char` | `string`

**'figure' — Figure**

'figure'

Create a figure containing contents of Signal Builder block.

Data Types: `char` | `double` | `string`

**Output Arguments****time — Time**

row vector | column cell vector | row cell vector | cell matrix

Time for the Signal Builder block, returned as row vector, column cell vector, row cell vector, or cell matrix. For the Signal Builder block, time is the *x*-coordinate.

`time` returns in different formats depending on the block configuration.

| Configuration       | Time Format                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 1 signal, 1 group   | Row vector of break points.                                                                                 |
| >1 signal, 1 group  | Column cell vector where each element corresponds to a separate signal and contains a row vector of points. |
| 1 signal, >1 group  | Row cell vector where each element corresponds to a separate group and contains a row vector of points.     |
| >1 signal, >1 group | Cell matrix where each element (i, j) corresponds to signal i and group j.                                  |

**data — Data**

row vector | column cell vector | row cell vector | cell matrix

Data of the Signal Builder block, returned as a one-dimensional array. For the Signal Builder block, time is the *y*-coordinate.

`data` takes different formats depending on the block configuration.

| Configuration       | Data Format                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 1 signal, 1 group   | Row vector of break points.                                                                                 |
| >1 signal, 1 group  | Column cell vector where each element corresponds to a separate signal and contains a row vector of points. |
| 1 signal, >1 group  | Row cell vector where each element corresponds to a separate group and contains a row vector of points.     |
| >1 signal, >1 group | Cell matrix where each element (i, j) corresponds to signal i and group j.                                  |

Datasets must have the same number of elements as the signals in a signal group. Dataset format limitations for the `set`, `append`, and `appendgroup` functions include:

- Elements must be MATLAB timeseries data.  
Timeseries data and/or time cannot be empty.
- Timeseries data must be of type double.
- Timeseries data must be 1-D (scalar value at each time).

**signames — Signal names**

character vector | cell array of character vectors

Signal names, returned as a character vector or cell array of character vectors.

**block — Signal Builder block path or handle**

block handle

Signal Builder block path or handle, returned by block creation or append commands.

**ds — Dataset**

timeseries data elements | 1-D scalar data value at each time | nonempty data and/or time

Dataset of timeseries elements, returned as a `Simulink.SimulationData.Dataset` object.

**ds, ...dsN — Multiple datasets**

vectors of timeseries data elements | vectors of 1-D scalar data value at each time | nonempty data and/or time

One or more datasets of timeseries elements, returned as `Simulink.SimulationData.Dataset` objects.

**index — Group index**

active group index

Active signal group index.

**activeGroupLabel — Active group label**

index

Active group label, returned as an index.

**figh — Figure handle**

handle

Figure handle, returned when contents of Signal Builder block are printed to the hidden figure.

## More About

### Interpolating Missing Data Values

When specifying a periodic signal such as a Sine Wave, the `signalbuilder` function uses linear Lagrangian interpolation to compute data values for time steps that occur between time steps for which the `signalbuilder` function supplies data. When specifying periodic signals, specify them as a time vector that is defined as multiples of sample time, for example:

```
t = 0.2*[0:49]';
```

## Version History

**Introduced in R2007a**

**R2019a: signalbuilder Function is not Recommended**

*Not recommended starting in R2019a*

The signalbuilder function is not recommended. Use the signalEditor function instead.

“Signal Groups”

# signalEditor

Start Signal Editor

## Syntax

```
signalEditor
signalEditor(Name,Value)
```

## Description

signalEditor starts Signal Editor without an associated model.

signalEditor(Name,Value) starts signal Editor using additional options specified by one or more name-value pair arguments.

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify the name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

- Model - Model name, specified as a character array, for which Signal Editor is to start. You can specify one model per call to the signalEditor function.

---

**Note** Load the model before starting Signal Editor for it.

---

- DataSource - Data set name, specified as a character array, to be edited. You can specify one data set file per call to the signalEditor function.

---

**Note** You can start multiple sessions of Signal Editor for the same model. However, you can associate a data set file with only one Signal Editor at a time. A data set file cannot have multiple Signal Editor sessions associated with it.

---

To add a scenario to the Signal Editor interface, select **Scenario** from the **Insert** section of the Signal Editor toolstrip.

## Examples

### Start Signal Editor for a Model

Start the Signal Editor for the model, slxAutotransRootInportsExample.

Load the slxAutotransRootInportsExample model, then start Signal Editor for it.

```
openExample('slxAutotransRootInportsExample')
signalEditor('Model','slxAutotransRootInportsExample');
```

### Start Signal Editor to Edit a Data Set File

Start Signal Editor to edit myFile.mat.

```
signalEditor('DataSource', 'myFile.mat');
```

### Start Signal Editor and Data Set File for a Model

Load the slexAutotransRootInportsExample model, then start Signal Editor for the model, and edit myFile.mat.

```
openExample('slexAutotransRootInportsExample')
signalEditor('Model', 'slexAutotransRootInportsExample', 'DataSource', 'myFile.mat');
```

## Version History

Introduced in R2017b

## sim

Simulate Simulink model

### Syntax

```
simOut = sim(simIn)
simOut = sim(simIn,Name,Value)

simOut = sim(modelName)
simOut = sim(modelName,Name,Value)
simOut = sim(modelName,paramStruct)
simOut = sim(modelName,configSet)
```

### Description

#### Simulink.SimulationInput Object Syntax

`simOut = sim(simIn)` runs one or more simulations of a Simulink model according to the properties defined on one or more `Simulink.SimulationInput` objects.

- If `simIn` is a scalar `Simulink.SimulationInput` object, then `simOut` is a scalar `Simulink.SimulationOutput` object.
- If `simIn` is an array of `Simulink.SimulationInput` objects, then `simOut` is an array of `Simulink.SimulationOutput` objects.

You can use a `SimulationInput` object to configure options and inputs for simulations, including:

- The model to simulate
- Source variables or files for external input data
- Block parameter values to use for the simulation
- Model configuration parameter values to use for the simulation

When a property of the `SimulationInput` object modifies a model or block parameter value, the value is modified during simulation and reverted at the end of the simulation.

When you configure programmatic simulations using `SimulationInput` objects, you can easily transition from using the `sim` function to using other functions, such as `parsim` and `batchsim`.

`simOut = sim(simIn,Name,Value)` simulates a model according to the properties defined on the `Simulink.SimulationInput` object `simIn` with additional options specified using one or more name-value arguments.

For a list of name-value arguments supported for the `Simulink.SimulationInput` syntax, see “`Simulink.SimulationInput` Object Syntax” on page 2-0 .

#### Model Name Syntax

`simOut = sim(modelName)` simulates the model specified by `modelName` using the current configuration parameter and block parameter values for the model.

- If the model has the **Single simulation output** parameter enabled, `simOut` is a `Simulink.SimulationOutput` object.
- If the model does not have the **Single simulation output** parameter enabled, `simOut` is a vector that contains the simulation times. For more information, see “Returning multiple output arguments not recommended” on page 2-442.

`simOut = sim(modelName,Name,Value)` simulates the model specified by `modelName` with options specified using one or more name-value arguments. For example, you can modify a model configuration parameter value for the simulation by specifying the parameter name and value as a name-value argument.

When you modify model configuration parameters by providing inputs to the `sim` function, the changes are applied during simulation and reverted at the end of the simulation.

For a list of name-value arguments supported for the model name syntax, see “Model Name Syntax” on page 2-0 .

`simOut = sim(modelName,paramStruct)` simulates the model specified by `modelName` using the model configuration parameter values specified by the structure `paramStruct`.

`simOut = sim(modelName,configSet)` simulates the model specified by `modelName` using model configuration parameter values in the configuration set `configSet`.

## Examples

### Set Block Parameters for Simulation Using `Simulink.SimulationInput` Object

Modify the parameter values for blocks in a model using a `SimulationInput` object.

Open the model.

```
openExample("simulink_general/sl-demo_househeatExample")
```

Create a `SimulationInput` object for this model.

```
mdl = "sl-demo_househeat";
simIn = Simulink.SimulationInput(mdl);
```

Change the set point for the thermostat to 300 by modifying the **Value** parameter for the Set Point block.

```
simIn = setBlockParameter(simIn,"sl-demo_househeat/Set Point",...
 "Value","300");
```

Simulate the model.

```
out = sim(simIn);
```

### Simulate Model with Current Parameter Settings

Simulate the model `vdp` in its present state, whether the model is not loaded yet or is loaded with unsaved changes.

```
simOut = sim("vdp");
```

### Simulate Model with Options Specified in Structure

Simulate the model vdp using model configuration parameter values specified in a structure.

Create the structure paramStruct. Configure the model to log states using the variable name xoutNew.

```
paramStruct.SaveState = 'on';
paramStruct.StateSaveName = 'xoutNew';
```

Add more fields to the structure to configure the model to log outputs using the variable name youtNew.

```
paramStruct.SaveOutput = 'on';
paramStruct.OutputSaveName = 'youtNew';
```

Simulate the model using the options specified in the structure.

```
simOut = sim('vdp',paramStruct)

simOut =
 Simulink.SimulationOutput:

 xoutNew: [64x2 double]
 youtNew: [64x2 double]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

### Simulate Model Using Simulink.Configset Object

Open the model vdp and get the Simulink.ConfigSet object for the active configuration.

```
mdl = "vdp";
open_system(mdl)
cs = getActiveConfigSet(mdl);
```

Create a copy of the Simulink.ConfigSet object. Then, use the set\_param function to modify parameter values in the configuration set. Configure the parameters in the ConfigSet object to:

- Use an absolute tolerance of 1e-5
- Log states using the variable name xoutNew
- Log outputs using the variable name youtNew

```
csNew = copy(cs);
set_param(csNew, "AbsTol", "1e-5", ...
 "SaveState", "on", "StateSaveName", "xoutNew", ...
 "SaveOutput", "on", "OutputSaveName", "youtNew")
```

Simulate the model using the modified Simulink.ConfigSet object.

```

simOut = sim mdl,csNew)

simOut =
 Simulink.SimulationOutput:

 xoutNew: [65x2 double]
 youtNew: [65x2 double]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

```

## Input Arguments

### **simIn** — Simulation configuration

Simulink.SimulationInput object

Simulation configuration, specified as a Simulink.SimulationInput object. The properties of the SimulationInput object specify options and parameter values to use in the simulation, including:

- The model to simulate
- Source variables or files for external input data
- Block parameter values to use for the simulation
- Model configuration parameter values to use for the simulation

The values defined in the properties of the SimulationInput object are applied to the model for the simulation and reverted at the end of simulation.

### **modelName** — Model to simulate

string | character vector

Model to simulate, specified as a string or a character vector.

Example: `simOut = sim("vdp")` simulates the model named `vdp` using the parameter values currently configured in the model.

Data Types: char | string

### **paramStruct** — Model configuration to simulate

structure

Model configuration to simulate, specified as a structure. The fields of the structure are the names of model configuration parameters. The value for each field indicates the parameter value to use in simulation. For example, to simulate a model from a start time of 5 to a stop time of 10, create this structure:

```

paramStruct.StartTime = "5";
paramStruct.StopTime = "10";

```

Data Types: struct

### **configSet** — Model configuration to simulate

Simulink.Configset object

Model configuration to simulate, specified as a Simulink.ConfigSet object.

## Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `simOut = sim(simIn,"UseFastRestart","on")` runs a set of simulations configured using an array of `Simulink.SimulationInput` objects with fast restart enabled.

Example: `simOut = sim(modelName,"Solver","ode15s","StopTime","30")` configures a simulation of the model specified by `modelName` to use the `ode15s` solver with a stop time of 30.

The `sim` function supports different name-value arguments depending on whether you specify the first input as a `Simulink.SimulationInput` object or as the name of the model to simulate. In addition to the arguments listed on this page, you can specify values for model configuration parameters using inputs to the `sim` function.

- When the first input argument is a `Simulink.SimulationInput` object, configure model parameter values for the simulation on the input object using the `setModelParameter` function.
- When the first input argument is the model name, specify any model configuration parameter as a name-value argument.

### Simulink.SimulationInput Object Syntax

#### UseFastRestart — Option to enable fast restart

'off' (default) | 'on'

Option to enable fast restart, specified as 'off' or 'on'. Fast restart reduces the time required to run a set of simulations by skipping the compilation and termination phases when appropriate. Consider using fast restart when you run multiple simulations of the same model.

For more information, see “How Fast Restart Improves Iterative Simulations”.

This argument is supported only when you specify the first input argument for the `sim` function as a `Simulink.SimulationInput` object.

Example: `sim(simIn,"UseFastRestart","on")`

Data Types: `char` | `string`

#### StopOnError — Option to stop process that started simulation when error occurs

'off' | 'on'

Option to stop process that started simulation when error occurs, specified as 'off' or 'on'.

- 'off' — When an error occurs in a simulation, that simulation stops and the process that started the simulation continues. For example, when you run a set of simulations using an array of `Simulink.SimulationInput` objects, if the first simulation encounters an error, that simulation stops and subsequent simulations still run.
- 'on' — When an error occurs in a simulation, that simulation and the process that started the simulation both stop. For example, when you run a set of simulations using an array of `Simulink.SimulationInput` objects, if the first simulation encounters an error, that simulation stops and subsequent simulations do not run.

This argument is supported only when you specify the first input argument for the `sim` function as a `Simulink.SimulationInput` object.

Example: `sim(simIn,"StopOnError","on")`

#### Tips

- When you specify the name of the model as the first input argument for the `sim` function, configure this behavior using the `CaptureErrors` name-value argument.
- When an error does not stop the process that started a simulation, error message information is captured in the `Simulink.SimulationOutput` object and the `Simulink.SimulationMetadata` object.
  - To view the message, use the `ErrorMessage` property of the `SimulationOutput` object.
  - For more information about the error, use the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object. The `ErrorDiagnostic` field includes information about the error, including the simulation phase where the error occurred.

Data Types: `char` | `string`

#### ShowProgress — Option to indicate simulation progress

'off' | 'on'

Option to indicate simulation progress, specified as 'off' or 'on'.

- 'off' — Simulations run without displaying progress messages.
- 'on' — Progress updates are displayed as simulations progress.

This option is useful when you run multiple simulations using an array of `Simulink.SimulationInput` objects.

This argument is supported only when you specify the first input argument for the `sim` function as a `Simulink.SimulationInput` object.

Example: `sim(simIn,"ShowProgress","on")`

#### ShowSimulationManager — Option to open Simulation Manager

'off' (default) | 'on'

Option to open Simulation Manager, specified as 'off' or 'on'. Use the **Simulation Manager** to monitor the progress of simulations you run. Consider using the Simulation Manager when you run multiple simulations using an array of `Simulink.SimulationInput` objects.

This argument is supported only when you specify the first input argument for the `sim` function as a `Simulink.SimulationInput` object.

Example: `sim(simIn,"ShowSimulationManager","on")`

#### Model Name Syntax

#### CaptureErrors — Option to continue process that started simulation if error occurs

'off' (default) | 'on'

Option to continue process that started simulation if error occurs, specified as 'off' or 'on'. By default, when you run a simulation using the `sim` function and specify the name of the model as the first input:

- Errors are reported in the MATLAB Command Window.
- Both the simulation and the process that invoked the simulation stop when the error occurs.
- The error message is not captured in the `Simulink.SimulationOutput` object or `Simulink.SimulationMetadata` object.

When you specify `CaptureErrors` as 'on', errors are reported only in the simulation outputs. The execution of the simulation with the error stops, but if the simulation was invoked by another process, that process continues. For example, when you run multiple simulations in a loop, if you specify `CaptureErrors` as 'on', subsequent simulations continue to run following a simulation with an error.

This argument is supported only when you specify the first input argument for the `sim` function as the name of the model to simulate.

Example: `sim("myModel", "CaptureErrors", "on")`

### Tips

- This option is not supported for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.
- When you specify one or more `Simulink.SimulationInput` objects as input to the `sim` function, configure this behavior using the `StopOnError` name-value argument.
- When you specify `CaptureErrors` as 'on', error message information is captured in the `Simulink.SimulationOutput` object and the `Simulink.SimulationMetadata` object.
  - To view the message, use the `ErrorMessage` property of the `SimulationOutput` object.
  - For more information about the error, use the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object. The `ErrorDiagnostic` field includes information about the error, including the simulation phase where the error occurred.

Data Types: `char` | `string`

### Debug — Option to start simulation in debug mode

'off' (default) | 'on'

Option to start simulation in debug mode, specified as 'off' or 'on'.

This argument is supported only when you specify the first input argument for the `sim` function as the name of the model to simulate.

Example: `sim("modelName", "Debug", "on")`

Data Types: `char` | `string`

### RapidAcceleratorUpToDateCheck — Option to disable rebuilding rapid accelerator target

'on' (default) | 'off'

Option to disable rebuilding rapid accelerator target, specified as 'on' or 'off'. When you specify this argument as 'on', changes that require rebuilding the rapid accelerator target are ignored. When you use this option, modify only options that do not require rebuilding the rapid accelerator target.

This argument is supported only when you specify the first input argument for the `sim` function as the name of the model to simulate.

Example: `sim("modelName", "RapidAcceleratorUpToDateCheck", "off")`

### Tips

To specify this option for a simulation configured using a `Simulink.SimulationInput` object, use the `setModelParameter` function.

```
simIn = Simulink.SimulationInput("myModel");
simIn = setModelParameter(simIn, "RapidAcceleratorUpToDateCheck", "off");
```

Data Types: `char` | `string`

### Timeout — Maximum simulation run time

positive scalar

Maximum simulation run time, specified as a positive scalar. Specify the time, in seconds, to allow the simulation to run. If the simulation runs for longer than the value you specify, the software issues a warning and stops the simulation. For example, if you specify `Timeout` as 30, the software stops the simulation and issues a warning if computing simulation results takes more than 30 seconds.

The `Timeout` parameter specifies a limit on the amount of clock time for a simulation to run. To specify the maximum time value to simulate, use the **Stop time** parameter.

This argument is supported only when you specify the first input argument for the `sim` function as the name of the model to simulate.

Example: `sim("modelName", "Timeout", 60)` configures a simulation to run for a maximum duration of 60 seconds.

### Tips

To specify this option for a simulation configured using a `Simulink.SimulationInput` object, use the `setModelParameter` function.

```
simIn = Simulink.SimulationInput("modelName");
simIn = setModelParameter(simIn, "Timeout", 60);
```

### Trace — Option to display summary of parameters before simulation

'siminfo'

Option to display summary of parameters before simulation, specified as 'siminfo'.

This argument is supported only when you specify the first input argument for the `sim` function as the name of the model to simulate.

Example: `sim("modelName", "Trace", "siminfo")`

Data Types: `char` | `string`

## Output Arguments

### simOut — Simulation outputs

`Simulink.SimulationOutput` object | array of `Simulink.SimulationOutput` objects | vector

Simulation outputs, returned as a `Simulink.SimulationOutput` object, an array of `Simulink.SimulationOutput` objects, or a vector. The `Simulink.SimulationOutput` object contains all data logged from simulation as well as metadata about the simulation, including timing information and diagnostics.

When you specify only the model name as an input argument and the model you simulate has the **Single simulation output** parameter disabled, the output from the `sim` function is a vector of simulation times. For the `sim` function to return results in a consistent format for any syntax, save the model with the **Single simulation output** parameter enabled.

## Tips

- To ensure the `sim` function returns results in the same format regardless of which input arguments you specify, save your model with the **Single simulation output** parameter enabled. With this option enabled, simulation results are returned as a `Simulink.SimulationOutput` that contains all logged data as well as simulation metadata, including timing information and diagnostics. Analyzing results from multiple simulations is easier when all simulation data and metadata is stored in a single object.
- To get a list of model configuration parameters, use the `getActiveConfigSet` function and the `get_param` function. For example, to see the configuration parameters for the model `vdp`, enter these commands in the MATLAB Command Window.

```
configSet = getActiveConfigSet("vdp");
configSetNames = get_param(configSet,"ObjectParameters")
```

The return from the `get_param` function lists the model configuration parameters such as `StopTime`, `SaveTime`, `SaveState`, `SaveOutput`, and `SignalLogging`.

- When you simulate a model hierarchy, model configuration parameters you specify as input arguments to the `sim` function apply to the top model.
- When you run a simulation using the `sim` function, the simulation runs until an error occurs or the simulation reaches the specified stop time. To programmatically run an interactive simulation that you can pause and continue programmatically, use the `set_param` function with the `SimulationCommand` input argument. For more information, see “Run Simulations Programmatically”.
- When you simulate a model with infinite stop time, stop the simulation from the MATLAB Command Window by pressing **Ctrl+C**. The simulation stops, and simulation results are not saved in the MATLAB workspace.
- Configure logging for time, states, and outputs using the Configuration Parameters dialog box. On the **Modeling** tab, under **Setup**, click **Model Settings**. Then, in the Configuration Parameters dialog box, select **Data Import/Export**.
- To log signals throughout a model, use signal logging or logging blocks such as the To Workspace block or the Record, XY Graph block. For more information about signal logging, see “Save Signal Data Using Signal Logging”.

## Version History

**Introduced before R2006a**

**R2009b: Returning multiple output arguments not recommended**

*Not recommended starting in R2009b*

Starting in R2009b, the `sim` function provides enhanced compatibility with parallel computing, including an option to return simulation results as a single simulation object, which simplifies data and variable management. The single simulation output syntax is recommended. Syntaxes that return more than one output argument are not recommended.

To configure a model to always return results as a single output object, use the **Single simulation output** parameter.

To simulate a model programmatically in R2009a and earlier, use this syntax.

```
[T,X,Y1,Y2,Yn] = sim('model',Timespan,Options,UT);
```

Only the `model` input argument is required. When you do not specify other input arguments, the simulation uses the current configuration parameter values for the model. When you specify additional arguments, those arguments override the current values for the model. When you specify an argument as `[]`, the simulation uses the current value in the model for that argument.

The tables describe the input and output arguments and provide information about how to update your code to use syntaxes recommended for R2009b and later.

**Input Argument Descriptions and Replacements**

| Input Argument | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Replacement                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model          | Name of model to simulate, specified as a character vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <p>No change.</p> <p>Starting in R2017a, you can specify the model to simulate using a <code>Simulink.SimulationInput</code> object.</p>                                                                                                                                                                                                                                                                                                                                                               |
| Timespan       | <p>Simulation start and stop times, specified as a scalar or a vector.</p> <ul style="list-style-type: none"> <li>• <b>TFinal</b> — Specifies the stop time for the simulation, which starts from zero.</li> <li>• <b>[TStart TFinal]</b> — Specifies the start time and the stop time for the simulation.</li> <li>• <b>[TStart OutputTimes TFinal]</b> — Specifies start and stop times for the simulation along with output times for which to calculate a value. When you do not specify output times, the simulation engine determines the times for which to calculate values. Specifying output times ensures that the simulation computes a value for each time you specify.</li> </ul> | <p>Configure these options by specifying model configuration parameters as name-value arguments:</p> <ul style="list-style-type: none"> <li>• <b>Stop time</b> — Specify the stop time for the simulation.</li> <li>• <b>Start time</b> — Specify the start time for the simulation.</li> <li>• <b>Output times</b> — Specify output times for which to calculate a value.</li> </ul> <p>Starting in R2017a, you can configure these options using a <code>Simulink.SimulationInput</code> object.</p> |

| T                  | Simulation times, returned as a vector.             | Access time, states, and output data through the <code>Simulink.SimulationOutput</code> object. When you log time, states, and outputs, the <code>SimulationOutput</code> object contains the logged data, which you can access as a property using a dot and the variable name for the logged data. For example, if the <code>SimulationOutput</code> object is returned as <code>simOut</code> , and you save time data to the variable <code>tout</code> :<br><br><code>tout = simOut.tout;</code><br><br>Use the model configuration parameters to specify data to log and the variables names for the logged data.<br><br><ul style="list-style-type: none"> <li>• <b>Time</b></li> <li>• <b>States</b></li> <li>• <b>Output</b></li> </ul> |
| X                  | Logged states, returned as an array or a structure. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Y1, Y2, . . . , YN | Logged outputs, returned as one or more vectors.    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### R2009b: SrcWorkspace argument not recommended

*Not recommended starting in R2009b*

Starting in R2009b, the `SrcWorkspace` name-value argument is not recommended. Specifying this argument can lead to transparency violations for parallel simulations. Instead of using values defined in a workspace, specify values for simulation as input arguments to the `sim` function.

- Before R2017a, specify parameter values for simulation using a structure that contains fields with names that match the parameter names and values that indicate the value to use for the parameter.

- Starting in R2017a, configure model parameter, block parameter, and variable values using a `Simulink.SimulationInput` object.

# simplot

Redirects to the Simulation Data Inspector

---

**Note** `simplot` will be removed in a future release. Use the Simulation Data Inspector instead.

---

## Syntax

```
simplot
```

## Description

`simplot` redirects to the Simulation Data Inspector and returns empty handles. This function is no longer supported and has been replaced by the Simulation Data Inspector. Use the **Simulation Data Inspector** button in the Simulink Editor to capture simulation output in the Simulation Data Inspector. Programmatically, use the function `Simulink.sdi.view` instead.

## See Also

`Simulink.sdi.view`

# simulink

Open Simulink Start Page

## Syntax

```
simulink
```

## Description

`simulink` opens the Simulink Start Page. From the Start Page, choose a model or project template or browse the examples.

## Examples

### Open Simulink from MATLAB Command Window

In the MATLAB Command Window, use the `simulink` function.

```
simulink
```

The Simulink Start Page opens.

## Tips

To start Simulink without opening the Library Browser or Start Page, use `start_simulink`, which is faster than `simulink`.

## Version History

**Introduced before R2006a**

### R2016a: `simulink` function opens Simulink Start Page

*Behavior changed in R2016a*

The behavior of the `simulink` function changed in R2016a. Formerly, it opened the Simulink Library Browser and loaded the Simulink block library.

- To open the Library Browser, use `sLibraryBrowser`.
- To only load the Simulink block library, use this command.

```
load_system simulink
```

## See Also

`start_simulink` | `sLibraryBrowser`

# simulinkproject

(Not recommended) Open project and get project object

---

**Note** simulinkproject is not recommended. Use currentProject or openProject instead. For more information, see “Compatibility Considerations”.

---

## Syntax

```
simulinkproject
simulinkproject(projectPath)

proj = simulinkproject
proj = simulinkproject(projectPath)
```

## Description

simulinkproject opens the project or brings focus to the tool if it is already open. After you open the tool, you can create projects or access recent projects using the **Project** tab.

simulinkproject(projectPath) opens the project specified by any file or folder under the project root in projectPath and gives focus to the project.

proj = simulinkproject returns a project object proj you can use to manipulate the project at the command line. You need to get a project object before you can use any of the other project functions.

proj = simulinkproject(projectPath) opens the project specified by projectPath and returns a project object.

## Examples

### Open Project Tool

Open the Project Tool.

```
simulinkproject
```

### Open a Project

Specify either the .prj file path or the folder that contains your .SimulinkProject folder and .prj file. The project opens and brings focus to the project.

```
simulinkproject('C:/projects/project1/')
```

### Open a Project and Get a Project Object

Open a specified project and get a project object to manipulate the project at the command line. To avoid your startup script opening windows that take focus away from the MATLAB Desktop, use `start_simulink` instead of the `simulink` function, and use `simulinkproject` with an output argument instead of `uiopen`. If you use `uiopen(myproject.prj)` this calls `simulinkproject` with no output argument and gives focus to the project.

```
start_simulink
proj = simulinkproject('C:/projects/project1/myproject.prj')
```

### Get Airframe Example Project

Open the Airframe project and create a project object to manipulate and explore the project at the command line.

```
sldemo_slproject_airframe
proj = simulinkproject
```

```
proj =
```

```
 ProjectManager with properties:
```

```
 Name: 'Simulink Project Airframe Example'
 Information: [1x1 slproject.Information]
 Dependencies: [1x1 slproject.Dependencies]
 Categories: [1x1 slproject.Category]
 Files: [1x31 slproject.ProjectFile]
 Shortcuts: [1x7 slproject.Shortcut]
 ProjectPath: [1x7 slproject.PathFolder]
 ProjectReferences: [1x0 slproject.ProjectReference]
 StartupFiles: [1x0 slproject.StartupFile]
 ShutdownFiles: [1x0 slproject.ShutdownFile]
 RootFolder: 'C:\slexamples\airframell'
```

### Find Project Commands

Find out what you can do with your project.

```
methods(proj)
```

```
Methods for class slproject.ProjectManager:
```

```
addFile
addFolderIncludingChildFiles
addPath
addReference
addShortcut
addShutdownFile
addStartupFile
close
createCategory
export
```

```

findCategory
findFile
isLoading
listModifiedFiles
listRequiredFiles
refreshSourceControl
reload
removeCategory
removeFile
removePath
removeReference
removeShortcut
removeShutdownFile
RemoveStartupFile

```

### Examine Project Properties Programmatically

After you get a project object using the `simulinkproject` function, you can examine project properties.

Examine the project files.

```
files = proj.Files
```

```
files =
```

```
1x31 ProjectFile array with properties:
```

```

Path
Labels
Revision
SourceControlStatus

```

Use indexing to access files in this list. The following command gets file number 14. Each file has properties describing its path, attached labels, and source control information.

```
proj.Files(15)
```

```
ans =
```

```
ProjectFile with properties:
```

```

Path: 'C:\slexamples\airframe24\models\DigitalControl.slx'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified

```

Examine the labels of the file.

```
proj.Files(15).Labels
```

```
ans =
```

```
Label with properties:
```

```

File: 'C:\slexamples\airframe24\models\DigitalControl.slx'
DataType: 'none'

```

```
Data: []
Name: 'Design'
CategoryName: 'Classification'
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.slx')
```

```
myfile =
```

```
ProjectFile with properties:
```

```
Path: 'C:\slexamples\airframe24\models\AnalogControl.slx'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified
```

Find out what you can do with the file.

```
methods(myfile)
```

```
Methods for class slproject.ProjectFile:
```

```
addLabel findLabel removeLabel
```

Update the file dependencies.

```
update(proj.Dependencies)
```

The project runs a dependency analysis to update the known dependencies between project files.

For more information on working with project files, including modified files and dependencies, see “Automate Project Tasks Using Scripts”.

## Input Arguments

### **projectPath** — Full path to project file or folder

character vector

Full path to project .prj file, or the path to the project root folder, or any subfolder or file under your project root, specified as a character vector.

Example: 'C:/projects/project1/myProject.prj'

Example: 'C:/projects/project1/'

## Output Arguments

### **proj** — Project

project object

Project, returned as a project object. Use the project object to manipulate the currently open project at the command line.

Properties of proj output argument.

| Project Property  | Description                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Categories        | Categories of project labels                                                                                                                  |
| Dependencies      | Dependencies between project files in a MATLAB digraph object                                                                                 |
| Files             | Paths and names of project files                                                                                                              |
| Information       | Information about the project such as the description, source control integration, repository location, and whether it is a top-level project |
| Name              | Project name                                                                                                                                  |
| ProjectPath       | Folders that the project puts on the MATLAB path                                                                                              |
| ProjectReferences | Folders that contain referenced projects. Contains read-only project objects for referenced projects.                                         |
| RootFolder        | Full path to project root folder                                                                                                              |
| Shortcuts         | An array of the shortcuts in this project                                                                                                     |
| ShutdownFiles     | An array of the shutdown files in this project                                                                                                |
| StartupFiles      | An array of the startup files in this project                                                                                                 |

## Tips

Alternatively, you can use `slproject.loadProject` to load a project, and `slproject.getCurrentProjects` to get a project object. Use `simulinkproject` to open projects and explore projects interactively. Use `slproject.getCurrentProjects` and `slproject.loadProject` for project automation scripts.

## Version History

### Introduced in R2012a

#### **R2019a: Simulink project API is not recommended**

*Not recommended starting in R2019a*

Starting in R2019a, instead of `simulinkproject` and related functions, use the `currentProject` or `openProject` functions in MATLAB. The Simulink project API will continue to be supported, but, after R2019a, new features will be available only if you use the new MATLAB project API. There are no plans to remove the Simulink project API at this time.

You can continue to use `simulinkproject` and related functions listed in `methods(simulinkproject)`. New functions added after R2019a, such as `runChecks` and `listImpactedFiles`, do not work with `simulinkproject`. Use `currentProject` instead.

The new MATLAB project API is part of the R2019a functionality enabling you to use projects in MATLAB, with or without Simulink. You can now share projects with users who do not have Simulink.

# Simulink.allBlockDiagrams

Find loaded Simulink models and libraries

## Syntax

```
bd = Simulink.allBlockDiagrams()
bd = Simulink.allBlockDiagrams(type)
```

## Description

`bd = Simulink.allBlockDiagrams()` returns all loaded block diagrams, including models and libraries.

`bd = Simulink.allBlockDiagrams(type)` returns either models or libraries.

## Examples

### Find Loaded Models

Find all loaded models in the current Simulink session, excluding libraries. The example shows a result from a typical session.

```
Simulink.allBlockDiagrams('model')
```

```
ans =

 237.0001
 56.0001
 2.0001
```

### Get Names of Loaded Block Diagrams

Find all loaded models in the current Simulink session and return results as names. Use `Simulink.allBlockDiagrams` with `get_param` to get the names. The example shows a result from a typical session and includes loaded libraries and models.

```
get_param(Simulink.allBlockDiagrams(), 'Name')
```

```
ans =

 5×1 cell array

 {'simulink_extras'}
 {'simulink' }
 {'sldemo_fuelsys' }
```

```
{'f14' }
{'vdp' }
```

### **Get Loaded Block Diagrams Based on Parameter**

Find all loaded models in the current Simulink session whose 'Dirty' parameter is 'on'.

```
bds = Simulink.allBlockDiagrams();
dirtyBds = bds(strcmp(get_param(bds,'Dirty'),'on'));
```

### **Input Arguments**

**type** — Type of block diagram whose blocks to return

'model' | 'library'

Type of block diagram whose blocks to return, specified as 'model' or 'library'.

### **Output Arguments**

**bd** — Loaded block diagrams

array of handles

Loaded block diagrams, returned as an array of handles.

### **Version History**

**Introduced in R2018a**

### **See Also**

# Simulink.architecture.add

Add tasks or triggers to selected architecture of model

## Syntax

```
Simulink.architecture.add(Type, Object)
```

## Description

`Simulink.architecture.add(Type, Object)` adds the new task or trigger `Object` of the specified `Type` to a model.

## Examples

### Add periodic trigger

Add a task, `MyTask1`, to the software node `MulticoreProcessor` of the selected architecture of the `slexMulticoreExample` model.

```
slexMulticoreExample;
Simulink.architecture.add('Task', 'slexMulticoreExample/MulticoreProcessor/Core2/MyTask1');
```

## Input Arguments

### Type — Object type

'PeriodicTrigger' | 'AperiodicTrigger' | 'Task'

Object type that identifies the kind of trigger or task to add, , specified as a 'PeriodicTrigger', 'AperiodicTrigger', or 'Task'.

- 'PeriodicTrigger'

Adds a periodic trigger to the architecture. Set the properties of the trigger with the `Simulink.architecture.set_param` function.

- 'AperiodicTrigger'

Adds an aperiodic trigger to the architecture. Set the properties of the trigger with the `Simulink.architecture.set_param` function.

- 'Task'

Adds a task to the architecture. Set the properties of the task with the `Simulink.architecture.set_param` function.

### Object — Trigger or task object identifier

character vector

Trigger or task object identifier to add to architecture, specified as a character vector.

Example: 'slexMulticoreExample/MulticoreProcessor/Core2/MyTask1'

Data Types: char

## **Version History**

**Introduced in R2014a**

### **See Also**

`Simulink.architecture.register`

# Simulink.architecture.config

Create or convert configuration for concurrent execution

## Syntax

```
Simulink.architecture.config(model, 'Convert')
Simulink.architecture.config(model, 'Add')
Simulink.architecture.config(model, 'OpenDialog')
```

## Description

`Simulink.architecture.config(model, 'Convert')` converts the active configuration set in the specified model to one for concurrent execution.

`Simulink.architecture.config(model, 'Add')` adds and activates a new configuration set for concurrent execution.

`Simulink.architecture.config(model, 'OpenDialog')` opens the Concurrent Execution dialog box for a model configuration.

## Examples

### Convert existing configuration set

Convert existing configuration set for concurrent execution in the model `vdp`.

```
vdp;
Simulink.architecture.config('vdp', 'Convert');
```

### Add new configuration set

Add a new configuration set (copied from the existing configuration set) for concurrent execution in the model `vdp`.

```
vdp;
Simulink.architecture.config('vdp', 'Add');
```

### Open Concurrent Execution dialog box

Open the Concurrent Execution dialog box in the model `slexMulticoreExample`.

```
slexMulticoreExample;
Simulink.architecture.config('slexMulticoreExample','OpenDialog');
```

## Input Arguments

### **model** — Model name

character vector

Model name whose configuration set you want to convert or add to, specified as a character vector.

Example:

Data Types: char

## Version History

Introduced in R2014a

# signalBuilderToSignalEditor

Import signal data and properties from Signal Builder block to Signal Editor block

## Syntax

```
signal_editor = signalBuilderToSignalEditor(signal_builder,Name,Value)
[signal_editor,sorted_group_index,sorted_group_names] =
signalBuilderToSignalEditor(signal_builder,Name,Value)
```

## Description

`signal_editor = signalBuilderToSignalEditor(signal_builder,Name,Value)` imports signal data and properties from Signal Builder block to the Signal Editor block. This function adds a Signal Editor block to the current model using the signal data and properties from the Signal Builder block. To contain the signal data and properties, the function creates a new MAT-file.

During the port, the `signalBuilderToSignalEditor` function:

- Unicode group names are prefixed with `Test_Case_`.
- Group names are converted to valid MATLAB variable names with leading and trailing white spaces removed.
- Group names are converted with trailing underscores removed.
- Remaining numbers maintained in the scenario name.
- Orders signal groups alphabetically.
- Creates unique group names from existing names following MATLAB conventions.

The `signalBuilderToSignalEditor` function does not support

- Models that contain test case parameters. You can successfully port data from the Signal Builder block, but you cannot initialize parameters with the Signal Editor block in test harnesses generated by Simulink Design Verifier.
- Models that contain Signal Builder signal generators created from the **Create and Connect Generator** context menu.

`[signal_editor,sorted_group_index,sorted_group_names] = signalBuilderToSignalEditor(signal_builder,Name,Value)` outputs vectors containing the signal groups and group names.

## Examples

### Replace Signal Builder Block with Signal Editor Block

This example shows how to replace an existing Signal Builder block with a Signal Editor block. To store signals from Signal Builder, the example creates `RoadProfilesMine.mat`.

```
model = 'ex_replace_signalbuilder';
open_system(model);
```

```

sbBlockH = [model '/Road Profiles'];
seBlockH = signalBuilderToSignalEditor(sbBlockH,...
'Replace',true,'FileName','RoadProfilesMine.mat');

```

Copyright 2018-2022 The MathWorks, Inc.

## Input Arguments

### **signal\_builder** — Signal Builder block to replace

current model (default) | scalar

Signal Builder block to replace, specified as a scalar.

Data Types: char | string

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'FileName','RoadProfilesMine.mat'`

### **FileName** — MAT-file that stores signals

'dataset.mat' (default) | scalar

MAT-file that `signalBuilderToSignalEditor` creates to store signals and properties, specified as a scalar. Do not use a file name from one locale in a different locale. When using the block on multiple platforms, consider specifying just the MAT-file name and having the MAT-file be on the MATLAB path.

Data Types: char | string

### **Replace** — Replace Signal Builder block with Signal Editor block

false (default) | true

Replace Signal Builder block with Signal Editor block, specified as true or false.

Data Types: logical

## Output Arguments

### **signal\_editor** — Signal Editor block handle

scalar

Signal Editor block handle, specified as a scalar.

### **sorted\_group\_index — List of Signal Builder group indices**

vector

List of Signal Builder group indices, specified as a vector and ordered as they will appear in the Signal Editor.

### **sorted\_group\_names — List of Signal Builder group names**

cell array

Signal Editor group names, specified as a cell array of vectors, in alphabetical order.

The names are unique valid MATLAB variable names generated from the Signal Builder group names.

.

## **Limitations**

The Signal Editor block can output a bus for each signal, but cannot output all signals in a single bus. If the Signal Builder block from which you are importing signal data has a bus as output, consider:

- Creating or using an existing `Simulink.Bus` bus object to contain the Signal Builder bus signals. The `Simulink.Bus` object contains the `Simulink.BusElement` that define each element in the `Simulink.Bus` object.
- In the Signal Editor user interface, creating a bus element and dragging and dropping the signals imported from the Signal Builder block into that bus element.
- After running the `signalBuilderToSignalEditor` function, select the **Output a bus signal** check box in the Signal Editor block and enter the Signal Builder bus object name in **Select bus object** text box.

## **Version History**

**Introduced in R2018a**

## Simulink.architecture.delete

Delete triggers and tasks from selected architecture of model

### Syntax

```
Simulink.architecture.delete(Object)
```

### Description

`Simulink.architecture.delete(Object)` deletes the specified object trigger or task.

### Examples

#### Delete task Plant

Delete the task Task3 from the Core2 periodic trigger of the MulticoreProcessor software node of the selected architecture of the `slexMulticoreExample` model.

```
slexMulticoreExample
Simulink.architecture.delete('slexMulticoreExample/MulticoreProcessor/Core2/Task3')
```

### Input Arguments

**Object** — Object to delete, specified as a character vector

character vector

Object to be deleted. Possible objects are:

- Periodic trigger

---

**Note** You cannot delete the last periodic trigger. The software node must contain at least one periodic trigger.

---

- Aperiodic trigger
- Task

Example: `[bdroot '/MulticoreProcessor/Core2/Task3']`

Data Types: char

## Version History

**Introduced in R2014a**

**See Also**

`Simulink.architecture.get_param` | `Simulink.architecture.add` |  
`Simulink.architecture.find_system` | `Simulink.architecture.importAndSelect` |  
`Simulink.architecture.profile` | `Simulink.architecture.register`

## Simulink.architecture.find\_system

Find objects under architecture object

### Syntax

```
object = Simulink.architecture.find_system(RootObject)
```

```
object = Simulink.architecture.find_system(RootObject, ParamName, ParamValue)
```

### Description

`object = Simulink.architecture.find_system(RootObject)` looks for all objects under `RootObject`.

`object = Simulink.architecture.find_system(RootObject, ParamName, ParamValue)` returns the object in `RootObject` whose parameter `ParamName` has the value `ParamValue`. Parameter name and value character vectors are case-sensitive.

### Examples

#### Look for all objects

To find all the objects in `slexMulticoreExample`:

```
slexMulticoreExample
t = Simulink.architecture.find_system('slexMulticoreExample')

t =

 'slexMulticoreExample'
 'slexMulticoreExample/MulticoreProcessor'
 'slexMulticoreExample/MulticoreProcessor/Core1'
 'slexMulticoreExample/MulticoreProcessor/Core1/Task1'
 'slexMulticoreExample/MulticoreProcessor/Core1/Task2'
 'slexMulticoreExample/MulticoreProcessor/Core2'
 'slexMulticoreExample/MulticoreProcessor/Core2/Task3'
 'slexMulticoreExample/MulticoreProcessor/Core2/Task4'
```

#### Look for all tasks

To find all the tasks in `slexMulticoreExample`:

```
slexMulticoreExample
t = Simulink.architecture.find_system('slexMulticoreExample', 'Type', 'Task')

t =

 'slexMulticoreExample/MulticoreProcessor/Core1/Task1'
 'slexMulticoreExample/MulticoreProcessor/Core1/Task2'
```

```
'slexMulticoreExample/MulticoreProcessor/Core2/Task3'
'slexMulticoreExample/MulticoreProcessor/Core2/Task4'
```

## Input Arguments

### RootObject — Object to search

character vector

Object to search for parameter value, specified as a character vector giving the object full path name. Possible objects are:

- Model
- Software node
- Hardware node
- Periodic trigger
- Aperiodic trigger
- Task

Example: 'slexMulticoreExample'

### ParamName — Name of parameter to find

character vector | scalar | vector

Name of the parameter to find. Possible values are:

- 'Name'
- 'Type'
- 'ClockFrequency'
- 'Color'
- 'Period'
- 'EventHandlerType'
- 'SignalNumber'
- 'EventName'

Example: 'EventName'

### ParamValue — Parameter value to find

character vector | scalar | vector

Parameter value to find, specified as a character vector, a scalar, or a vector.

Example: 'ERTDefaultEvent'

## Version History

Introduced in R2014a

**See Also**

# Simulink.architecture.get\_param

Get configuration parameters of architecture objects

## Syntax

```
ParamValue = Simulink.architecture.get_param(Object,ParamName)
```

## Description

`ParamValue = Simulink.architecture.get_param(Object,ParamName)` returns the value of the specified parameter for the object, `Object`. `ParamName` is case-sensitive.

## Examples

### Get period

Get the period of task `Task3` of trigger `Core2` of software node `MulticoreProcessor` of the selected architecture for the model `slexMulticoreExample`.

```
slexMulticoreExample;
p = Simulink.architecture.get_param('slexMulticoreExample/MulticoreProcessor/Core2/Task3','Period')

p =

0.2
```

## Input Arguments

### Object — Object whose parameter value to return

character vector

Object whose parameter value to return, specified as a character vector giving the object full path name. Possible objects are:

- Software node
- Hardware node
- Periodic trigger
- Aperiodic trigger
- Task

### ParamName — Parameter whose value to return

character vector

Name of a parameter for which `Simulink.architecture.get_param` returns a value.

The following are the possible `ParamName` values:

For a model:

- 'ArchitectureName'
- 'Type'

For a software node:

- 'Name'
- 'Type'

For a hardware node

- 'Name'
- 'ClockFrequency'
- 'Color'
- 'Type'

For a periodic trigger:

- 'Name'
- 'Period'
- 'Color'
- 'Type'

For an aperiodic trigger:

- 'Name'
- 'Color'
- 'EventHandlerType'
- 'SignalNumber'
- 'EventName'
- 'Type'

For a task:

- 'Name'
- 'Period'
- 'Color'
- 'Type'

## **Version History**

`Simulink.architecture.register`

# Simulink.architecture.importAndSelect

Import and select target architecture for concurrent execution environment for model

## Syntax

```
Simulink.architecture.importAndSelect(model,Architecture)
```

```
Simulink.architecture.importAndSelect(model,
CustomArchitectureDescriptionFile)
```

## Description

`Simulink.architecture.importAndSelect(model,Architecture)` imports and selects the built-in target architecture for the concurrent execution environment for the model.

Importing and selecting target architectures requires that the associated support packages or hardware is installed on your computer.

`Simulink.architecture.importAndSelect(model,CustomArchitectureDescriptionFile)` imports and selects the architecture from an XML-based architecture description file.

Importing and selecting target architectures requires that the associated support packages or hardware is installed on your computer.

## Examples

### Import and select a different architecture

Import and select the sample architecture to the model `slexMulticoreExample`.

```
slexMulticoreExample
Simulink.architecture.importAndSelect('slexMulticoreExample','Sample Architecture')
```

### Import and select a custom architecture

Import and select the custom architecture defined in the XML file `custom_arch.xml`. This example requires you to create a `custom_arch.xml` file first.

```
slexMulticoreExample
Simulink.architecture.importAndSelect('slexMulticoreExample','custom_arch.xml')
```

## Input Arguments

### **model** — Model

character vector

Model to import architecture to, specified as a character vector.

Data Types: char

### Architecture — Target architecture name

character vector

Target architecture name to import into the concurrent execution environment for the model.  
Possible target names are:

| Property                           | Description                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Multicore'                        | Single CPU with multiple cores                                                                                                                    |
| 'Sample Architecture'              | Example architecture consisting of single CPU with multiple cores and two FPGAs. You can use this architecture to model for concurrent execution. |
| 'Simulink Real-Time'               | Simulink Real-Time™ target                                                                                                                        |
| 'Xilinx Zynq ZC702 evaluation kit' | Xilinx® Zynq® ZC702 evaluation kit target                                                                                                         |
| 'Xilinx Zynq ZC706 evaluation kit' | Xilinx Zynq ZC706 evaluation kit target                                                                                                           |
| 'Xilinx Zynq Zedboard'             | Xilinx Zynq ZedBoard™ target                                                                                                                      |

Data Types: char

### CustomArchitectureDescriptionFile — Custom target architecture file

XML file

Custom target architecture file name, in XML format, that describes a custom target for the concurrent execution environment for the model, specified as a character vector giving the XML file name.

Example: `custom_arch.xml`

## Version History

Introduced in R2014a

### See Also

### Topics

“Define a Custom Architecture File”

# Simulink.architecture.profile

Generate profile report for model configured for concurrent execution

## Syntax

```
Simulink.architecture.profile(model)
Simulink.architecture.profile(model,numSamples)
```

## Description

`Simulink.architecture.profile(model)` generates a profile report for a model configured for concurrent execution. Subsequent calls to the command for the same model name overwrite the existing profile report.

`Simulink.architecture.profile(model,numSamples)` specifies the number of samples to generate a profile report.

## Examples

### Generate profile report

Generate profile report for the model `slexMulticoreExample`.

```
slexMulticoreExample;
Simulink.architecture.profile('slexMulticoreExample');
```

The command creates the file `slexMulticoreExample_ProfileReport.html` in the current folder and opens it.

### Generate profile report for 120 time steps

Generate profile report for the model `slexMulticoreExample` with data for 120 time steps.

```
slexMulticoreExample;
Simulink.architecture.profile('slexMulticoreExample',120);
```

The command creates the file `slexMulticoreExample_ProfileReport.html` in the current folder.

## Input Arguments

### **model** — Model to profile

character vector

Model to profile, specified as a character vector. Specify a model that is configured for concurrent execution.

Data Types: char

**numSamples — Number of time steps**

100 (default) | real, positive integer

Number of time steps, specified as a real, positive integer. This value determines the number of steps to collect data for in the profiled model.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Version History

**Introduced in R2014a**

`Simulink.architecture.register`

### Topics

“Profile and Evaluate Explicitly Partitioned Models on a Desktop”

# Simulink.architecture.register

Add custom target architecture to concurrent execution target architecture selector

## Syntax

```
Simulink.architecture.register(CustomArchFile)
```

## Description

`Simulink.architecture.register(CustomArchFile)` adds an XML-format custom target architecture file `CustomArchFile` to the concurrent execution target architecture selector. To access this selector, click the **Select** button on the Concurrent Execution pane of the Concurrent Execution dialog box.

## Examples

### Add custom target architecture

Add custom target architecture defined in the XML file `custom_arch.xml` to the concurrent execution target architecture selector. This example requires you to create a `custom_arch.xml` first.

```
slexMulticoreExample
Simulink.architecture.register('custom_arch.xml')
```

## Input Arguments

### CustomArchFile — Custom target architecture file

XML file

Custom target architecture file that describes a custom target for concurrent execution, specified as an XML file.

## Version History

Introduced in R2014a

## See Also

`Simulink.architecture.set_param` | `Simulink.architecture.add` |  
`Simulink.architecture.delete` | `Simulink.architecture.find_system` |

## Simulink.Block.getInternalDataType

Get data type of block parameter

### Syntax

```
dataType = Simulink.Block.getInternalDataType(block,parameter,mode)
dataType = Simulink.Block.getInternalDataType(block,parameter)
```

### Description

`dataType = Simulink.Block.getInternalDataType(block,parameter,mode)` returns the data type of block parameter when its value is set to `Inherit: Inherit via internal rule`. Specify `mode` to compile or not compile the model before returning the data type.

`dataType = Simulink.Block.getInternalDataType(block,parameter)` returns the data type of the parameter from the previous model compilation.

### Examples

#### Return Data Type for Parameters

Return the data type for the Gain block of the `slex_getInternalDataType` model.

#### Gain Block ParamDataTypeStr Parameter with Uncompiled Model

Return the data type for the `ParamDataTypeStr` parameter in the Gain block.

Set model to `slex_getInternalDataType`.

```
model='slex_getInternalDataType';
```

Load `slex_getInternalDataType`.

```
load_system('slex_getInternalDataType');
```

Get the data type of the Gain block with uncompiled model.

```
dataType=Simulink.Block.getInternalDataType([model, '/Gain'],...
 'ParamDataTypeStr','cached')
```

```
dataType =
'auto'
```

#### Gain Block ParamDataTypeStr Parameter with Compiled Model

Get the data type of the Gain block with compiled model.

```
dataType=Simulink.Block.getInternalDataType([model, '/Gain'],...
 'ParamDataTypeStr','compiled')
```

```
dataType =
'ufix16_En15'
```

## Input Arguments

### **block** — Block

character vector | block handle

Block, specified as a character vector or block handle.

Example: [model, '/Gain']

### **parameter** — Block parameter

character vector | string

Block parameter programmatic name, specified as character vector or string. This parameter must be set to `Inherit: Inherit` via `internal` rule in the model.

Example: 'ParamDataTypeStr'

Data Types: char | string

### **mode** — Model compilation

cached (default) | compiled

Model compilation, specified as:

- `cached` — Return data before model is compiled.
- `compiled` — Return data after model is compiled.

The function compiles the model based on this setting.

Example: 'cached'

## Output Arguments

### **dataType** — Data type of parameter

scalar

Data type of parameter, returned as a scalar character vector.

## Limitations

This function returns the data type for only these blocks:

- `Sqrt` — `IntermediateResultsDataTypeStr`
- 1-D Lookup Table block, 2-D Lookup Table block, and n-D Lookup Table block — `IntermediateResultsDataTypeStr` or `FractionDataTypeStr`
- `Gain` — `ParamDataTypeStr`

## Version History

**Introduced in R2023a**

**See Also**

Gain | Sqrt | 1-D Lookup Table | 2-D Lookup Table | n-D Lookup Table

**Topics**

Control Block Parameter Data Types

# Simulink.architecture.set\_param

Set architecture object properties

## Syntax

```
Simulink.architecture.set_param(Object, ParamName, ParamValue)
```

## Description

`Simulink.architecture.set_param(Object, ParamName, ParamValue)` sets the specified parameter of `Object` to the specified value. Parameter name and value character vectors are case sensitive.

## Examples

### Set software node name

Set the software node name from `MulticoreProcessor` to `MyCPUNewName`.

```
slexMulticoreExample
Simulink.architecture.set_param([bdroot '/MulticoreProcessor'], 'Name', 'MyCPUNewName');
```

### Change Periodic

Set `Core2` trigger period to `.01`.

```
slexMulticoreExample
Simulink.architecture.set_param([bdroot '/MyCPUNewName/Core2'], 'Period', '.01')
```

## Input Arguments

### Object — Object whose parameter value to set

character vector

Object whose parameter value to set, specified as a character vector giving the object full path name. Possible objects are:

- Software node
- Hardware node
- Periodic trigger
- Aperiodic trigger
- Task

### ParamName — Name of the parameter to set

character vector

Name of parameter whose value to set.

These are the possible parameters whose values you can set for each of the object types:

For software node:

- 'Name' — Name of the software node.

For hardware node:

- 'Name' — Name of the hardware node.
- 'ClockFrequency' — Frequency of the hardware node clock.
- 'Color' — Color of the trigger icon, specified as an RGB triplet (vector).

For a periodic trigger:

- 'Name' — Name of the trigger.
- 'Period' — Period of the trigger.
- 'Color' — Color of the trigger icon, specified as an RGB triplet (vector).

For an aperiodic trigger:

- 'Name' — Name of the trigger.
- 'Color' — Color of the trigger icon, specified as an RGB triplet (vector).
- 'EventHandlerType' — Trigger source for the interrupt-driven task. Possible values:
  - 'Event (Windows)'
  - 'Posix Signal (Linux/VxWorks 6.x)'
- 'SignalNumber' — Signal number for the trigger. You can set this value only if `EventHandlerType` is set to `Event (Windows)`.
- 'EventName' — Event name for the trigger. You can set this value only if `EventHandlerType` is set to `Posix Signal (Linux/VxWorks 6.x)`.

For task:

- 'Name' — Name of the task.
- 'Period' — Period of the task.
- 'Color' — Color of the task icon, specified as an RGB triplet (vector).

Data Types: char

**ParamValue — Value to set the parameter to**

character vector | vector

Value to set the parameter to, specified as a character vector, scalar, or vector. The possible values depend on the parameter.

Example: 'MyCPUNewName'

## Simulink.Block.getSampleTimes

Return sample time information for a block

### Syntax

```
ts = Simulink.Block.getSampleTimes(block)
```

### Input Arguments

*block*

Full name or handle of a Simulink block

### Output Arguments

*ts*

The command returns *ts* which is a 1xn array of Simulink.SampleTime objects associated with the model passed to Simulink.Block.getSampleTimes. Here *n* is the number of sample times associated with the block. The format of the returns is:

```
1xn Simulink.SampleTime
Package: Simulink
value: [1x2 double]
Description: [char string]
ColorRGBValue: [1x3 double]
Annotation: [char string]
OwnerBlock: [char string]
ComponentSampleTimes: [1x2 struct]
Methods
```

- *value* — A two-element array of doubles that contains the sample time period and offset
- *Description* — A character vector or string that describes the sample time type
- *ColorRGBValue* — A 1x3 array of doubles that contains the red, green and blue (RGB) values of the sample time color
- *Annotation* — A character vector or string that represents the annotation of a specific sample time (e.g., 'D1')
- *OwnerBlock* — For asynchronous and variable sample times, a character vector or string containing the full path to the block that controls the sample time. For all other types of sample times, an empty character vector or string.
- *ComponentSampleTimes* — A structure array of elements of the same type as Simulink.BlockDiagram.getSampleTimes if the sample time is an async union or if the sample time is hybrid and the component sample times are available.

### Description

`ts = Simulink.Block.getSampleTimes(block)` performs an update diagram and then returns the sample times of the block connected to the input argument *mdl/signal*. This method performs an update diagram to ensure that the sample time information returned is up-to-date. If the model is already in the compiled state via a call to the model API, then an update diagram is not necessary.

Using this method allows you to access all information in the Sample Time Legend programmatically.

## Simulink.BlockDiagram.addBusToVector

Convert virtual bus signals into vector signals by adding Bus to Vector blocks

### Syntax

```
[destBlocks, busToVectorBlocks, ignoredBlocks] =
Simulink.BlockDiagram.addBusToVector(model)
[destBlocks, busToVectorBlocks, ignoredBlocks] =
Simulink.BlockDiagram.addBusToVector(model, includeLibs)
[destBlocks, busToVectorBlocks, ignoredBlocks] =
Simulink.BlockDiagram.addBusToVector(model, includeLibs, reportOnly)
[destBlocks, busToVectorBlocks, ignoredBlocks] =
Simulink.BlockDiagram.addBusToVector(model, includeLibs, reportOnly, strictOnly)
```

### Description

[destBlocks, busToVectorBlocks, ignoredBlocks] = Simulink.BlockDiagram.addBusToVector(model) searches a model, excluding any library blocks, for bus signals used implicitly as vectors, and returns the results of the search.

[destBlocks, busToVectorBlocks, ignoredBlocks] = Simulink.BlockDiagram.addBusToVector(model, includeLibs) searches a model, and if includeLibs is true, includes in the search library blocks for bus signals used implicitly as vectors.

[destBlocks, busToVectorBlocks, ignoredBlocks] = Simulink.BlockDiagram.addBusToVector(model, includeLibs, reportOnly) searches a model, and if reportOnly is set to false, then the function inserts a Bus to Vector block into each bus that is used as a vector in any block that it searches. The insertion replaces the implicit use of a bus as a vector with an explicit conversion of the bus to a vector. The source and destination blocks of the signal do not change.

If Simulink.BlockDiagram.addBusToVector adds Bus to Vector blocks to the model or any library, the function changes the saved copy of the diagram.

If Simulink.BlockDiagram.addBusToVector changes a library block, the change affects every instance of that block in every model that uses the library.

[destBlocks, busToVectorBlocks, ignoredBlocks] = Simulink.BlockDiagram.addBusToVector(model, includeLibs, reportOnly, strictOnly) searches a model, and if strictOnly is true, the function checks for input bus signals used implicitly as vectors that are fed into one of these blocks. These blocks cannot take virtual bus signals, but they can accept nonvirtual bus signals:

- Delay
- Selector
- Assignment
- Vector Concatenate
- Reshape

- Permute Dimensions

## Examples

### Identify Bus-To-Vector Conversions

Model `ex_bus_to_vector` simulates correctly, but the input to the Gain block is a bus, while the output is a vector. The Gain block implicitly converts the bus to a vector.

Open the model.

```
openExample('simulink/ConvertBusSignalToAVectorExample',...
'supportingFile','ex_bus_to_vector.slx')
```

Identify buses treated as vectors.

```
[blocks] = Simulink.BlockDiagram.addBusToVector(...
'ex_bus_to_vector')

Processing block diagram 'ex_bus_to_vector'
Number of blocks left that are connected to a bus being used as a vector: 2
Done processing block diagram 'ex_bus_to_vector'

blocks =

 1x2 struct array with fields:

 BlockPath
 InputPort
 LibPath
```

To understand the relationship between `Simulink.BlockDiagram.addBusToVector` and the **Bus signal treated as vector** configuration parameter, see “Manage Bus-to-Vector Conversions” on page 12-16.

### Add Bus to Vector Blocks

Model `ex_bus_to_vector` simulates correctly, but the input to the Gain block is a bus, while the output is a vector. The Gain block implicitly converts the bus to a vector.

Open the model.

```
openExample('simulink/ConvertBusSignalToAVectorExample',...
'supportingFile','ex_bus_to_vector.slx')
```

Insert Bus to Vector blocks.

When you use function `Simulink.BlockDiagram.addBusToVector` with `reportOnly` set to `false`, the function saves the model. To create a writable copy of model `ex_bus_to_vector`, this example uses the `save_system` function.

```
save_system('ex_bus_to_vector','ex_bus_to_vector_blocks');
[blocks,busToVectors] = Simulink.BlockDiagram.addBusToVector(...
'ex_bus_to_vector_blocks',true,false);
```

The Gain block no longer implicitly converts the bus to a vector. The inserted Bus to Vector block performs the conversion explicitly. The Bus to Vector block is virtual and does not affect simulation results, code generation, or performance.

To understand the relationship between `Simulink.BlockDiagram.addBusToVector` and the **Bus signal treated as vector** configuration parameter, see “Manage Bus-to-Vector Conversions” on page 12-16.

## Input Arguments

### **model** — Model name or handle

character vector | string scalar | numeric scalar

Model name or handle, specified as a character vector, string scalar, or numeric scalar.

Data Types: double | char | string

### **includeLibs** — Search library blocks

false (default) | true

Search library blocks, specified as `false` or `true`.

- `false` — Search only the blocks in the model.
- `true` — Search library blocks for bus signals used implicitly as vectors.

Specify as the second argument.

Data Types: `logical`

### **reportOnly** — Report results without changing model

`true` (default) | `false`

Choice to report results without changing the model, specified as `false` or `true`.

- `false` — Update the model by inserting Bus to Vector blocks for bus signals that are implicitly used as vectors.
- `true` — Report search results, but do not change the model.

Specify as the third argument. Also specify the `model` and `includeLibs` arguments.

Data Types: `logical`

### **strictOnly** — Check input bus signals used implicitly as vectors that feed blocks that can accept nonvirtual, but not virtual, bus signals

`false` (default) | `true`

Check input bus signals used implicitly as vectors that feed blocks that can accept nonvirtual, but not virtual, bus signals, specified as `false` or `true`. If `strictOnly` is `true`, the function checks for input bus signals used implicitly as vectors that are fed into one of these blocks. These blocks cannot take virtual bus signals, but they can accept nonvirtual bus signals.

- Delay
- Selector
- Assignment
- Vector Concatenate
- Reshape
- Permute Dimensions

Specify as the fourth argument. You must also specify the `model`, `includeLibs`, and `reportOnly` arguments.

Data Types: `logical`

## **Output Arguments**

### **destBlocks** — Blocks connected to buses but that treat buses as vectors

array of structures

Blocks connected to buses that treat buses as vectors, returned as an array of structures. Each structure in the array contains these fields:

- `BlockPath` — Character vector specifying the path to the block to which the bus connects.
- `InputPort` — Integer specifying the input port to which the bus connects.
- `LibPath` — If the block is a library block instance, and if `includeLibs` is `true`, the field value is the path to the source library block. Otherwise, `LibPath` is empty (`[]`).

### **busToVectorBlocks** — Bus to Vector blocks added by function

cell array

Bus to Vector blocks added by function, specified as a cell array. If `reportOnly` is set to `false`, the cell array contains the paths to each Bus to Vector block that the function added to replace buses used as vectors. Otherwise, `busToVectorBlocks` is empty (`[]`).

### **ignoredBlocks — Cases where function cannot insert Bus to Vector block**

array of structures

Cases where function cannot insert Bus to Vector block, specified as an array of structures. Each structure in the array contains these fields:

- `BlockPath` — Character vector specifying the path to the block to which the bus connects.
- `InputPort` — Integer specifying the input port to which the bus connects.

These cases occur when a Bus to Vector cannot be inserted because the input virtual bus signal consists of elements with mixed attributes.

### **Tips**

- Before you execute this function:
  - 1** Ensure that the model compiles without error.
  - 2** Save the model.
- Back up the model and any libraries before calling the function with `reportOnly` set to `false`.
- To preview the effects of the change on blocks in all models, call `Simulink.BlockDiagram.addBusToVector` with `includeLibs` set to `true` and `reportOnly` set to `true`. Then, examine the information returned in the `destBlocks` output argument.

# Simulink.BlockDiagram.arrangeSystem

Improve layout of block diagram

## Syntax

```
Simulink.BlockDiagram.arrangeSystem(bd)
Simulink.BlockDiagram.arrangeSystem(bd,FullLayout=tf)
```

## Description

`Simulink.BlockDiagram.arrangeSystem(bd)` improves the layout of the specified block diagram by realigning, resizing, and moving blocks and straightening signal lines.

`Simulink.BlockDiagram.arrangeSystem(bd,FullLayout=tf)` specifies whether to apply the automated layout even when the automated layout might not improve upon the original layout.

## Examples

### Arrange Programmatically Populated Model

You can use `Simulink.BlockDiagram.arrangeSystem` with any open model, and it is particularly useful with models you populate programmatically.

Blocks in the model `ex_arrange_system` are poorly arranged.

```
open_system('ex_arrange_system')
```

Blocks in its subsystem are also poorly arranged.

```
open_system('ex_arrange_system/Subsystem')
```

Programmatically arrange blocks in the top layer of the specified system.

```
Simulink.BlockDiagram.arrangeSystem('ex_arrange_system')
```

```
Simulink.BlockDiagram.arrangeSystem('ex_arrange_system/Subsystem')
```

### Force Automated Layout

By default, `Simulink.BlockDiagram.arrangeSystem` applies an automated layout only when the automated layout is expected to improve upon the original layout. You can force this function to apply the layout even when the automated layout might not improve upon the original layout.

Blocks in the model `ForceArrangeSystem` are arranged well.

```
open_system('ex_arrange_system2')
```

The automated layout might not improve upon the original layout because the blocks are already arranged well.

Suppose you want to apply the automated layout regardless of whether the automated layout is an improvement. To force the automated layout, set `FullLayout` to `true`.

```
Simulink.BlockDiagram.arrangeSystem('ex_arrange_system2',FullLayout='true')
```

## Input Arguments

### **bd** — Block diagram of system

character vector | string scalar | numeric scalar

Block diagram of system, specified as a character vector, string scalar, or numeric scalar.

Specify one of the following options:

- System name (must not include a path or extension)
- System handle
- Subsystem block path

Data Types: double | char | string

### **tf** — Option to force automated layout

'false' (default) | 'true'

Option to force automated layout, specified as 'true' or 'false'.

- 'true' — Applies the automated layout even when the automated layout might not improve upon the original layout
- 'false' — Applies the automated layout only when the automated layout is expected to improve upon the original layout.

# Simulink.BlockDiagram.buildRapidAcceleratorTarget

Build Rapid Accelerator target for model and return run-time parameter set

## Syntax

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget mdl)
```

## Description

`rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(mdl)` builds a Rapid Accelerator target for model, `mdl`, and returns run-time parameter set, `rtp`.

## Examples

### Build Rapid Accelerator Target for Model

In the MATLAB Command Window, type:

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget('f14')
Building the rapid accelerator target for model: f14
Successfully built the rapid accelerator target for model: f14

rtp =

 modelChecksum: [2.6812e+09 2.7198e+09 589261472 4.0180e+09]
 parameters: [1x1 struct]
```

## Input Arguments

### **mdl** — Simulink model name

string

Name or handle of a Simulink model

Example: 'modelName'

## Output Arguments

### **rtp** — Run-time parameter

string

Run-time parameter set that contains two elements:

- `modelChecksum`- 1x4 vector that encodes the structure of the model.
- `parameters`- A structure of the tunable parameters in the model. This structure contains the following fields.

**Run-time parameters**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dataTypeName | The data type name, for example, double.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| dataTypeId   | Internal data type identifier for use by Simulink Coder.                                                                                                                                                                                                                                                                                                                                                                                                   |
| complex      | Complex type or real type specification. Value is 0 if real, 1 if complex.                                                                                                                                                                                                                                                                                                                                                                                 |
| dtTransIdx   | Internal data type identifier for use by Simulink Coder.                                                                                                                                                                                                                                                                                                                                                                                                   |
| values       | All values associated with this entry in the <code>parameters</code> substructure.                                                                                                                                                                                                                                                                                                                                                                         |
| map          | Mapping structure information that correlates the values to the model tunable parameters. This structure contains the following fields: <ul style="list-style-type: none"> <li><b>Identifier:</b> Tunable parameter name.</li> <li><b>ValueIndices:</b> Start and end indices into the values field, [startIdx, endIdx]</li> <li><b>Dimensions:</b> Dimension of this tunable parameter (matrices are generally stored in column-major format).</li> </ul> |

## Simulink.BlockDiagram.copyContentsToSubsystem

Copy graphical contents from system to empty subsystem

### Syntax

```
Simulink.BlockDiagram.copyContentsToSubsystem(sys, subsystem)
```

### Description

`Simulink.BlockDiagram.copyContentsToSubsystem(sys, subsystem)` copies the blocks, lines, and annotations of the specified system to the specified subsystem. It does not affect nongraphical information such as configuration sets.

Use this function to convert a referenced model derived from an atomic subsystem into an atomic subsystem that is equivalent to the original subsystem.

To use this function:

- The specified system must be loaded in memory.
- The specified subsystem must be loaded in memory.
- The specified system must not contain the specified subsystem.
- The specified subsystem must not contain any blocks or lines. Other types of information can exist in the subsystem and are unaffected by the function. To delete the graphical content of the destination subsystem, use `Simulink.SubSystem.deleteContents`.

### Examples

#### Copy Block Diagram of Model to Subsystem

Copy the contents of a referenced model to an empty subsystem.

Open the `sldemo_mdref_basic` model.

```
openExample('sldemo_mdref_basic')
```

Add an empty subsystem to the model.

```
add_block('built-in/Subsystem', 'sldemo_mdref_basic/Subsystem')
```

Load the `sldemo_mdref_counter` referenced model that contains the contents to copy.

```
load_system('sldemo_mdref_counter')
```

Copy the graphical contents from the `sldemo_mdref_counter` referenced model to the empty subsystem.

```
Simulink.BlockDiagram.copyContentsToSubsystem...
('sldemo_mdref_counter', 'sldemo_mdref_basic/Subsystem')
```

## Input Arguments

### **sys** — System name or handle

numeric scalar | character vector | string scalar

System name or handle, specified as a numeric scalar, character vector, or string scalar.

The system name must not include a path or extension.

Example: 'model1'

Data Types: double | char | string

### **subsys** — Subsystem block path or handle

numeric scalar | character vector | string scalar

Subsystem block path or handle, specified as a numeric scalar, character vector, or string scalar.

Example: 'model2/Subsystem'

Data Types: double | char | string

## Version History

**Introduced in R2007a**

## Simulink.BlockDiagram.createSubsystem

Create subsystem containing specified set of blocks

### Syntax

```
Simulink.BlockDiagram.createSubsystem(blocks)
Simulink.BlockDiagram.createSubsystem()
Simulink.BlockDiagram.createSubsystem(____,Name,Value)
```

### Description

`Simulink.BlockDiagram.createSubsystem(blocks)` creates a subsystem and moves the specified blocks into it. All of the specified blocks must originally reside in the same block diagram.

If any of the blocks have unconnected ports, the function creates and connects Inport and Outport blocks to them inside the subsystem.

If any of the blocks are input or output port blocks, the function creates Inport and Outport blocks in the parent system to connect to the corresponding ports on the new Subsystem block.

`Simulink.BlockDiagram.createSubsystem()` replaces the currently selected blocks with a new subsystem that contains those blocks.

`Simulink.BlockDiagram.createSubsystem( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, 'Name', 'MySubsystem' names the new subsystem 'MySubsystem'.

### Examples

#### Create Subsystem from Model

Open or load the example model.

```
CreateSubsystemModel
```

Get the block handles for all blocks at the top level of the model by using the `Simulink.findBlocks` function.

```
bh = Simulink.findBlocks('CreateSubsystemModel');
```

Replace the contents of the model with a subsystem that contains the model contents.

```
Simulink.BlockDiagram.createSubsystem(bh);
```

#### Create Named Subsystem from Model

Open or load the example model.

## CreateSubsystemModel

Get the block handles for all blocks at the top level of the model by using the `Simulink.findBlocks` function.

```
bh = Simulink.findBlocks('CreateSubsystemModel');
```

Replace the contents of the model with a subsystem named `ss1` that contains the model contents.

```
Simulink.BlockDiagram.createSubsystem(bh, 'Name', 'ss1');
```

## Input Arguments

### blocks — Block handles

numeric array

Block handles, specified as a numeric array. To get block handles, use the `Simulink.findBlocks` or `gcbh` functions.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Simulink.BlockDiagram.createSubsystem(blocks, 'Name', 'MySubsystemName')`

### Name — Name of new subsystem

character vector | string scalar

Name of the new subsystem, specified as the comma-separated pair consisting of `'Name'` and a character vector or string scalar.

Data Types: `char` | `string`

### MakeNameUnique — Option to make subsystem name unique

`'on'` (default) | `'off'`

Option to make the subsystem name unique, specified as the comma-separated pair consisting of `'MakeNameUnique'` and `'on'` or `'off'`.

If the value that you specify for `Name` is already used in the diagram:

- `'on'` — Uses the next available increment of the name. For example, if `Name` is set to `'Controller'` and the diagram already contains a block named `'Controller'`, the function names the new subsystem `'Controller1'`.
- `'off'` — Returns an error.

### Dependencies

To use this parameter, specify a value for the `Name` argument.

Data Types: char | string

# Simulink.BlockDiagram.deleteContents

Delete graphical contents of system

## Syntax

```
Simulink.BlockDiagram.deleteContents(sys)
```

## Description

`Simulink.BlockDiagram.deleteContents(sys)` deletes the blocks, lines, and annotations in the specified system, which must be loaded in memory.

## Examples

### Delete Graphical Content from Model

Open the f14 model.

```
open_system('f14')
```

Delete the graphical content of the model, including all subsystems.

```
Simulink.BlockDiagram.deleteContents('f14')
```

## Input Arguments

### **sys** — System name or handle

character vector | string scalar | numeric scalar

System name or handle, specified as a character vector, string scalar, or numeric scalar.

A system name must not include a path or extension.

Example: 'myModel'

Data Types: double | char | string

## Tips

To delete the contents of a Subsystem block, use the `Simulink.SubSystem.deleteContents` function.

## Version History

Introduced in R2007a

## See Also

# Simulink.BlockDiagram.getAlgebraicLoops

Show algebraic loops in a model

## Syntax

```
Simulink.BlockDiagram.getAlgebraicLoops(model)
[loops,h] = Simulink.BlockDiagram.getAlgebraicLoops(model)
```

## Description

`Simulink.BlockDiagram.getAlgebraicLoops(model)` returns a list of algebraic loops in a model as a vector of `AlgebraicLoops` objects.

The Algebraic Loops viewer provides a tabular list of all algebraic loops in the model. Use the Algebraic Loops viewer to control the display of algebraic loops in your model.

```
[loops,h] = Simulink.BlockDiagram.getAlgebraicLoops(model)
```

## Examples

### Highlight all algebraic loops in model

Open the `ex_sl-demo_hydcyl` model.

In the **Diagnostics** pane of Model Configuration Parameters, set **Algebraic loop** to none or warning. Setting this parameter to error prevents the model from compiling.

Compile the model without any errors. The model must compile before you can highlight any algebraic loops.

At the MATLAB command prompt, enter:

```
mdl = 'ex_sl-demo_hydcyl';
load_system(mdl);
Simulink.BlockDiagram.getAlgebraicLoops(bdroot)
```

AlgebraicLoop with properties:

```

 Model: [1x1 Simulink.BlockDiagram]
 Id: [0 1]
VariableBlockHandles: [198.0001 145.0001]
 BlockHandles: [9x1 double]
 IsArtificial: 0
```

The resulting output shows that the model has one algebraic loop, which contains three blocks.

Running the `getAlgebraicLoops` function also opens the Algebraic Loop viewer. Use the Algebraic loop viewer to highlight specific algebraic loops in your model or all the loops.

The selected loops are highlighted in the corresponding model, in.

## Input Arguments

### model – Model to highlight

string scalar | character vector

Name of the model being tested, specified as a string scalar or character vector. You can also pass the most recently opened model using `bdroot`.

---

**Note** The model must be loaded into memory using either `open_system` or `load_system`.

---

Data Types: char | string

## Output Arguments

### Loops – Algebraic loops

vector of AlgebraicLoop objects

Every algebraic loop in the model returned as an `AlgebraicLoop` object that contains the following information:

- `Model`— `Simulink.BlockDiagram` object representing the model
- `Id`— Index of the algebraic loop in the model
- `VariableBlockHandles`: Handles to blocks that have been assigned algebraic variables
- `BlockHandles`—Handles to all the blocks contained in the algebraic loop
- `IsArtificial`— Boolean value indicating whether the loop is an artificial algebraic loop.

#### **h — Handle to control UI**

`matlab.ui.Figure` handle

The control UI is a MATLAB figure window. Use the UI handle `h` to control it programmatically. For more information, see [Figure Properties](#).

## Simulink.BlockDiagram.expandSubsystem

Replace subsystem with subsystem contents

### Syntax

```
Simulink.BlockDiagram.expandSubsystem(subsys)
Simulink.BlockDiagram.expandSubsystem(subsys, 'CreateArea', specifier)
```

### Description

`Simulink.BlockDiagram.expandSubsystem(subsys)` replaces the specified subsystem with its contents in the block diagram that contains it. The file that contains the subsystem must be open or loaded.

You can expand virtual subsystems that are not masked, linked, or commented. For details, see “What Subsystems Can You Expand?”.

`Simulink.BlockDiagram.expandSubsystem(subsys, 'CreateArea', specifier)` provides the option of not creating an area around the expanded subsystem contents.

### Examples

#### Expand Subsystem

Replace a subsystem with its contents.

Open the example model, which contains a subsystem that separates functionally related blocks.

```
open_system('SubsystemExpansionModel')
```

Expand the subsystem.

```
Simulink.BlockDiagram.expandSubsystem('SubsystemExpansionModel/Subsystem')
```

An area that contains the subsystem contents replaces the Subsystem block.

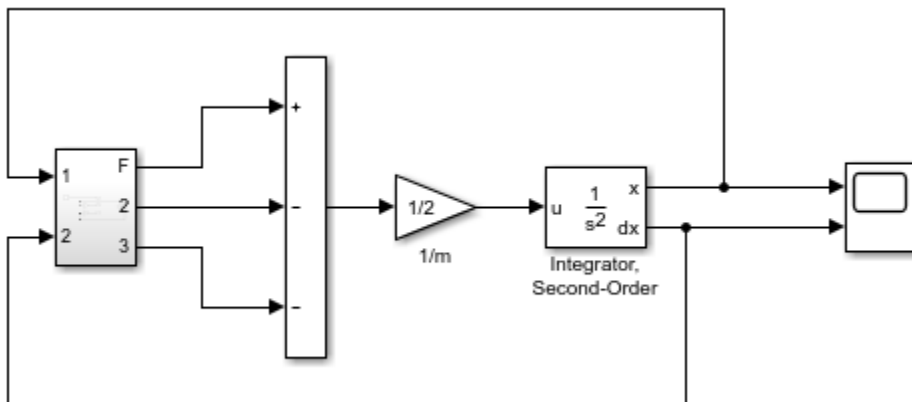

### Expand Subsystem Without Creating Area

Replace a subsystem with its contents without creating an area that surround the contents.

Open the example model, which contains a subsystem that separates functionally related blocks.

```
open_system('SubsystemExpansionModel')
```

Expand the subsystem.

```
Simulink.BlockDiagram.expandSubsystem(...
 'SubsystemExpansionModel/Subsystem', 'CreateArea', 'Off')
```

The subsystem contents replace the Subsystem block.

## Input Arguments

### **subsys** — Subsystem block path or handle

character vector | string scalar | numeric scalar

Subsystem block path or handle, specified as a character vector, string scalar, or numeric scalar.

Data Types: double | char | string

### **specifier** — Option to create area around contents

'on' (default) | 'off'

Option to create area around contents, specified as 'on' to create the area or 'off' to not create the area.

Data Types: char | string

## Version History

Introduced in R2014a

# Simulink.BlockDiagram.getChecksum

Return model checksum

## Syntax

```
[checksum,details] = Simulink.BlockDiagram.getChecksum('model')
```

## Description

[*checksum,details*] = Simulink.BlockDiagram.getChecksum('model') returns the checksum of the specified model. Simulink software computes the checksum based on attributes of the model and the blocks the model contains.

One use of this command is to determine why the Accelerator mode in Simulink software regenerates code. For an example, see “Determine Why Simulink Accelerator Is Regenerating Code” on page 13-589.

---

**Note** Simulink.BlockDiagram.getChecksum compiles the specified model, if the model is not already in a compiled state.

---

This command accepts the argument *model*, which is the full name or handle of the model for which you are returning checksum data.

This command returns the following output:

- *checksum* — Array of four 32-bit integers that represents the model's 128-bit checksum.
- *details* — Structure of the form

```
ContentsChecksum: [1x1 struct]
InterfaceChecksum: [1x1 struct]
ContentsChecksumItems: [nx1 struct]
InterfaceChecksumItems: [mx1 struct]
```

- **ContentsChecksum** — Structure of the following form that represents a checksum that provides information about all blocks in the model.

```
Value: [4x1 uint32]
MarkedUnique: [bool]
```

- **Value** — Array of four 32-bit integers that represents the model's 128-bit checksum.
- **MarkedUnique** — True if any blocks in the model have a property that prevents code reuse.
- **InterfaceChecksum** — Structure of the following form that represents a checksum that provides information about the model.

```
Value: [4x1 uint32]
MarkedUnique: [bool]
```

- **Value** — Array of four 32-bit integers that represents the model's 128-bit checksum.
- **MarkedUnique** — Always true. Present for consistency with ContentsChecksum structure.

- `ContentsChecksumItems` and `InterfaceChecksumItems` — Structure arrays of the following form that contain information that Simulink software uses to compute the checksum for `ContentsChecksum` and `InterfaceChecksum`, respectively:

Handle: [char array]  
Identifier: [char array]  
Value: [type]

- `Handle` — Object for which Simulink software added an item to the checksum. For a block, the handle is a full block path. For a block port, the handle is the full block path and a character vector that identifies the port.
- `Identifier` — Descriptor of the item Simulink software added to the checksum. If the item is a documented parameter, the identifier is the parameter name.
- `Value` — Value of the item Simulink software added to the checksum. If the item is a parameter, `Value` is the value returned by

`get_param(handle, identifier)`

`Simulink.BlockDiagram.getChecksum` returns a checksum that depends on why and how you compiled the model. This function also compiles the model if it is not in a compiled state. The model compiles for:

- Simulation— if the simulation mode is Accelerator or you have not installed Simulink Coder
- Code generation— in all other cases

To compile the model before calling `Simulink.BlockDiagram.getChecksum`, use this command, replacing `modelName` with the name of your model:

```
modelName([], [], [], 'compile')
```

---

**Note** The checksum that `Simulink.BlockDiagram.getChecksum` returns can vary from the checksum returned if you first compile the model programmatically using the model name programmatic interface (see “Use Model Name as Programmatic Interface”) before calling `Simulink.BlockDiagram.getChecksum`.

---

## Tip

The structural checksum reflects changes to the model that can affect the simulation results, including:

- Changing the solver type, for example from `Variable-step` to `Fixed-step`
- Adding or deleting blocks or connections between blocks
- Changing the values of nontunable block parameters, for example, the **Seed** parameter of the Random Number block
- Changing the number of inputs or outputs of blocks, even if the connectivity is vectorized
- Changing the number of states or the initial states in the model
- Selecting a different function in the Trigonometric Function block
- Changing signs used in a Sum block
- Adding a Target Language Compiler (TLC) file to inline an S-function

Examples of model changes that do not affect the structural checksum include:

- Changing the position of a block
- Changing the position of a line
- Resizing a block
- Adding, removing, or changing a model annotation

## **Version History**

**Introduced in R2006b**

## Simulink.BlockDiagram.getExecutionOrder

Open Execution Order pane

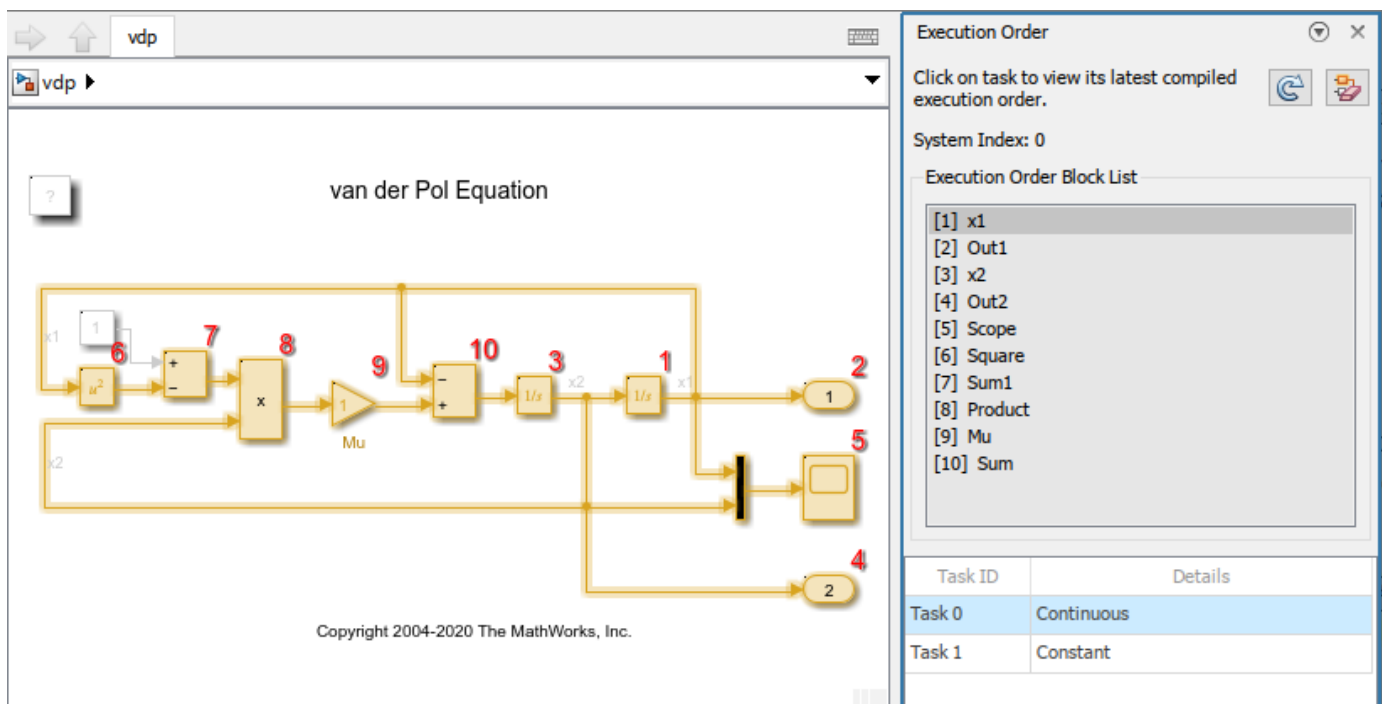

### Syntax

```
Simulink.BlockDiagram.getExecutionOrder(model)
Simulink.BlockDiagram.getExecutionOrder(model,task)
```

### Description

`Simulink.BlockDiagram.getExecutionOrder(model)` opens the **Execution Order** pane for the specified model `model`.

The **Execution Order** pane opens on the right side of the Simulink Editor.

The screenshot shows the Simulink Editor interface. On the left, a Simulink block diagram for a 'van der Pol Equation' is displayed. The blocks are numbered 1 through 10. On the right, the 'Execution Order' pane is open, showing a list of tasks and their details.

**Execution Order**

Click on task to view its latest compiled execution order.

System Index: 0

Execution Order Block List

- [1] x1
- [2] Out1
- [3] x2
- [4] Out2
- [5] Scope
- [6] Square
- [7] Sum1
- [8] Product
- [9] Mu
- [10] Sum

| Task ID | Details    |
|---------|------------|
| Task 0  | Continuous |
| Task 1  | Constant   |

`Simulink.BlockDiagram.getExecutionOrder(model,task)` highlights the task that corresponds to the specified task ID number `task`.

### Examples

#### Get Execution Order

Open the **Execution Order** pane and highlight the first task, which has a task ID of 0.

```
Simulink.BlockDiagram.getExecutionOrder('vdp')
```

### Highlight Task to View Execution Order

Open the **Execution Order** pane and highlight the task with a task ID of 1.

```
Simulink.BlockDiagram.getExecutionOrder('vdp',1)
```

## Input Arguments

### **model** — Model name

character vector | string scalar

Model name, specified as a character vector or string scalar.

Data Types: char | string

### **task** — Task ID number

integer

Task ID number, specified as an integer.

Data Types: double

## Version History

**Introduced in R2022b**

## See Also

“Control and Display Execution Order”

“Specify Block Execution Priority and Tag”

## Simulink.BlockDiagram.getInitialState

Return initial state data of block diagram

### Syntax

```
x0 = Simulink.BlockDiagram.getInitialState('model')
```

### Description

`x0 = Simulink.BlockDiagram.getInitialState('model')` returns the initial state data of the block diagram specified by the input argument *model*. You can use this initial state data as the initial state for simulating a model or to provide an initial state condition to the linearization commands. To specify the initial state for a simulation, use the `LoadInitialState` model argument or the **Data Import/Export > Initial state** configuration parameter.

To specify the format for the initial state data, use the `SaveFormat` model argument. The default format is 'Dataset'. Other formats 'Array', 'Structure', and 'StructureWithTime'. Alternatively, you can set the initial state format using the **Data Import/Export > Format** configuration parameter.

- If format is 'Dataset', then the `Simulink.BlockDiagram.getInitialState` function returns a `Simulink.SimulationData.Dataset` object.
- For other format settings, the function returns a structure of the form:

```
time: 0
signals: [1xn struct]
```

where *n* is the number of states contained in the model, including any models referenced by Model blocks. The `signals` field is a structure of the form:

```
values: [1xm double]
dimensions: [1x1 double]
label: [char array]
blockName: [char array]
inReferencedModel: [bool]
sampleTime: [1x2 double]
```

- `values` — Numeric array of length *m*, where *m* is the number of states in the signal
- `dimensions` — Length of the `values` vector
- `label` — Indication of whether the state is continuous (CSTATE) or discrete. If the state is discrete:

The name of the discrete state is shown for S-function blocks.

The name of the discrete state is shown for those built-in blocks that assign their own names to discrete states.

DSTATE is used in all other cases.

- `blockName` — Full path to block associated with this state

- `inReferencedModel` — Indication of whether the state originates in a model referenced by a Model block (1) or in the top model (0)
- `sampleTime` — Array containing the sample time and offset of the block that owns the state

Using this function to return the initial state data simplifies specifying initial state values for models with multiple states. Each state is associated with the full path to its parent block.

## Version History

Introduced in R2006b

### Topics

Initial state

Format

## Simulink.BlockDiagram.getSampleTimes

Return all sample times associated with model

### Syntax

```
ts = Simulink.BlockDiagram.getSampleTimes('model')
```

### Description

`ts = Simulink.BlockDiagram.getSampleTimes('model')` performs an update diagram and then returns the sample times associated with the block diagram *model*. The update diagram ensures that the sample time information returned is up to date. If the model is already in the compiled state via a call to the model API, then an update diagram is not necessary.

Using this method allows you to access all information in the Sample Time Legend programmatically.

### Input Arguments

*model*

Name or handle of a Simulink model

### Output Arguments

*ts*

The command returns a  $1 \times n$  array of `Simulink.SampleTime` objects associated with the model passed to `Simulink.BlockDiagram.getSampleTimes`. Here  $n$  is the number of sample times associated with the block diagram. The format of the returns is as follows:

```
1xn Simulink.SampleTime
Package: Simulink
value: [1x2 double]
Description: [char string]
ColorRGBValue: [1x3 double]
Annotation: [char string]
OwnerBlock: [char string]
ComponentSampleTimes: [1x2 struct]
Methods
```

- **value** — A two-element array of doubles that contains the sample time period and offset.
- **Description** — A character vector or string that describes the sample time type.
- **ColorRGBValue** — A  $1 \times 3$  array of doubles that contains the red, green, and blue (RGB) values of the sample time color.
- **Annotation** — A character vector or string that represents the annotation of a specific sample time (e.g., 'D1').
- **OwnerBlock** — For asynchronous and variable sample times, a character vector or string containing the full path to the block that controls the sample time. For all other types of sample times, an empty character vector or string.

- `ComponentSampleTimes` — A structure array of elements of the same type as `Simulink.BlockDiagram.getSampleTimes` if the sample time is an async union or if the sample time is hybrid and the component sample times are available.

## **Version History**

**Introduced in R2009a**

## **See Also**

`Simulink.Block.getSampleTimes`

## Simulink.BlockDiagram.propagateConfigSet

Propagate top model configuration reference to referenced models

### Syntax

```
[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model)
[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model, 'include', refModels)
[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model, 'exclude', refModels)
handle = Simulink.BlockDiagram.propagateConfigSet(model, 'gui')
```

### Description

`[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model)` propagates the configuration reference for `model` to all referenced models. Execute the function from a writable folder.

`[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model, 'include', refModels)` propagates the configuration reference for `model` to the models in the `refModels` list. Execute the function from a writable folder.

`[isPropagated, convertedModels] = Simulink.BlockDiagram.propagateConfigSet(model, 'exclude', refModels)` propagates the configuration reference for `model` to all referenced models in the hierarchy except for the models in the `refModels` list. Execute the function from a writable folder.

`handle = Simulink.BlockDiagram.propagateConfigSet(model, 'gui')` opens the **Configuration Reference Propagation to Referenced Models** dialog box.

### Examples

#### Propagate a Configuration Reference to All Referenced Models

```
openExample('simulink/VisualizeModelReferenceHierarchiesExample')
[isPropagated, convertedModels] = ...
Simulink.BlockDiagram.propagateConfigSet('sldemo_mdref_depgraph')
```

#### Propagate a Configuration Reference to Listed Referenced Models

```
openExample('simulink/VisualizeModelReferenceHierarchiesExample')
[isPropagated, convertedModels] = ...
Simulink.BlockDiagram.propagateConfigSet(...
'sldemo_mdref_depgraph', 'include', ...
{'sldemo_mdref_heater', 'sldemo_mdref_house'})
```

## Propagate a Configuration Reference to Referenced Models with Exclusions

```
openExample('simulink/VisualizeModelReferenceHierarchiesExample')
[isPropagated,convertedModels] = ...
Simulink.BlockDiagram.propagateConfigSet(...
'sldemo_mdhref_depgraph','exclude',...
{'sldemo_mdhref_heater','sldemo_mdhref_house'})
```

## Open the Configuration Reference Propagation to Referenced Models Dialog Box for a Model

```
openExample('simulink/VisualizeModelReferenceHierarchiesExample')
Simulink.BlockDiagram.propagateConfigSet(...
'sldemo_mdhref_depgraph','gui')
```

## Input Arguments

### model — Top model

character vector | string scalar

Top model with configuration reference to propagate, specified as a character vector or string scalar.

Example: 'mdl'

### refModels — Referenced models

cell array of character vectors | string array

List of referenced models to be included or excluded in propagation, specified as a cell array of character vectors or string array.

Example: {'mdl1','mdl2','mdl3'}

## Output Arguments

### isPropagated — Success of propagation

false (default) | true

Indication of whether configuration reference propagation is successful, specified as a Boolean.

### convertedModels — Converted models

cell array of character vectors

List of converted model names, specified as a cell array of character vectors.

### handle — Handle to dialog box

handle

Handle to the **Configuration Reference Propagation to Referenced Models** dialog box. Returned when you specify the 'gui' argument to the function.

## Version History

Introduced in R2012b

**See Also**

`Simulink.BlockDiagram.restoreConfigSet`

**Topics**

“Share a Configuration Across Referenced Models”

“Share a Configuration with Multiple Models”

# Simulink.BlockDiagram.refreshBlocks

Update variants, linked blocks, and model references to reflect changes

## Syntax

```
Simulink.BlockDiagram.refreshBlocks(model)
```

## Description

`Simulink.BlockDiagram.refreshBlocks(model)` refreshes all variants, linked blocks, and Model blocks in the specified model.

The Model blocks update only when the **Model block version mismatch** and **Port and parameter mismatch** configuration parameters are set to none or warning. The Model blocks do not update when either configuration parameter is set to error.

To refresh blocks in referenced models, call this function for each referenced model.

## Examples

### Refresh Model Blocks Programmatically

You can programmatically refresh all Model blocks in a model with the `Simulink.BlockDiagram.refreshBlocks` function.

Open the example model, which contains two Model blocks that are out of date with the model they reference.

```
open_system('RefreshModelBlockModel');
```

```
Warning: Ports and parameters of Model block 'RefreshModelBlockModel/Model1' do not reflect changes.
```

```
Warning: Number of input ports must match between Model block 'RefreshModelBlockModel/Model1' (1) and referenced model 'RefreshModelBlockModel' (2).
```

```
Warning: Ports and parameters of Model block 'RefreshModelBlockModel/Model' do not reflect changes.
```

```
Warning: Number of input ports must match between Model block 'RefreshModelBlockModel/Model' (1) and referenced model 'RefreshModelBlockModel' (2).
```

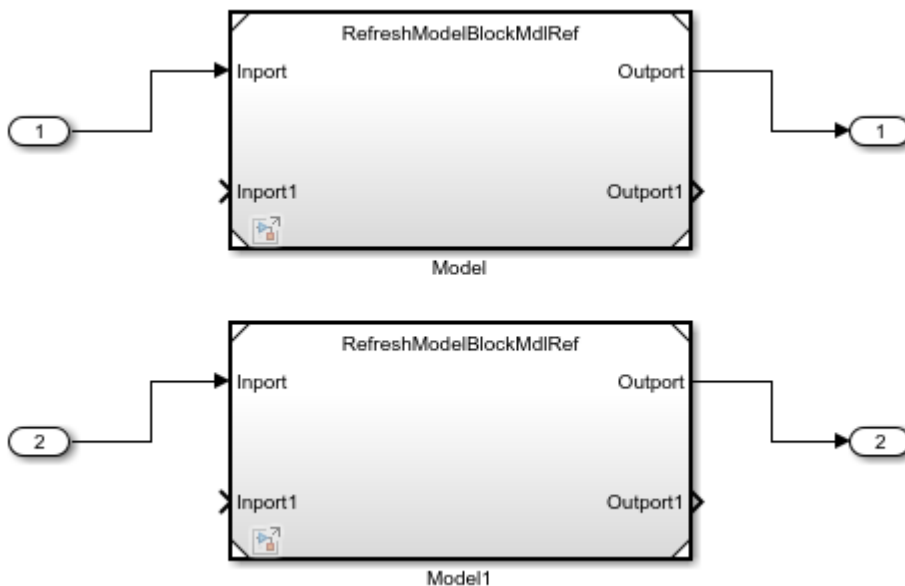

The top model has the **Port and parameter mismatch** configuration parameter set to **error**. The number of input and output ports in the referenced model has increased from one to two, but each Model block displays only one input and output port.

To support a bulk refresh of the Model blocks, set the **Port and parameter mismatch** configuration parameter to **warning** or **none**.

```
set_param('RefreshModelBlockModel', ...
 'ModelReferenceIOMismatchMessage', 'none')
```

Then, refresh the Model blocks.

```
Simulink.BlockDiagram.refreshBlocks('RefreshModelBlockModel');
```

Each Model block updates to display two input and output ports, matching the number of input and output ports in the referenced model.

## Input Arguments

### **model** — Name or handle of loaded model

character vector | string scalar | numeric scalar

Name or handle of loaded model, specified as a character vector, string scalar, or numeric scalar.

Example: `Simulink.BlockDiagram.refreshBlocks("myModel")`

Example: `Simulink.BlockDiagram.refreshBlocks(h)`, where *h* is a model handle

### Tips

Do not try to manually specify the number of a handle, for example, `5.007`, because you usually need to specify more digits than MATLAB displays. Assign the handle to a variable and use that variable name.

Data Types: `char` | `string` | `double`

### Tips

To refresh a specified Model block even when the **Model block version mismatch** or **Port and parameter mismatch** configuration parameter is set to `error`, use the `Simulink.ModelReference.refresh` function.

## Alternative Functionality

In the Simulink Toolstrip, on the **Modeling** tab, click the **Update Model** button arrow. Then, select **Refresh Blocks**.

## Version History

Introduced in R2023a

## See Also

# Simulink.BlockDiagram.restoreConfigSet

Restore model configuration for converted models

## Syntax

```
[isRestored, restoredModels] = Simulink.BlockDiagram.restoreConfigSet(model)
```

## Description

```
[isRestored, restoredModels] = Simulink.BlockDiagram.restoreConfigSet(model)
```

restores the model configuration for all converted models after propagating a configuration reference from a top model to the referenced models. Execute the function from a writable folder.

## Examples

### Restore the Model Configuration for Converted Models

```
openExample('simulink/VisualizeModelReferenceHierarchiesExample')
[isRestored, restoredModels] = ...
Simulink.BlockDiagram.restoreConfigSet('sldemo_mdref_depgraph');
```

## Input Arguments

### model — Top model

character vector | string scalar

Name of top model, specified as a character vector or string scalar.

Example: 'mdl'

## Output Arguments

### isRestored — Success of restoration

false (default) | true

Indication of whether configuration reference propagation is successful, specified as a Boolean.

### restoredModels — Restored models

cell array of character vectors

List of restored model names, specified as a cell array of character vectors.

## Version History

Introduced in R2012b

Simulink.BlockDiagram.propagateConfigSet

**Topics**

“Share a Configuration Across Referenced Models”

“Share a Configuration with Multiple Models”

# Simulink.BlockDiagram.loadActiveConfigSet

**Package:** Simulink.BlockDiagram

Load, associate, and activate configuration set with model

## Syntax

```
Simulink.BlockDiagram.loadActiveConfigSet(model, file)
```

## Description

`Simulink.BlockDiagram.loadActiveConfigSet(model, file)` loads a configuration set, attaches it to a model, and makes it the active configuration set for the model.

## Examples

### Load and Activate a Configuration Set

Load a saved configuration set to a model and activate it.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`. Save the active configuration set to a file.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
Simulink.BlockDiagram.saveActiveConfigSet('sldemo_fuelsys', 'fuelsys_config_set.m')
```

Open the `vdp` model. Load the saved configuration set to `vdp` and activate it.

```
vdp
Simulink.BlockDiagram.loadActiveConfigSet('vdp', 'fuelsys_config_set.m')
```

## Input Arguments

### **model** — Target model

character vector | string scalar

Name or handle of the target model for which you want to use the configuration set, specified as a character vector or string scalar.

Example: `'my_model'`

### **file** — Name of file

character vector | string scalar

Name of the file that contains the configuration set, specified as a character vector or string scalar.

Example: `'configset.m'`

## Tips

- If you load a configuration set with the same name as the active configuration set, Simulink overwrites the active configuration set.
- If you load a configuration set with the same name as an inactive configuration set associated with the model, Simulink detaches the inactive configuration from the model.
- If you load a configuration set object that contains an invalid custom target, Simulink sets the System target file (Simulink Coder) parameter to `ert.tlc`.

## Version History

Introduced in R2010b

# Simulink.BlockDiagram.saveActiveConfigSet

**Package:** Simulink.BlockDiagram

Save active configuration set of model

## Syntax

```
Simulink.BlockDiagram.saveActiveConfigSet(model, file)
```

## Description

`Simulink.BlockDiagram.saveActiveConfigSet(model, file)` saves the active configuration set of a model to an `.m` file or MAT-file.

## Examples

### Save a Configuration Set

Save the configuration set from the `sldemo_fuelsys` model as a `ConfigSet` object in the file `my_config_set.mat`.

Open the “Model a Fault-Tolerant Fuel Control System” on page 13-124 example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

Save the active configuration set.

```
Simulink.BlockDiagram.saveActiveConfigSet('sldemo_fuelsys','my_config_set.mat')
```

## Input Arguments

### **model** — Model using configuration set

character vector | string scalar

Name or handle of the model that uses the configuration set that you want to save, specified as a character vector or string scalar.

Example: `'my_model'`

### **file** — Name of file

character vector | string scalar

Name of the file to save the configuration set, specified as a character vector or string scalar. If you specify an `.m` extension, the file contains a function that creates a configuration set object. If you specify a `.mat` extension, the file contains a configuration set object. If you do not provide a file extension, the active configuration set is saved to a file with a `.m` extension. Do not specify `filename` to be the same as a model name; otherwise, the software cannot determine which file contains the configuration set object when loading the file.

**Note** If you specify a `.mat` extension when you save the active configuration set, all of the parameters are preserved. If you specify a `.m` extension, the `.m` file does not include hidden or disabled parameters.

---

Example: `'configset.m'`

## Version History

**Introduced in R2010b**

“Save a Configuration Set”

## Simulink.BlockDiagram.routeLine

Route existing lines of model

### Syntax

```
Simulink.BlockDiagram.routeLine(lines)
Simulink.BlockDiagram.routeLine('DeferredLines')
```

### Description

`Simulink.BlockDiagram.routeLine(lines)` takes an array of existing line handles as input and routes the corresponding lines. Routing existing lines improves line route quality and avoids overlaps with other lines and obstacles in the model.

To find the line handles in the model you want to route, use the `find_system` or `get_param` function.

`Simulink.BlockDiagram.routeLine('DeferredLines')` performs all line updates that the `LineUpdate` model parameter defers while a script runs. For this command to route lines, all of these conditions must apply:

- The `LineUpdate` model parameter is set to 'deferred'.
- The script that contains this command affects line routing before using this command.
- If the script saves models, the script affects line routing after using the `save_system` function and before using this command.

### Examples

#### Route Existing Lines of Model

Route existing lines of a model that overlap with other lines and blocks in the model.

Open the model `ex_route_lines`.

```
open_system('ex_route_lines');
```

The two lines in the top-level system overlap with each other and with a block. To route these lines, create an array of line handles by using `find_system`. Then, call `Simulink.BlockDiagram.routeLine` with this array as input.

```
lineHandles = find_system(gcs,'FindAll','On','SearchDepth',1,'Type','Line');
Simulink.BlockDiagram.routeLine(lineHandles);
```

The updated model has no overlaps.

### Route Lines Affected by Script

When the `LineUpdate` model parameter is set to `'deferred'`, scripts postpone line routing until they pause, complete, or run the `Simulink.BlockDiagram.routeLine('DeferredLines')` command.

Model `ex_route_deferred_lines` contains virtual subsystems with numerous signal lines connecting them.

To see how the `Simulink.BlockDiagram.routeline('DeferredLines')` command works with the `LineUpdate` model parameter, set this parameter to `'deferred'`.

```
set_param(0,'LineUpdate','deferred');
```

### Capture Image Before Routing Deferred Lines

Run a MATLAB® script that loads the model, moves blocks within the model, and saves an image of the model.

```
load_system('ex_route_deferred_lines');
set_param([gcs '/Subsystem2'],'Position',[765 -370 855 -330]);
set_param([gcs '/Subsystem3'],'Position',[300 215 390 335]);
set_param([gcs '/Subsystem4'],'Position',[270 -135 360 -95]);
print('-s','deferred_lines_unrouted','-dpng');
```

Because the script saves an image of the model before the deferred lines are routed, lines overlap other lines and obstacles in the model.

### Capture Image After Routing Deferred Lines

Run a MATLAB script that loads the original model, moves blocks within the model, updates affected line routing, and saves an image of the model.

```
load_system('ex_route_deferred_lines');
set_param([gcs '/Subsystem2'],'Position',[765 -370 855 -330]);
set_param([gcs '/Subsystem3'],'Position',[300 215 390 335]);
set_param([gcs '/Subsystem4'],'Position',[270 -135 360 -95]);
Simulink.BlockDiagram.routeLine('DeferredLines');
print('-s','deferred_lines_routed','-dpng');
```

Adding command `Simulink.BlockDiagram.routeLine('DeferredLines')` before the print function improves line routing in the saved image.

## Input Arguments

### **lines** — Handles of lines to route

numeric array

Handles of lines to route, specified as a numeric array. To find the line handles in your model, use the `find_system` or `get_param` function.

Data Types: `double`

## Limitations

- Line routing can require additional empty space on the Simulink canvas. If the canvas does not have the required empty space, using `Simulink.BlockDiagram.routeLine` might not improve line route quality.
- For large models with many lines to route, `Simulink.BlockDiagram.routeLine` can take several minutes to execute.

# Simulink.Bus.addElementToPort

Add element to root input bus element port

## Syntax

```
Simulink.Bus.addElementToPort(model,port,element)
```

## Description

`Simulink.Bus.addElementToPort(model,port,element)` adds the specified element to the specified root input bus element port in the specified model. This function does not add a block to the model.

## Examples

### Add Elements to Bus Element Port

Suppose you want to create a model that receives a bus. The input bus contains a bus named `sinusoidal`, a signal named `constant`, and a bus named `nonsinusoidal`. The `sinusoidal` bus contains signals named `sine` and `chirp`. The `nonsinusoidal` bus contains signals named `pulse` and `saw`.

Open a new model named `myModel`.

```
model = new_system("myModel");
open_system(model);
```

Add an In Bus Element block to the model. Name the port `myBusPort`, and specify `sine` as the element selected by the block. When you specify `sine`, use dots to indicate the levels of bus hierarchy.

```
add_block("simulink/Ports & Subsystems/In Bus Element",...
 "myModel/In Bus Element",...
 PortName="myBusPort",...
 Element="sinusoidal.sine");
```

When you do not specify an element for the block to select, by default, the block selects an element named `signal1`.

Add the remaining elements to the input port that corresponds with the In Bus Element block.

```
Simulink.Bus.addElementToPort("myModel",...
 "myBusPort",...
 "sinusoidal.chirp");
Simulink.Bus.addElementToPort("myModel",...
 "myBusPort",...
 "constant");
Simulink.Bus.addElementToPort("myModel",...
 "myBusPort",...
 "nonsinusoidal.pulse");
```

```
Simulink.Bus.addElementToPort("myModel",...
 "myBusPort",...
 "nonsinusoidal.saw");
```

## Input Arguments

### **model** — Model name

character vector | string scalar

Model name, specified as a character vector or string scalar.

Data Types: char | string

### **port** — Root input bus element port name

character vector | string scalar

Root input bus element port name, specified as a character vector or string scalar.

### Limitations

Input bus element ports of subsystems are not supported.

Data Types: char | string

### **element** — New bus element

character vector | string scalar

New bus element, specified as a character vector or string scalar.

For elements of nested buses, use dots to indicate each level of bus hierarchy. For example, to add a nested bus named `sinusoidal` with an element named `sine`, set `element` to `sinusoidal.sine`.

To add an element to a bus when a `Simulink.Bus` object specifies the bus hierarchy, edit the `Bus` object.

Data Types: char | string

## Alternative Functionality

In the In Bus Element block dialog box, click the **Add element** button arrow. Then, select **Add element without block**.

## Version History

Introduced in R2022b

# Simulink.Bus.cellToObject

Convert cell array containing bus information to Simulink.Bus objects

## Syntax

```
Simulink.Bus.cellToObject(busCell)
Simulink.Bus.cellToObject(busCell,scope)
```

## Description

`Simulink.Bus.cellToObject(busCell)` creates a set of `Simulink.Bus` objects in the MATLAB base workspace from a cell array of bus information.

`Simulink.Bus.cellToObject(busCell,scope)` creates a set of `Simulink.Bus` objects in the data dictionary specified by `scope` from a cell array of bus information.

## Examples

### Create Simulink.Bus Object from Cell Array of Bus Information

This example shows how to create and use a cell array to generate `Simulink.Bus` objects in the base workspace.

To define the elements that the Bus object contains, create an array of `Simulink.BusElement` objects or a cell array of the property values for the `BusElement` objects.

When you define the elements in an array of `BusElement` objects, you must specify the values that differ from the default.

```
elementsArray(1) = Simulink.BusElement;

elementsArray(2) = Simulink.BusElement;
elementsArray(2).Name = 'b';
elementsArray(2).Min = -3;
elementsArray(2).Max = 3;
elementsArray(2).Unit = 'm';
elementsArray(2).Description = 'b is distance from the origin.';
```

When you define the elements in a cell array of property values, you must specify the element name, dimensions, data type, complexity, and sampling mode. You can also specify the dimensions mode, minimum, maximum, units, and description.

```
elementsCellArray = {{'a',1,'double',-1,'real','Sample'}; ...
 {'b',1,'double','real','Sample',...
 'Fixed',-3,3,'m','b is distance from the origin'}};
```

In this example, `elementsArray` and `elementsCellArray` create the same `BusElement` objects in the Bus objects.

Create a cell array with two subordinate cell arrays that define Bus objects. For each Bus object, specify the bus name, header file, description, data scope, alignment, preserve element dimensions,

and elements. For the first Bus object, specify the elements using `elementsArray`. For the second Bus object, specify the elements using `elementsCellArray`.

```
busCells = { ...
 { ...
 'myBusObjArray', ...
 'MyHeader.h', ...
 'My description', ...
 'Exported', ...
 '-1', ...
 '0', ...
 elementsArray,...
 }, ...
 { ...
 'myBusObjCellArray', ...
 'MyHeader.h', ...
 'My description', ...
 'Exported', ...
 '-1', ...
 '0', ...
 elementsCellArray,...
 }, ...
};
```

Generate the Bus objects in the base workspace from the cell array of cell arrays.

```
Simulink.Bus.cellToObject(busCells)
```

Compare the generated Bus objects in the **Type Editor**.

```
typeeditor
```

The Bus objects are identical other than their names.

## Input Arguments

### **busCell** — Simulink.Bus object information

cell array of cell arrays

Bus object information, specified as a cell array of cell arrays. Each subordinate cell array must contain this Bus object information:

- 1 Bus name
- 2 Header file
- 3 Description
- 4 Data scope
- 5 Alignment
- 6 Preserve Element Dimensions
- 7 Elements

The `elements` field is a cell array that contains this information for each of the `Simulink.BusElement` objects that the Bus object references:

The `elements` field must contain arrays or cell arrays with this information for each of the `Simulink.BusElement` objects that the `Bus` object references:

- 1 Element name
- 2 Dimensions
- 3 Data type
- 4 Sample time (optional) — If you specify a sample time, specify an inherited sample time (-1). A noninherited sample time causes an error during model compilation. For more information, see “Simulink.BusElement objects no longer support the SampleTime property” on page 2-537.
- 5 Complexity
- 6 Sampling mode

The `elements` field arrays or cell arrays can also contain this information:

- 1 Dimensions mode
- 2 Minimum
- 3 Maximum
- 4 Units
- 5 Description

Example: `Simulink.Bus.cellToObject(busCell);`

### scope — Data dictionary to contain Simulink.Bus objects

`Simulink.data.Dictionary` object

Data dictionary, specified as a `Simulink.data.Dictionary` object. Before you use this argument, represent the dictionary with a `Simulink.data.Dictionary` object by using, for example, the `Simulink.data.dictionary.create` or `Simulink.data.dictionary.open` function.

If `scope` is empty, the function uses the MATLAB base workspace as the source of the `Bus` objects.

Example: `Simulink.Bus.cellToObject(busCell,dataDictionaryObject);`

## Tips

The inverse function is `Simulink.Bus.objectToCell`.

## Version History

**Introduced before R2006a**

### **R2020b: Simulink.BusElement objects no longer support the SampleTime property**

*Errors starting in R2020b*

The `SampleTime` property of `Simulink.BusElement` objects is no longer supported.

`BusElement` objects that specify a sample time cause an error during compile. To remove the sample time specification from a `BusElement` object, set its `SampleTime` to -1.

`Simulink.Bus.cellToObject` continues to accept cell arrays that specify sample time for bus elements. `Simulink.Bus.objectToCell`, `Simulink.Bus.save`, and

`Simulink.Bus.createObject` continue to return cell arrays or arrays that include the sample time when it is noninherited. When the sample time is inherited (-1), they omit it. Similarly, the **Type Editor** and **Model Explorer** omit the sample time when it is inherited.

To specify the sample time for an element of a bus, use the `SampleTime` block parameter of corresponding blocks. For example, you can use `In Bus Element`, `Out Bus Element`, and `Signal Specification` blocks to specify sample time.

**R2016b: Simulink.BusElement objects will no longer support the SamplingMode property**  
*Not recommended starting in R2016b*

In R2016b, the `SamplingMode` property of `Simulink.BusElement` objects was removed. Scripts that use the `SamplingMode` property of `Simulink.BusElement` objects continue to work. `Simulink.Bus.cellToObject` continues to require the `SamplingMode` field and `Simulink.Bus.objectToCell` continues to include the sampling mode in the output cell arrays.

In a future release, support for the `SamplingMode` property will be removed.

To specify whether a signal is sample-based or frame-based, define the sampling mode of input signals at the block level instead of at the signal level.

# Simulink.Bus.createMATLABStruct

Create MATLAB structures that use the same hierarchy and attributes as buses

## Syntax

```
structs = Simulink.Bus.createMATLABStruct(buses)
structs = Simulink.Bus.createMATLABStruct(buses,values)
structs = Simulink.Bus.createMATLABStruct(buses,values,dims)
structs = Simulink.Bus.createMATLABStruct(buses,values,dims,scope)
```

## Description

`structs = Simulink.Bus.createMATLABStruct(buses)` creates one or more MATLAB structures that have the same hierarchy and attributes as the specified buses. The resulting structures use the ground values of the buses. Use this syntax to create initialization structures for multiple bus ports.

`structs = Simulink.Bus.createMATLABStruct(buses,values)` creates one or more structures that use the specified values.

`structs = Simulink.Bus.createMATLABStruct(buses,values,dims)` creates one or more structures that have the specified dimensions. To create a structure for an array of buses, include the `dims` argument.

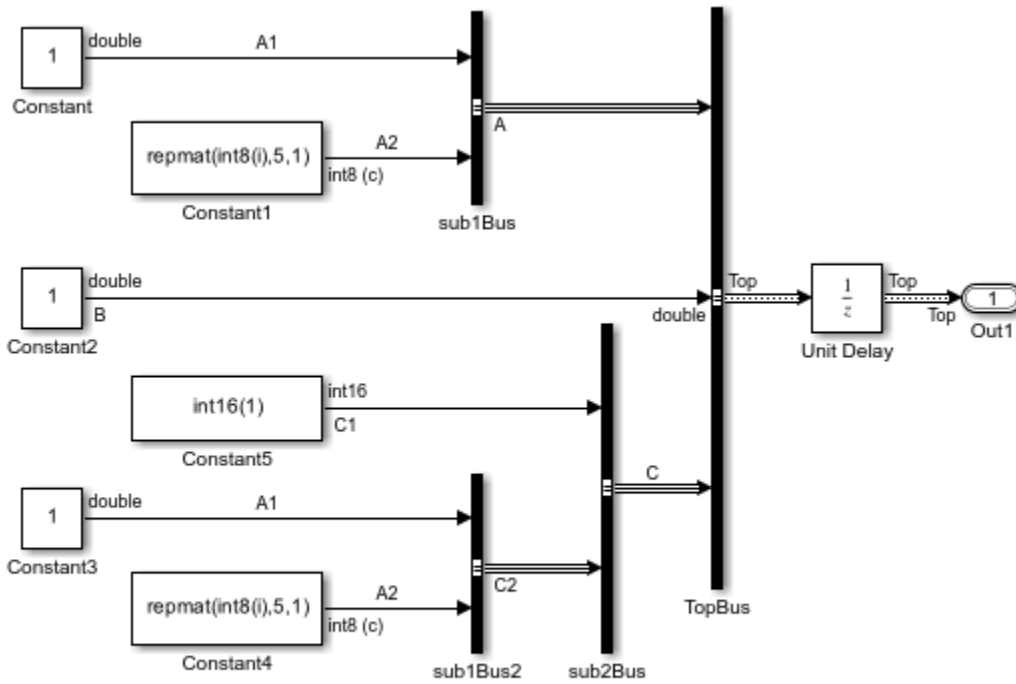

`structs = Simulink.Bus.createMATLABStruct(buses,values,dims,scope)` creates one or more structures in the data dictionary specified by `scope`.

## Examples

### Create MATLAB Structure from Bus Object

Open and simulate model `ex_bus_initial_conditions`.

```
open_system('ex_bus_initial_conditions')
sim('ex_bus_initial_conditions');
```

Copyright 2004-2018 The MathWorks, Inc.

Create a MATLAB structure using bus object Top, which model ex\_bus\_initial\_conditions loads.

```
mStruct = Simulink.Bus.createMATLABStruct('Top');
```

Set a value for the field of the mStruct structure that corresponds to bus element A1 of bus A.

```
mStruct.A.A1 = 3;
mStruct.A
```

ans =

struct with fields:

```
A1: 3
A2: [5x1 int8]
```

Simulink sets the other fields in the structure to the ground values of the corresponding bus elements.

You can use mStruct as the initial condition structure for the Unit Delay block.

### Initialize Signal Elements that Use a Data Type Other than Double

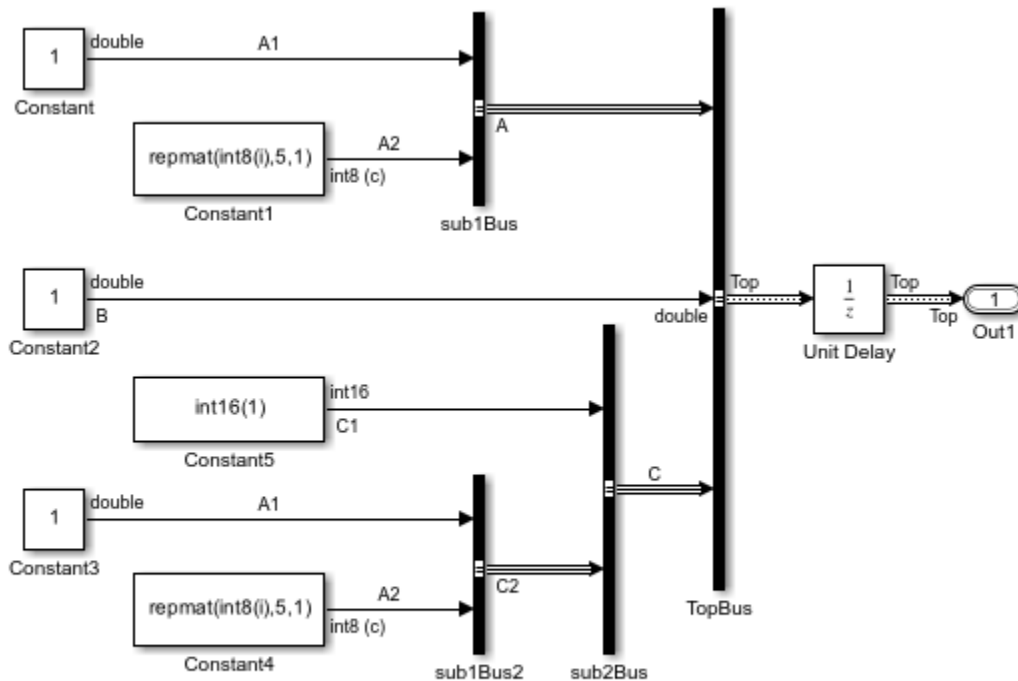

Create a MATLAB structure for a bus whose signal elements use a data type other than double. Use a partial structure to specify initialization values for a subset of the elements. When you create the

partial structure, match the data types of the fields with the data types of the corresponding elements.

Open and simulate model `ex_bus_initial_conditions`.

```
open_system('ex_bus_initial_conditions')
sim('ex_bus_initial_conditions');
```

Copyright 2004-2018 The MathWorks, Inc.

The `C1` signal element that the block labeled `Constant5` produces uses the data type `int16`.

Find the port handle for the Bus Creator block port that produces the `Top` bus signal.

```
ph = get_param('ex_bus_initial_conditions/TopBus', 'PortHandles');
```

Create a partial structure that specifies values for a subset of the elements in the bus signal created by the `TopBus` block. To set the value of the `C.C1` field, use a typed expression. Match the data type in the expression with the data type of the signal element in the model (`int16`).

```
PartialstructForK = struct('B',3,'C',struct('C1',int16(5)));
```

Create a full structure by using the port handle (`ph`) for the `TopBus` block. Override the ground values for the `C.C1` and `B` elements.

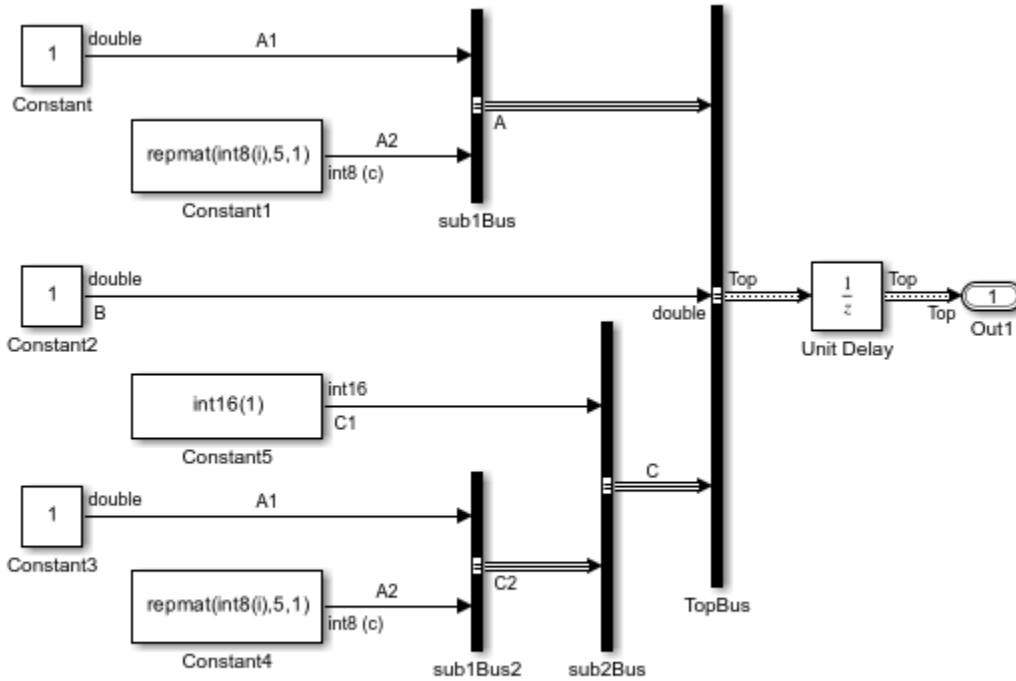

```
outPort = ph.Outport;
mStruct = Simulink.Bus.createMATLABStruct(outPort,PartialstructForK);
```

The field `C.C1` in the output structure continues to use the data type `int16`.

### Create MATLAB Structure with Specified Dimensions

Open and simulate model ex\_bus\_initial\_conditions.

```
open_system('ex_bus_initial_conditions')
sim('ex_bus_initial_conditions');
```

Copyright 2004-2018 The MathWorks, Inc.

Create a partial structure for a subset of bus elements in the bus created by the TopBus block.

```
PartialStructForK = struct('A',struct('A1',4),'B',3)
```

```
PartialStructForK =
 struct with fields:
 A: [1x1 struct]
 B: 3
```

Create a MATLAB structure using bus object Top, a partial structure, and dimensions for the resulting structure.

```
structFromBus = Simulink.Bus.createMATLABStruct...
('Top',PartialStructForK,[2 3])
```

```
structFromBus =
```

2x3 struct array with fields:

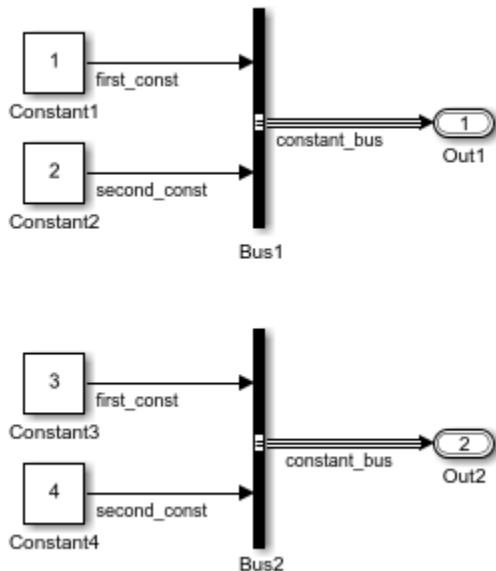

A  
B  
C

### Create Cell Array of MATLAB Structures

To create initialization structures for multiple bus ports, specify port handles as arguments for `Simulink.Bus.createMATLABStruct`. The resulting cell array of structures uses ground values.

Open and simulate model `ex_two_outports_create_struct`.

```
open_system('ex_two_outports_create_struct')
sim('ex_two_outports_create_struct');
```

Find the port handles for the Bus Creator blocks Bus1 and Bus2.

```
ph_1 = get_param...
 ('ex_two_outports_create_struct/Bus Creator', 'PortHandles');
ph_2 = get_param...
 ('ex_two_outports_create_struct/Bus Creator1', 'PortHandles');
```

Create a MATLAB® structure using an array of port handles.

```
mStruct = Simulink.Bus.createMATLABStruct([ph_1.Outport ph_2.Outport])
```

```
mStruct =
 2x1 cell array
 {1x1 struct}
```

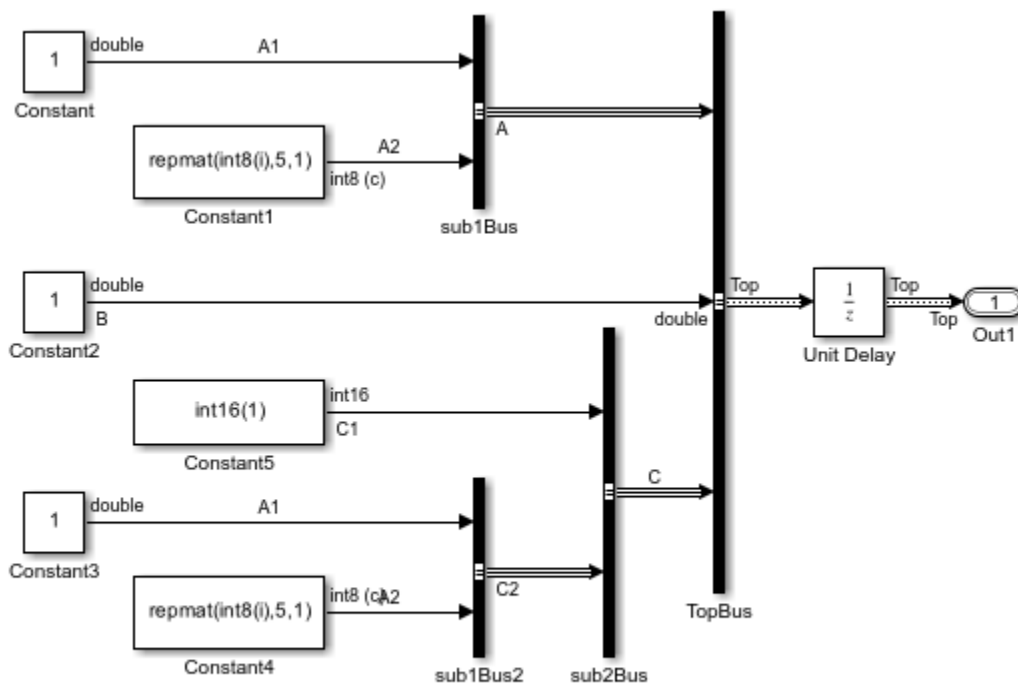

```
{1x1 struct}
```

### Create MATLAB Structure from Bus Port and Partial Structure

Create a MATLAB structure based on a port that connects to a bus signal. Use a partial structure to specify values for a subset of the bus elements in the bus that connects to the port.

Open and simulate model `ex_bus_initial_conditions`.

```
open_system('ex_bus_initial_conditions')
sim('ex_bus_initial_conditions');
```

Copyright 2004-2018 The MathWorks, Inc.

Find the port handle for the Bus Creator block port that produces the Top bus signal. The Output handle is the handle that you need.

```
ph = get_param('ex_bus_initial_conditions/TopBus', 'PortHandles')
```

```
ph =
```

```
struct with fields:
```

```
 Inport: [37.0046 41.0100 439.0044]
 Output: 440.0042
 Enable: []
 Trigger: []
```

```

 State: []
 LConn: []
 RConn: []
 Ifaction: []
 Reset: []
 Event: []

```

Create a partial structure for the bus signal created by the TopBus block. You can use a partial structure to specify values for a subset of bus elements.

```
PartialstructForK = struct('A',struct('A1',4),'B',3)
```

```

PartialstructForK =
 struct with fields:
 A: [1x1 struct]
 B: 3

```

Bus elements represented by structure fields `Top.B` and `Top.A` are at the same level in the bus hierarchy. You can use this partial structure to override the ground values for the B and A bus signal elements.

When you create a structure from a bus object or from a bus port, you can use a partial structure as an optional argument.

Create a MATLAB structure by using the port handle (ph) for the TopBus block. Override the ground values for the A.A1 and B bus elements.

```
outPort = ph.Outport;
mStruct = Simulink.Bus.createMATLABStruct(outPort,PartialstructForK)
```

```

mStruct =
 struct with fields:
 A: [1x1 struct]
 B: 3
 C: [1x1 struct]

```

## Input Arguments

### buses — Source of bus information

Simulink.Bus object name | port handle | cell array of Simulink.Bus object names | array of port handles

Source of the bus information, specified as a Bus object name, port handle, cell array of Bus object names, or array of port handles.

- If you use a Bus object name, then the Bus object must be in the MATLAB base workspace or the data dictionary used by the model. The data type for a Bus object name is `char` or `string`.

- If you use a port handle, then the model must compile successfully before you use this function. The data type for a port handle is `double`.
- For an array of buses, you cannot use a port handle.
- If you use the `dims` argument, then for the `buses` argument, use a `Bus` object or cell array of `Bus` objects.

Specifying a cell array of `Bus` object names or an array of port handles creates multiple structures with one `Simulink.Bus.createMATLABStruct` call and provides better performance than using separate `Simulink.Bus.createMATLABStruct` calls to create the structures.

Example: `struct = Simulink.Bus.createMATLABStruct('BusObject')`

Example: `structs = Simulink.Bus.createMATLABStruct({'BusObject','BusObject1'})`

Example: `struct = Simulink.Bus.createMATLABStruct(portHandle)`

Example: `structs = Simulink.Bus.createMATLABStruct([portHandle,portHandle1])`

Data Types: `double` | `char` | `string` | `struct` | `cell`

### **values** — Values for subset of elements in resulting structure

`[]` | partial structure | cell array

Values for a subset of elements in the resulting structure, specified as an empty matrix (`[]`), partial structure, or cell array. The cell array must contain a partial structure or empty matrix for each specified source of bus information.

For information on creating partial structures, see “Create Partial Structures for Initialization”.

To use ground values, use an empty matrix.

Example: `struct = Simulink.Bus.createMATLABStruct('BusObject',PartialStruct)`

Data Types: `struct` | `cell`

### **dims** — Dimensions of resulting structure

scalar | vector | cell array

Dimensions of the resulting structure, specified as a vector.

Each dimension element must be an integer that is greater than or equal to 1. If you specify a partial structure for the `values` argument, each dimension element must be greater than or equal to its corresponding dimension element in the partial structure.

Example: `struct = Simulink.Bus.createMATLABStruct('BusObject',PartialStruct,[2 3])`

Example: `structs = Simulink.Bus.createMATLABStruct({'Bus','Bus1','Bus2'},{[], [], []}, {1,2,3})`

Data Types: `double` | `cell`

### **scope** — Data dictionary to contain MATLAB structure

`Simulink.data.Dictionary` object

Data dictionary, specified as a `Simulink.data.Dictionary` object. Before you use this argument, represent the dictionary with a `Simulink.data.Dictionary` object by using, for example, the `Simulink.data.dictionary.create` or `Simulink.data.dictionary.open` function.

If `scope` is empty, the function uses the MATLAB base workspace as the source of the Bus objects.

Example: `structs = Simulink.Bus.createMATLABStruct({'Bus', 'Bus1', 'Bus2'}, {[], [], []}, {1, 1, 1}, dataDictionaryObject)`

## Output Arguments

### **structs** — Structures with same signal hierarchy and attributes as buses

MATLAB structure | cell array of MATLAB structures

Structures with the same signal hierarchy and attributes as buses, returned as a MATLAB structure or a cell array of MATLAB structures.

The structure dimensions depend on the input arguments you specify:

- If you specify only the `buses` argument, then the dimension is 1.
- If you also specify the `values` argument, then the dimensions match the dimensions of `values`.
- If you specify the `dims` argument, then the dimensions match the dimensions of `dims`.

## Tips

- If you use the `Simulink.Bus.createMATLABStruct` function repeatedly for the same model (for example, in a loop in a script), you can improve performance by avoiding multiple model compilations. For improved speed, put the model in compile before using the function multiple times. For example, to put the `vdp` model in compile, use this command:

```
vdp([], [], [], 'compile')
```

After you create the MATLAB structure, terminate the compile by using this command:

```
vdp([], [], [], 'term')
```

- You can use the **Type Editor** to invoke the `Simulink.Bus.createMATLABStruct` function. In the Type Editor, select the Bus object for which you want to create a MATLAB structure. Then, in the toolstrip, click **MATLAB Structure**.

You can edit the MATLAB structure in the MATLAB Editor and evaluate the code to create or update the values in this structure.

- You can use the `Simulink.Bus.createMATLABStruct` function to specify the initial value of the output of a referenced model.

# Simulink.Bus.createObject

Create `Simulink.Bus` objects from blocks or MATLAB structures

## Syntax

```
busInfo = Simulink.Bus.createObject(model,blocks)
busInfo = Simulink.Bus.createObject(struct)
busInfo = Simulink.Bus.createObject(___,file)
busInfo = Simulink.Bus.createObject(___,file,format)
busInfo = Simulink.Bus.createObject(struct,file,format,scope)
```

## Description

`busInfo = Simulink.Bus.createObject(model,blocks)` creates `Simulink.Bus` objects for the specified blocks and returns information about the created Bus objects.

If you specify a block that corresponds to a bus hierarchy, this function creates Bus objects for each bus in the hierarchy.

If the model uses a data dictionary, the Bus objects are created in the data dictionary. Otherwise, they are created in the base workspace.

`busInfo = Simulink.Bus.createObject(struct)` creates Bus objects from a structure that can contain MATLAB timeseries, MATLAB timetable, and `matlab.io.datastore.SimulationDatastore` objects or a numeric structure.

If you specify a structure with hierarchy, this function creates Bus objects for each structure in the hierarchy.

The Bus objects are created in the base workspace.

`busInfo = Simulink.Bus.createObject( ___,file)` saves Bus objects in a function that defines object properties in a cell array of cell arrays, then creates the Bus objects by calling `Simulink.Bus.cellToObject`.

Specify any of the input argument combinations in the previous syntaxes followed by the `file` argument.

`busInfo = Simulink.Bus.createObject( ___,file,format)` saves Bus objects in a function with the specified format. The function can define object properties using cell arrays or arrays.

`busInfo = Simulink.Bus.createObject(struct,file,format,scope)` creates the Bus objects in the data dictionary specified by `scope`.

## Examples

### Create Simulink.Bus Object from Bus Creator Block

Open the example model.

```
open_system('BusObjectCreationModel')
```

Create a Bus object that corresponds with the bus created by the Bus Creator block.

```
busInfo = Simulink.Bus.createObject('BusObjectCreationModel',...
 'BusObjectCreationModel/Bus Creator');
```

### Create and Save Simulink.Bus Objects in a Function

Create Bus objects from two Bus Creator blocks and save the Bus object definition in a function.

Open the example model.

```
open_system('BusObjectCreationModel');
```

Assign the block handle for the Bus Creator block to a variable with the `getSimulinkBlockHandle` function.

```
bc = getSimulinkBlockHandle('BusObjectCreationModel/Bus Creator');
```

Alternatively, you can select a Bus Creator block in the model then use the `gcbh` function to get its block handle.

Assign the block handle for the Bus Creator1 block to a variable.

```
bc1 = getSimulinkBlockHandle('BusObjectCreationModel/Bus Creator1');
```

To create a Bus object, specify the block handle variables in a vector. To save the Bus object definition, also specify a file name.

```
busInfo = Simulink.Bus.createObject('BusObjectCreationModel',...
 [bc bc1], 'BusObjectFunction');
```

Since these Bus Creator blocks create a bus hierarchy, specifying only the Bus Creator1 block creates both Bus objects in the Workspace and in the function.

Compare the BusObjectFunction against the function created by this command.

```
topBusInfo = Simulink.Bus.createObject('BusObjectCreationModel',...
 bc1, 'BusObjectFunctionFromHierarchy');
```

For a function that is formatted to be easier to read, specify the function format as `object`.

```
topBusInfo1 = Simulink.Bus.createObject('BusObjectCreationModel',...
 bc1, 'BusObjectFunctionFormatted', 'object');
```

## Create Simulink.Bus Objects from MATLAB Structures

When you create a nonvirtual bus with a Constant block, you must specify a MATLAB structure for **Constant value** and a Simulink.Bus object as the **Output data type**.

For this example, create a structure that contains other structures.

```
bus_struct.A.A1 = 0;
bus_struct.A.A2 = [0 + 0i;0 + 0i;0 + 0i;0 + 0i;0 + 0i];
bus_struct.B = 5;
bus_struct.C.C1 = 0;
bus_struct.C.C2.A1 = 0;
bus_struct.C.C2.A2 = [0 + 0i;0 + 0i;0 + 0i;0 + 0i;0 + 0i];
```

Create the Bus objects that correspond with the structure.

```
busInfo = Simulink.Bus.createObject(bus_struct);
```

The function creates four Bus objects. The Bus object named `s1Bus1` corresponds to the top-level structure and uses a default Bus object name. The Bus objects named `A`, `C`, and `C2` correspond to the nested structures.

To view the Bus objects, open the **Type Editor**.

```
typeeditor
```

## Input Arguments

**model** — Model name or handle

character vector

Model name or handle, specified as a character vector.

The model you specify must compile successfully.

**blocks — Blocks associated with buses**

character vector | cell array of block path names | vector of block handles

Blocks associated with buses, specified as a character vector, cell array of block path names, or vector of block handles. For one block, specify the full path name of the block. For multiple blocks, specify either a cell array of block path names or a vector of block handles.

This function can create Bus objects from these blocks:

- Bus Creator blocks
- Subsystem Inport blocks
- Subsystem Outport blocks

If you specify a block associated with a bus hierarchy, the function also creates Bus objects for all nested buses in the hierarchy.

**struct — Structure of objects or numeric structure**

structure of MATLAB timeseries, MATLAB timetable, and matlab.io.datastore.SimulationDatastore objects | numeric structure

Structure of objects or numeric structure, specified as a structure that can contain MATLAB timeseries, MATLAB timetable, and matlab.io.datastore.SimulationDatastore objects or a numeric structure.

**file — Name of function being generated**

character vector

Name of function being generated, specified as a character vector. The file name must be unique.

**format — Format of function being generated**

'cell' (default) | 'object'

Format of function being generated, specified as either 'cell' or 'object'. The 'cell' format is more compact, but the 'object' format is easier to read.

The 'cell' format saves the Bus object definitions in a cell array of cell arrays and creates the Bus objects by calling `Simulink.Bus.cellToObject`. Each subordinate cell array represents a Bus object and contains these properties:

- 1 Bus name
- 2 Header file
- 3 Description
- 4 Data scope
- 5 Alignment
- 6 Preserve Element Dimensions
- 7 Elements

The `elements` field is a cell array that contains this information for each of the `Simulink.BusElement` objects that the Bus object references:

- 1 Element name
- 2 Dimensions
- 3 Data type
- 4 Sample time — The cell array contains this field when the sample time is not inherited. A noninherited sample time causes an error during model compilation. For more information, see “Simulink.BusElement objects no longer support the SampleTime property” on page 2-553.
- 5 Complexity
- 6 Dimensions mode
- 7 Minimum
- 8 Maximum
- 9 Units
- 10 Description

The 'object' format saves the Bus object definitions as arrays. The function uses array indexing to access elements of the array and dot notation to assign property values.

### scope — Data dictionary to contain Simulink.Bus objects

`Simulink.data.Dictionary` object

Data dictionary, specified as a `Simulink.data.Dictionary` object. Before you use this argument, represent the dictionary with a `Simulink.data.Dictionary` object by using, for example, the `Simulink.data.dictionary.create` or `Simulink.data.dictionary.open` function.

If `scope` is empty, the function uses the MATLAB base workspace as the source of the Bus objects.

## Output Arguments

### busInfo — Bus object information

structure array

Bus object information, returned as a structure array.

When you specify `blocks`, each element of the `busInfo` structure array corresponds to one block and contains these fields:

- `block` — Handle of the block
- `busName` — Name of the Bus object associated with the block

When you specify a `struct`, the `busInfo` structure contains these fields:

- `block` — Empty matrix (`[]`)
- `busName` — Name of the Bus object that corresponds to the structure

## Version History

Introduced before R2006a

**R2020b: Simulink.BusElement objects no longer support the SampleTime property**

*Errors starting in R2020b*

The `SampleTime` property of `Simulink.BusElement` objects is no longer supported.

`BusElement` objects that specify a sample time cause an error during compile. To remove the sample time specification from a `BusElement` object, set its `SampleTime` to `-1`.

`Simulink.Bus.cellToObject` continues to accept cell arrays that specify sample time for bus elements. `Simulink.Bus.objectToCell`, `Simulink.Bus.save`, and `Simulink.Bus.createObject` continue to return cell arrays or arrays that include the sample time when it is noninherited. When the sample time is inherited (`-1`), they omit it. Similarly, the **Type Editor** and **Model Explorer** omit the sample time when it is inherited.

To specify the sample time for an element of a bus, use the `SampleTime` block parameter of corresponding blocks. For example, you can use `In Bus Element`, `Out Bus Element`, and `Signal Specification` blocks to specify sample time.

# Simulink.Bus.objectToCell

Use `Simulink.Bus` objects to create cell array containing bus information

## Syntax

```
cells = Simulink.Bus.objectToCell(busNames)
cells = Simulink.Bus.objectToCell(busNames,scope)
```

## Description

`cells = Simulink.Bus.objectToCell(busNames)` creates a cell array of bus information from a set of `Simulink.Bus` objects in the MATLAB base workspace. The cell array contains subordinate cell arrays that define each Bus object. The order of elements in the output cell array corresponds to the order of names in the input cell array.

`cells = Simulink.Bus.objectToCell(busNames,scope)` creates a cell array of bus information from a set of Bus objects in the data dictionary specified by `scope`. The cell array contains subordinate cell arrays that define each Bus object. The order of elements in the output cell array corresponds to the order of names in the input cell array.

## Examples

### Create Cell Array Containing Bus Object Information

Use the `Simulink.Bus.objectToCell` function to create a cell array of information about `Simulink.Bus` objects in the base workspace.

Open a model that has two Bus objects defined, CONTROL and MAIN.

```
open_system('ex_bus_object_tutorial_using_objects')
```

Create a cell array of information about the CONTROL Bus object.

```

cells = Simulink.Bus.objectToCell({'CONTROL'});
cells{1}

ans=1x7 cell array
 {'CONTROL'} {0x0 char} {0x0 char} {'Auto'} {'-1'} {'0'} {2x1 cell}

```

## Input Arguments

### **busNames** — Names of Simulink.Bus objects

cell array of Bus object names

Bus objects for which to create cell arrays of Bus object information, specified as a cell array. Specify the Bus object names as character vectors. If `busNames` is empty, the function converts all Bus objects in the base workspace or data dictionary.

Example: `cells = Simulink.Bus.objectToCell({'busObject'})`

### **scope** — Data dictionary that contains Simulink.Bus objects

`Simulink.data.Dictionary` object

Data dictionary, specified as a `Simulink.data.Dictionary` object. Before you use this argument, represent the dictionary with a `Simulink.data.Dictionary` object by using, for example, the `Simulink.data.dictionary.create` or `Simulink.data.dictionary.open` function.

If `scope` is empty, the function uses the MATLAB base workspace as the source of the Bus objects.

Example: `cells = Simulink.Bus.objectToCell({'busObject'},dataDictionaryObject)`

## Output Arguments

### **cells** — Bus object information

cell array of cell arrays

Bus object information, specified as a cell array of cell arrays. Each subordinate cell array contains these Bus object properties:

- 1 Bus name
- 2 Header file
- 3 Description
- 4 Data scope
- 5 Alignment
- 6 Preserve Element Dimensions
- 7 Elements

The `elements` field is a cell array that contains this information for each of the `Simulink.BusElement` objects that the Bus object references:

- 1 Bus element name
- 2 Dimensions
- 3 Data type

- 4 Sample time — The cell array contains this field when the sample time is not inherited. A noninherited sample time causes an error during model compilation. For more information, see “Simulink.BusElement objects no longer support the SampleTime property” on page 2-557.
- 5 Complexity
- 6 Sampling mode
- 7 Dimensions mode
- 8 Minimum
- 9 Maximum
- 10 Units
- 11 Description

## Tips

The inverse function is `Simulink.Bus.cellToObject`.

## Version History

### Introduced in R2007a

#### **R2020b: Simulink.BusElement objects no longer support the SampleTime property**

*Errors starting in R2020b*

The `SampleTime` property of `Simulink.BusElement` objects is no longer supported.

`BusElement` objects that specify a sample time cause an error during compile. To remove the sample time specification from a `BusElement` object, set its `SampleTime` to `-1`.

`Simulink.Bus.cellToObject` continues to accept cell arrays that specify sample time for bus elements. `Simulink.Bus.objectToCell`, `Simulink.Bus.save`, and `Simulink.Bus.createObject` continue to return cell arrays or arrays that include the sample time when it is noninherited. When the sample time is inherited (`-1`), they omit it. Similarly, the **Type Editor** and **Model Explorer** omit the sample time when it is inherited.

To specify the sample time for an element of a bus, use the `SampleTime` block parameter of corresponding blocks. For example, you can use `In Bus Element`, `Out Bus Element`, and `Signal Specification` blocks to specify sample time.

#### **R2016b: Simulink.BusElement objects will no longer support the SamplingMode property**

*Not recommended starting in R2016b*

In R2016b, the `SamplingMode` property of `Simulink.BusElement` objects was removed. Scripts that use the `SamplingMode` property of `Simulink.BusElement` objects continue to work. `Simulink.Bus.cellToObject` continues to require the `SamplingMode` field and `Simulink.Bus.objectToCell` continues to include the sampling mode in the output cell arrays.

In a future release, support for the `SamplingMode` property will be removed.

To specify whether a signal is sample-based or frame-based, define the sampling mode of input signals at the block level instead of at the signal level.

# Simulink.Bus.save

Save Simulink.Bus objects in function

## Syntax

```
Simulink.Bus.save(fileName)
Simulink.Bus.save(fileName,format)
Simulink.Bus.save(fileName,format,busNames)
Simulink.Bus.save(fileName,format,busNames,scope)
```

## Description

`Simulink.Bus.save(fileName)` saves all `Simulink.Bus` objects from the MATLAB base workspace in a function. The generated function defines object properties in a cell array of cell arrays, then creates the Bus objects by calling `Simulink.Bus.cellToObject`.

`Simulink.Bus.save(fileName,format)` saves the Bus objects in a function with the specified format. The function can define object properties using cell arrays or arrays.

`Simulink.Bus.save(fileName,format,busNames)` saves only the specified Bus objects in a function.

`Simulink.Bus.save(fileName,format,busNames,scope)` saves the Bus objects from the data dictionary specified by `scope` in a function.

## Examples

### Save a Simulink.Bus Object

Use the `Simulink.Bus.save` function to save a Bus object.

Create a cell array of Bus object information.

```
busCell = { ...
 { ...
 'myBusObj', ...
 'MyHeader.h', ...
 'My description', ...
 'Exported', ...
 '-1', ...
 '0', ...
 {'a',1,'double','real','Sample'}; ...
 {'b',1,'double','real','Sample', ...
 'Fixed',-3,3,'m','b is distance from the origin'}}, ...
 } ...
 { ...
 'myBusObj1', ...
 'MyHeader1.h', ...
 'My description', ...
 'Exported', ...
```

```

 '-1', ...
 '0', ...
 {'c',1,'double','real','Sample'}; ...
 {'d',1,'double','real','Sample'}}, ...
 } ...
};

```

Generate Bus objects in the base workspace from the cell array.

```
Simulink.Bus.cellToObject(busCell);
```

Save the Bus objects in a function, using the default format.

```
Simulink.Bus.save('BusObjectFunctionCellFormat');
```

For a function that is formatted to be easier to read, specify the function format as 'object'.

```
Simulink.Bus.save('BusObjectFunctionObjectFormat','object');
```

To save only one of the Bus objects in a function, specify the Bus object name.

```
Simulink.Bus.save('BusObjectFunctionSubset','cell',{'myBusObj'});
```

## Input Arguments

### **fileName** — Name of function to generate

character vector

Name of function to generate, specified as a character vector. The file name must be unique.

Example: `Simulink.Bus.save('BusObjectFunction');`

### **format** — Format of function to generate

'cell' (default) | 'object'

Format of function to generate, specified as either 'cell' or 'object'. The 'cell' format is more compact, but the 'object' format is easier to read.

The 'cell' format saves the Bus object definitions in a cell array of cell arrays and creates the Bus objects by calling `Simulink.Bus.cellToObject`. Each subordinate cell array represents a Bus object and contains these properties:

- 1 Bus name
- 2 Header file
- 3 Description
- 4 Data scope
- 5 Alignment
- 6 Preserve Element Dimensions
- 7 Elements

The elements field is a cell array that contains this information for each of the `Simulink.BusElement` objects that the Bus object references:

- 1 Element name
- 2 Dimensions
- 3 Data type
- 4 Sample time — The cell array contains this field when the sample time is not inherited. A noninherited sample time causes an error during model compilation. For more information, see “Simulink.BusElement objects no longer support the SampleTime property” on page 2-561.
- 5 Complexity
- 6 Dimensions mode
- 7 Minimum
- 8 Maximum
- 9 Units
- 10 Description

The 'object' format saves the Bus object definitions as arrays. The function uses array indexing to access elements of the array and dot notation to assign property values.

Example: `Simulink.Bus.save('BusObjectFunction','object');`

#### **busNames — Bus objects to save**

empty cell array | cell array of bus objects

Bus objects to save, specified as an empty cell array ({} ) or a cell array of Bus object names.

When you specify a cell array of Bus object names, only the specified Bus objects are saved.

When you specify an empty cell array, all Bus objects are saved. Use an empty cell array to save all Bus objects in the data dictionary specified by scope.

Example: `Simulink.Bus.save('BusObjectFunction','cell',{'myBusObj'});`

#### **scope — Data dictionary that contains Bus objects**

`Simulink.data.Dictionary` object

Data dictionary, specified as a `Simulink.data.Dictionary` object. Before you use this argument, represent the dictionary with a `Simulink.data.Dictionary` object by using, for example, the `Simulink.data.dictionary.create` or `Simulink.data.dictionary.open` function.

If scope is empty, the function uses the MATLAB base workspace as the source of the Bus objects.

Example: `Simulink.Bus.save('BusObjectFunction','cell',{},dataDictionaryObject);`

## **Version History**

**Introduced before R2006a**

### **R2020b: Simulink.BusElement objects no longer support the SampleTime property**

*Errors starting in R2020b*

The SampleTime property of Simulink.BusElement objects is no longer supported.

BusElement objects that specify a sample time cause an error during compile. To remove the sample time specification from a BusElement object, set its SampleTime to -1.

`Simulink.Bus.cellToObject` continues to accept cell arrays that specify sample time for bus elements. `Simulink.Bus.objectToCell`, `Simulink.Bus.save`, and `Simulink.Bus.createObject` continue to return cell arrays or arrays that include the sample time when it is noninherited. When the sample time is inherited (-1), they omit it. Similarly, the **Type Editor** and **Model Explorer** omit the sample time when it is inherited.

To specify the sample time for an element of a bus, use the `SampleTime` block parameter of corresponding blocks. For example, you can use `In Bus Element`, `Out Bus Element`, and `Signal Specification` blocks to specify sample time.

# Simulink.clearIntEnumType

Delete enumeration classes defined by `Simulink.defineIntEnumType`

## Syntax

```
Simulink.clearIntEnumType(typeName)
Simulink.clearIntEnumType()
```

## Description

`Simulink.clearIntEnumType(typeName)` deletes a specific enumeration class that is defined by `Simulink.defineIntEnumType`. The function generates a warning if the class name is invalid or if a class cannot be deleted because instances of the class exist.

`Simulink.clearIntEnumType()` deletes all enumeration classes that are defined by `Simulink.defineIntEnumType`. The function generates a warning if a class cannot be deleted because instances of the class exist.

## Examples

### Delete a Specific Dynamic Enumerated Data Type

Define an enumeration type and confirm that it has been created.

```
Simulink.defineIntEnumType('myEnumType', {'e1', 'e2'}, [1 2]);
myResult = Simulink.findIntEnumType('myEnumType')
```

Delete the enumeration type that you created and confirm that it is no longer there.

```
Simulink.clearIntEnumType('myEnumType');
myResult = Simulink.findIntEnumType('myEnumType')
```

### Delete All Dynamic Enumerated Data Types

Define two enumeration types and confirm that they have been created.

```
Simulink.defineIntEnumType('myEnumType1', {'e1', 'e2'}, [1 2]);
Simulink.defineIntEnumType('myEnumType2', {'e3', 'e4'}, [3 4]);
myResult = Simulink.findIntEnumType()
```

Delete all enumeration types and confirm that no enumeration types exist.

```
Simulink.clearIntEnumType();
myResult = Simulink.findIntEnumType()
```

## Input Arguments

### **typeName** — Name of enumeration class

character vector or string

Name of a specific enumeration class that is defined by `Simulink.defineIntEnumType`, specified as a character vector or string.

Example: 'myEnumType'

Data Types: char | string

## Version History

**Introduced in R2018b**

## See Also

enumeration | `Simulink.defineIntEnumType` | `Simulink.findIntEnumType`

# Simulink.createFromTemplate

Create model or project from template

## Syntax

```
Simulink.createFromTemplate(templatename)
h = Simulink.createFromTemplate(templatename)
h = Simulink.createFromTemplate(templatename,Name,Value)
```

## Description

`Simulink.createFromTemplate(templatename)` creates a model or a project from the template file specified by `templatename`. The new project is created in the default project folder.

`h = Simulink.createFromTemplate(templatename)` creates a model or a project from the template file and returns `h`, either a numeric model handle or a `currentProject` object.

`h = Simulink.createFromTemplate(templatename,Name,Value)` specifies additional options as one or more `Name, Value` pair arguments.

## Examples

### Create a Model from a Template

```
Simulink.createFromTemplate('simple_simulation.sltx')
```

### Create a Project from a Template and Get the Handle

Create a project from a template, specify the name and root folder, and return the handle to the new project (a `currentProject` object) for manipulating it programmatically.

```
proj = Simulink.createFromTemplate('code_generation_example.sltx','Name','myProject','Folder','C
```

## Input Arguments

### **templatename** — Template file name

character vector

Template file name, specified as a character vector. If the template is not on the MATLAB path, specify the fully-qualified path to the template file and `*.sltx` extension.

Example:

Data Types: `char`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example:

#### **FoLder — Project root folder**

character vector

Project root folder, if creating a new project, specified as a character vector.

Data Types: char

#### **Name — New model or project name**

character vector

New model or project name, specified as a character vector.

Data Types: char

### **Output Arguments**

#### **h — Handle**

numeric handle | `currentProject`

Handle to the new model project, returned either as a numeric model handle or a `currentProject` object.

## **Version History**

# Simulink.data.adapters.catalog

List registered file adapters

## Syntax

`Simulink.data.adapters.catalog`

## Description

`Simulink.data.adapters.catalog` displays the list of registered file adapters, which are derived from the `Simulink.data.adapters.BaseMatlabFileAdapter` base class. For each registered adapter, the display provides the class name, display name, supported extensions, and full path of the adapter.

## Examples

### List Registered File Adapters

List the registered file adapters available on the MATLAB path.

`Simulink.data.adapters.catalog`

| Class Name   | Adapter Name  | Extensions | Full Path              |
|--------------|---------------|------------|------------------------|
| "XMLAdapter" | "XML Adapter" | "XML"      | "C:\Work\XMLAdapter.m" |

## Version History

## Topics

"Create External File Adapter for Loading Variables into Simulink.SimulationInput Object"

# Simulink.data.adapters.registerAdapter

Register custom file adapter

## Syntax

```
Simulink.data.adapters.registerAdapter(adapterClassName)
```

## Description

`Simulink.data.adapters.registerAdapter(adapterClassName)` registers the custom external file adapter class `adapterClassName`, which is derived from the `Simulink.data.adapters.BaseMatlabFileAdapter` base class. The adapter registration can be added to a startup script so that the adapter is available for each MATLAB session.

## Examples

### Register XML File Adapter

Register the XML file adapter `XMLAdapter` to make it available during the MATLAB session.

```
Simulink.data.adapters.registerAdapter('XMLAdapter');
```

## Input Arguments

### `adapterClassName` — File adapter class name

string | character array

File adapter class name, specified as a string or character array.

Example: 'adapterName'

Data Types: char | string

## Version History

Introduced in R2022b

## See Also

“Create External File Adapter for Loading Variables into Simulink.SimulationInput Object”

# Simulink.data.adapters.unregisterAdapter

Unregister custom file adapter

## Syntax

```
Simulink.data.adapters.unregisterAdapter(adapterClassName)
```

## Description

`Simulink.data.adapters.unregisterAdapter(adapterClassName)` unregisters the custom external file adapter class `adapterClassName`, which is derived from the `Simulink.data.adapters.BaseMatlabFileAdapter` base class.

## Examples

### Unregister XML File Adapter

Unregister the XML file adapter `XMLAdapter`.

```
Simulink.data.adapters.unregisterAdapter('XMLAdapter');
```

## Input Arguments

### `adapterClassName` — File adapter class name

string | character array

File adapter class name, specified as a string or character array.

Example: 'adapterName'

Data Types: char | string

## Version History

Introduced in R2022b

## Simulink.data.assigninGlobal

Modify variable values in context of Simulink model

### Syntax

```
Simulink.data.assigninGlobal(modelName,varName,varValue)
```

### Description

`Simulink.data.assigninGlobal(modelName,varName,varValue)` assigns the value `varValue` to the variable or data dictionary entry `varName` in the context of the Simulink model `modelName`. `assigninGlobal` creates the variable or data dictionary entry if it does not already exist. The function operates in the Design Data section of the data dictionary that is linked to the target model or in the MATLAB base workspace if the target model is not linked to any data dictionary.

If the target model is linked to a data dictionary that references other dictionaries, `assigninGlobal` searches for `varName` in the entire dictionary hierarchy. If `assigninGlobal` does not find a matching entry, the function creates an entry in the dictionary that is linked to the target model.

### Examples

#### Modify Variable in Model with or Without Data Dictionary

Create a variable `myNewVariable` with value 237 in the context of the Simulink model `vdp.slx`, which is not linked to any data dictionary. `myNewVariable` appears as a variable in the MATLAB base workspace.

```
Simulink.data.assigninGlobal('vdp','myNewVariable',237)
```

Create a variable `myNewEntry` with value `true` in the context of the model `sldemo_fuelsys_dd_controller.slx`, which is linked to the data dictionary `sldemo_fuelsys_dd_controller.sldd`. The entry `myNewEntry` appears in the Design Data section of the dictionary.

```
openExample('simulink_automotive/UseDDForFuelContSysExample')
sldemo_fuelsys_dd_controller
Simulink.data.assigninGlobal('sldemo_fuelsys_dd_controller',...
'myNewEntry',true)
```

Confirm the addition of `myNewEntry` to the data dictionary `sldemo_fuelsys_dd_controller.sldd` by viewing the dictionary in Model Explorer.

```
myDictionaryObj = Simulink.data.dictionary.open(...
'sldemo_fuelsys_dd_controller.sldd');
show(myDictionaryObj)
```

## Input Arguments

### **modelName** — Name of target Simulink model

character vector

Name of target Simulink model, specified as a character vector.

Example: 'myTestModel'

Data Types: char

### **varName** — Name of target variable or data dictionary entry

character vector

Name of target variable or data dictionary entry, specified as a character vector.

Example: 'myTargetVariable'

Data Types: char

### **varValue** — Value to assign to variable or data dictionary entry

MATLAB expression

Value to assign to variable or data dictionary entry, specified as a MATLAB expression that returns any valid data type or data dictionary content.

Example: 27.5

Example: myBaseWorkspaceVariable

Example: Simulink.Parameter

## Tips

- `assigninGlobal` helps you transition Simulink models to using data dictionaries. You can use the function to assign values to model variables before and after linking a model to a data dictionary.

## Version History

Introduced in R2015a

“What Is a Data Dictionary?”

“Considerations Before Migrating to Data Dictionary”

## Simulink.data.dictionary.cleanupWorkerCache

Restore defaults after parallel simulation with data dictionary

### Syntax

```
Simulink.data.dictionary.cleanupWorkerCache
```

### Description

`Simulink.data.dictionary.cleanupWorkerCache` restores default settings after you have finished parallel simulation of a model that is linked to a data dictionary. Use this function in a `spmd` block, after you finish parallel simulation using `parfor` blocks, to restore default settings that were altered by the `Simulink.data.dictionary.setupWorkerCache` function.

During parallel simulation of a model that is linked to a data dictionary, you can allow each worker to access and modify the data in the dictionary independently of other workers. The function `Simulink.data.dictionary.setupWorkerCache` grants each worker a unique dictionary cache to allow independent access to the data, and the function `Simulink.data.dictionary.cleanupWorkerCache` restores cache settings to their default values.

You must have a Parallel Computing Toolbox license to perform parallel simulation using a `parfor` block.

### Examples

#### Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values”.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.sldd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
 Simulink.data.dictionary.setupWorkerCache
```

```

end

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
 % Create objects to interact with dictionary data
 % You must create these objects for every iteration of the parfor-loop
 dictObj = Simulink.data.dictionary.open(dd);
 sectObj = getSection(dictObj, 'Design Data');
 entryObj = getEntry(sectObj, 'MODE');
 % Suppose MODE is a Simulink.Parameter object stored in the data dictionary

 % Modify the value of MODE
 temp = getValue(entryObj);
 temp.Value = CtrlValues(index);
 setValue(entryObj,temp);

 % Simulate and store simulation output in the nondistributed array
 simOut{index} = sim(model);

 % Each worker must discard all changes to the data dictionary and
 % close the dictionary when finished with an iteration of the parfor-loop
 discardChanges(dictObj);
 close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spmd
 bdclose(model)
 Simulink.data.dictionary.cleanupWorkerCache
end

```

---

**Note** If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

---

## Version History

Introduced in R2015a

# Simulink.data.dictionary.closeAll

Close all connections to all open data dictionaries

## Syntax

```
Simulink.data.dictionary.closeAll
Simulink.data.dictionary.closeAll(dictFileName)
Simulink.data.dictionary.closeAll(____,unsavedAction)
```

## Description

`Simulink.data.dictionary.closeAll` attempts to close all connections to all data dictionaries that are open. For example, if you create objects, such as `Simulink.data.Dictionary`, that refer to a dictionary, that dictionary is open.

Some commands and functions, such as `Simulink.data.dictionary.cleanupWorkerCache`, cannot operate when dictionaries are open. It is a best practice to close each connection individually by using functions and methods such as the `close` method of a `Simulink.data.Dictionary` object. To find dictionaries that are open, use `Simulink.data.dictionary.getOpenDictionaryPaths`. However, you can use this function to close all connections to all dictionaries.

You can also use this function to close dictionaries in a shutdown script that is part of a project.

`Simulink.data.dictionary.closeAll(dictFileName)` closes all connections to the dictionary named `dictFileName`. If you open multiple dictionaries that use this file name (for example, if the dictionaries have different file paths), the function closes all connections to all of the dictionaries.

You cannot specify `dictFileName` as a full file path such as `'C:\temp\myDict.sldd'`.

`Simulink.data.dictionary.closeAll( ____,unsavedAction)` closes all connections to the target dictionaries by discarding or saving unsaved changes. You can choose whether to save or discard all changes to all of the target dictionaries.

## Examples

### Close All Connections to All Open Dictionaries

Discard any unsaved changes. All of the entries in the dictionaries revert to the last saved state.

```
Simulink.data.dictionary.closeAll('-discard')
```

### Close All Connections to Single Data Dictionary

Open multiple connections to a data dictionary, make a change, and close all of the connections by discarding the unsaved change.

At the command prompt, open a data dictionary by creating a `Simulink.data.Dictionary` object that refers to the dictionary.

For example, open the “Using a Data Dictionary to Manage the Data for a Fuel Control System” on page 13-139 example data dictionary.

```
openExample('simulink_automotive/UseDDForFuelContSysExample'
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
```

Display the dictionary in the Model Explorer

```
show(dictObj)
```

You now have two connections to this dictionary: The `Simulink.data.Dictionary` object and the Model Explorer.

Make a change to the dictionary by adding an entry.

```
dDataSectObj = getSection(dictObj, 'Design Data');
addEntry(dDataSectObj, 'myEntry', 5.2);
```

The `Simulink.data.dictionary.Section` object `dDataSectObj` is a third connection to the dictionary.

Close the connections to the dictionary. Discard the unsaved change.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd.sldd', '-discard')
```

The dictionary no longer appears as a node in the **Model Hierarchy** pane of the Model Explorer. The `Simulink.data.Dictionary` object `dictObj` is disconnected from the dictionary. You cannot interact with the dictionary by using the `Simulink.data.dictionary.Section` object `dDataSectObj`.

Clear the objects that referred to the dictionary.

```
clear dictObj dDataSectObj
```

## Input Arguments

### **dictFileName** — File name of target data dictionary or dictionaries

character vector

File name of target data dictionary or dictionaries, specified as a character vector. Use the file extension `sldd`.

Example: `'myDict.sldd'`

Data Types: `char`

### **unsavedAction** — Action for unsaved changes

`'-discard'` | `'-save'`

Action for unsaved changes, specified as `'-discard'` (to discard changes) or `'-save'` (to save changes). If you call `Simulink.data.dictionary.closeAll` without the `unsavedAction` argument, Simulink reports an error if the data dictionary has unsaved changes.

## Tips

A data dictionary is open if any of these conditions are true:

- The dictionary appears as a node in the **Model Hierarchy** pane of the Model Explorer. To close this connection to the dictionary, right-click the node in Model Explorer and select **Close**. Alternatively, use the `hide` method of a `Simulink.data.Dictionary` object.
- You created an object of any of these classes that refer to the dictionary:
  - `Simulink.data.Dictionary`
  - `Simulink.data.dictionary.Section`
  - `Simulink.data.dictionary.Entry`

To close these connections to the dictionary, use the `close` method of the `Simulink.data.Dictionary` object or clear the object. Clear the `Simulink.data.dictionary.Section` and `Simulink.data.dictionary.Entry` objects.

- A model that is linked to the dictionary is open. To close this connection to the dictionary, close the model.

## Version History

## Simulink.data.dictionary.create

Create new data dictionary and create `Simulink.data.Dictionary` object

### Syntax

```
dictionaryObj = Simulink.data.dictionary.create(dictionaryFile)
```

### Description

`dictionaryObj = Simulink.data.dictionary.create(dictionaryFile)` creates a data dictionary file in your current working folder or in a file path you can specify in `dictionaryFile`. The function returns a `Simulink.data.Dictionary` object representing the new data dictionary.

### Examples

#### Create New Data Dictionary and Data Dictionary Object

Create a data dictionary `myNewDictionary.sldd` in your current working folder and a `Simulink.data.Dictionary` object representing the new data dictionary. Assign the object to the variable `myDictionaryObj`.

```
myDictionaryObj = Simulink.data.dictionary.create('myNewDictionary.sldd')
```

```
myDictionaryObj =
```

```
Dictionary with properties:
```

```

 DataSourcees: {0x1 cell}
 HasAccessToBaseWorkspace: 0
EnableAccessToBaseWorkspace: 0
 HasUnsavedChanges: 0
 NumberOfEntries: 0

```

### Input Arguments

#### **dictionaryFile** — Name of new data dictionary

character vector

Name of new data dictionary, specified as a character vector containing the file name and, optionally, path of the dictionary to create. If you do not specify a path, `Simulink.data.dictionary.create` creates the new data dictionary file in your working MATLAB folder.

`Simulink.data.dictionary.create` also supports file paths specified relative to your working folder.

Example: `'myDictionary.sldd'`

Example: `'C:\Users\jsmith\myDictionary.sldd'`

Example: `'..\myOtherDictionary.sldd'`

Data Types: char

## Output Arguments

### **dictionaryObj** — Newly created data dictionary

`Simulink.data.Dictionary` object

Newly created data dictionary, returned as a `Simulink.data.Dictionary` object.

## Alternatives

You can use the Simulink Editor to create a data dictionary and link it to a model. See “Migrate Single Model to Use Dictionary” for more information.

## Version History

**Introduced in R2015a**

## See Also

`Simulink.data.Dictionary` | `Simulink.data.dictionary.open`

## Topics

“Store Data in Dictionary Programmatically”

“What Is a Data Dictionary?”

## Simulink.data.dictionary.getOpenDictionaryPaths

Return file names and paths of open data dictionaries

### Syntax

```
openDDs = Simulink.data.dictionary.getOpenDictionaryPaths
openDDs = Simulink.data.dictionary.getOpenDictionaryPaths(dictFileName)
```

### Description

`openDDs = Simulink.data.dictionary.getOpenDictionaryPaths` returns the file names and paths of all data dictionaries that are open. For example, a data dictionary is open if you create objects, such as `Simulink.data.Dictionary`, that refer to the dictionary. If you open two or more dictionaries that have the same file name but different file paths, this function returns multiple file paths.

Before executing commands and functions that cannot operate when dictionaries are open, use this function to identify open dictionaries so that you can close them. For example, when you run parallel simulations as described in “Sweep Variant Control Using Parallel Simulation”, this function helps you identify open dictionaries before executing the command `Simulink.data.dictionary.cleanupWorkerCache`.

`openDDs = Simulink.data.dictionary.getOpenDictionaryPaths(dictFileName)` returns the file paths of data dictionaries that have the file name `dictFileName`. If you open two or more dictionaries that have the same file name but different file paths, you can use this syntax to return all of the file paths.

### Examples

#### Identify and Close All Open Data Dictionaries

Open, identify, and close a data dictionary. After you close the connections to the dictionary, you can use commands and functions, such as `Simulink.data.dictionary.cleanupWorkerCache`, that cannot operate when dictionaries are open.

At the command prompt, open a data dictionary by creating a `Simulink.data.Dictionary` object that refers to the dictionary.

For example, open the “Using a Data Dictionary to Manage the Data for a Fuel Control System” on page 13-139 example data dictionary.

```
openExample('simulink_automotive/UseDDForFuelContSysExample'
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
```

Display the dictionary in the Model Explorer

```
show(dictObj)
```

Identify all of the dictionaries that are open.

```
openDDs = Simulink.data.dictionary.getOpenDictionaryPaths;
```

The file path of the dictionary that you opened, `sldemo_fuelsys_dd.sldd`, appears in the cell array of character vectors `openDDs`.

Close the connection from the Model Explorer to the dictionary.

```
hide(dictObj)
```

The dictionary no longer appears as a node in the **Model Hierarchy** pane of the Model Explorer.

Close the connection from the `Simulink.data.Dictionary` object to the dictionary.

```
close(dictObj)
clear dictObj
```

## Input Arguments

### **dictFileName** — File name of target data dictionary or dictionaries

character vector

File name of target data dictionary or dictionaries, specified as a character vector. Use the file extension `sldd`.

Example: `'myDict.sldd'`

Data Types: `char`

## Output Arguments

### **openDDs** — File names and paths of open data dictionaries

cell array of character vectors

File names and paths of open data dictionaries, returned as a cell array of character vectors.

## Tips

A data dictionary is open if any of these conditions are true:

- The dictionary appears as a node in the **Model Hierarchy** pane of the Model Explorer. To close this connection to the dictionary, right-click the node in Model Explorer and select **Close**. Alternatively, use the `hide` method of a `Simulink.data.Dictionary` object.
- You created an object of any of these classes that refer to the dictionary:
  - `Simulink.data.Dictionary`
  - `Simulink.data.dictionary.Section`
  - `Simulink.data.dictionary.Entry`

To close these connections to the dictionary, use the `close` method of the `Simulink.data.Dictionary` object or clear the object. Clear the `Simulink.data.dictionary.Section` and `Simulink.data.dictionary.Entry` objects.

- A model that is linked to the dictionary is open. To close this connection to the dictionary, close the model.

## **Version History**

# Simulink.data.dictionary.open

Open data dictionary for editing

## Syntax

```
dictionaryObj = Simulink.data.dictionary.open(dictionaryFile)
```

## Description

`dictionaryObj = Simulink.data.dictionary.open(dictionaryFile)` opens the specified data dictionary and returns a `Simulink.data.Dictionary` object representing an existing data dictionary identified by its file name and, optionally, file path with `dictionaryFile`.

Make sure any dictionaries referenced by the target dictionary are on the MATLAB path.

## Examples

### Open Existing Data Dictionary

Open the data dictionary `myDictionary_ex_API.sldd` and represent it with a `Simulink.data.Dictionary` object named `myDictionaryObj`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd')
```

```
myDictionaryObj =
```

Dictionary with properties:

```
 DataSourcees: {'myRefDictionary_ex_API.sldd'}
 HasUnsavedChanges: 0
 NumberOfEntries: 4
```

## Input Arguments

### **dictionaryFile** — Target data dictionary

character vector

Target data dictionary, specified as a character vector containing the file name and, optionally, path of the dictionary. If you do not specify a path, `Simulink.data.dictionary.open` searches the MATLAB path for the specified file. `Simulink.data.dictionary.open` also supports paths specified relative to the MATLAB working folder.

Example: `'myDictionary_ex_API.sldd'`

Example: `'C:\Users\jsmith\myDictionary_ex_API.sldd'`

Example: `'..\myOtherDictionary.sldd'`

Data Types: char

# Simulink.data.dictionary.setupWorkerCache

Enable parallel simulation with data dictionary

## Syntax

```
Simulink.data.dictionary.setupWorkerCache
```

## Description

`Simulink.data.dictionary.setupWorkerCache` prepares the workers in a parallel pool for simulating a model that is linked to a data dictionary. Use this function in a `spmd` block, prior to starting a `parfor` block, to provide the workers in a parallel pool a way to safely interact with a single data dictionary.

During parallel simulation of a model that is linked to a data dictionary, you can allow each worker to access and modify the data in the dictionary independently of other workers.

`Simulink.data.dictionary.setupWorkerCache` temporarily provides each worker in the pool with its own data dictionary cache, allowing the workers to use the data in the dictionary without permanently changing it.

You must have a Parallel Computing Toolbox license to perform parallel simulation using a `parfor` block.

## Examples

### Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values”.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.slidd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
 Simulink.data.dictionary.setupWorkerCache
end
```

```

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
 % Create objects to interact with dictionary data
 % You must create these objects for every iteration of the parfor-loop
 dictObj = Simulink.data.dictionary.open(dd);
 sectObj = getSection(dictObj,'Design Data');
 entryObj = getEntry(sectObj,'MODE');
 % Suppose MODE is a Simulink.Parameter object stored in the data dictionary

 % Modify the value of MODE
 temp = getValue(entryObj);
 temp.Value = CtrlValues(index);
 setValue(entryObj,temp);

 % Simulate and store simulation output in the nondistributed array
 simOut{index} = sim(model);

 % Each worker must discard all changes to the data dictionary and
 % close the dictionary when finished with an iteration of the parfor-loop
 discardChanges(dictObj);
 close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spmd
 bdclose(model)
 Simulink.data.dictionary.cleanupWorkerCache
end

```

---

**Note** If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

---

# Simulink.data.evalInGlobal

Evaluate MATLAB expression in context of Simulink model

## Syntax

```
returnValue = Simulink.data.evalInGlobal(modelName,expression)
```

## Description

`returnValue = Simulink.data.evalInGlobal(modelName,expression)` evaluates the MATLAB expression `expression` in the context of the Simulink model `modelName` and returns the values returned by `expression`. `evalInGlobal` evaluates `expression` in the Design Data section of the data dictionary that is linked to the target model or in the MATLAB base workspace if the target model is not linked to any data dictionary.

## Examples

### Evaluate MATLAB Expression in Model with or Without Data Dictionary

Evaluate the MATLAB expression `myNewVariable = 237;` in the context of the model `vdp`, which is not linked to any data dictionary. `myNewVariable` appears as a variable in the MATLAB base workspace.

```
Simulink.data.evalInGlobal('vdp','myNewVariable = 237;')
```

Evaluate the MATLAB expression `myNewEntry = true;` in the context of the model `sldemo_fuelsys_dd_controller`, which is linked to the data dictionary `sldemo_fuelsys_dd_controller.sldd`. `myNewEntry` appears as an entry in the Design Data section of the dictionary.

```
openExample('simulink_automotive/UseDDForFuelContSysExample')
sldemo_fuelsys_dd_controller
Simulink.data.evalInGlobal('sldemo_fuelsys_dd_controller',...
'myNewEntry = true;')
```

Confirm the creation of the entry `myNewEntry` in the data dictionary `sldemo_fuelsys_dd_controller.sldd` by viewing the dictionary in Model Explorer.

```
openExample('simulink_automotive/UseDDForFuelContSysExample')
sldemo_fuelsys_dd_controller
myDictionaryObj = Simulink.data.dictionary.open(...
'sldemo_fuelsys_dd_controller.sldd');
show(myDictionaryObj)
```

## Input Arguments

### **modelName** — Name of target Simulink model

character vector

Name of target Simulink model, specified as a character vector.

Example: 'myTestModel'

Data Types: char

**expression — MATLAB expression to evaluate**

character vector

MATLAB expression to evaluate, specified as a character vector.

Example: 'a = 5.3'

Example: 'whos'

Example: 'CurrentSpeed.Value = 290.73'

Data Types: char

**Output Arguments****returnValue — Value returned by specified expression**

valid entry or variable value

Value returned by the specified MATLAB expression.

**Tips**

- `evalinGlobal` helps you transition Simulink models to the use of data dictionaries. You can use the function to manipulate model variables before and after linking a model to a data dictionary.

**Version History**

**Introduced in R2015a**

**See Also**

`evalin` | `Simulink.data.assigninGlobal` | `Simulink.data.existsInGlobal`

**Topics**

“Store Data in Dictionary Programmatically”

“Using a Data Dictionary to Manage the Data for a Fuel Control System” on page 13-139

# Simulink.data.existsInGlobal

Check existence of variable in context of Simulink model

## Syntax

```
varExists = Simulink.data.existsInGlobal(modelName,varName)
```

## Description

`varExists = Simulink.data.existsInGlobal(modelName,varName)` returns an indication of the existence of a variable or data dictionary entry `varName` in the context of the Simulink model `modelName`. `Simulink.data.existsInGlobal` searches the Design Data section of the data dictionary that is linked to the target model or the MATLAB base workspace if the target model is not linked to any data dictionary.

## Examples

### Determine Existence of Variable in Model with or Without Data Dictionary

Determine the existence of a variable `PressVect` in the context of the Simulink model `vdp.slx`, which is not linked to any data dictionary.

```
Simulink.data.existsInGlobal('vdp','PressVect')
```

```
ans =
```

```
0
```

Because `vdp.slx` is not linked to any data dictionary, `existsInGlobal` searches only in the MATLAB base workspace for `PressVect`.

Determine the existence of a variable `PressVect` in the context of the Simulink model `sldemo_fuelsys_dd_controller.slx`, which is linked to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

Open the “Using a Data Dictionary to Manage the Data for a Fuel Control System” on page 13-139 example model `sldemo_fuelsys_dd_controller`.

```
openExample('simulink_automotive/UseDDForFuelContSysExample')
sldemo_fuelsys_dd_controller
Simulink.data.existsInGlobal('sldemo_fuelsys_dd_controller','PressVect')
```

```
ans =
```

```
1
```

Because `sldemo_fuelsys_dd_controller` is linked to the data dictionary `sldemo_fuelsys_dd_controller.slidd`, `existsInGlobal` searches for `PressVect` only in the Design Data section of the dictionary.

## Input Arguments

### **modelName** — Name of target Simulink model

character vector

Name of target Simulink model, specified as a character vector.

Example: `'myTestModel'`

Data Types: `char`

### **varName** — Name of target variable or data dictionary entry

character vector

Name of target variable or data dictionary entry, specified as a character vector.

Example: `'myTargetVariable'`

Data Types: `char`

## Output Arguments

### **varExists** — Indication of existence of target variable or data dictionary entry

1 | 0

Indication of existence of target variable or data dictionary entry, returned as 1 to indicate existence or 0 to indicate absence.

## Tips

- `existsInGlobal` helps you transition Simulink models to the use of data dictionaries. You can use the function to find model variables before and after linking a model to a data dictionary.

## Alternatives

You can use Model Explorer to search a data dictionary or any workspace for entries or variables.

## Version History

Introduced in R2015a

## See Also

`exist` | `Simulink.data.assignInGlobal` | `Simulink.data.evalInGlobal`

## Topics

“Store Data in Dictionary Programmatically”

# Simulink.data.getEnumTypeInfo

Get information about enumerated data type

## Syntax

```
information = Simulink.data.getEnumTypeInfo(enumTypeName,infoRequest)
```

## Description

`information = Simulink.data.getEnumTypeInfo(enumTypeName,infoRequest)` returns information about an enumerated data type `enumTypeName`.

Use this function only to return information about an enumerated data type. To customize an enumerated data type, for example, by specifying a default enumeration member or by controlling the scope of the type definition in generated code, see “Customize Simulink Enumeration”.

## Examples

### Return Default Value of Enumerated Data Type

Get the default enumeration member of an enumerated data type `LEDcolor`. Suppose `LEDcolor` defines two enumeration members, `GREEN` and `RED`, and uses `GREEN` as the default member.

```
Simulink.data.getEnumTypeInfo('LEDcolor','DefaultValue')
```

```
ans =
 GREEN
```

### Get Scope of Enumerated Data Type Definition in Generated Code

For an enumerated data type `LEDcolor`, find out if generated code exports or imports the definition of the type to or from a header file.

```
Simulink.data.getEnumTypeInfo('LEDcolor','DataScope')
Simulink.data.getEnumTypeInfo('LEDcolor','HeaderFile')
```

```
ans =
Auto

ans =
''
```

Because `DataScope` is 'Auto' and `HeaderFile` is empty, generated code defines the enumerated data type `LEDcolor` in the header file `model_types.h` where `model` is the name of the model used to generate code.

## Input Arguments

### **enumTypeName** — Name of target enumerated data type

character vector

Name of the target enumerated data type, specified as a character vector.

Example: 'myFirstEnumType'

Data Types: char

### **infoRequest** — Information to return

valid character vector

Information to return, specified as one of the character vector options in the table.

| Specified value | Information returned                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Example return value  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| 'DefaultValue'  | The default enumeration member, returned as an instance of the enumerated data type.                                                                                                                                                                                                                                                                                                                                                                                   | enumMember1           |
| 'Description'   | The custom description of this data type, returned as a character vector. Returns an empty character vector if a description was not specified for the type.                                                                                                                                                                                                                                                                                                           | 'My first enum type.' |
| 'HeaderFile'    | The name of the custom header file that defines the data type in generated code, returned as a character vector. Returns an empty character vector if a header file was not specified for the type.                                                                                                                                                                                                                                                                    | 'myEnumType.h'        |
| 'DataScope'     | Indication whether generated code imports or exports the definition of the data type. A return value of 'Auto' indicates generated code defines the type in the header file <code>model_types.h</code> or imports the definition from the header file identified by <code>HeaderFile</code> . A return value of 'Exported' or 'Imported' indicates generated code exports or imports the definition to or from the header file identified by <code>HeaderFile</code> . | 'Exported'            |
| 'StorageType'   | The integer data type used by generated code to store the numeric values of the enumeration members, returned as a character vector. Returns 'int' if you did not specify a storage type for the enumerated type, in which case generated code uses the native integer type of the hardware target.                                                                                                                                                                    | 'int32'               |

| Specified value           | Information returned                                                                                                                   | Example return value |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| 'AddClassNameToEnumNames' | Indication whether generated code prefixes the names of enumeration members with the name of the data type. Returned as true or false. | true                 |

## Version History

Introduced in R2014b

## Simulink.data.isSupportedEnumClass

Determine whether an enumeration class is valid for Simulink

### Syntax

```
valid = Simulink.data.isSupportedEnumClass(enumClass)
```

### Description

`valid = Simulink.data.isSupportedEnumClass(enumClass)` returns true if `enumClass` is a valid enumeration class for Simulink.

### Examples

#### Determine if Enumeration Class is Valid

Define an enumeration class of basic colors, then confirm that it is valid.

```
Simulink.defineIntEnumType('BasicColors', ...
 {'Red', 'Yellow', 'Blue'}, ...
 [0;1;2]);
Simulink.data.isSupportedEnumClass('BasicColors')
```

```
ans =

 logical

 1
```

Perform the same validity check by using the `meta.class` object as the input.

```
Simulink.data.isSupportedEnumClass(?BasicColors)
```

```
ans =

 logical

 1
```

Check if `Simulink.NumericType` is a valid enumeration class by using the `meta.class` object as the input.

```
Simulink.data.isSupportedEnumClass(?Simulink.NumericType)
```

```
ans =

 logical
```

0

## Input Arguments

### **enumClass** — Enumeration class

character vector | `meta.class`

Enumeration class, specified as a character vector or as `meta.class` object.

Example: `'myEnumClass'` or `?myEnumClass`

## Output Arguments

### **valid** — Whether enumeration class is valid

logical

If the input value refers to a valid enumeration class for Simulink, `valid` is `true`, otherwise `valid` is `false`.

## Version History

**Introduced in R2014b**

“Simulink Enumerations”

## Simulink.data.isSupportedEnumObject

Determine whether an enumeration object is valid for Simulink

### Syntax

```
valid = Simulink.data.isSupportedEnumObject(enumObject)
```

### Description

`valid = Simulink.data.isSupportedEnumObject(enumObject)` returns true if `enumObject` is a valid enumeration object for Simulink.

### Examples

#### Determine if Enumeration Object is Valid

Define an enumeration class of basic colors.

```
Simulink.defineIntEnumType('BasicColors', ...
 {'Red', 'Yellow', 'Blue'}, ...
 [0;1;2]);
```

Confirm that an instance of the enumeration class is valid.

```
Simulink.data.isSupportedEnumObject(BasicColors.Yellow)
```

```
ans =

 logical

 1
```

Call the function with input that is not an enumeration object.

```
Simulink.data.isSupportedEnumObject(5)
```

```
ans =

 logical

 0
```

### Input Arguments

#### **enumObject** — Enumeration object

enumeration object

Instance of a defined enumeration, specified as an enumeration object.

Example: `myEnumObject`

## Output Arguments

### **valid** — Whether enumeration class is valid

logical

If the input value refers to a valid enumeration object for Simulink, `valid` is `true`, otherwise `valid` is `false`.

## Version History

**Introduced in R2014b**

### Topics

“Simulink Enumerations”

## Simulink.defineIntEnumType

Define enumerated data type

### Syntax

```
Simulink.defineIntEnumType(ClassName, CellofEnums,IntValues)
Simulink.defineIntEnumType(__ , 'Description',ClassDesc)
Simulink.defineIntEnumType(__ , 'DefaultValue',DefValue)
Simulink.defineIntEnumType(__ , 'DataScope',ScopeSelection)
Simulink.defineIntEnumType(__ , 'HeaderFile',FileName)
Simulink.defineIntEnumType(__ , 'AddClassNameToEnumNames',Flag)
Simulink.defineIntEnumType(__ , 'StorageType',DataType)
```

### Description

`Simulink.defineIntEnumType(ClassName, CellofEnums,IntValues)` defines an enumeration named `ClassName` with enumeration values specified with `CellofEnums` and underlying numeric values specified by `IntValues`.

`Simulink.defineIntEnumType( __ , 'Description',ClassDesc)` defines the enumeration with a description.

`Simulink.defineIntEnumType( __ , 'DefaultValue',DefValue)` defines a default value for the enumeration, which is one of the character vectors you specify for `CellofEnums`.

`Simulink.defineIntEnumType( __ , 'DataScope',ScopeSelection)` specifies whether the data type definition should be imported from, or exported to, a header file during code generation.

`Simulink.defineIntEnumType( __ , 'HeaderFile',FileName)` specifies the name of a header file containing the enumeration class definition for use in code generated from a model.

`Simulink.defineIntEnumType( __ , 'AddClassNameToEnumNames',Flag)` specifies whether the code generator applies the class name as a prefix to the enumeration values that you specify for `CellofEnums`. For `Flag`, specify `true` or `false`. For example, if you specify `true`, the code generator would use `BasicColors_Red` instead of `Red` to represent an enumerated value.

`Simulink.defineIntEnumType( __ , 'StorageType',DataType)` specifies the data type used to store the enumerations' underlying integer values in code generated from a model.

### Examples

#### Import Enumeration Class Definition Into Workspace

Assume an external data dictionary includes the following enumeration:

```
BasicColors.Red(0), BasicColors.Yellow(1), BasicColors.Blue(2)
```

Import the enumeration class definition into the MATLAB workspace while specifying `int16` as the underlying integer data type for generated code:

```

Simulink.defineIntEnumType('BasicColors', ...
 {'Red', 'Yellow', 'Blue'}, ...
 [0;1;2], ...
 'Description', 'Basic colors', ...
 'DefaultValue', 'Blue', ...
 'HeaderFile', 'mybasiccolors.h', ...
 'DataScope', 'Exported', ...
 'AddClassNameToEnumNames', true, ...
 'StorageType', 'int16');

```

## Input Arguments

### ClassName — Name of enumerated data type

character vector | string

The name of the enumerated data type, specified as a character vector or string.

Example: 'BasicColors'

### CellOfEnums — Enumerations for data type

cell array of character vectors

Enumerations for the data type, specified as a cell array of character vectors.

Example: {'Red', 'Yellow', 'Blue'}

### IntValues — Numeric enumeration values

array of numeric values

Numeric enumeration values, specified as an array. For uint32-based enumerations, enumeration values must be less than or equal to `intmax('int32')`.

Example: [0;1;2]

### ClassDesc — Description of enumeration data type

character vector

Description of the enumeration data type, specified as a character vector.

Example: 'Basic colors'

### DefValue — Default enumeration value

character vector

The default enumeration value, specified as a character vector. The value is one of the character vectors specified for `CellOfEnums`.

Example: 'Blue'

### FileName — Header file

character vector

That header file that is to contain the data type definition, specified as a character vector. By default, the generated `#include` directive uses the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <mytypes.h>`, specify `FileName` as `'<myTypes.h>'`.

Example: 'mybasiccolors.h'

**ScopeSelection — Action for data type definition**`'Auto'` (default) | `'Exported'` | `'Imported'`

Action to take for the data type definition during code generation , specified as one of these values:

- `'Auto'` — If no value is specified for `HeaderFile`, export the type definition to `model_types.h` where `model` is the model name. If a value is specified for `HeaderFile`, import the data type definition from the specified header file.
- `'Exported'` — Export the data type definition to a header file. If no value is specified for `HeaderFile`, the header file name defaults to `type.h`, where `type` is the data type name.
- `'Imported'` — Import the data type definition from a header file. If no value is specified for `HeaderFile`, the header file name defaults to `type.h`, where `type` is the data type name.

Set the data scope selection to `Imported` or `Exported` to avoid potential MISRA C:2012 violations.

**Flag — Whether class name is a prefix to enumeration**`false` or `0` (default) | `true` or `1`

Whether the code generator applies the class name as a prefix to the enumerations, specified as a numeric or logical `1` (`true`) or `0` (`false`).

Example: `true`

**DataType — Data type used to store enumeration values**`'int8'` | `'int16'` | `'int32'` | `'uint8'` | `'uint16'` | `'uint32'`

Data type used to store the enumerations' underlying integer values in generated code, specified as a character vector.

Example: `'int16'`

## Version History

Introduced in R2010b

# Simulink.defaultModelTemplate

Set or get default model template

## Syntax

```
Simulink.defaultModelTemplate(templatename)
templatepath = Simulink.defaultModelTemplate
```

## Description

`Simulink.defaultModelTemplate(templatename)` sets the template file specified by `templatename` as the default model template to use for new models. This setting is persistent between Simulink sessions.

`templatepath = Simulink.defaultModelTemplate` gets the full path to the current default model template.

## Examples

### Set the default model template

```
Simulink.defaultModelTemplate('simple_simulation.sltx')
```

### Get the default model template

```
mydefaulttemplate = Simulink.defaultModelTemplate
```

### Clear and restore the default model template

Use `set_param` to set a root block diagram parameter. This clears the default template so that new models will inherit this property of the root block diagram, and warns.

```
set_param(0, 'StopTime', '99');
```

Restore the default template.

```
Simulink.defaultModelTemplate('$restore');
```

## Input Arguments

### templatename — Template file name

character vector

Template file name, specified as a character vector. If the template is not on the MATLAB path, specify the fully-qualified path to the template file and `*.sltx` extension.

Example: \\Home\username\Documents\MATLAB\template.sltx

Data Types: char

## **Output Arguments**

### **templatepath — Template path**

character vector

Template path, specified as a character vector, showing the full path to the current default model template.

## **Version History**

**Introduced in R2016b**

# Simulink.exportToTemplate

Create template from model or project

## Syntax

```
templatefile = Simulink.exportToTemplate(obj,templatename)
templatefile = Simulink.exportToTemplate(obj,templatename,Name,Value)
```

## Description

`templatefile = Simulink.exportToTemplate(obj,templatename)` creates a template file (*templatename*.sltx) from a model or project specified by `obj`.

If you have project templates created in R2014a or earlier (.zip files), use `Simulink.exportToTemplate` to upgrade them to .sltx files, then you can use them in the start page.

`templatefile = Simulink.exportToTemplate(obj,templatename,Name,Value)` specifies additional template options as one or more Name, Value pair arguments.

## Examples

### Create a Template from a Model

Open the vdp model and create a template from it.

```
openExample('vdp.slx');
myvdptemplate = Simulink.exportToTemplate(bdroot,'vdptemplate')
```

### Create a Template from a Model and Specify Description

Open the vdp model and create a template from it, specifying a description.

```
openExample('vdp.slx');
myvdptemplate = Simulink.exportToTemplate(bdroot,'vdptemplate','Description','Use this template')
```

## Input Arguments

### **obj** — Model, library, or project

character vector | numeric handle | `slproject.ProjectManager`

Model, library, or project, specified by name or numeric handle, or a `slproject.ProjectManager` object returned by the `currentProject` function.

Data Types: `double` | `char`

### **templatename** — Template file name

character vector

Template file name, specified as a character vector that can optionally include the fully-qualified path to a template file and \*.sltx extension.

Data Types: char

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: Title, 'My Project Template'

### **Group — Group of template**

character vector

Group of template, specified as a character vector. On the Start Page, templates are shown under group headings.

Example: 'My Templates'

Data Types: char

### **Author — Author of template**

character vector

Author of template, specified as a character vector.

Data Types: char

### **Description — Description of template**

character vector

Description of template, specified as a character vector.

Data Types: char

### **ThumbnailFile — Thumbnail image file name**

character vector

Thumbnail image file name, specified as a character vector.

Data Types: char

### **Title — Title of model or project template**

character vector

Title of template, specified as a character vector. On the Start Page, the templates titles are shown on the tiles. The title can be different from the file name, and you can use any characters in the title. The default value is the name of the model or project.

Example: 'My Project Template'

Data Types: char

## Output Arguments

### **templatefile** — Template file

character vector

Template file, returned as *templatename.slx* file.

## Version History

Introduced in R2016a

## Simulink.exportToVersion

Export model, library, or project for use in previous version of Simulink

### Syntax

```
exported_file = Simulink.exportToVersion(modelname, target_filename, version)
exported_file = Simulink.exportToVersion(modelname, target_filename, version,
Name, Value)
exported_project = Simulink.exportToVersion(proj, zipfilename, version)
exported_project = Simulink.exportToVersion(proj, zipfilename, version,
exportReferencedProjects)
```

### Description

`exported_file = Simulink.exportToVersion(modelname, target_filename, version)` exports the model or library `modelname` to a file named `target_filename` in a format that the specified previous Simulink version can load.

If the system contains functionality not supported by the specified Simulink software version, the command removes the functionality and replaces any unsupported blocks with empty masked subsystem blocks colored yellow. As a result, the converted system may generate different results.

The `save_system` `ExportToVersion` option is a legacy option for this functionality that is also supported.

`exported_file = Simulink.exportToVersion(modelname, target_filename, version, Name, Value)` specifies additional options as one or more name-value pair arguments.

`exported_project = Simulink.exportToVersion(proj, zipfilename, version)` exports the project `proj` to a ZIP file `zipfilename` in a format that the specified previous Simulink version can load.

`exported_project = Simulink.exportToVersion(proj, zipfilename, version, exportReferencedProjects)` exports the top-level project `proj` and all referenced projects to a ZIP file `zipfilename` in a format that the specified previous Simulink version can load.

### Examples

#### Export a Model to a Previous Version

Get the current top-level system and export it.

```
Simulink.exportToVersion(bdroot, 'mymodel.slx', 'R2014b');
```

#### Export a Model to a Previous Version and Break Links

Get the current top-level system and export it, replacing links to library blocks with copies of the library blocks in the saved file.

```
Simulink.exportToVersion(bdroot, 'mymodel.slx', 'R2014b', 'BreakUserLinks', true);
```

## Export a Project to a Previous Version

Get the current top-level project and export it.

```
sldemo_slproject_airframe_references;
proj = currentProject;
Simulink.exportToVersion(proj, 'myzipfilename', 'R2019a');
```

Export the current top-level project and all referenced projects.

```
Simulink.exportToVersion(proj, 'myzipfilename', 'R2019a', true);
```

## Input Arguments

### modelName — Model to export

character vector | string scalar

Model to export, specified as a character vector or string scalar, without any file extension. The model must be loaded and unmodified. The target file must not be the same as the model file.

Data Types: char | string

### target\_filename — Exported file name

character vector | string scalar

Exported file name, specified as a character vector or string scalar. The target file must not be the same as the model file.

Example: 'mymodel.slx'

Data Types: char | string

### proj — Project to export

matlab.project.Project object

Project to export, specified as a matlab.project.Project object. Use currentProject to create a project object from the currently loaded project.

### zipfilename — Exported ZIP file name

character vector | string scalar

ZIP file name containing the exported project, specified as a character vector or string scalar.

Example: 'myzipfile.zip'

Data Types: char | string

### version — MATLAB release name

'R2013B' | 'R2014A\_MDL' | 'R2016B\_SLX' | ...

MATLAB case-insensitive release name, specified as a character vector or string scalar. The MATLAB release name specifies a previous Simulink version. Simulink.exportToVersion exports the system to a format that the specified previous Simulink version can load. You can export your models up to 7 years of previous releases. You cannot export to your current version.

You can specify model file format as SLX or MDL using the suffix `_MDL` or `_SLX`. If you do not specify a format, you export your default model file format. You cannot specify the model files format when exporting a project.

Example: 'R2015B'

Data Types: `char` | `string`

### **exportReferencedProjects — Export referenced projects to a previous Simulink version**

`false` (default) | `true` | ...

(Optional) Export referenced projects to a previous release, specified as `true` or `false`.

If `true`, `Simulink.exportToVersion` exports the top-level and all referenced projects to a previous release, and includes the references in the ZIP file. Extracting the ZIP file creates a copy of the referenced projects and links them to the top-level project.

If `false`, `Simulink.exportToVersion` only exports the top-level project to a previous release. `Simulink.exportToVersion` preserves the existing absolute and relative link to the references. For a working project on extraction, the references must be at the same absolute and relative paths.

The argument is ignored if the project does not have references.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example:

### **AllowPrompt — Allow prompt or message dialog box**

`false` (default) | `true` | `'on'` | `'off'`

Allow prompt or message dialog box, specified by a logical value that indicates whether to display any output prompt or message in a dialog box or only messages at the command line. For example, prompts to make files writable, or messages about exported versions. If you want to allow prompts, then set to `true`. or `on`.

### **BreakUserLinks — Break user-defined links**

`false` (default) | `true` | `'on'` | `'off'`

Break user-defined links, specified by a logical value that indicates whether the function replaces links to user-defined library blocks with copies of the library blocks in the saved file.

### **BreakToolboxLinks — Break all toolbox links**

`false` (default) | `true` | `'on'` | `'off'`

Break all toolbox links, specified by a logical value that indicates whether the function replaces links to built-in MathWorks library blocks with copies of the library blocks in the saved file. The `'BreakToolboxLinks'` option affects Simulink library blocks and blocks from any other libraries supplied with MathWorks toolboxes or blocksets.

---

**Note** The 'BreakToolboxLinks' option can result in compatibility issues when upgrading to newer versions of Simulink software. For example:

- Any masks on top of library links to Simulink S-functions will not upgrade to the new version of the S-function.
- Any library links to masked subsystems in a Simulink library will not upgrade to the new subsystem behavior.
- Any broken links prevent the automatic library forwarding mechanism from upgrading the link. See “Maintain Compatibility of Library Blocks Using Forwarding Tables”.

If you have saved a model with broken links to built-in libraries, use the Upgrade Advisor to scan the model for out-of-date blocks and upgrade the Simulink blocks to their current versions.

---

## Output Arguments

### **exported\_file** — Exported file

character vector

Path of the exported file, returned in the format that the specified previous Simulink version can load.

### **exported\_project** — Exported project in a ZIP file

character vector

Path of the ZIP file containing the exported project, returned in the format that the specified previous Simulink version can load.

## Limitations

Simulink.exportToVersion does not support exporting external test harnesses to previous releases.

- For models with external test harnesses, Simulink.exportToVersion automatically converts them to internal test harnesses.
- For projects containing models with external test harnesses, Simulink.exportToVersion exports the projects and reports the test harnesses as missing files.

## Version History

Introduced in R2016a

### See Also

save\_system

### Topics

“Save Models”

## **Simulink.history.clear**

Clear the Simulink start page and editor history

### **Syntax**

```
Simulink.history.clear
```

### **Description**

`Simulink.history.clear` clears the list of favorites and the list of recent models and projects in the Simulink start page and editor.

### **Examples**

#### **Clear All Simulink History**

To clear all Simulink history, in the Command Window, type:

```
Simulink.history.clear()
```

### **Version History**

**Introduced in R2020b**

### **See Also**

# Simulink.fileGenControl

Specify root folders for files generated by diagram updates and model builds

## Syntax

```
cfg = Simulink.fileGenControl('getConfig')
Simulink.fileGenControl(Action,Name,Value)
```

## Description

`cfg = Simulink.fileGenControl('getConfig')` returns a handle to an instance of the `Simulink.FileGenConfig` object, which contains the current values of these file generation control parameters:

- `CacheFolder` - Specifies the root folder for model build artifacts that are used for simulation, including Simulink® cache files.
- `CodeGenFolder` - Specifies the root folder for code generation files.
- `CodeGenFolderStructure` - Controls the folder structure within the code generation folder.

To get or set the parameter values, use the `Simulink.FileGenConfig` object.

These Simulink preferences determine the initial parameter values for the MATLAB session:

- **Simulation cache folder** - `CacheFolder`
- **Code generation folder** - `CodeGenFolder`
- **Code generation folder structure** - `CodeGenFolderStructure`

`Simulink.fileGenControl(Action,Name,Value)` performs an action that uses the file generation control parameters of the current MATLAB session. Specify additional options with one or more `name,value` pair arguments.

## Examples

### Get File Generation Control Parameter Values

To obtain the file generation control parameter values for the current MATLAB session, use `getConfig`.

```
cfg = Simulink.fileGenControl('getConfig');
myCacheFolder = cfg.CacheFolder;
myCodeGenFolder = cfg.CodeGenFolder;
myCodeGenFolderStructure = cfg.CodeGenFolderStructure;
```

### Set File Generation Control Parameters by Using Simulink.FileGenConfig Object

To set the file generation control parameter values for the current MATLAB session, use the `setConfig` action. First, set values in an instance of the `Simulink.FileGenConfig` object. Then,

pass the object instance. This example assumes that your system has `aNonDefaultCacheFolder` and `aNonDefaultCodeGenFolder` folders.

```
% Get the current configuration
cfg = Simulink.fileGenControl('getConfig');

% Change the parameters to non-default locations
% for the cache and code generation folders
cfg.CacheFolder = fullfile('C:', 'aNonDefaultCacheFolder');
cfg.CodeGenFolder = fullfile('C:', 'aNonDefaultCodeGenFolder');
cfg.CodeGenFolderStructure = 'TargetEnvironmentSubfolder';

Simulink.fileGenControl('setConfig', 'config', cfg);
```

### Set File Generation Control Parameters Directly

You can set file generation control parameter values for the current MATLAB session without creating an instance of the `Simulink.FileGenConfig` object. This example assumes that your system has `aNonDefaultCacheFolder` and `aNonDefaultCodeGenFolder` folders.

```
myCacheFolder = fullfile('C:', 'aNonDefaultCacheFolder');
myCodeGenFolder = fullfile('C:', 'aNonDefaultCodeGenFolder');

Simulink.fileGenControl('set', 'CacheFolder', myCacheFolder, ...
 'CodeGenFolder', myCodeGenFolder, ...
 'CodeGenFolderStructure', ...
 Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder);
```

If you do not want to generate code for different target environments in separate folders, for `'CodeGenFolderStructure'`, specify the value `Simulink.filegen.CodeGenFolderStructure.ModelSpecific`.

### Reset File Generation Control Parameters

You can reset the file generation control parameters to values from Simulink preferences.

```
Simulink.fileGenControl('reset');
```

### Create Simulation Cache and Code Generation Folders

To create file generation folders, use the `set` action with the `'createDir'` option. You can keep previous file generation folders on the MATLAB path through the `'keepPreviousPath'` option.

```
%
myCacheFolder = fullfile('C:', 'aNonDefaultCacheFolder');
myCodeGenFolder = fullfile('C:', 'aNonDefaultCodeGenFolder');

Simulink.fileGenControl('set', ...
 'CacheFolder', myCacheFolder, ...
 'CodeGenFolder', myCodeGenFolder, ...
```

```
'keepPreviousPath',true, ...
'createDir',true);
```

## Input Arguments

### Action — Specify action

'reset' | 'set' | 'setConfig'

Specify an action that uses the file generation control parameters of the current MATLAB session:

- 'reset' - Reset file generation control parameters to values from Simulink preferences.
- 'set' - Set file generation control parameters for the current MATLAB session by directly passing values.
- 'setConfig' - Set file generation control parameters for the current MATLAB session by using an instance of a `Simulink.FileGenConfig` object.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Simulink.fileGenControl(Action, Name, Value);`

### config — Specify instance of Simulink.FileGenConfig

object handle

Specify the `Simulink.FileGenConfig` object instance containing file generation control parameters that you want to set.

Option for `setConfig`.

Example: `Simulink.fileGenControl('setConfig', 'config', cfg);`

### CacheFolder — Specify simulation cache folder

character vector

Specify a simulation cache folder path value for the `CacheFolder` parameter.

Option for `set`.

Example: `Simulink.fileGenControl('set', 'CacheFolder', myCacheFolder);`

### CodeGenFolder — Specify code generation folder

character vector

Specify a code generation folder path value for the `CodeGenFolder` parameter. You can specify an absolute path or a path relative to build folders. For example:

- 'C:\Work\mymodelsimcache' and '/mywork/mymodelgencode' specify absolute paths.
- 'mymodelsimcache' is a path relative to the current working folder (pwd). The software converts a relative path to a fully qualified path at the time the `CacheFolder` or `CodeGenFolder`

parameter is set. For example, if `pwd` is  `'/mywork'`, the result is  `'/mywork/mymodelsimcache'`.

- `'../test/mymodelgencode'` is a path relative to `pwd`. If `pwd` is  `'/mywork'`, the result is  `'/test/mymodelgencode'`.

Option for `set`.

Example: `Simulink.fileGenControl('set', 'CodeGenFolder', myCodeGenFolder);`

### **CodeGenFolderStructure — Specify generated code folder structure**

`Simulink.filegen.CodeGenFolderStructure.ModelSpecific` (default) |  
`Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder`

Specify the layout of subfolders within the generated code folder:

- `Simulink.filegen.CodeGenFolderStructure.ModelSpecific` (default) - Place generated code in subfolders within a model-specific folder.
- `Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder` - If models are configured for different target environments, place generated code for each model in a separate subfolder. The name of the subfolder corresponds to the target environment.

Option for `set`.

Example: `Simulink.fileGenControl('set', 'CacheFolder', myCacheFolder, ...  
'CodeGenFolder', myCodeGenFolder, ... 'CodeGenFolderStructure', ...  
Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder);`

### **keepPreviousPath — Keep previous folder paths on MATLAB path**

`false` (default) | `true`

Specify whether to keep the previous values of `CacheFolder` and `CodeGenFolder` on the MATLAB path:

- `true` - Keep previous folder path values on MATLAB path.
- `false` (default) - Remove previous folder path values from MATLAB path.

Option for `reset`, `set`, or `setConfig`.

Example: `Simulink.fileGenControl('reset', 'keepPreviousPath', true);`

### **createDir — Create folders for file generation**

`false` (default) | `true`

Specify whether to create folders for file generation if the folders do not exist:

- `true` - Create folders for file generation.
- `false` (default) - Do not create folders for file generation.

Option for `set` or `setConfig`.

Example: `Simulink.fileGenControl('set', 'CacheFolder', myCacheFolder,  
'CodeGenFolder', myCodeGenFolder, 'keepPreviousPath', true,  
'createDir', true);`

## Avoid Naming Conflicts

Using `Simulink.fileGenControl` to set `CacheFolder` and `CodeGenFolder` adds the specified folders to your MATLAB search path. This function has the same potential for introducing a naming conflict as using `addpath` to add folders to the search path. For example, a naming conflict occurs if the folder that you specify for `CacheFolder` or `CodeGenFolder` contains a model file with the same name as an open model. For more information, see “What Is the MATLAB Search Path?” and “Files and Folders that MATLAB Accesses”.

To use a nondefault location for the simulation cache folder or code generation folder:

- 1 Delete any potentially conflicting artifacts that exist in:
  - The current working folder, `pwd`.
  - The nondefault simulation cache and code generation folders that you intend to use.
- 2 Specify the nondefault locations for the simulation cache and code generation folders by using `Simulink.fileGenControl` or Simulink preferences.

## Output Arguments

### **cfg** — Current values of file generation control parameters

object handle

Instance of a `Simulink.FileGenConfig` object, which contains the current values of file generation control parameters.

## Version History

Introduced in R2010b

## Simulink.findBlocks

Find blocks in Simulink models

### Syntax

```
bl = Simulink.findBlocks(sys)
bl = Simulink.findBlocks(sys,options)
bl = Simulink.findBlocks(sys,Param1,Value1,...,ParamN,ValueN)
bl = Simulink.findBlocks(sys,Param1,Value1,...,ParamN,ValueN,options)
```

### Description

`bl = Simulink.findBlocks(sys)` returns handles to all blocks in the model or subsystem `sys`.

`bl = Simulink.findBlocks(sys,options)` finds blocks that match the criteria specified by a `Simulink.FindOptions` object.

`bl = Simulink.findBlocks(sys,Param1,Value1,...,ParamN,ValueN)` finds blocks whose block parameters have the specified values.

`bl = Simulink.findBlocks(sys,Param1,Value1,...,ParamN,ValueN,options)` finds blocks whose parameters have the specified values and that match the criteria specified by a `FindOptions` object.

### Examples

#### Find Blocks in a Model

Return handles for all blocks in the model `vdp`.

```
load_system('vdp');
bl = Simulink.findBlocks('vdp')
```

```
bl =
```

```
1.0e+03 *
 9.4450
 9.4460
 9.4470
 9.4480
 9.4490
 9.4500
 9.4510
 9.4520
 9.4530
 9.4540
 9.4550
 9.4560
 9.4570
 9.4580
```

Return block names.

```
bl = getfullname(Simulink.findBlocks('vdp'))
```

```
bl =
```

```
14x1 cell array
```

```
{'vdp/Constant' }
{'vdp/More Info' }
{'vdp/More Info/Model Info'}
{'vdp/Mu' }
{'vdp/Mux' }
{'vdp/Product' }
{'vdp/Scope' }
{'vdp/Square' }
{'vdp/Sum' }
{'vdp/Sum1' }
{'vdp/x1' }
{'vdp/x2' }
{'vdp/Out1' }
{'vdp/Out2' }
```

Return block handles for the block whose name is Mu.

```
Simulink.findBlocks('vdp', 'Name', 'Mu')
```

```
ans =
```

```
9.4480e+03
```

## Input Arguments

**sys** — Model or subsystem to find blocks in

character vector | string array

Model or subsystem to find blocks in, specified as a character vector or string array.

Example: 'vdp' "f14/Aircraft Dynamics Model"

**options** — Search constraints

Simulink.FindOptions object

Search constraints, specified as a Simulink.FindOptions object.

## Output Arguments

**bl** — Search results

array of handles

Search results, returned as an array of handles.

## Version History

Introduced in R2018a

**See Also**

# Simulink.findBlocksOfType

Find specified type of block in Simulink models

## Syntax

```
bl = Simulink.findBlocksOfType(sys,type)
bl = Simulink.findBlocksOfType(sys,type,options)
bl = Simulink.findBlocksOfType(sys,type,Param1,Value1,...,ParamN,ValueN)
bl = Simulink.findBlocksofType(sys,type,Param1,Value1,...,ParamN,ValueN,
options)
```

## Description

`bl = Simulink.findBlocksOfType(sys,type)` returns handles to all blocks of the specified type in the model or subsystem `sys`.

`bl = Simulink.findBlocksOfType(sys,type,options)` matches the criteria specified by a `FindOptions` object.

`bl = Simulink.findBlocksOfType(sys,type,Param1,Value1,...,ParamN,ValueN)` finds blocks whose parameters have the specified values.

`bl = Simulink.findBlocksofType(sys,type,Param1,Value1,...,ParamN,ValueN,options)` finds blocks whose parameters have the specified values and that match the criteria specified by a `FindOptions` object.

## Examples

### Find Blocks of a Type in Model

Find all blocks of type Gain in the model `vdp`.

```
load_system('vdp');
Simulink.findBlocksOfType('vdp','Gain')
```

```
ans =
 7.0001
```

To return block names instead of handles, use `getfullname`.

```
getfullname(Simulink.findBlocksOfType('vdp','Gain'))
```

```
ans =
 'vdp/Mu'
```

## Find Blocks of a Type Using Search Options

Load the model `sldemo_clutch`. Then, create a `FindOptions` object and use it to constrain the search of `GoTo` blocks in the model to the `Unlocked` system.

```
openExample('sldemo_clutch');
f = Simulink.FindOptions('SearchDepth',1);
bl = Simulink.findBlocksOfType('sldemo_clutch/Unlocked','Goto',f)

bl =

 166.0001
 167.0001
```

## Input Arguments

### **sys** — Model or subsystem to find blocks in

character vector | string array

Model or subsystem to find blocks in, specified as a character vector or string array.

Example: `'vdp' "f14/Aircraft Dynamics Model"`

### **type** — Block type

character vector | string scalar

Block type, specified as a character vector or string scalar. Use `get_param` with the `'BlockType'` parameter to get the block type.

### **options** — Search constraints

`simulink.FindOptions` object

Search constraints, specified as a `Simulink.FindOptions` object.

Example: `Simulink.FindOptions('SearchDepth',1)`

## Output Arguments

### **bl** — Search results

array of handles

Search results, returned as an array of handles.

## Version History

Introduced in R2018a

# Simulink.findIntEnumType

Find enumeration classes defined by `Simulink.defineIntEnumType`

## Syntax

```
result = Simulink.findIntEnumType(typeName)
result = Simulink.findIntEnumType()
```

## Description

`result = Simulink.findIntEnumType(typeName)` returns the `meta.class` object for class `type` that is defined by `Simulink.defineIntEnumType`. Use the returned `meta.class` object to query attributes of the enumeration class. If the class does not exist, the function returns an empty `meta.class` object.

`result = Simulink.findIntEnumType()` returns `meta.class` objects for all enumeration classes that are defined by `Simulink.defineIntEnumType`. Use the returned `meta.class` objects to query attributes of the enumeration classes.

## Examples

### Find a Specific Dynamic Enumerated Data Type

Define an enumeration type.

```
Simulink.defineIntEnumType('myEnumType', {'e1', 'e2'}, [1 2]);
```

Check for the enumeration type that you have created.

```
myResult = Simulink.findIntEnumType('myEnumType')
```

```
myResult =
```

```
class with properties:
```

```

 Name: 'myEnumType'
 Description: ''
DetailedDescription: ''
 Hidden: 0
 Sealed: 0
 Abstract: 0
 Enumeration: 1
ConstructOnLoad: 0
HandleCompatible: 0
InferiorClasses: {[1x1 meta.class]}
ContainingPackage: [0x0 meta.package]
RestrictsSubclassing: 0
 PropertyList: [0x1 meta.property]
 MethodList: [150x1 meta.method]
 EventList: [0x1 meta.event]
```

```
EnumerationMemberList: [2×1 meta.EnumeratedValue]
SuperclassList: [1×1 meta.class]
```

### **Find All Dynamic Enumerated Data Types**

Define two enumeration types.

```
Simulink.defineIntEnumType('myEnumType1', {'e1', 'e2'}, [1 2]);
Simulink.defineIntEnumType('myEnumType2', {'e3', 'e4'}, [3 4]);
```

Check for the enumeration types that you have created.

```
myResult = Simulink.findIntEnumType()
```

### **Input Arguments**

#### **typeName — Name of enumeration class**

character vector or string

Name of a specific enumeration class that is defined by `Simulink.defineIntEnumType`, specified as a character vector or string.

Example: 'myEnumType'

Data Types: char | string

### **Output Arguments**

#### **result — Search results**

array of `meta.class` objects

Search result, returned as an array of `meta.class` objects. If there are no enumeration classes, the array is empty.

## **Version History**

**Introduced in R2018b**

### **See Also**

[enumeration](#) | [Simulink.clearIntEnumType](#) | [Simulink.defineIntEnumType](#)

# Simulink.findTemplates

Find model or project templates with specified properties

## Syntax

```
filename = Simulink.findTemplates(templatename)
filename = Simulink.findTemplates(templatename,Name,Value)
[filename,info] = Simulink.findTemplates(templatename)
```

## Description

`filename = Simulink.findTemplates(templatename)` returns the names and `TemplateInfo` objects for all matching templates that include `templatename`.

`filename = Simulink.findTemplates(templatename,Name,Value)` also specifies additional template properties as one or more `Name, Value` pair arguments.

`[filename,info] = Simulink.findTemplates(templatename)` returns the names and `TemplateInfo` objects for all matching templates.

## Examples

### Find a Particular Template

Get the full path to the default model template.

```
filename = Simulink.findTemplates('factory_default_model');
```

### Find All Templates With Specified Folders or Authors

Get all templates inside folders called `work`.

```
filename = Simulink.findTemplates('work/')
```

Get all templates for which the `Author` property includes the character vector `Smith`.

```
filename = Simulink.findTemplates('*', 'Author', 'Smith')
```

### Find All DSP Templates and Get TemplateInfo Objects

Get the paths to all DSP model templates, and `sltemplate.TemplateInfo` objects for each of them.

```
[filename,info] = Simulink.findTemplates('dsp*', 'Type', 'Model');
```

## Input Arguments

### **templatename — Template name**

character vector

Template name, specified as a character vector containing a portion of a file name, which can contain the wildcard asterisk character “\*”.

Example:

Data Types: char

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

You can specify regular expressions for any of the Value character vectors, e.g., including the wildcard asterisk character “\*”.

Example: 'Author', '\*son'

### **Type — Model, library, or project**

'Model' | 'Library' | 'Project'

Model, library, or project template type, specified as a character vector for model, library, or project.

Example: 'Simscape'

Data Types: char

### **Title — Title of template**

character vector

Title of template, specified as a character vector.

Example: 'Simscape'

Data Types: char

### **Group — Group of template**

character vector

Group of template, specified as a character vector. On the Start Page, templates are shown under group headings.

Example: 'Simscape'

Data Types: char

### **Author — Author of template**

character vector

Author of template, specified as a character vector.

Data Types: char

**Description — Description of template**

character vector

Description of template, specified as a character vector.

Data Types: char

**Output Arguments****filename — Template name**

character vector | cell array of character vectors

Template names of matching templates, returned as character vectors.

**info — Template information**

template info objects | array of template info objects

Template information of matching templates, returned as `sltemplate.TemplateInfo` objects.

**Version History**

**Introduced in R2016a**

**See Also**

`Simulink.createFromTemplate` | `Simulink.exportToTemplate`

**Topics**

“Create Template from Model”

“Using Templates to Create Standard Project Settings”

## Simulink.findVars

Analyze relationship between variables and blocks in models

### Syntax

```
[variables] = Simulink.findVars(context)
[variables] = Simulink.findVars(context,variablefilter)
[variables] = Simulink.findVars(____,Name,Value)
```

### Description

`[variables] = Simulink.findVars(context)` finds and returns variables that are used in the blocks and models specified by `context`, including subsystems and referenced models. The function returns an empty vector if `context` does not use any variables.

`[variables] = Simulink.findVars(context,variablefilter)` finds only the variables or enumerated types that are specified by `variablefilter`. For example, use this syntax to determine where a variable is used in a model.

`[variables] = Simulink.findVars( ____,Name,Value)` finds variables with additional options specified by one or more `Name,Value` pair arguments. For example, you can search for unused variables. You can also search for enumerated data types that are used in `context`, in addition to variables.

### Examples

#### Variables in Use in a Model

Find variables used by `MyModel`.

```
variables = Simulink.findVars('MyModel');
```

#### Specific Variable in Use in a Model

Find all uses of the base workspace variable `k` by `MyModel`. Use the cached results to avoid compiling `MyModel`.

```
variables = Simulink.findVars('MyModel','Name','k',...
'SearchMethod','cached','SourceType','base workspace');
```

#### Regular Expression Matching

Find all uses of a variable whose name matches the regular expression `^trans`.

```
variables = Simulink.findVars('MyModel', 'Regex', 'on', ...
 'Name', '^trans');
```

### Variables Common to Two Models

Given two models, find the variables used by the first model, the second, and both

```
model1Vars = Simulink.findVars('model1');
model2Vars = Simulink.findVars('model2');
commonVars = intersect(model1Vars,model2Vars);
```

### Variables Not Used in a Model

Find the variables that are defined in the model workspace of MyModel but that are not used by the model.

```
unusedVars = Simulink.findVars('MyModel', 'FindUsedVars', 'off', ...
 'SourceType', 'model workspace');
```

### Specific Variable Not Used in a Model

Determine if the base workspace variable k is not used by MyModel.

```
varObj = Simulink.VariableUsage('k', 'base workspace');
unusedVar = Simulink.findVars('MyModel', varObj, ...
 'FindUsedVars', 'off');
```

### Variables Used by a Block

Find the variables that are used by the block Gain1 in MyModel.

```
variables = Simulink.findVars('MyModel', ...
 'Users', 'MyModel/Gain1');
```

### Variables Used in a Model Reference Hierarchy

Find the variables that are used in a model reference hierarchy. Begin the search with the model MyNestedModel, and search the entire hierarchy below MyNestedModel.

```
variables = Simulink.findVars('MyNestedModel', 'SearchReferencedModels', 'on');
```

### Variables and Enumerated Types Used in a Model

Find variables and enumerated types that are used in MyModel.

```
varsAndEnumTypes = Simulink.findVars('MyModel','IncludeEnumTypes','on');
```

## Input Arguments

### context — Models and blocks to search

character vector | string | cell array of character vectors | string array

Models and blocks to search, specified as a character vector, string, cell array of character vectors, or a string array. You can specify `context` in one of the following ways:

- The name of a model. For example, ('vdp') specifies the model `vdp.slx`.
- The name or path of a block or masked block. For example, ('vdp/Gain1') specifies a block named `Gain1` at the root level of the model `vdp.slx`.
- A cell array of model or block names.

Data Types: `char` | `cell`

### variablefilter — Specific variables to find

array of `Simulink.VariableUsage` objects

Specific variables to find, specified as an array of `Simulink.VariableUsage` objects. Each `Simulink.VariableUsage` object identifies a variable to find.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: 'FindUsedVars','off'

### FindUsedVars — Find variables that are used or not used

'on' (default) | 'off'

Flag to find variables that are explicitly used or not used, specified as the comma-separated pair consisting of 'FindUsedVars' and 'on' or 'off'. If you specify `FindUsedVars` as 'off', the function finds variables that are not used in context but that are defined in the workspace specified by `SourceType`.

Example: 'FindUsedVars','off'

### IncludeEnumTypes — Find enumerated types that are used

'off' (default) | 'on'

Flag to find enumerated data types that are used, specified as the comma-separated pair consisting of 'IncludeEnumTypes' and 'on' or 'off'. The function finds enumerated types that are used explicitly in context as well as types that define variables that are used in context.

The function does not report details about which blocks or objects are using the enumerated types.

If you specify `SourceType` as 'base workspace', 'model workspace', or 'mask workspace', the function does not report enumerated types because those sources cannot define enumerated types.

You cannot find unused enumerated types by specifying `FindUsedVars` as `'off'`.

Example: `'IncludeEnumTypes', 'on'`

### **RegExp — Enable regular expression matching**

`'off'` (default) | `'on'`

Flag to enable regular expression matching for input arguments, specified as the comma-separated pair consisting of `'RegExp'` and `'on'`. You can match only input arguments that have character vector values.

Example: `'RegExp', 'on'`

### **SearchMethod — Compile status**

`'compiled'` (default) | `'cached'`

Compile status, specified as the comma-separated pair consisting of `'SearchMethod'` and one of these values:

- `'compiled'` — Return up-to-date results by compiling every model in the search context before search.
- `'cached'` — Return quicker results by using results cached during the previous compile.

Example: `'SearchMethod', 'compiled'`

### **SearchReferencedModels — Enable search in referenced models**

`'off'` (default) | `'on'`

Flag to enable search in referenced models, specified as the comma-separated pair consisting of `'SearchReferencedModels'` and `'on'`.

If a referenced model uses a global variable, such as a variable stored in a data dictionary, the function returns this global variable when called on the parent model. If `SearchReferencedModels` is set to `'on'`, the `Simulink.VariableUsage` object returned by the function specifies a block in the referenced model as the variable user. Otherwise, the object specifies the Model block as the user.

Example: `'SearchReferencedModels', 'on'`

### **Name — Name of a variable or enumerated type to search for**

character vector | string

Name of a variable or enumerated data type to search for, specified as the comma-separated pair consisting of `'Name'` and a character vector or string.

Example: `'Name', 'trans'`

Data Types: char

### **SourceType — Workspace or source defining the variables or enumerated types**

character vector | string

Workspace or source defining the variables, specified as the comma-separated pair of `'SourceType'` and one of these options:

- `'base workspace'`
- `'model workspace'`

- 'mask workspace'
- 'data dictionary'

The function filters results for variables that are defined in the specified source.

Example: 'SourceType', 'base workspace'

If you search for enumerated data types by specifying 'IncludeEnumTypes' as 'on', 'SourceType' represents the way an enumerated type is defined. You can specify one of these options:

- 'MATLAB file'
- 'dynamic class'
- 'data dictionary'

The function filters results for enumerated types that are defined in the specified source.

Example: 'SourceType', 'MATLAB file'

If you do not specify SourceType, the function does not filter results by source.

### **Users — Name of block to search for variables**

character vector | string

Name of specific block to search for variables, specified as the comma-separated pair consisting of 'Users' and a character vector or string.

To search a set of specific blocks, enable regular expression matching by specifying RegExp as 'on' and use regular expressions in the character vector. For example, you can specify 'Users', 'MyModel/Gain\*' to search all blocks in MyModel whose names begin with Gain.

Example: 'Users', 'MyModel/Gain1'

Example: 'Users', 'MyModel/mySubsystem/Gain2'

Example: 'Users', 'MyModel/Gain\*'

## **Limitations**

Simulink.findVars does not work with these constructs:

- MATLAB code in scripts and initialization and callback functions.
- Libraries and blocks in libraries.
- Variables in MATLAB Function blocks, except for input arguments. However, Simulink.findVars can find enumerated types anywhere they are used in MATLAB Function blocks.
- Calls directly to MATLAB from a Stateflow block.
- S-functions that use data type variables registered using ssRegisterDataType. To make the variables searchable, use ssRegisterTypeFromNamedObject instead.
- Variables inside a string.
- Fields in a struct.
- Top models configured for parallel model reference builds. In this case, Simulink.findVars does not work when called with either of these name-value arguments:

- 'SearchMethod' specified as 'cached'
- 'SearchReferencedModels' specified as 'on'

Simulink.findVars discovers variable usage in inactive subsystem variants only if you set the **Variant activation time** parameter to code `compile` in the Variant Subsystem block dialog box. If you do not select this check box, the function does not discover variable usage in inactive variants.

# Simulink.fmuexport.ExportSimulinkProjectToFMU

Export project as Functional Mockup Unit (FMU)

## Syntax

```
Simulink.fmuexport.ExportSimulinkProjectToFMU(project,model,Name,Value)
```

## Description

`Simulink.fmuexport.ExportSimulinkProjectToFMU(project,model,Name,Value)` exports a project as a Functional Mockup Unit (FMU) and sets the `model` as the main interface model.

## Examples

### Export Model and Set FMU Icon

If the Simulink model `EngineGasDynamics.slx` exists in the `project root/models/` folder, use the following command to export the FMU from project root:

```
project = slproject.getCurrentProject; ...
Simulink.fmuexport.ExportSimulinkProjectToFMU(project,'models/EngineGasDynamics.slx','-fmuname',fullfile(project.RootFolder,'EngineGasDynamics.slx'))
```

## Input Arguments

### **project** — Project to export

scalar (default)

Project to export, specified as a string.

Data Types: `string`

### **model** — Model that defines main interface

scalar (default)

Model that defines the main interface, specified as a string.

Data Types: `string`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example:

**-fmuname** — The location and name of the generated FMU relative to the current working folder

`string`

If not specified, FMU is saved to current directory folder with the same name as the main model.

Data Types: `string`

**-description — The description of the generated FMU**

`string` (default)

The information is saved in `modelDescription.xml` inside FMU.

Data Types: `string`

**-author — The author of the generated FMU**

`string` (default)

The information is saved in `modelDescription.xml` inside FMU.

Data Types: `string`

**-copyright — The copyright of the generated FMU**

`string` (default)

The information is saved in `modelDescription.xml` inside FMU.

Data Types: `string`

**-license — The license of the generated FMU**

`string` (default)

The information is saved in `modelDescription.xml` inside FMU.

Data Types: `string`

**-fmuicon — An icon file for the generated FMU**

`string` (default)

The icon file must be in PNG format. If not specified, generated FMU has no icon file.

Data Types: `string`

## Simulink.getFileChecksum

Checksum of file

### Syntax

```
checksum = Simulink.getFileChecksum(filename)
```

### Description

`checksum = Simulink.getFileChecksum(filename)` returns the checksum of the specified file, using the MD5 checksum algorithm. Use the checksum to see if the file has changed compared to a previous checksum. You can use checksums as part of an audit trail.

Use `Simulink.getFileChecksum` to get a checksum for any file. If the file contents do not change from one checksum to the next, the checksum from `Simulink.getFileChecksum` stays the same. Otherwise, the checksum is different with each change to the file contents.

For functional information on a model, use `Simulink.BlockDiagram.getChecksum` instead. `Simulink.BlockDiagram.getChecksum` looks at the functional aspect of the model. If the functional aspect doesn't change, then `Simulink.BlockDiagram.getChecksum` returns the same checksum.

For example, if you moved a block, the file contents are different (measured by `Simulink.getFileChecksum`) but the function of the model is unchanged (measured by `Simulink.BlockDiagram.getChecksum`).

### Examples

#### Get Checksum of a File

Use `fullfile` to specify a full path to a file and get the checksum.

```
filechecksum = Simulink.getFileChecksum(fullfile(matlabroot, 'toolbox', ...
'matlab', 'demos', 'gatlin.mat'));
```

### Input Arguments

**filename** — File name to get checksum for

file of any type

File name to get checksum for, with file extension and optional full path. Use `fullfile` to specify a full path to a file, or use the form 'C:\Work\filename.mat'.

Example: 'lengthoffline.m'

Data Types: char

## Output Arguments

**checksum** — Checksum value

character vector

Checksum value in a 32-character vector.

## Version History

**Introduced in R2014b**

### See Also

`Simulink.BlockDiagram.getChecksum` | `Simulink.SubSystem.getChecksum`

## Simulink.getOutputInheritsInitialValue

Determine if conditional subsystem Output block inherits initial output value

### Syntax

```
tf = Simulink.getOutputInheritsInitialValue(outblock)
```

### Description

`tf = Simulink.getOutputInheritsInitialValue(outblock)` evaluates whether `outblock` is a conditional subsystem Output block that inherits its initial output value from an input signal connected to the conditional subsystem. If so, it returns `true`. If not, it returns `false`. The return value is `true` under the same circumstances as the  badge is displayed next to the Output block on the Simulink canvas, as described in “Conditional Subsystem Initial Output Values”.

For the return value to be accurate, update or run the model before calling this function.

The value returned by this function is meaningful only if the model is using simplified initialization mode. See “Simplified Initialization Mode”. If the model is using classic initialization mode, the return value is always `false`.

### Examples

#### Determine If Output Block Inherits Initial Output Value

The model `my_model` contains the enabled subsystem `EnabledSub1`, which contains Output blocks `Out1` and `Out2`.

```
set_param('my_model/EnabledSub1/Out1','InitialOutput','0'); % Explicit initial output value
set_param('my_model','SimulationCommand','Update'); % Update model
inherits = Simulink.getOutputInheritsinitialValue('my_model/EnabledSub1/Out1')
```

```
inherits =
```

```
logical
```

```
0
```

```
set_param('my_model/EnabledSub1/Out2','InitialOutput','[]'); % Inherit initial output value
set_param('my_model','SimulationCommand','Update'); % Update model
inherits = Simulink.getOutputInheritsinitialValue('my_model/EnabledSub1/Out2')
```

```
inherits =
```

```
logical
```

```
1
```

```
inherits = Simulink.getOutputInheritsinitialValue({'my_model/EnabledSub1/Out1','my_model/EnabledSub1/Out2'})
```

```
inherits =

 2×1 logical array

 0
 1
```

## Input Arguments

### **outblock** — Identifier of conditional subsystem Output block

character vector | string scalar | numeric handle

Identifier of conditional subsystem Output block, specified as a character vector, string scalar, or numeric handle. Multiple block identifiers may be specified as a vector or a 1-dimensional cell array.

Example: 'my\_model/EnabledSub1/Out1'

Data Types: character vector | string scalar | handle | vector | cell array

## Output Arguments

### **tf** — Whether block inherits its initial output value

logical

Whether block inherits its initial output value, returned as a logical `true` or `false`. If the input value refers to an Output block connected to a conditional subsystem and the block inherits its initial output value from that subsystem's input signal, `tf` is `true`. Otherwise, `tf` is `false`. If the input value is a vector or a cell array, `tf` is a logical column vector.

For the return value to be accurate, update or run the model before calling this function.

Data Types: logical | logical vector

## Version History

Introduced in R2021a

## Simulink.getSuppressedDiagnostics

Return `Simulink.SuppressedDiagnostic` objects associated with a block, subsystem, or model

### Syntax

```
suppressed_diagnostics = Simulink.getSuppressedDiagnostics(source)
```

### Description

`suppressed_diagnostics = Simulink.getSuppressedDiagnostics(source)` returns an array of `Simulink.SuppressedDiagnostic` objects that are associated with the specified source.

### Examples

#### Get All Simulink.SuppressedDiagnostic Objects on a Specific Block

To get all suppressed diagnostics associated with a specified block, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

Use the `Simulink.suppressDiagnostic` function to suppress the parameter precision loss warning thrown by the Constant block, `one`.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', ...
 'SimulinkFixedPoint:util:fxpParameterPrecisionLoss');
```

Get the `Simulink.SuppressedDiagnostic` objects associated with the block.

```
suppressed_diagnostic =
 Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/one');
```

### Input Arguments

#### source — System, block, or model object throwing warning

model | subsystem | block path | block handle

The source of the diagnostic, specified as a model, subsystem, block path, block handle, cell array of block paths, or cell array of block handles.

To get the block path, use the `gcb` function.

To get the block handle, use the `getSimulinkBlockHandle` function.

Data Types: `char` | `cell`

## Output Arguments

**suppressed\_diagnostics** — Suppressed diagnostics

array

Suppressed diagnostics, returned as an array of `Simulink.SuppressedDiagnostic` objects.

## Version History

Introduced in R2016b

### See Also

## Simulink.ID.getHandle

(Not recommended) Get handle of object associated with Simulink Identifier

---

**Note** `Simulink.ID.getHandle` is not recommended. Use alternative functions instead.

- For blocks, use `getSimulinkBlockHandle`.
- For annotations, use `find_system` or `getCurrentAnnotation`.
- For Stateflow® objects, use `find`.

For more information, see “Compatibility Considerations”.

---

### Syntax

```
handle = Simulink.ID.getHandle(SID)
```

### Description

`handle = Simulink.ID.getHandle(SID)` returns the handle of the object for the specified Simulink Identifier `SID`.

### Examples

#### Get Handle of Block

Open the model `vdp`.

```
vdp
```

Get the Simulink Identifier (SID) of the Sum block.

```
SID = Simulink.ID.getSID('vdp/Sum');
```

Get the handle of the Sum block using the SID.

```
handle = Simulink.ID.getHandle(SID)
```

### Input Arguments

#### SID — Simulink Identifier

character vector | string scalar

Simulink Identifier (SID), specified as a character vector or string scalar.

To get the SID for an object, use the `Simulink.ID.getSID` function.

Example: `'vdp:4'`

Data Types: `char` | `string`

## Output Arguments

### handle — Object handle

numeric scalar

Object handle, returned as a numeric scalar.

Data Types: `double`

## Version History

### Introduced in R2009b

#### R2020a: Not recommended

*Not recommended starting in R2020a*

`Simulink.ID.getHandle` is not recommended. Use alternative functions instead.

- For blocks, use the `getSimulinkBlockHandle` function.
- For annotations, use the `find_system` or `getCurrentAnnotation` functions.
- For Stateflow objects, use `find`.

This table shows some typical usages of `Simulink.ID.getHandle` and how to update your code.

| Handle Type      | Not Recommended                                                                                                                               | Recommended                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Block            | <pre>SID = Simulink.ID.getSID('vdp/handle'); handle = Simulink.ID.getHandle(SID)</pre>                                                        | <pre>handle = getSimulinkBlockHandle('vdp/Su')</pre>                                                                                          |
| Annotation       | <pre>object = getCurrentAnnotation; SID = Simulink.ID.getSID(object); handle = Simulink.ID.getHandle(SID)</pre>                               | <pre>object = getCurrentAnnotation; handle = object.Handle</pre>                                                                              |
| Stateflow object | <pre>chart = find(slroot, '-isa', 'Stateflow.Chart', 'Name', 'shift_logi'); SID = Simulink.ID.getSID(chart); Simulink.ID.getHandle(SID)</pre> | <pre>chart = find(slroot, '-isa', 'Stateflow.Chart', 'Name', 'shift_logi'); The Stateflow handle is equivalent to the Stateflow object.</pre> |

`getSimulinkBlockHandle` | `find_system` | `getCurrentAnnotation` | `find`

## Simulink.ID.getSID

(Not recommended) Get Simulink Identifier

---

**Note** Simulink.ID.getSID is not recommended. Use handles, paths, or objects instead of Simulink® Identifiers. For more information, see “Compatibility Considerations”.

---

### Syntax

```
SID = Simulink.ID.getSID(object)
```

### Description

`SID = Simulink.ID.getSID(object)` returns the Simulink Identifier (SID) of the selected object object.

An SID is a unique and unmodifiable designation that Simulink automatically assigns.

The SID format is `model_name:sid_number`, where:

- `model_name` is the name of the model that contains the object.
- `sid_number` is a unique number within the model, assigned by Simulink.

An SID includes additional colons in certain cases, for example, on an instance of a block from a custom library.

### Examples

#### Get SID of Block

Open the model `vdp`.

```
vdp
```

Get the SID of the Mu block.

```
SID = Simulink.ID.getSID('vdp/Mu')
```

### Input Arguments

#### **object** — Name or handle of object

character vector | string scalar | numeric scalar

Name or handle of object, specified as a character vector, string scalar, or numeric scalar.

Example: `'vdp/Mu'`

Data Types: `double` | `char` | `string`

## Output Arguments

### **SID — Simulink Identifier**

string scalar

Simulink Identifier (SID), returned as a string scalar.

Data Types: `string`

## Version History

### **Introduced in R2009b**

### **R2020a: Not recommended**

*Not recommended starting in R2020a*

`Simulink.ID.getSID` is not recommended. Use handles, paths, or objects instead of Simulink Identifiers.

- For blocks, use the `find_system` or `getSimulinkBlockHandle` functions.
- For annotations, use the `find_system` or `getCurrentAnnotation` functions.
- For Stateflow objects, use the `find` function.

### **See Also**

`find_system` | `getSimulinkBlockHandle` | `getCurrentAnnotation` | `find`

## Simulink.ID.hilite

(Not recommended) Highlight object associated with Simulink Identifier

---

**Note** Simulink.ID.hilite is not recommended. Use hilite\_system instead. For more information, see “Compatibility Considerations”.

---

### Syntax

```
Simulink.ID.hilite(SID)
Simulink.ID.hilite(SID,style)
```

### Description

Simulink.ID.hilite(SID) highlights the object associated with the Simulink Identifier SID.

Simulink.ID.hilite(SID,style) uses the specified highlighting style.

### Examples

#### Highlight Block

Open the model vdp.

```
vdp
```

Get the Simulink Identifier of the Mu block.

```
muSID = Simulink.ID.getSID('vdp/Mu')
```

Highlight the Mu block.

```
Simulink.ID.hilite(muSID)
```

#### Highlight Block Using a Highlight Style

Open the model vdp.

```
vdp
```

Get the Simulink Identifier of the Mu block.

```
muSID = Simulink.ID.getSID('vdp/Mu')
```

Highlight the Mu block using the style 'fade'.

```
Simulink.ID.hilite(muSID, 'fade')
```

## Input Arguments

### SID — Simulink Identifier

character vector | string scalar

Simulink Identifier, specified as a character vector or string scalar.

To get the SID for an object, use the `Simulink.ID.getSID` function.

Example: `'vdp:4'`

### style — Highlighting style

'find' (default) | character vector | string scalar

Highlighting style, specified as one of these values.

- 'default' — Default color scheme: red outline, yellow fill.
- 'none' — Clears the highlight.

To clear all highlighting, on the **Debug** tab, in the **Trace Signal** button group, click the **Remove trace** button.

- 'debug' — Uses default color scheme.
- 'different' — Applies red outline, white fill.
- 'error' — Uses default color scheme.
- 'fade' — Applies gray outline, white fill.
- 'find' — Applies dark blue outline, blue fill.
- 'lineTrace' — Applies red outline, blue fill.
- 'unique' — Dark blue outline, white fill.
- 'user1', 'user2', 'user3', 'user4', 'user5' — Applies custom highlight: black outline, white fill by default (that is, no highlight).

In addition, you can use these color schemes. The first word is the outline and the second is the fill color.

- 'orangeWhite'
- 'blackWhite'
- 'redWhite'
- 'blueWhite'
- 'greenWhite'

You can customize the appearance of any of the styles. See “Customize a Highlighting Style” on page 2-327.

## Version History

Introduced in R2009b

**R2020a: Not recommended**

*Not recommended starting in R2020a*

Simulink.ID.hilite is not recommended. Use hilite\_system instead.

This table shows a typical usage of Simulink.ID.hilite and how to update your code.

| <b>Not Recommended</b>                                         | <b>Recommended</b>      |

# Simulink.importExternalCTypes

Generate Simulink representations of custom data types defined by C or C++ code

## Syntax

```
importInfo = Simulink.importExternalCTypes(headerFiles)
importInfo = Simulink.importExternalCTypes(modelName)
importInfo = Simulink.importExternalCTypes(____,Name,Value)
```

## Description

`importInfo = Simulink.importExternalCTypes(headerFiles)` parses the C or C++ header files (.h or .hpp) identified by `headerFiles` for `typedef`, `struct`, and `enum` type definitions, and generates Simulink representations of the types. The output, `importInfo`, identifies the successfully and unsuccessfully imported types.

You can use the Simulink representations to:

- Reuse your existing algorithmic C code and, through simulation, test its interaction with your Simulink control algorithm. For an example that shows how to use the Legacy Code Tool, see “Integrate C Function Whose Arguments Are Pointers to Structures”.
- Generate code (Simulink Coder) that reuses the types and data that your existing code defines. You can then integrate and compile the generated and existing code into a single application. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” (Embedded Coder).
- Create and organize data (signals, parameters, and states) in a model by using standard data types that your organization defines in C code.
  - To create structures of signals in Simulink, use nonvirtual buses. See “Group Signals or Messages into Virtual Buses”.
  - To create structures of parameters, use MATLAB structures and `Simulink.Parameter` objects. See “Organize Related Block Parameter Definitions in Structures”.
  - To create enumerated data, see “Use Enumerated Data in Simulink Models”.
  - To match a primitive `typedef` statement, use a `Simulink.AliasType` object to set parameter and signal data types in a model.

By default, the function:

- Imports an enumerated type by generating a script file that derives an enumeration class from `Simulink.IntEnumType`, as described in “Define Simulink Enumerations”. If necessary, you can then edit the class definition to customize it (for example, by implementing the `addClassNameToEnumNames` method).
- Imports a structure type by generating a `Simulink.Bus` object in the base workspace.
- Imports a primitive `typedef` statement by generating a `Simulink.AliasType` object in the base workspace.

- Interprets generic C data types, such as `int` or `short`, according to the word lengths of your host computer. For example, for most modern machines, `int` has a 32-bit word length, so the function represents an `int` structure field as a bus element that uses the Simulink data type `int32`.

To override this default behavior, identify your target hardware board by using the `HardwareImplementation` pair argument.

For additional information about default behavior, see “Tips” on page 2-661.

`importInfo = Simulink.importExternalCTypes(modelName)` generates Simulink representations of custom C data types by analyzing a model that you identify with `modelName`. When you use the **Simulation Target** configuration parameters in a model to identify header files for inclusion during simulation, use this syntax to import types for the purpose of simulating the model on your host computer. The function interprets generic C data types according to the word lengths of your host computer.

When you use this syntax, do not use pair arguments, such as `HardwareImplementation`, that can conflict with the configuration parameters of the target model. When you use such pair arguments with this syntax, the function generates a warning.

`importInfo = Simulink.importExternalCTypes( ____, Name, Value)` specifies additional options using one or more name-value pair arguments. You can use this syntax to:

- Specify the names of types to import by using the `Names` pair argument.
- Control the way that Simulink stores the imported types, for example, by generating the types in a Simulink data dictionary. Use the `MATFile` and `DataDictionary` pair arguments.
- Control the way that the function interprets generic C data types. Use the `HardwareImplementation` pair argument.
- Maintain synchrony between the C-code definitions and the Simulink representations by attempting to import the updated C-code definitions again. You can choose whether to overwrite the existing Simulink representations. Use the `Overwrite` and `Verbose` pair arguments.

## Examples

### Import Simple Structure and Enumerated Types

This example shows how to generate Simulink representations of a C structure type (`struct`) and an enumerated (`enum`) data type from a header file.

- 1 In your current folder, create the file `ex_cc_simpleTypes.h`.

```
typedef enum {
 PWR_LOSS = 0, /* Default value */
 OVERSPD,
 PRESS_LOW,
} fault_T;

typedef struct {
 double coeff;
 double init;
} params_T;
```

- 2 Generate Simulink representations of the types by calling `Simulink.importExternalCTypes`.

```
Simulink.importExternalCTypes('ex_cc_simpleTypes.h');
```

The function creates a `Simulink.Bus` object, `params_T`, in the base workspace.

- 3 To inspect the properties of the object, open the Type Editor.

```
typeeditor
```

Each bus element uses a name and a data type (`double`) that match the corresponding structure field in `ex_cc_simpleTypes.h`.

- 4 In your current folder, inspect the generated file, `fault_T.m`, which defines the enumerated type `fault_T` as an enumeration class.

You can use the bus object and the enumeration class to set signal and parameter data types in Simulink models.

### Import Structure Type Whose Fields Use Custom Data Types

This example shows how to generate a Simulink representation of a structure type whose fields use custom data types (`typedef`).

Create the file `ex_integer_aliases.h` in your current folder.

```
typedef int sint_32;
typedef unsigned short uint_16;
```

Create the file `ex_cc_struct_alias.h` in your current folder.

```
#include "ex_integer_aliases.h"
typedef struct {
 sint_32 accum;
 uint_16 index;
} my_ints_T;
```

Import the structure type into Simulink as a `Simulink.Bus` object in the base workspace. Import the `typedef` statements as `Simulink.AliasType` objects.

```
Simulink.importExternalCTypes('ex_cc_struct_alias.h');
```

Inspect the data types of the bus elements in the bus object. For example, inspect the `DataType` property of the first bus element, which corresponds to the structure field `accum`.

```
my_ints_T.Elements(1)
```

```
ans =
```

```
 BusElement with properties:
```

```
 Name: 'accum'
 Complexity: 'real'
 Dimensions: 1
 DataType: 'sint_32'
```

```

 Min: []
 Max: []
DimensionsMode: 'Fixed'
 SampleTime: -1
 Unit: ''
Description: ''

```

The `Simulink.importExternalCTypes` function uses the generated `Simulink.AliasType` objects to set the data types of the bus elements.

Inspect the `Simulink.AliasType` objects in the base workspace. For example, the object named `sint_32` corresponds to one of the `typedef` statements in `ex_integer_aliases.h`.

```
sint_32
```

```
sint_32 =
```

```
AliasType with properties:
```

```

Description: ''
DataScope: 'Imported'
HeaderFile: 'ex_integer_aliases.h'
BaseType: 'int32'

```

For most host computers (which the function targets by default), the word length of `int` is 32 bits and the word length of `unsigned short` is 16 bits. The function maps `int` and `unsigned short` to the Simulink types `int32` and `uint16`.

If you have Embedded Coder, the code that you generate from the model can use `sint_32` and `uint_16` instead of the standard data type names, `int32_T` and `uint16_T`.

### Store Imported Types in Data Dictionary

This example shows how to store the imported data types in a Simulink data dictionary. A data dictionary stores data specifications (such as for signals and block parameter values), data types, and other design data for one or more Simulink models.

In your current folder, create the file `ex_cc_simpleTypes.h`.

```

typedef enum {
 PWR_LOSS = 0, /* Default value */
 OVERSPD,
 PRESS_LOW,
} fault_T;

typedef struct {
 double coeff;
 double init;
} params_T;

```

Create a subfolder called `myDictionaries`.

```
mkdir('myDictionaries')
```

Generate Simulink representations of the types by calling `Simulink.importExternalCTypes`. Permanently store the type definitions by creating a new data dictionary, `ex_cc_myTypes.sldd`, in the new subfolder.

```
Simulink.importExternalCTypes('ex_cc_simpleTypes.h',...
 'DataDictionary','ex_cc_myTypes.sldd',...
 'OutputDir','myDictionaries');
```

To inspect the contents of the dictionary, set your current folder to `myDictionaries` and double-click the dictionary file.

To use the Simulink representations in the dictionary, you must link a model or models to the dictionary. See “Migrate Models to Use Simulink Data Dictionary”.

### Import Only Specified Types

This example shows how to generate Simulink representations only for enumerated and structure data types that you identify by name.

In your current folder, create the file `ex_cc_manySimpleTypes.h`. The file defines three structure types: `params_T`, `signals_T`, and `states_T`.

```
typedef struct {
 double coeff;
 double init;
} params_T;

typedef struct {
 double flow_rate;
 double steam_press;
} signals_T;

typedef struct {
 double accum;
 double error;
} states_T;
```

Generate Simulink representations only for `params_T` and `signals_T`.

```
Simulink.importExternalCTypes('ex_cc_manySimpleTypes.h',...
 'Names',{'params_T','signals_T'});
```

The `Simulink.Bus` objects, `params_T` and `signals_T`, appear in the base workspace.

### Import Types for 16-Bit Hardware

By default, `Simulink.importExternalCTypes` represents an enumerated data type by creating an enumeration class that derives from the built-in class `Simulink.IntEnumType`. When you simulate or generate code from a model that uses the generated class, configuration parameters that you select for the model (for example, on the **Hardware Implementation** pane) determine the specific integer length that `Simulink.IntEnumType` and the enumeration class employ.

By default, the function interprets generic, primitive C data types, such as `short` and `int`, according to the word lengths of your host computer. For example, to represent an `int` structure field, the function typically applies the 32-bit data type `int32` to the corresponding bus element. When you want to simulate and generate code for hardware other than your host computer, use the `HardwareImplementation` pair argument to identify the target hardware and, by extension, the word lengths of the hardware.

This example shows how to import data types from code that you intend to use on 16-bit hardware. For this board, `int` has a 16-bit length, and each item of enumerated data (`enum`) consumes 16 bits.

In your current folder, create the file `ex_cc_intTypes.h`.

```
typedef enum {
 PWR_LOSS = 0, /* Default value */
 OVERSPD,
 PRESS_LOW,
} fault_T;

typedef struct {
 int coeff;
 int init;
} params_T;
```

The code defines an enumerated data type and a structure type whose fields use the generic C data type `int`.

To generate an accurate Simulink representation of the structure type, first open an existing model or create a new model. For this example, create a new model named `ex_hdwImpl_16bit`.

In the new model, set **Configuration Parameters > Hardware Implementation > Device vendor** to `Atmel`. Set **Device type** to `AVR`.

Alternatively, at the command prompt, use these commands to create and configure the model:

```
new_system('ex_hdwImpl_16bit', 'Model');
set_param('ex_hdwImpl_16bit', 'ProdHWDeviceType', 'Atmel->AVR')
```

Generate Simulink representations of the types. To specify the word lengths of the target 16-bit hardware, extract the model configuration parameters (which include the **Hardware Implementation** settings) as a `Simulink.ConfigSet` object.

```
configSet = getActiveConfigSet('ex_hdwImpl_16bit');
Simulink.importExternalCTypes('ex_cc_intTypes.h', 'HardwareImplementation', configSet);
```

The `Simulink.Bus` object `params_T` appears in the base workspace. The bus elements, such as `coeff`, use the Simulink data type `int16`.

```
params_T.Elements(1)
```

```
ans =
```

```
 BusElement with properties:
```

```
 Name: 'coeff'
 Complexity: 'real'
```

```

Dimensions: 1
 DataType: 'int16'
 Min: []
 Max: []
DimensionsMode: 'Fixed'
 Unit: ''
Description: ''

```

In your current folder, the file `fault_T.m` defines the enumeration class `fault_T`. The class derives from `Simulink.IntEnumType`, so you must use model configuration parameters to identify the target hardware and, by extension, the correct native integer length.

### Import Structure Type Whose Fields Use 16-Bit Fixed-Point Data Types

Create the file `ex_cc_fixpt_struct.h` in your current folder.

```

typedef struct {
 int coeff; /* Word length 16,
 binary fraction length 7 */

 int init; /* Word length 16,
 binary fraction length 3 */
} params_T;

```

The file defines a structure type whose fields use fixed-point data types. For example, the structure stores the field `coeff` in a signed, 16-bit integer data type. A binary fraction length of 7 relates the stored integer value to the real-world value.

Suppose that this code operates on 16-bit hardware (such that the generic C data type `int` has a 16-bit word length). To generate a Simulink representation of the type, first create a `coder.HardwareImplementation` object that identifies the hardware.

```

hdw = coder.HardwareImplementation;
hdw.ProdHWDeviceType = 'Atmel->AVR';

```

Generate a Simulink representation of the structure type.

```

Simulink.importExternalCTypes('ex_cc_fixpt_struct.h',...
 'HardwareImplementation',hdw);

```

The `Simulink.Bus` object, `params_T`, appears in the base workspace. Each bus element, such as `coeff`, uses the data type `int16`.

```
params_T.Elements(1)
```

```
ans =
```

```

BusElement with properties:
 Name: 'coeff'
 Complexity: 'real'

```

```
Dimensions: 1
 DataType: 'int16'
 Min: []
 Max: []
DimensionsMode: 'Fixed'
 Unit: ''
Description: ''
```

`Simulink.importExternalCTypes` cannot infer the fixed-point scaling (binary fraction length) from the C code. You must manually specify the data types of the bus elements. To specify the data types at the command prompt, use the `fixdt` function.

```
params_T.Elements(1).DataType = 'fixdt(1,16,7)';
params_T.Elements(2).DataType = 'fixdt(1,16,3)';
```

To specify the data types interactively (by using the Data Type Assistant), use the Type Editor.

```
typeeditor
```

## Manually Synchronize Simulink Representations with C-Code Definitions

This example shows how to maintain the Simulink representations of C data types whose definitions you modify during the life of a modeling project.

### Import Custom C Types

Create the file `ex_cc_myTypes_rec.h` in your current folder. The file defines a custom structure type.

```
typedef struct {
 double flow;
 double pres;
 double tqe;
} sigStructType;
```

Generate a `Simulink.Bus` object that represents the type.

```
Simulink.importExternalCTypes('ex_cc_myTypes_rec.h');
```

### Modify Type Definition in C Code

In `ex_cc_myTypes_rec.h`, add a field named `spd` to `sigStructType`.

In the same file, create a new structure type, `stateStructType`.

```
typedef struct {
 double flow;
 double pres;
 double tqe;
 double spd;
} sigStructType;

typedef struct {
```

```

 double err;
 double read;
 double write;
} sigStructType;

```

### Attempt to Import Types Again

Attempt to generate bus objects that represent the types.

```
importInfo = Simulink.importExternalTypes('ex_cc_myTypes_rec.h');
```

The function generates warnings at the command prompt. Instead of relying on the warnings, you can inspect the output, `importInfo`, to determine whether the function failed to import any types.

```
importInfo.failedToImport.Bus
```

```
ans =
```

```

1x1 cell array

{'sigStructType'}

```

The function did not import `sigStructType`. The corresponding bus object in the base workspace still has only three bus elements. To determine the reason that the function did not import `sigStructType`, inspect the `report` field of `importInfo`.

Import `sigStructType` again. This time, overwrite the existing bus object.

```
importInfo = Simulink.importExternalTypes('ex_cc_myTypes_rec.h', ...
 'Names', importInfo.failedToImport.Bus, 'Overwrite', 'on');
```

When you overwrite existing Simulink representations, any customizations that you made to the Simulink representations (such as the application of fixed-point data types to bus elements) are overwritten.

## Input Arguments

### headerFiles — Names and paths of header files to parse

character vector | cell array of character vectors | string scalar | string array

Names and paths of header files to parse, specified as a character vector, cell array of character vectors, string, or string array. Include the `.h` or `.hpp` file extension.

If you use a hierarchy of included (`#include`) header files to define your types, when you specify `HeaderFiles`, you need to identify only the entry-point files. The function parses the included files as well as the identified entry-point files. If the included files are not in the same folder as the corresponding entry-point file, use the `IncludeDirs` pair argument to identify the additional folders.

Example: `'myHeader.h'`

Example: `{'thisHeader.hpp', 'thatHeader.hpp'}`

Data Types: `char` | `cell` | `string`

### modelName — Name of loaded Simulink model for which to import types

character vector | string scalar

Name of a loaded Simulink model for which to import types, specified as a character vector or string scalar. A model is loaded if, for example, you open the model or use the `load_system` function. When you use this argument, the function:

- Searches the model configuration parameters for custom header files and parses those header files for data types to import. Only the configuration parameters on the **Simulation Target** pane affect this search.

For example, if in the model you set **Configuration Parameters > Simulation Target > Include headers** to `#include "myTypes.h"`, the function parses `myTypes.h` for types to import.

- Interprets generic C data types such as `int` or `short` according to the word lengths of your host computer. Do not use the `HardwareImplementation` pair argument to override this interpretation.

Example: `'myModel'`

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

```
Simulink.importExternalCTypes('myHdr.h','DataDictionary','myDictionary.sldd')
```

### MATFile — Name and path of MAT-file to create for storing generated objects

`''` (empty) (default) | character vector | string scalar

Name and, optionally, path of the MAT-file to create for storing generated `Simulink.Bus` and `Simulink.AliasType` objects, specified as a character vector or string. If you do not use `MATFile`, by default, the function generates the objects in the base workspace.

The function does not generate enumeration definitions in MAT-files.

If you import some `struct` types and primitive `typedef` statements by using `MATFile` and later import some of the same types again by using `MATFile`, the function entirely replaces the old MAT-file with a new one. The function discards any changes that you made to the contents of the old MAT-file.

You cannot use the `MATFile` and `DataDictionary` pair arguments simultaneously.

Example: `'myMat.mat'`

Example: `'myMat'`

Example: `fullfile('subfolder','myMat')`

Data Types: `char` | `string`

### DataDictionary — Name and path of Simulink data dictionary to use or create for storing types

`''` (default) | character vector | string scalar

Name and, optionally, path of the Simulink data dictionary to use or create for storing generated enumerations and objects, specified as a character vector or string. When you use this pair argument, the function imports enumerated types as `Simulink.data.dictionary.EnumTypeDefinition` objects, and stores those objects (as well as `Simulink.Bus` objects and `Simulink.AliasType` objects) in the target dictionary.

For information about data dictionaries, see “What Is a Data Dictionary?”.

You can optionally specify a `.sldd` extension.

You cannot use the `DataDictionary` and `MATFile` pair arguments simultaneously.

Example: `'myDict.sldd'`

Example: `'myDict'`

Example: `fullfile('subfolder','myDict.sldd')`

Data Types: `char` | `string`

### **Names — Names of types to import**

`''` (default) | character vector | cell array of character vectors | string scalar | string array

Names of types to import, specified as a character vector, cell array of character vectors, string, or string array. By default, if you do not use `Names`, the function attempts to import all of the custom types that the identified header files define.

To match multiple type names with a single character vector, use an asterisk (\*).

Example: `'myEnumType'`

Example: `{'myEnumType','myStructType'}`

Example: `'my*Type'`

Data Types: `char` | `cell` | `string`

### **Defines — Compiler options to define macros that influence type definitions**

`''` (default) | character vector | string scalar

Compiler options to define macros that influence C type definitions, specified as a character vector, or string scalar. For example, a macro influences a type definition if you enclose the definition in an `#ifdef` block that checks whether the macro is defined.

Use `Defines` to specify macro definitions that you otherwise define through compiler options such as `-D`.

Example: `'SIGSTRUCT=1'`

Example: `'SIGSTRUCT=1 ENUM=1'`

Data Types: `char` | `string`

### **UnDefines — Compiler options to delete macros that influence type definitions**

`''` (default) | character vector | string scalar

Compiler options to delete macros that influence C type definitions, specified as a character vector or string scalar. For example, a macro influences a type definition if you enclose the definition in an `#ifdef` block that checks whether the macro is defined.

Use `UnDefines` to specify macro deletions that you otherwise define through compiler options such as `-U`.

Example: `'SIGSTRUCT'`

Example: `'SIGSTRUCT ENUM'`

Data Types: `char` | `string`

### **IncludeDirs — Folders that contain subordinate, included header files**

`''` (default) | character vector | cell array of character vectors | string scalar | string array

Folders that contain subordinate, included (`#include`) header files, specified as a character vector, cell array of character vectors, string, or string array. Use this pair argument to enable the function to locate and parse additional header files on which the primary header files (which you specify with the `headerFiles` argument) depend.

If you use the `modelName` syntax instead of the `headerFiles` syntax, in the target model, you can use the **Simulation Target** configuration parameters to specify include paths. In that case, you do not need to use the `IncludeDirs` pair argument.

Example: `'myHeaders'`

Example: `fullfile('myProject','myHeaders')`

Example:

```
{fullfile('myProject','myHeaders'),fullfile('myProject','myOtherHeaders')}
```

Data Types: `char` | `cell` | `string`

### **OutputDir — Folder for storing generated files**

`''` (default) | character vector | string scalar

Folder for storing generated files, specified as a character vector or string. The function places generated files, such as `classdef` script files and data dictionary files, in this folder.

The folder that you specify must exist before you use the function.

Example: `'myDictionaries'`

Example: `fullfile('myProject','myDictionaries')`

Data Types: `char` | `string`

### **Language — Language to parse header files**

`'Auto'` (default) | `'C'` | `'C++'`

Parse and import compatible data types from C and C++ header files. If specify header files that contain C++ features, specify the `Language` to `'C++'` to import compatible C data types.

When data types are imported from a header file with `hpp` extension, if the `Language` setting is not specified or set to `'Auto'`, `'C++'` is selected to parse your header files. C++ classes and C++ struct types are ignored. Empty structs are not imported.

If you import header files from a loaded model and the `Language` is not specified or set to `'Auto'`, the `Language` setting is inherited from the model's custom settings. If the imported model already has a `Language` setting in **Configuration Parameters > Simulation Target**, this setting is overshadowed by imported model's setting.

**HardwareImplementation — Word lengths for interpreting generic, primitive C data types**

'' (default) | Simulink.ConfigSet object | coder.HardwareImplementation object

Word lengths for interpreting generic, primitive C data types, specified as a `Simulink.ConfigSet` or `coder.HardwareImplementation` object.

- To use a `Simulink.ConfigSet` object, you can extract a configuration set from a model by using functions such as `getConfigSet` and `getActiveConfigSet`. This technique enables you to use the Configuration Parameters dialog box to identify your target hardware (through the **Hardware Implementation** configuration parameters).
- To use a `coder.HardwareImplementation` object (which you create and configure programmatically), specify properties of the object, such as `ProdHWDeviceType`, to identify your target hardware. The object then sets other properties, such as `ProdBitPerInt`, that reflect the native integer size of the hardware.

The function inspects the object to determine which Simulink integer data types to employ when interpreting generic C data types such as `int`. For example, if you create a `coder.HardwareImplementation` object to identify 16-bit hardware and then use the function to import a structure type whose fields use the C data type `int`, the function generates a bus object whose bus elements use the Simulink data type `int16`. The function uses the production hardware settings, not the test hardware settings.

For more information about hardware implementation settings for Simulink models, see “Configure Run-Time Environment Options” (Simulink Coder).

**Overwrite — Specification to overwrite existing Simulink representations**

'off' (default) | 'on'

Specification to overwrite existing Simulink representations, specified as 'on' or 'off'. If an imported type already has a representation in Simulink:

- If you specify 'off' or if you do not specify `Overwrite`, the function does not import the type. In the output argument, `importInfo`, the `failedToImport` field identifies the type.
- If you specify 'on', the function overwrites the existing Simulink representation.

If you use the function to import some types into the base workspace or a data dictionary and later customize the generated Simulink representations, when you use the function again and set `Overwrite` to 'on', the function does not preserve your customizations. These customizations can include:

- In an enumeration class definition, implementing extra methods or modifying the generated methods such as `getDataScope` (see “Customize Simulink Enumeration”).
- Modifying the properties of a generated `Simulink.Bus` or `Simulink.AliasType` object (for example, manually setting the data types of bus elements to a fixed-point data type).

**Verbose — Specification to generate messages for successful import operations**

'off' (default) | 'on'

Specification to generate messages for successful import operations, specified as 'on' or 'off'.

- If you specify 'off' or if you do not specify `Verbose`, the function imports types silently. Messages do not appear in the Command Window unless the function cannot import a type.

- If you specify 'on', the function generates a message in the Command Window for each operation during the import process.

## Output Arguments

### **importInfo** — Information about types that were imported and not imported

structure

Information about types that were imported and not imported, returned as a structure with these fields.

### **report** — Descriptions of types that were imported and not imported

character vector

Descriptions of types that were imported and not imported, returned as a character vector. Inspect the value of this field to determine the reason that the function could not import a type.

### **failedToImport** — Types that were not imported

structure

Types that were not imported, returned as a structure with these fields.

| Field Name | Field Value                     | Purpose                                                                    |
|------------|---------------------------------|----------------------------------------------------------------------------|
| Bus        | Cell array of character vectors | Names of structure ( <code>struct</code> ) types that were not imported.   |
| Enum       | Cell array of character vectors | Names of enumerated types ( <code>enum</code> ) that were not imported.    |
| AliasType  | Cell array of character vectors | Names of primitive <code>typedef</code> statements that were not imported. |

### **importedTypes** — Types that were successfully imported

structure

Types that were successfully imported, returned as a structure with these fields.

| Field Name | Field Value                     | Purpose                                                                                                                                                                                    |
|------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bus        | Cell array of character vectors | Names of structure ( <code>struct</code> ) types that were imported. The generated <code>Simulink.Bus</code> objects use these names.                                                      |
| Enum       | Cell array of character vectors | Names of enumerated types ( <code>enum</code> ) that were imported. The generated enumeration classes or <code>Simulink.data.dictionary.EnumTypeDefinition</code> objects use these names. |

| Field Name | Field Value                     | Purpose                                                                                                             |
|------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------|
| AliasType  | Cell array of character vectors | Names of primitive typedef statements that were imported. The generated Simulink.AliasType objects use these names. |

## Limitations

- The function does not support:
  - C data types that do not correspond to a type that Simulink supports. For example, Simulink does not recognize an equivalent for `long double`. For information about data types that Simulink supports, see “Data Types Supported by Simulink”.
  - Pointer types, such as a structure that defines a field whose value is a pointer or a `typedef` statement whose base type is a pointer type.
  - Unions.
- If a structure field represents fixed-point data, or if a `typedef` statement maps to a fixed-point base type, the function sets the data type of the corresponding bus element or `Simulink.AliasType` object to the relevant Simulink integer type (such as `int16`). The importer cannot determine the fixed-point scaling by parsing the C code. After using the function, you must manually specify the data type of the bus element or the base type of the `Simulink.AliasType` object by using the `fixdt` function.

## Tips

- You must configure the **Simulation Target** configuration parameters for your model to include (`#include`) the header file which defines the imported enumeration or structure type in these cases:
  - You use the type in a MATLAB Function block. See “Control Imported Bus and Enumeration Type Definitions”.
  - You use the type in a Stateflow chart. See “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow).
  - You use the type in a C Function or C Caller block.
  - The type is not declared with a `typedef` statement.

---

**Note** To import types that are not named in a `typedef` statement, ensure the **Simulation Target** configuration parameter **Import custom code** is selected. This parameter is selected by default.

---

- By default:
  - For an imported enumeration, because the Simulink enumeration class derives from `Simulink.IntEnumType`, when you simulate or generate code from a model, the enumeration uses the integer size that is native to your target hardware. You specify the characteristics of your target hardware by using model configuration parameters such as **Production device vendor and type** and **Native word size in production hardware**.

- For an imported structure type:
  - The function imports a structure field as numerically complex only if the field uses one of the corresponding Simulink Coder structure types as the data type. For example, if a structure field in your external code uses the data type `cint8_T`, the function imports the field as a bus element (`Simulink.BusElement` object) whose data type is `int8` and whose `Complexity` property is set to `'complex'`.
  - For nested structures, the function generates a bus object for each unique structure type.
- For an imported structure or enumeration type, if your external code uses a `typedef` statement to name the type, the name of the generated bus object or Simulink enumeration class matches the `typedef` name. If your code does not use a `typedef` statement to name the type, the name of the object or class is the tag name of the type, unless that name conflicts with a type name that is defined in a `typedef` statement elsewhere in your header files, in which case the type is not imported into Simulink. If you do not specify a tag name or apply a `typedef` name, Simulink generates an arbitrary name for the object or class.
- The function configures the generated Simulink representations as imported for the purposes of simulation and code generation. For example, for bus objects, the function sets the `DataScope` property to `'Imported'` and the `HeaderFile` property to the name of your external header file. To simulate or generate code from a model that uses one of these Simulink representations, you must make your header file available to the model.
- When you specify files for `Simulink.importExternalCTypes` to use or generate, for example, by using the `DataDictionary` pair argument:
  - If the existing files to use are in your current folder or on the MATLAB path, you do not need to specify a file path. You can specify the file name by itself.
  - To control the folder location of generated files, you can specify paths as well as file names. You can also use the `OutputDir` pair argument.

# Simulink.io.getFileTypeDiagnostics

Return structure with NamespaceErrors field for Simulink.io.FileType objects

## Syntax

```
diagnosticStruct = Simulink.io.getFileTypeDiagnostics()
```

## Description

`diagnosticStruct = Simulink.io.getFileTypeDiagnostics()` returns a structure with field `NamespaceErrors` `diagnosticStruct` for `Simulink.io.FileType` objects.

## Examples

### Get Diagnostics for Simulink.io.FileType Objects

Get diagnostics for `Simulink.io.FileType` objects and return in `diagnosticStruct`.

```
diagnosticStruct = Simulink.io.getFileTypeDiagnostics()
```

```
diagnosticStruct =
 struct with fields:
 NamespaceErrors: {}
```

In this example, there are no diagnostics.

## Output Arguments

### **diagnosticStruct** — Structure of NamespaceErrors field for Simulink.io.FileType objects

structure with cell array

Structure of diagnostics for `Simulink.io.FileType` objects, returned as a structure with a cell array of `NamespaceErrors` fields. The first column in the cell array is the name of the name space plugin. In this example output, the name of the name space plugin is `not.here`.

```
diagnosticStruct =
 struct with fields:
 NamespaceErrors: { 'not.here' 'Unknown package name ' ' '.' }
```

# Simulink.LibraryDictionary.clear

**Package:** Simulink.LibraryDictionary

Clear library dictionary dependency analysis

## Syntax

```
Simulink.LibraryDictionary.clear
```

## Description

`Simulink.LibraryDictionary.clear` clears any previous library dependency analysis that has been performed on a library hierarchy with attached data dictionaries. When you first attach a dictionary to a library and save that library, Simulink opens and performs this analysis on each library in the current folder as well as in the folder of that library (if different than the current folder). Simulink stores the analysis in the user preference folder. Subsequent changes to a library in the hierarchy results in analysis of only relevant library changes.

Run this function only if you intend to reanalyze the entire library hierarchy.

## Examples

### Clear Library Dependency Analysis for Library Dictionaries

To perform a full reanalysis of dependencies for a library hierarchy with attached data dictionaries, clear any previously stored dependency analysis.

```
Simulink.LibraryDictionary.clear
```

## Version History

Introduced in R2021a

## See Also

`Simulink.LibraryDictionary.refresh` |  
`Simulink.LibraryDictionary.resetLibraryLinks`

## Topics

# Simulink.LibraryDictionary.refresh

**Package:** Simulink.LibraryDictionary

Update library dictionary dependencies

## Syntax

```
Simulink.LibraryDictionary.refresh
Simulink.LibraryDictionary.refresh(libraryDir)
Simulink.LibraryDictionary.refresh(model)
```

## Description

`Simulink.LibraryDictionary.refresh` performs a library dependency analysis on a library hierarchy with attached data dictionaries from the current folder. When you first attach a dictionary to a library and save that library, Simulink opens and performs this analysis on each library in the specified folder as well as in the folder of that library (if different than the current folder). Simulink stores the analysis in the user preference folder. Subsequent changes to a library in the hierarchy result in analysis of only relevant library changes.

Because performing this library dependency analysis can be an expensive operation, call the `Simulink.LibraryDictionary.refresh` function only when you have made changes to your library hierarchy and want to ensure that your library dictionary dependencies are current.

`Simulink.LibraryDictionary.refresh(libraryDir)` performs a library dependency analysis on a library hierarchy with attached data dictionaries from the specified library folder.

`Simulink.LibraryDictionary.refresh(model)` performs a library dependency analysis on a library hierarchy with attached data dictionaries for the specified model.

## Examples

### Refresh Library Dependency Analysis from the Current Folder

Perform a library dependency analysis on a library hierarchy with attached data dictionaries from the current folder.

```
Simulink.LibraryDictionary.refresh
```

### Refresh Library Dependency Analysis from a Specified Folder

Perform a library dependency analysis on a library hierarchy with attached data dictionaries from a specified library folder.

```
Simulink.LibraryDictionary.refresh('C:/Work/myLibraryDir/')
```

## Refresh Library Dependency Analysis for a Specified Model

Perform a library dependency analysis on a library hierarchy with attached data dictionaries for a specified model.

```
Simulink.LibraryDictionary.refresh('myModel.slx')
```

## Input Arguments

### libraryDir — Library folder

character vector

Library folder to use for dependency analysis, specified as a character vector.

Example: 'myLibraryDir'

Data Types: char

### model — Model

character vector

Model to use for dependency analysis, specified as a character vector.

Example: 'myModel'

Data Types: char

## Version History

Introduced in R2021a

# Simulink.LibraryDictionary.resetLibraryLinks

**Package:** Simulink.LibraryDictionary

Clear cached information on library dictionary links

## Syntax

```
Simulink.LibraryDictionary.resetLibraryLinks
```

## Description

`Simulink.LibraryDictionary.resetLibraryLinks` clears previously cached information on library dictionary links. Use this function when you are unable to link your library to a library dictionary due to cache corruption. After calling this function, the ability to link your library to a library dictionary is restored, but information on previously linked library dictionaries is lost.

## Examples

### Clear Cached Link Information for Library Dictionaries

To restore the ability to link your library to a library dictionary, remove corrupt cache information.

```
Simulink.LibraryDictionary.resetLibraryLinks
```

## Version History

**Introduced in R2022a**

# addParameterCondition

Creates a mask parameter condition for constraint

## Syntax

```
constraintObj.addParameterCondition(pc)
constraintObj.addParameterCondition(Name=Value)
```

## Description

`constraintObj.addParameterCondition(pc)` and `constraintObj.addParameterCondition(Name=Value)` creates mask parameter conditions on the constraint using the name-value arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

#### **Name** — Name of mask parameter

character vector (default)

Name of the masked parameter specified as a string.

Data Types: `string`

#### **Value** — Possible values for mask parameter

cell array (default)

Values for the masked parameter specified as a cell array.

Data Types: `cell`

## Examples

Create an instance of `Simulink.Mask.PortConstraint`.

```
consObj = Simulink.Mask.PortConstraint
```

Add the parameter condition.

```
consObj.addParameterCondition('Name', 'p1', 'Values', {'10', '20'})
```

```
ans =
```

```
ParameterCondition with properties:
```

Name: 'p1'  
Values: {2×1 cell}

## **Version History**

# getParameterCondition

Returns parameter condition associated with constraint

## Syntax

```
consObj.getParameterCondition(parameterName)
```

## Description

`consObj.getParameterCondition(parameterName)` displays the parameter name and its values.

## Input Arguments

### **parameterName** — Name of masked parameter

character vector (default)

Name of the masked parameter specified, as a character vector or string.

Data Types: char | string

## Examples

```
consObj.addParameterCondition('Name', 'p1', 'Values', {'10', '20'})
consObj.getParameterCondition('p1')
```

```
ans =
```

```
ParameterCondition with properties:
```

```
 Name: 'p1'
 Values: {2×1 cell}
```

## removeAllParameterConditions

Removes all parameter conditions from constraint

### Syntax

```
consObj.removeAllParameterConditions()
```

### Description

`consObj.removeAllParameterConditions()` removes all the parameter conditions from the constraint.

### Examples

Add parameter condition.

```
consObj=amaskObj.getPortConstraint('pc1')
consObj.addParameterCondition('Name', 'p1', 'Values', {'10', '20'})
```

Remove parameter condition

```
consObj.removeAllParameterCondition()
consObj.getParameterCondition('p1')
```

## Version History

### Topics

“Validate Input and Output Port Signals Using Port Constraints”

# removeParameterCondition

Removes specified parameter condition on constraint

## Syntax

```
consObj.removeParameterCondition(parameterName)
```

## Description

`consObj.removeParameterCondition(parameterName)` removes the specified parameter condition from the constraint.

## Input Arguments

### **parameterName** — Name of masked parameter

character vector (default) | string

Name of the masked parameter to be removed from the constraint, specified as a character vector.

Data Types: `string`

## Example

Add parameter condition.

```
consObj=amaskObj.getPortConstraint('pc1')
consObj.addParameterCondition('Name','p1','Values',{'10','20'})
```

Remove parameter condition

```
consObj.removeParameterCondition('p1')
consObj.getParameterCondition('p1')
```

Parameter condition for parameter name 'p1'  
not present in port constraint 'pc1'.

## Version History

Introduced in R2022a

## addPortConstraint

Create port constraint on a mask object

### Syntax

```
maskObj.addPortConstraint(pc),
maskObj.addPortConstraint(Name=Value)
```

### Description

`maskObj.addPortConstraint(pc)`, `maskObj.addPortConstraint(Name=Value)`. Creates port constraint on a mask object by adding options specified as name-value pair arguments.

### Input Arguments

#### **pc** — Port constraint object

`Simulink.Mask.PortConstraint` object

Port constraint object, specified as a `Simulink.Mask.PortConstraint` object.

Data Types: `char` | `cell`

#### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

#### **Name** — Name of the constraint

`string` (default) | character vector

Name of the constraint specified as a string.

#### **ParameterConditions** — Parameters and its values

`cell array` (default)

Example: `ParameterConditions={ 'Name', 'parameter1', 'Values', {'10','20'} }`

sets `Parameter Conditions` as a `Parameter Condition` object with a `Name` of `'parameter1'` and `Values` of `{'10','20'}`.

#### **Rule** — Data type, complexity, and dimension associated with the constraint

vector of `Simulink.Mask.PortConstraintRule` object

Datatype, complexity, and dimension for the constraint, specified as a cell array.

#### **DiagnosticLevel** — Type of diagnostic message

`error` (default) | `warning`

The type of diagnostic message displayed when validation condition fails specified as `error` or `warning`.

**DiagnosticMessage — Diagnostic message**

character vector (default)

The diagnostic message that is displayed when the validation fails, specified as a character vector.

**Examples****Create Port Constraint with Mask Object**

```
% Create an instance of Simulink.Mask.ParameterCondition
p1 = Simulink.Mask.ParameterCondition;
p1.Name = 'param1';
p1.Values = {'on'};
p2=Simulink.Mask.ParameterCondition;
p1.Name = 'param2';
p1.Values ={'0', '1'};
```

Create a `Simulink.Mask.PortConstraint` object, then set its properties using dot notation. Use `p1` and `p2` as its Parameter Conditions.

```
pc = Simulink.Mask.PortConstraint;
pc.Name = 'pc1';
pc.ParameterConditions = ['p1','p2'];
pc.Rule.DataType = {'double','int8'};
pc.Rule.Complexity={'real'};
pc.DiagnosticLevel = 'warning';
pc.DiagnosticMessage = 'Invalid data at port';
```

Get the mask object `maskObj`, then add the port constraint to it.

```
maskObj.addPortConstraint(pc);
```

**Create Port Constraint Directly with Name-Value pair Arguments**

```
%Get mask object
aMaskObj = Simulink.Mask.get('model\subsystem');

%Add a port constraint directly using name-value pair arguments
aMaskObj.addPortConstraint('Name','pc3','ParameterConditions',
 { {'Name','parameter1', 'Values', {'10','20'} },
 {'Name', 'parameter2', 'Values', {'10','20'} } },
 'Rule', {'DataType', {'double','int32'}, 'Complexity', {'real'} } ,
 'DiagnosticLevel', 'error','DiagnosticMessage', 'Invalid Data')
```

```
ans =
```

```
PortConstraint with properties:
```

```

 Name: 'pc3'
ParameterConditions: [1x2 Simulink.Mask.ParameterCondition]
 Rule: [1x1 Simulink.Mask.PortConstraintRule]
DiagnosticLevel: 'error'
DiagnosticMessage: 'Invalid Data'
```

```
%Get the Rule object
pc1.Rule
```

ans =

PortConstraintRule with properties:

```
 DataType: {2×1 cell}
 Dimension: {0×1 cell}
 Complexity: {'real'}
 FixedPointConstraint: [1×1 Simulink.Mask.FixedPointConstraint]
```

## Version History

Introduced in R2022a

### Topics

“Validate Input and Output Port Signals Using Port Constraints”

# addPortConstraintAssociation

Associate port constraints to port identifiers

## Syntax

```
aMaskObj.addPortConstraintAssociation(name, port identifiers)
```

## Description

`aMaskObj.addPortConstraintAssociation(name, port identifiers)` associates specified port constraint to the specified port identifiers. You can associate multiple port identifiers to the same port constraint.

## Input Arguments

### Name — Name of port constraint

character vector (default) | string

Name of the port constraint, specified as a string.

Data Types: char | string

### portIdentifier — Name of port identifiers

cell array (default)

Name of the port identifiers, specified as a cell array. You can associate same port constraint with multiple port identifiers.

Data Types: cell

## Examples

```
% Get a mask object
aMaskObj = Simulink.Mask.get(gcb);
aMaskObj.PortIdentifiers;
aMaskObj.addPortConstraintAssociation('pc3',{'pi_1'});
```

## Version History

Introduced in R2022a

## See Also

`getPortConstraintAssociation` | `removePortConstraintAssociation` | `removeAllPortConstraintAssociation`

## Topics

“Validate Input and Output Port Signals Using Port Constraints”

# getPortConstraint

Displays attributes of specified port constraint

## Syntax

```
aMaskObj.getPortConstraint(name)
```

## Description

`aMaskObj.getPortConstraint(name)` displays the attributes of the specified port constraint.

## Input Arguments

### name — Name of the port constraint

character vector | string

Name of the port constraint, specified as a string. An error is displayed if the port constraint does not exist.

## Examples

### View Port Constraints

- `%Get mask object and view port constraints`  
`aMaskObj.getPortConstraint('pc3')`

```
ans =
```

```
PortConstraint with properties:
```

```
 Name: 'pc3'
ParameterConditions: [1x2 Simulink.Mask.ParameterCondition]
 Rule: [1x1 Simulink.Mask.PortConstraintRule]
DiagnosticLevel: 'error'
DiagnosticMessage: 'Invalid Data'
```

## Version History

Introduced in R2022a

# getPortConstraintAssociation

Displays port identifiers associated with port constraint

## Syntax

```
aMaskObj.getPortConstraintAssociation(name)
```

## Description

`aMaskObj.getPortConstraintAssociation(name)` returns the port identifiers associated with port constraint.

## Input Arguments

### **name — Name of port constraint**

character vector (default) | string

Name of the port constraint, specified as a string.

Data Types: char | string

## Examples

```
aMaskObj.getPortConstraintAssociation('pc3')
```

## Version History

Introduced in R2022a

## See Also

## removeAllPortConstraints

Remove all port constraints on masked block

### Syntax

```
aMaskObj.removeAllPortConstraints()
```

### Description

`aMaskObj.removeAllPortConstraints()` removes all the port constraints from the masked block.

### Examples

```
amaskObj=Simulink.Mask.get(model1/subsystem)
amaskObj.removeAllPortConstraints()
amaskObj.getPortConstraint('pc1')
```

Constraints 'pc1' is not available in the block 'model1/Subsystem'.

## Version History

Introduced in R2022a

### See Also

“Validate Input and Output Port Signals Using Port Constraints”

# removePortConstraint

Remove specified port constraint

## Syntax

```
aMaskObj.removePortConstraint(name)
```

## Description

`aMaskObj.removePortConstraint(name)` removes the specified port constraint from the mask object.

## Input Arguments

### Name — Name of the port constraint

character vector (default) | string

Name of the port constraints to be removed from the mask object, specified as a character vector. An error is displayed if the port constraint does not exist.

Example: `aMaskObj.removePortConstraint('pc3');`

## Example

```
amaskObj=Simulink.Mask.get(model1/subsystem)
amaskObj.removePortConstraints('pc1')
amaskObj.getPortConstraint('pc1')
```

Constraints 'pc1' is not available in the block 'model1/Subsystem'.

## Version History

## Topics

“Validate Input and Output Port Signals Using Port Constraints”

## removeRule

Remove all datatype, complexity, and dimension attributes of port constraint rule

### Syntax

```
consObj.removeRule()
```

### Description

`consObj.removeRule()` clears all the data type, complexity, and dimension attributes of the port constraint rule. The empty rule object is still available in the port constraint object.

### Examples

```
consObj=Simulink.Mask.PortConstraint;
rule = Simulink.Mask.PortConstraintRule;
pcl.DataType = {'double','int32'};
pcl.complexity = {'real'};
consObj.setRule(rule);
consObj.removeRule();
```

## Version History

Introduced in R2022a

### See Also

`setRule`

### Topics

“Validate Input and Output Port Signals Using Port Constraints”

## setRule

Create rules that are validated against data at port

### Syntax

```
consObj.setRule(rule)
consObj.setRule(Name=Value)
```

### Description

`consObj.setRule(rule)` adds the object of type `Simulink.Mask.PortConstraintRule` rule to the object.

`consObj.setRule(Name=Value)` creates a rule using name-value arguments and adds it to port constraint object.

### Input Arguments

#### rule — Rule object

`Simulink.Mask.PortConstraintRule` object (default)

Rule object, specified as a `Simulink.Mask.PortConstraintRule` object.

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

#### Data Type — Permitted data types

cell array (default) | string

Permitted data types, specified as a cell array. The allowed values are `int`, `double`, `fixed point` and so on.

#### Dimension — Permitted dimension for port signals

cell array of character vector (default) | string

The allowed values in the array are `scalar`, `vector`, `2dmatrix`, `ndmatrix`, `rowvector`, and `colvector`.

#### Complexity — Complexity of port signal

character vector (default) | string

The allowed complexity, specified as a cell array. The allowed values in the array are `real` and `complex`.

#### FixedPointConstraint — Fixed point constraints of port signal

character vector (default)

Set the `Signedness`, `bias`, `Wordlength`, and `Scaling` for fixed point data type.

## Examples

### Set Rules Using ConstraintRule Object

```
%Get an instance of Simulink.Mask.PortConstraintRule
consObj=Simulink.Mask.PortConstraint;
rule = Simulink.Mask.PortConstraintRule;
pc1.DataType = {'double','int32'};
pc1.complexity = {'real'};
consObj.setRule(rule);
```

### Set Rules as Name-Value Pair Arguments

```
% Create an instance of Simulink.Mask.PortConstraint to set the rule
constraint.setRule('DataType',{'fixedpoint'},'Dimension',{'scalar'},
'Complexity',{'real'})
```

```
ans =
```

```
PortConstraintRule with properties:
```

```
 DataType: {'fixedpoint'}
 Dimension: {'scalar'}
 Complexity: {'real'}
FixedPointConstraint: [1x1 Simulink.Mask.FixedPointConstraint]
```

```
rule = constraint.getRule
```

```
rule =
```

```
PortConstraintRule with properties:
```

```
 DataType: {'fixedpoint'}
 Dimension: {'scalar'}
 Complexity: {'real'}
FixedPointConstraint: [1x1 Simulink.Mask.FixedPointConstraint]
```

```
%Define the properties of FixedPointConstraint
rule.FixedPointConstraint.Scaling = "binary";
rule.FixedPointConstraint.Signedness = "unsigned";
rule.FixedPointConstraint.WordLength = "[8:12]";
rule.FixedPointConstraint
```

```
ans =
```

```
FixedPointConstraint with properties:
```

```
 Scaling: 'binary'
 Bias: ''
Signedness: 'unsigned'
WordLength: '[8:12]'
```

## Version History

Introduced in R2022a

## addPortIdentifier

Creates a port identifier to identify port in mask

### Syntax

```
maskObj.addPortIdentifier(Name=Value)
```

### Description

`maskObj.addPortIdentifier(Name=Value)` creates a port identifier to identify a particular port in the mask object.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

#### Name — Name for the port identifier

empty character vector (default) | string

Name of the port identifier, specified as a character vector. This name uniquely identifies the port identifier in the mask.

Data Types: `char` | `string`

#### Type — Type of port

`input` (default) | `output`

Type of the port, specified as either `Input` or `Output`.

Data Types: `string`

#### IdentifierType — Type of identifier

`index` (default) | `name`

Type of identifier, specified as `name` or `index`. Specify `name` if you want to identify the ports using a name, otherwise specify `index`, if you want to identify the ports using a port index.

Data Types: `string`

#### Identifier — Port identifier appearing in block

character vector (default)

Port identifier appearing in the block, specified as a character vector. If the `IdentifierType` is `index`, you can specify the identifiers in one of these formats:

- **Index:** The index to associate the port with the port identifier. For example, '3' associates port '3' with the port identifier.

- Lower port index:Upper port index: The lower port index and upper port index to associate all the ports between the indices with the port identifier. For example, '2:4' associates ports 2, 3, and 4 with the port identifier.
- List of port indices: The ports separated by comma to associate the ports with the port identifier. For example, 3,5,7. This associates the ports 3, 5, and 7 with the port identifier. Duplicates are not allowed.
- : The name of the port is specified.

Port name: String: If IdentifierType is name, this parameter is the name of the port.

Data Types: string

## Examples

```
amaskObj.addPortIdentifier('Name','pi1','Type','Input','IdentifierType','index','Identifier','2')
```

```
ans =
```

```
PortIdentifier with properties:
```

```
 Name: 'pi1'
 Type: 'Input'
IdentifierType: 'index'
Identifier: '2'
```

```
aMaskObj.addPortIdentifier('Name','pi2','IdentifierType','name','Identifier','common_gain')
```

```
ans =
```

```
PortIdentifier with properties:
```

```
 Name: 'pi2'
 Type: ''
IdentifierType: 'name'
Identifier: 'common_gain'
```

## Version History

## getPortIdentifier

Displays attributes of specified port identifier

### Syntax

```
aMaskObj.getPortIdentifier(portIdentifier)
```

### Description

`aMaskObj.getPortIdentifier(portIdentifier)` displays the attributes of the specified port identifier.

### Input Arguments

#### **portIdentifier** — Name of port identifier

character vector (default) | string

Name of the port identifier, specified as character vector or string.

Data Types: char | string

### Examples

```
aMaskObj.getPortIdentifier('pil')
```

```
ans =
```

```
PortIdentifier with properties:
```

```
 Name: 'pil'
 Type: 'Input'
IdentifierType: 'index'
 Identifier: '2'
```

## Version History

**Introduced in R2022a**

# removeAllPortIdentifiers

Removes all port identifiers from mask object

## Syntax

```
aMaskObj.removeAllPortIdentifiers()
```

## Description

`aMaskObj.removeAllPortIdentifiers()` removes all the port identifiers from the mask object.

## Examples

Add port identifier

```
amaskObj.addPortIdentifier('Name','pi1','Type','Input','IdentifierType','index','Identifier','2')
```

Remove port identifiers

```
amaskObj.removeAllPortIdentifiers();
amaskObj.getPortIdentifier('pi1');
```

Port Identifier 'pi1' does not exist in the block 'model1/Subsystem'.

## Version History

Introduced in R2022a

## removePortIdentifier

Removes specified port identifier from mask object

### Syntax

```
aMaskObj.removePortIdentifier(portIdentifier)
```

### Description

`aMaskObj.removePortIdentifier(portIdentifier)` removes the specified port identifier on the mask object.

### Input Arguments

#### **portIdentifier** — Name of port identifier

string

Name of the port identifier to be removed from the mask object, specified as a string or character vector.

Data Types: char | string

### Example

Add port identifier

```
amaskObj.addPortIdentifier('Name','pil','Type','Input','IdentifierType','index','Identifier','2')
```

Remove port identifier

```
amaskObj.removeAllPortIdentifier('pil');
amaskObj.getPortIdentifier('pil');
```

Port Identifier 'pil' does not exist in the block 'model1/Subsystem'.

## Version History

Introduced in R2022a

### Topics

“Validate Input and Output Port Signals Using Port Constraints”

# Simulink.MDLInfo.getDescription

Extract SLX, SLXP, or MDL file description without loading file

## Syntax

```
d = Simulink.MDLInfo.getDescription(file)
```

## Description

`d = Simulink.MDLInfo.getDescription(file)` returns the description of the specified SLX, SLXP, or MDL file without loading the file.

## Examples

### Get Model Description

Get the description of the vdp model without loading it or creating a `Simulink.MDLInfo` object for it.

```
d = Simulink.MDLInfo.getDescription('vdp')

d =

 'The van der Pol Equation

 This is a simulation of a nonlinear second order system.'
```

## Input Arguments

### file — Name of SLX, SLXP, or MDL file

character vector | string scalar

Name of the SLX, SLXP, or MDL file, specified as a character vector or string scalar.

The file name can include a partial path, complete path, relative path, or no path. When you do not provide a path, the file extension is optional.

To avoid unexpected results caused by shadowed files that share a name, specify a fully qualified file name.

```
Example: Simulink.MDLInfo('vdp')
```

```
Example: Simulink.MDLInfo('mymodel.slx')
```

```
Example: Simulink.MDLInfo('mydir/mymodel.slx')
```

```
Example: Simulink.MDLInfo('C:/mydir/mymodel.slx')
```

Data Types: char | string

## **Version History**

**Introduced in R2009b**

### **See Also**

`Simulink.MDLInfo` | `Simulink.MDLInfo.getMetadata`

# Simulink.MDLInfo.getMetadata

Extract SLX, SLXP, or MDL file metadata without loading file

## Syntax

```
m = Simulink.MDLInfo.getMetadata(file)
```

## Description

`m = Simulink.MDLInfo.getMetadata(file)` returns the metadata structure associated with the specified SLX, SLXP, or MDL file without loading the file.

The metadata structure contains the names and attributes of arbitrary data associated with the file. The structure fields can be character vectors, numeric matrices of type `double`, or more structures.

## Examples

### Add and Check File Metadata

Create a structure that contains metadata information.

```
m.TestStatus = 'untested';
m.ExpectedCompletionDate = '01/01/2011';
```

Create a model, update the 'Metadata' parameter, and save the metadata in the model.

```
new_system('MDLInfoMetadataModel')
set_param('MDLInfoMetadataModel','Metadata',m)
save_system('MDLInfoMetadataModel')
```

Check the model for metadata without loading the model or creating a `Simulink.MDLInfo` object.

```
Simulink.MDLInfo.getMetadata('MDLInfoMetadataModel')
```

```
ans =
```

```
struct with fields:
```

```
TestStatus: 'untested'
ExpectedCompletionDate: '01/01/2011'
```

## Input Arguments

**file** — Name of SLX, SLXP, or MDL file

character vector | string scalar

Name of the SLX, SLXP, or MDL file, specified as a character vector or string scalar.

The file name can include a partial path, complete path, relative path, or no path. When you do not provide a path, the file extension is optional.

To avoid unexpected results caused by shadowed files that share a name, specify a fully qualified file name.

Example: `Simulink.MDLInfo('vdp')`

Example: `Simulink.MDLInfo('mymodel.slx')`

Example: `Simulink.MDLInfo('mydir/mymodel.slx')`

Example: `Simulink.MDLInfo('C:/mydir/mymodel.slx')`

Data Types: `char` | `string`

## **Tips**

To add metadata to an SLX or MDL file, create a metadata structure that contains the information you require and use the `set_param` function to attach it to the file. To extract the information without loading the file, use `metadata` instead of adding custom data by using the `add_param` function.

## **Version History**

`Simulink.MDLInfo` | `Simulink.MDLInfo.getDescription`

# Simulink.ModelAdvisor.getModelAdvisor

Get Model Advisor object for system or subsystem

## Syntax

```
ma = Simulink.ModelAdvisor.getModelAdvisor(system,new)
```

## Description

Use the `ma = Simulink.ModelAdvisor.getModelAdvisor(system,new)` method to return an instance of a `Simulink.ModelAdvisor` class for the model or subsystem that you specify by using the `system` input argument.

## Input Arguments

### **system** — Model or subsystem name

character vector

Name of model or subsystem for which you obtain the corresponding `Simulink.ModelAdvisor` object.

Example: 'sldemo\_fuelsys\_dd\_controller'

Example: 'sldemo\_fuelsys\_dd\_controller/airflow\_calc'

Data Types: char

### **new** — New Model Advisor object

character vector

This argument is optional except when changing the Model Advisor working scope from one system to another without closing the previous session. Alternatively, you can close the previous session before invoking the `getModelAdvisor` method.

Data Types: char

## Output Arguments

### **ma** — Model Advisor object

`Simulink.ModelAdvisor` object

`Simulink.ModelAdvisor` object for a model or subsystem that you specify by using a `system` input argument.

## Version History

Introduced in R2006a

**See Also**

Simulink.ModelAdvisor

# Simulink.ModelAdvisor.openConfigUI

Starts Model Advisor Configuration Editor

## Syntax

```
Simulink.ModelAdvisor.openConfigUI(ma)
```

## Description

Use the `Simulink.ModelAdvisor.openConfigUI(ma)` method to open the Model Advisor Configuration Editor. Use the Model Advisor Configuration Editor to create custom Model Advisor configurations.

The Model Advisor Configuration Editor is available with Simulink Check. For more information, see “Use the Model Advisor Configuration Editor to Customize the Model Advisor” (Simulink Check).

Before starting the Model Advisor Configuration Editor, make sure that the current folder is writable. If the folder is not writable, you see an error message when you start the Model Advisor Configuration Editor.

The Model Advisor Configuration Editor uses the `s\prj` folder in the **Code generation folder** to store reports and other information. If the `s\prj` folder does not exist in the code generation folder, the Model Advisor Configuration Editor creates it. For more information, see “Manage Simulation Targets for Referenced Models”.

## Input Arguments

### **ma** — Model Advisor object

`Simulink.ModelAdvisor` object

`Simulink.ModelAdvisor` object for which you want to open the Model Advisor Configuration Editor.

## Version History

**Introduced in R2006a**

## See Also

`Simulink.ModelAdvisor`

## Simulink.ModelAdvisor.reportExists

Determine whether Model Advisor report exists for model or subsystem

### Syntax

```
exists = Simulink.ModelAdvisor.reportExists(system)
```

### Description

Use the `exists = Simulink.ModelAdvisor.reportExists(system)` method to determine whether a Model Advisor report exists in the `slprj/modeladvisor` subfolder of the MATLAB working folder.

### Input Arguments

**system — Model or subsystem**

character vector

Model or subsystem for which you want to determine whether a Model Advisor report exists.

### Output Arguments

**exists — Boolean value indicating whether Model Advisor report exists**

Boolean

Boolean value that indicates whether Model Advisor report exists. A value of 1 indicates that the report exists. A value of 0 indicates that the report does not exist.

### Version History

Introduced in R2006a

### See Also

Simulink.ModelAdvisor

# Simulink.ModelReference.refresh

Force update to Model block to reflect changes to referenced model

## Syntax

```
Simulink.ModelReference.refresh(modelBlock)
```

## Description

`Simulink.ModelReference.refresh(modelBlock)` updates the specified Model block, `modelBlock`, to reflect changes to the referenced model. The block updates even when the **Model block version mismatch** or **Port and parameter mismatch** configuration parameter is set to error.

## Examples

### Force Refresh of Model Block Programmatically

You can programmatically refresh a Model block in a parent model that has the **Port and parameter mismatch** configuration parameter set to error.

Open the example model, which contains two Model blocks that are out of date with the model they reference.

```
open_system('RefreshModelBlockModel');
```

```
Warning: Ports and parameters of Model block 'RefreshModelBlockModel/Model1' do not reflect changes to referenced model.
```

```
Warning: Number of input ports must match between Model block 'RefreshModelBlockModel/Model1' (1) and referenced model (2).
```

```
Warning: Ports and parameters of Model block 'RefreshModelBlockModel/Model' do not reflect changes to referenced model.
```

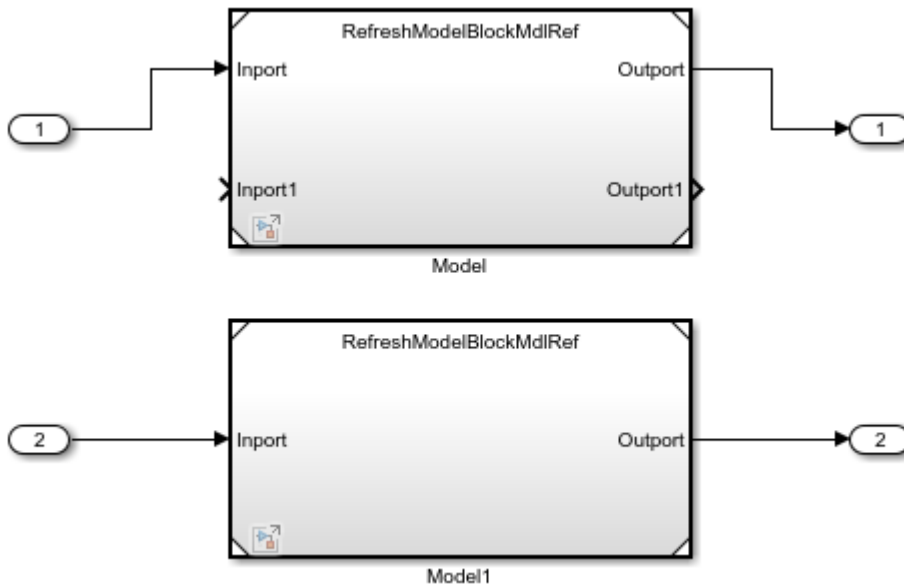

```
Warning: Number of input ports must match between Model block 'RefreshModelBlockModel/Model' (1) and referenced model (2).
```

The top model has the **Port and parameter mismatch** configuration parameter set to **error**. The number of input and output ports in the referenced model has increased from one to two, but each Model block displays only one input and output port.

Refresh one of the Model blocks.

```
Simulink.ModelReference.refresh('RefreshModelBlockModel/Model');
```

The number of ports on the refreshed Model block now matches the number of ports for the referenced model. The other Model block remains unchanged.

## Input Arguments

### **modelBlock** — Name or handle of Model block

character vector | string scalar | numeric scalar

Name or handle of Model block, specified as a character vector, string scalar, or numeric scalar.

Example: `Simulink.ModelReference.refresh('mymodel/Model')`

Example: `Simulink.BlockDiagram.refreshBlocks(h)`, where *h* is a Model block handle

#### Tips

Do not try to manually specify the number of a handle, for example, `5.007`, because you usually need to specify more digits than MATLAB displays. Assign the handle to a variable and use that variable name.

Data Types: `char` | `string` | `double`

#### Tips

To refresh all variants, linked blocks, and Model blocks in a model, use the `Simulink.BlockDiagram.refreshBlocks` function. With this function, the Model blocks update only when the **Model block version mismatch** and **Port and parameter mismatch** configuration parameters are set to `none` or `warning`. The Model blocks do not update when either configuration parameter is set to `error`.

## Alternative Functionality

Select a Model block. In the Simulink Toolstrip, on the **Model Block** tab, click **Refresh** .

## Version History

Introduced in R2020a

## **removeAllPortConstraintAssociation**

Removes the associations of all port constraints from mask

### **Syntax**

```
aMaskObj.removeAllPortConstraintAssociation()
```

### **Description**

`aMaskObj.removeAllPortConstraintAssociation()` removes the associations of all the port constraints from the mask object.

### **Examples**

```
aMaskObj.removeAllPortConstraintAssociations;
```

## **Version History**

**Introduced in R2022a**

# removePortConstraintAssociation

Remove association between port constraint and port identifiers

## Syntax

```
aMaskObj.removePortConstraintAssociation(portConstraint, portIdentifier)
aMaskObj.removePortConstraintAssociation(portConstraint)
```

## Description

`aMaskObj.removePortConstraintAssociation(portConstraint, portIdentifier)` removes the association between the specified port constraint and the port identifier.

`aMaskObj.removePortConstraintAssociation(portConstraint)` removes all the associated port identifiers with the port constraint.

## Input Arguments

### **portConstraint** — Name of port constraint

character vector (default) | string

Name of the port constraint, specified as a string.

Data Types: char | string

### **portIdentifier** — Port identifier

character vector (default) | string

Name of the port identifier to be removed from the port constraint association is specified as a string.

Data Types: char | string

## Examples

```
%Specify the port constraint and port identifier
aMaskObj.removePortConstraintAssociation('pc3','pi_1');
%Specify port constraint
aMaskObj.removePortConstraintAssociation('pc3');
```

## Version History

Introduced in R2022a

## Simulink.ProtectedModel.createHarness

Create harness model that provides isolated environment for testing protected model

### Syntax

```
h = Simulink.ProtectedModel.createHarness(pname)
h = Simulink.ProtectedModel.createHarness(pname,hname)
```

### Description

`h = Simulink.ProtectedModel.createHarness(pname)` creates and opens a harness model for the specified protected model. The harness model provides an isolated environment for testing the protected model. The name of the harness model is the name of the protected model followed by `_harness`.

`h = Simulink.ProtectedModel.createHarness(pname,hname)` specifies the name or path of the harness model.

### Examples

#### Create Harness Model for Protected Model

To test a protected model in an isolated environment, use the provided harness model or create a harness model for the protected model.

Suppose you receive a protected model named `sldemo_mdhref_counter.slxp` and do not receive a harness model for it. Using the same platform that was used to create the protected model, create a harness model for the protected model.

```
h = Simulink.ProtectedModel.createHarness('sldemo_mdhref_counter.slxp');
```

The harness model is set up for simulation of the protected model.

### Input Arguments

#### **pname** — Name of protected model

character vector | string scalar

Name of protected model, specified as a character vector or string scalar.

You can specify the name with or without the `.slxp` extension, however, you cannot specify a full path or partial path. The file must be on the MATLAB path.

Example: `Simulink.ProtectedModel.createHarness('model.slxp')`

Data Types: `char` | `string`

#### **hname** — Name of harness model

character vector | string scalar

Name of harness model being created, specified as a character vector or string scalar.

You can specify the name with or without the `.slx` extension.

To save the model in a specific location, specify the full path or a partial path for the harness model, including the name and extension. Otherwise, the harness model is saved in the working directory.

Example: `Simulink.ProtectedModel.createHarness('model.slxp','harness.slx')`

Data Types: `char` | `string`

## Output Arguments

### **h** — Harness model

handle

Harness model, returned as a handle.

Data Types: `double`

## Alternative Functionality

If you have a Simulink Coder or HDL Coder license, create a harness model as part of the model protection process by using one of these options:

- In the Create Protected Model dialog box, set **Contents** to Protected model (`.slxp`) and dependencies in a project, or select **Create harness model for protected model**.
- Using the `Simulink.ModelReference.protect`, set 'Project' or 'Harness' to true.

When you create the harness model as part of the model protection process, you have more information to provide the harness model. Without this information, you might not be able to create a harness model for the protected model.

## Version History

## Simulink.ProtectedModel.getPublisher

Return information about publisher that signed the protected model

### Syntax

```
[publisher,tf] = Simulink.ProtectedModel.getPublisher(protectedModel)
```

### Description

`[publisher,tf] = Simulink.ProtectedModel.getPublisher(protectedModel)` returns the name of the publisher that signed `protectedModel` and whether the certificate is verified by a trusted certificate authority. To verify the certificate, the corresponding certificate file must be in your computer's trusted certificate authority store.

### Examples

#### Get Name of Publisher that Signed Protected Model

Get publisher information for the protected model `signed_model_name`.

```
Simulink.ProtectedModel.getPublisher('signed_model_name.slxp')
```

The function returns the name of the publisher that signed the protected model.

#### Get Publisher and Verification Status of Protected Model

Verify the publisher and status of the protected model `signed_model_name`.

```
[publisher, verified] = Simulink.ProtectedModel.getPublisher('signed_model_name.slxp');
```

The variable `publisher` represents the name of the publisher that signed the model. `verified` has a value of 1 if the signature is verified by a trusted certificate authority.

### Input Arguments

#### **protectedModel** — Name of signed protected model

character vector | string scalar

Name of the signed protected model, specified as a character vector or a string scalar.

Example: `'my_model.slxp'`

### Output Arguments

#### **publisher** — Name of publisher

character vector | string scalar

Name of publisher that signed the protected model, returned as a character vector or string scalar. If the signature is not verified by a trusted certificate authority, `publisher` returns empty.

**tf — True or false result**

1 | 0

True or false result, returned as a 1 or 0. `tf` returns 1 if the signature on the protected model is verified by a trusted certificate authority.

## Version History

Introduced in R2020a

# Simulink.ProtectedModel.suppressSignatureVerification

Suppress digital signature verification of protected models

## Syntax

```
Simulink.ProtectedModel.suppressSignatureVerification(protectedModel)
Simulink.ProtectedModel.suppressSignatureVerification(protectedModel,
suppressionSetting)
```

## Description

`Simulink.ProtectedModel.suppressSignatureVerification(protectedModel)` suppresses the error that indicates whether the signature on the model `protectedModel` is unverified. Note that this does not suppress the error if the protected model was changed after it was signed. In this case, you cannot use the protected model.

`Simulink.ProtectedModel.suppressSignatureVerification(protectedModel, suppressionSetting)` disables or enables suppression for the model that you specify. To re-enable signature verification, specify `false` for the `suppressionSetting`. To enable signature verification for all protected models, specify `'All'` for the `model` argument. You cannot suppress verification for all models at once.

## Examples

### Suppress Signature Verification for Model

Suppress the verification of the digital signature for a protected model

Disable signature verification for a protected model named `myProtectedModel`.

```
Simulink.ProtectedModel.suppressSignatureVerification('myProtectedModel.slxp');
```

### Enable Signature Verification for All Protected Models

Enable the verification of digital signatures on all protected models that you open.

```
Simulink.ProtectedModel.suppressSignatureVerification('All', false);
```

If you previously suppressed signature verification for individual protected models, verification is re-enabled for those models.

## Input Arguments

**protectedModel** — Protected model  
character vector | string scalar | `'All'`

Protected model for which you want to suppress digital signature verification, specified as a character vector or string scalar. To re-enable signature verification for all protected models, specify 'All' for this argument and `false` for the second argument. You cannot suppress signature verification for all protected models at once.

Example: 'myProtectedModel.slxp'

Example: 'All'

### **suppressionSetting — Whether to suppress signature verification**

`true` or `1` (default) | `false` or `0`

Whether to suppress digital signature verification for the specified model, specified as a numeric or logical `1` (`true`) or `0` (`false`).

## **Version History**

**Introduced in R2020b**

"Reference Protected Models from Third Parties"

# Simulink.ProtectedModel.verifySignature

Verify digital signature on protected model

## Syntax

```
Simulink.ProtectedModel.verifySignature(protectedModel)
```

## Description

`Simulink.ProtectedModel.verifySignature(protectedModel)` verifies the digital signature on the protected model. If the signature is not valid, the function returns an error that indicates why the signature is invalid. A signature is invalid in the following cases:

- The protected model was changed after it was signed.
- The protected model was not signed.
- The protected model was signed with an expired certificate.
- The protected model was self-signed with a certificate issued by the publisher.
- The protected model was signed with a missing or invalid certificate.
- The certificate in your system certificate authority store is missing or invalid.
- The model was signed with an invalid key.

## Examples

### Verify Digital Signature of Protected Model

Verify the digital signature for the protected model `signed_model_name`.

```
Simulink.ProtectedModel.verifySignature('signed_model_name.slxp')
```

The function returns an error if the signature on the protected model cannot be verified.

## Input Arguments

### **protectedModel** — Name of signed protected model

character vector | string scalar

Name of the signed protected model, specified as a character vector or a string scalar.

Example: `'my_model.slxp'`

## Version History

**Introduced in R2020a**

## Simulink.restoreDiagnostic

Restore diagnostic warnings to a specific block, subsystem, or model

### Syntax

```
Simulink.restoreDiagnostic(source)
Simulink.restoreDiagnostic(source, message_id)
Simulink.restoreDiagnostic(diagnostic)
Simulink.restoreDiagnostic(system, 'FindAll', 'on')
```

### Description

`Simulink.restoreDiagnostic(source)` restores all suppressed diagnostics associated with the blocks specified by `source`.

`Simulink.restoreDiagnostic(source, message_id)` restores all instances of `message_id` on the blocks specified by `source`.

`Simulink.restoreDiagnostic(diagnostic)` restores the suppressed diagnostics associated with `MSLDiagnostic` object `diagnostic`.

`Simulink.restoreDiagnostic(system, 'FindAll', 'on')` restores all suppressed diagnostics associated with the system specified by `system`.

### Examples

#### Restore All Diagnostics for a Specified Block

To restore all suppressed diagnostics on a specified block, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

Create a cell array of message identifiers. Use the `Simulink.suppressDiagnostic` function to suppress these multiple diagnostics from the Constant block, `one`.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss',...
 'SimulinkFixedPoint:util:fxpParameterUnderflow'};
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', diags);
```

Remove all suppressions and restore diagnostics to the block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');
```

## Restore a Diagnostic for a Specified Block

To restore a suppressed diagnostic on a specified block, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

Use the `Simulink.suppressDiagnostic` function to suppress the parameter precision loss warning thrown by the Constant block, one.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', ...
 'SimulinkFixedPoint:util:fxpParameterPrecisionLoss');
```

Remove the suppression and restore diagnostics to the block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one', ...
 'SimulinkFixedPoint:util:fxpParameterPrecisionLoss');
```

## Restore All Diagnostics for a Specified System

To restore all suppressed diagnostics on a specified subsystem, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

To restore all diagnostics from a system, use `'FindAll'`, `'on'` to search within the system hierarchy. Specify the system or system handle within which to search.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert', ...
 'FindAll', 'On');
```

## Restore All Diagnostics for a Specified Model

To restore all suppressed diagnostics on a specified model, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for

suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

To restore all diagnostics from a model, specify the model name or model handle.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo', 'FindAll', 'on');
```

## Input Arguments

### **source** — Block or model object throwing diagnostic

block path | block handle

The source of the diagnostic, specified as a block path, block handle, cell array of block paths, or cell array of block handles.

To get the block path, use the `gcb` function.

To get the block handle, use the `getSimulinkBlockHandle` function.

Data Types: char | cell

### **message\_id** — message identifier of diagnostic

message identifier | cell array of message identifiers

Message identifier of the diagnostic, specified as a character vector or a cell array of character vectors. You can find the message identifier of warnings and errors thrown during simulation by accessing the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object associated with a simulation. You can also use the `lastwarn` function.

Data Types: char | cell

### **system** — Name of subsystem or model

character vector

The subsystem name, subsystem handle, model name, or model handle specified as a character vector.

Data Types: char

### **diagnostic** — Diagnostic object

`MSLDiagnostic` object

Diagnostic specified as an `MSLDiagnostic` object. Access the `MSLDiagnostic` object through the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object.

Data Types: struct

## Version History

Introduced in R2016b

## Simulink.saveVars

(Not recommended) Save workspace variables and their values in MATLAB code format

---

**Note** `Simulink.saveVars` is not recommended. Use `matlab.io.saveVariablesToScript` instead.

---

### Syntax

```
Simulink.saveVars(filename)
Simulink.saveVars(filename, var1,...,varN)
Simulink.saveVars(filename, '-regex',RegExps)
Simulink.saveVars(filename, __, UpdateOption)
Simulink.saveVars(filename, __, Configuration)
Simulink.saveVars(filename, __, MatlabVer)
[r1, r2] = Simulink.saveVars(filename, __)
```

### Description

`Simulink.saveVars(filename)` saves all variables in the current workspace for which MATLAB code can be generated to a MATLAB file named `filename.m`. If MATLAB code cannot be generated for a variable, the variable is saved into a companion MAT-file named `filename.mat`, and a warning is generated. If either file already exists, it is overwritten. The file name cannot match the name of any variable in the current workspace, and can optionally include the suffix `.m`. Using `Simulink.saveVars` has no effect on the contents of any workspace.

Executing the MATLAB file restores the variables saved in the file to the current workspace. If a companion MAT-file exists, code in the MATLAB file loads the MAT-file, restoring its variables also. When both a MATLAB file and a MAT-file exist, do not load the MATLAB file unless the MAT file is available, or an error will occur. Do not load a MAT-file directly, or incomplete data restoration will result. No warning occurs if loading a file overwrites any existing variables.

You can edit a MATLAB file that `Simulink.saveVars` creates. You can insert comments between or within the MATLAB code sections for saved variables. However, if you later use `Simulink.saveVars` to update or append to the file, only comments between MATLAB code sections will be preserved. Internal comments should therefore be used only in files that you do not expect to change any further.

You must not edit the header section in the MATLAB file, which comprises the first five comment lines. `Simulink` does not check that a manually edited MATLAB file is syntactically correct. Do not edit any MATLAB code in the file. You cannot edit a MAT-file and should never attempt to do so.

`Simulink.saveVars(filename, var1,...,varN)` saves only the variables specified by `var1,...,varN`. You can use the wildcard character `*` to save all variables that match a pattern. The `*` matches one or more characters, including non-alphanumeric characters.

`Simulink.saveVars(filename, '-regex',RegExps)` saves only variables whose names match one of the regular expressions in the comma-separated list of expressions `RegExps`. See “Regular Expressions” for more information. A call to the function can specify both `VarNames` and `'-regexps', RegExps`, in that order and comma-separated.

`Simulink.saveVars(filename, ___, UpdateOption)` saves the variables as directed by `UpdateOption`.

`Simulink.saveVars(filename, ___, Configuration)` saves the variables according to the specified configuration options.

`Simulink.saveVars(filename, ___, MatlabVer)` saves any MAT-file that it creates in the format required by the MATLAB version specified by `MatlabVer`.

`[r1, r2] = Simulink.saveVars(filename, ___)` returns the variables saved in `r1` and `r2`.

## Examples

### Explore Options for Saving Workspace Variables

Define some base workspace variables, then save them to a MATLAB file using a variety of input arguments.

Define some base workspace variables then save them to a new MATLAB file `myVars.m`.

```
a = 1;
b = 2.5;
c = 'A string';
d = {a,b,c};
Simulink.saveVars('myVars');
```

Define additional base workspace variables, then append them to the existing file `myVars.m` without changing the values previously saved in the file.

```
K = Simulink.Parameter;
myType = fixdt(1,16,3);
Simulink.saveVars('myVars', '-append', 'K', 'myType');
```

Update the variables `V1` and `V2` with their values in a MATLAB file, or for any whose value cannot be converted to MATLAB code, in a MAT-file. The file must already exist. Any array with more than 10 elements will be saved to a MAT-file that can be loaded on any version of MATLAB. The return argument `r1` lists the names of any variables saved to a MATLAB file; `r2` lists any saved to a MAT-file.

```
[r1, r2] = Simulink.saveVars('MyFile', 'V1', 'V2', '-update',
'-maxnumel', 10, '-v4');
```

Specify a 2-D slice for the output of the `my3Dtable` 3-D array. Specify that the 2-D slice expands along the first and third dimensions. Review the generated MATLAB code.

```
my3Dtable = zeros(3, 4, 2, 'single');
Simulink.saveVars('mfile.m', 'my3Dtable', '-2dslice', 1, 3);
```

```
my3Dtable = zeros(3, 4, 2, 'single');
my3Dtable(:,1,:) = single(...
 [1 13;
 5 17;
 9 21]);
my3Dtable(:,2,:) = single(...
 [2 14;
 6 18];
```

```

 10 22]);
my3DTable(:,3,:) = single(...
 [3 15;
 7 19;
 11 23]);
my3DTable(:,4,:) = single(...
 [4 16;
 8 20;
 12 24]);

```

## Input Arguments

### **filename** — Name of file to create or update

character vector | string scalar

Name of file that the function creates or updates, specified as a character vector or string scalar. The file name cannot match the name of any variable in the current workspace. The file name can have the suffix `.m`, but the function ignores it.

### **var1, ..., varN** — Variables to save

character vector | string scalar

A variable or sequence of comma-separated variables, specified as a character vector or string scalar. The function saves only the specified variables to the output file. You can use the wildcard character `*` to save all variables that match a pattern. The `*` matches one or more characters, including non-alphanumeric characters.

Example: `Simulink.saveVars('myFile','A*')` saves all variables in the workspace whose names start with `A` with their values.

### **RegExps** — Regular expression

character vector | string

A regular expression or sequence of comma-separated regular expressions, specified as a character vector or string. The function saves to the output file only those variables whose names match one of the expressions. See “Regular Expressions” for more information. A call to the function can specify both `VarNames` and `'-regexp', RegExps`, in that order and comma-separated.

Example: `Simulink.saveVars('myFile','-regexp','v*')`

### **UpdateOption** — Function action

'-create' (default) | 'update' | '-append'

Keyword that controls the action of the function, specified as one of these values:

- `'-create'` — Create a new MATLAB file (and MAT-file if needed).
- `'-update'` — Update the existing MATLAB file (and MAT-file if needed) specified by `filename` by changing only the specified variables that already exist in the file or files. The order of the variables in the file or files is preserved.
- `'-append'` — Update the existing MATLAB file (and MAT-file if needed) specified by `filename` by:
  - Updating the specified variables that already exist in the file or files, preserving the existing order.

- Appending the specified variables that do not exist in the file or files.

### Configuration — Configuration options

'-maxnumel' | '-maxlevels' | '-textwidth' | '-2dslice'

Configuration options for the function, specified as any or all of these values, in any order, separated by commas if more than one appears:

- '-maxnumel' MaxNum — Limits the number of elements saved for an array to MaxNum, which must be an integer between 0 and 10000. If an array is larger than that, the whole array appears in the MAT-file rather than the MATLAB script file, generating a warning. Default: 1000
- '-maxlevels' MaxLevels — Limits the number of levels saved for a structure or cell array to MaxLevels, which must be an integer between 0 and 200. If a structure or cell array is deeper than that, the whole entity appears in the MAT-file rather than the MATLAB script file, generating a warning. Default: 20
- '-textwidth' TextWidth — Sets the text wrap width in the MATLAB script file to TextWidth, which must be an integer between 32 and 256. Default: 76
- '-2dslice' — Sets two dimensions for 2-D slices that represent n-D (where n is greater than 2) arrays of char, logic, or numeric data. Using the '-2dslice' option produces more readable generated code that is consistent with how MATLAB displays n-D array data.

Simulink.saveVars uses the first two dimensions of the n-D array to specify the size of the 2-D slice, unless you supply two positive integer arguments after the -2dslice option. If you specify two integer arguments:

- The two integers must be positive.
- The two integers must be less than or equal to the number of dimensions of the n-D array.
- The second integer must be greater than the first.

---

**Note** You can use the MATLAB Preferences to change the defaults for the -maxnumel, -maxlevels, '-2dslice', and -textwidth configuration options. In the **Workspace** pane, use the options in the **Saving variables as MATLAB script files** group.

---

### MatlabVer — MATLAB version

'-v7.3' | '-v7.0' | '-v6' | '-v4'

MATLAB version whose syntax will be used by any MAT-file saved by the function, specified by values including:

- '-v7.3' — 7.3 or later
- '-v7.0' — 7.0 or later
- '-v6' — Version 6 or later
- '-v4' — Any MATLAB version

## Output Arguments

### r1 — Variables saved to a MATLAB file

cell array of character vectors

Variables that were saved to a MATLAB file, specified as a cell array of character vectors.

**r2 — Variables saved to a MAT- file**

cell array of character vectors

Variables that were saved to a MAT-file, specified as a cell array of character vectors.

**Limitations**

The `Simulink.saveVars` function:

- Does not preserve shared references.
- Ignores dynamic properties of objects.
- Saves the following to the MAT-file although they could appear in the MATLAB file:
  - `Simulink.ConfigSet` objects with custom target components. (Use the `Simulink.ConfigSet` method `saveAs` instead.)
  - `Simulink.Timeseries` and `Simulink.ModelDataLogs` objects.

If you save many variables, the generated MATLAB file can contain many lines of code and take a long time to execute. To avoid the long execution time, consider these alternatives:

- Permanently store variables in a data dictionary instead of using `Simulink.saveVars`. A data dictionary also provides more tools for managing variables. See “Determine Where to Store Variables and Objects for Simulink Models”.
- Save variables in a MAT-file by using the `save` function.

**Tips**

- If you do not need to save variables in an easily-understood form, see the `save` function.
- If you need to save only bus objects, use the `Simulink.Bus.save` function.
- If you need to save only a configuration set, use the `Simulink.ConfigSet.saveAs` method.

# simulink.schedule.createSchedule

Create a new schedule using provided schedule and ordering

## Syntax

```
outputSchedule = createSchedule(inputSchedule, partitionOrder)
outputSchedule = createSchedule(inputSchedule, partitionOrder,
'IgnoreExtra', true)
```

## Description

`outputSchedule = createSchedule(inputSchedule, partitionOrder)` creates a new `simulink.schedule.OrderedSchedule` object, `sch` with all the partitions present in the `simulink.schedule.OrderedSchedule` object, `inputSchedule`, according to order specified by the vector, `partitionOrder`.

`outputSchedule = createSchedule(inputSchedule, partitionOrder, 'IgnoreExtra', true)` creates a new `simulink.schedule.OrderedSchedule` object, `sch` with all the partitions present in the `simulink.schedule.OrderedSchedule`, `Schedule`, according to order specified by the parameter, `partitionOrder` while ignoring any partitions that are not already present in `sch`. `PartitionOrder` must contain all partitions of `inputSchedule`.

## Input Arguments

**inputSchedule** — A `simulink.schedule.Orderedschedule` object  
object

An existing `simulink.schedule.Orderedschedule` object copied to create new schedule.

**partitionOrder** — A vector of partition names  
vector

Partition names in the desired order, specified as a vector of strings.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'IgnoreExtra', true`

**IgnoreExtra** — Ignore additional partitions  
`false` (default) | `true`

When specified as `true`, the `createSchedule` function ignores any additional partitions in `partitionOrder` that are not present in the object, `inputSchedule`.

## Output Arguments

**outputSchedule** — New `simulink.schedule.Orderedschedule` object  
object

A new or modified `simulink.schedule.Orderedschedule` object.

## Version History

Introduced in R2020a

# Simulink.sdi.addToRun

**Package:** Simulink.sdi

Import data into existing run in Simulation Data Inspector using run ID

## Syntax

```
sigIDs = Simulink.sdi.addToRun(runID, 'vars', var, var2, ..., varn)
sigIDs = Simulink.sdi.addToRun(runID, 'namevalue', sourceNames, sigValues)

sigIDs = Simulink.sdi.addToRun(runID, 'file', filename)
sigIDs = Simulink.sdi.addToRun(runID, 'file', filename, Name=Value)
```

## Description

### Import Data from Workspace

`sigIDs = Simulink.sdi.addToRun(runID, 'vars', var, var2, ..., varn)` imports data from one or more variables into the Simulation Data Inspector by adding one or more signals to the run that corresponds to the specified run ID.

To import data into a new run, use the `Simulink.sdi.Run.create` function or the `Simulink.sdi.createRun` function.

`sigIDs = Simulink.sdi.addToRun(runID, 'namevalue', sourceNames, sigValues)` imports data from one or more variables into the Simulation Data Inspector by adding one or more signals to the run that corresponds to the specified run ID. The `sourceNames` argument specifies values to use for the data source in the metadata for the signals added to the run.

### Import Data from File

`sigIDs = Simulink.sdi.addToRun(runID, 'file', filename)` imports data from a file into the Simulation Data Inspector by adding one or more signals to the run that corresponds to the specified run ID. You can use a built-in file reader to import data from a MAT file, CSV file, Microsoft Excel file, or MDF file.

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class.

`sigIDs = Simulink.sdi.addToRun(runID, 'file', filename, Name=Value)` imports data from a file into the Simulation Data Inspector by adding one or more signals to the run that corresponds to the specified run ID according to options specified using one or more name-value arguments. For example, `sheets=["sheet1" "sheet2"]` specifies the sheets from which to import data when importing data from an Excel file.

## Examples

## Add Workspace Data to Run

This example shows how to use `Simulink.sdi.addToRun` to add workspace data to a run in the Simulation Data Inspector.

### Generate Workspace Data

Generate workspace data to add to a simulation run in place of measured data, input data, or any other data that you want to associate with the simulation.

```
time = linspace(0, 60, 201);
cos_vals = 2*cos(2*pi/6.8*time);
cos_ts = timeseries(cos_vals, time);
cos_ts.Name = 'cosine';
```

### Simulate Model

Simulate the `slexAircraftExample` model to create a run containing the simulation outputs.

```
load_system('slexAircraftExample');
sim('slexAircraftExample', 'SaveFormat', 'Dataset');
```

### Add Workspace Data to Simulation Run

Add the workspace data to the run. Then, view the results in the Simulation Data Inspector.

```
% Get run ID
count = Simulink.sdi.getRunCount;
runID = Simulink.sdi.getRunIDByIndex(count);

% Add data to run
sigIDs = Simulink.sdi.addToRun(runID, 'vars', cos_ts);

Simulink.sdi.view
```

## Input Arguments

### **runID** — Run ID for run to which you want to add imported data

scalar

Run ID for run to which you want to add imported data, specified as a scalar.

The Simulation Data Inspector assigns a unique ID to each run when the run is created. You can access run IDs for runs in the Simulation Data Inspector using the `Simulink.sdi.getAllRunIDs` and `Simulink.sdi.getRunIDByIndex` functions.

### **var** — Data to import

variable

Data to import, specified as a variable. The Simulation Data Inspector supports time-based data in which sample values are associated with sample times. The Simulation Data Inspector supports all loading and logging data formats, including `timeseries` and `Simulink.SimulationData.Dataset`.

Example: `myData`

**sourceNames — Source names for imported data**

cell array of character vectors

Source names for imported data, specified as a cell array of character vectors. The source name is used to set the `RootSource`, `TimeSource`, and `DataSource` properties of the `Simulink.sdi.Signal` objects created from the data specified by the `sigValues` input.

Provide a `sourceNames` input when you specify 'namevalue' for the second argument.

Example: {'sig1','sig2'}

**sigValues — Data to import**

cell array of variables

Data to import, specified as a cell array of variables.

Provide a `sigValues` input when you specify 'namevalue' for the second argument.

Example: {var1,var2}

**filename — Name of file with data to import**

character vector

Name of file with data to import, specified as a character vector. Provide a `filename` input when you specify 'file' for the second argument.

You can create a run from these types of files using file readers built into the Simulation Data Inspector:

- MAT-file
- CSV file
- Microsoft Excel file that contains data formatted according to “Microsoft Excel Import, Export, and Logging Format”.
- MDF file with one of these extensions:
  - .mdf
  - .mf4
  - .mf3
  - .data
  - .dat

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class. You can also write a custom reader to use instead of the built-in reader for any file extension. For an example, see “Import Data Using a Custom File Reader”.

Example: 'simulation.mat'

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: sheets=["sheet1" "sheet2"]

**reader — File reader to use to import data**

string | character vector

File reader to use to import data, specified as a string or character vector.

The Simulation Data Inspector prioritizes using a registered custom reader when one is available for the file. When you do not specify a reader, the Simulation Data Inspector uses the first custom reader registered for the file. If no custom readers are registered, the data is imported using the built-in reader.

Specify the reader input when:

- You want to use the built-in reader to import data for a file that is also supported by a custom reader.
- Multiple registered custom readers support the file.

To determine which readers are available to import your file, use the `io.reader.getSupportedReadersForFile` function.

Example: "MyExcelReader"

Example: "built-in"

**sheets — Sheets in Excel file from which to import data**

string array | cell array of character vectors

Sheets in Excel file from which to import data, specified as a string array or a cell array of character vectors. By default, the Simulation Data Inspector imports data from all sheets. Use the `sheets` name-value argument when you do not want to import data from all sheets in the Excel file.

When the data in the file does not include simulation numbers and source information, the data on each sheet is imported into a separate run. For more information about formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: ["sheet1" "sheet2"]

**model — Model with definitions of user-defined data types**

string | character vector

Model with definitions of user-defined data types, specified as a string or character vector.

When you load data from an Excel file that defines signal data types using user-defined data types, such as enumerations, buses, or aliases, the Simulation Data Inspector needs access to the type definition to import the data. You can provide access to the type definitions by:

- Loading the associated object into the MATLAB workspace.
- Specifying the `model` name-value argument to use type definitions saved in the model workspace or a data dictionary.

For more information on formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: "myModel.slx"

## Output Arguments

**sigIDs** — Signal IDs for signals created from imported data

scalar | vector

Signal IDs for signals created from imported data, returned as a scalar or a vector.

## Version History

## Simulink.sdi.addTrigger

Add trigger to signal to control display updates in the Simulation Data Inspector

### Syntax

```
Simulink.sdi.addTrigger(sig)
Simulink.sdi.addTrigger(sig,Name,Value)
```

### Description

`Simulink.sdi.addTrigger(sig)` adds a rising-edge trigger using normal mode and auto-level to the `Simulink.sdi.Signal` object, `sig`. The trigger determines when plots in the Simulation Data Inspector update to display new data for streaming signals.

`Simulink.sdi.addTrigger(sig,Name,Value)` adds trigger to the specified signal with trigger settings specified by one or more name-value pair arguments. For example, `'Mode','Normal'` configures normal mode behavior for the trigger. Triggers in the Simulation Data Inspector behave the same as triggers in the Scope block. For details regarding trigger types and settings, see “Scope Triggers Panel”.

### Examples

#### Programmatically Configure Triggers in the Simulation Data Inspector

Add a trigger to a signal in the Simulation Data Inspector to specify criteria that determine when to update plots to display fresh data. Triggers can allow you to capture transient signal behavior and can help stabilize the display of periodic signals so you can take measurements.

Simulate the `Triggers` model. Data in the model logs to the Simulation Data Inspector.

```
open_system('Triggers');
out = sim('Triggers');
```

Then, add a trigger to the `Pulse` signal. Configure the trigger as a falling-edge trigger with a threshold of 0.5.

```
trigRun = Simulink.sdi.getCurrentSimulationRun('Triggers');
pulseSig = getSignalsByName(trigRun,'Pulse');
Simulink.sdi.addTrigger(pulseSig,'Type','Edge','Level',0.5);
```

You can verify that the trigger was added and configured correctly by opening the Simulation Data Inspector using `Simulink.sdi.view` and clicking the trigger icon next to the `Pulse` signal to check the configuration. You can also use the `Simulink.sdi.getTrigger` function to check which signal is used to generate trigger events and the trigger configuration.

```
[sig,trigOpts] = Simulink.sdi.getTrigger;
```

```
sig.Name
```

```
ans =
'Pulse'
```

```
trigOpts
```

```
trigOpts = struct with fields:
 Mode: 'Auto'
 Type: 'Edge'
 Position: 0.5000
 Delay: 0
 SourceChannelComplexity: 'Scalar'
 Polarity: 'Positive'
 AutoLevel: 1
 Level: 0.5000
 UpperLevel: 0
 LowerLevel: 1.2252e-311
 Hysteresis: 0
 MinTime: 0
 MaxTime: Inf
 Timeout: 0
 Holdoff: 0
```

When you do not want to use a trigger to control when the Simulation Data Inspector updates the plots with fresh data, you can remove the trigger using the `Simulink.sdi.removeTrigger` function.

```
Simulink.sdi.removeTrigger
```

You can verify that the trigger was removed in the Simulation Data Inspector UI or using the `Simulink.sdi.getTrigger` function. The `Simulink.sdi.getTrigger` function returns an empty array of `Simulink.sdi.Signal` objects when no trigger is configured in the Simulation Data Inspector.

```
sig = Simulink.sdi.getTrigger;
size(sig)
```

```
ans = 1×2
 0 0
```

## Input Arguments

### **sig** – Signal used to detect trigger events

`Simulink.sdi.Signal` object

Signal used to detect trigger events, specified as a `Simulink.sdi.Signal` object.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'Type', 'PulseWidth', 'Polarity', 'Falling'` configures a falling-edge, auto-leveled trigger in auto mode.

**Mode — When display updates in response to trigger event**

Auto (default) | Normal | Once

When display updates in response to trigger event, specified as the comma-separated pair consisting of 'Mode' and one of these options:

- **Auto** — Plots update in response to each trigger event, and the plots update if no trigger event occurs for the duration of time range displayed.
- **Normal** — Plots update in response to each trigger event.
- **Once** — Plots update in response to the first trigger event. You can manually rearm the trigger using the Simulation Data Inspector.

Example: 'Mode', 'Normal' configures the trigger to use normal mode.

**Position — Where trigger event appears in plot**

50 (default) | numeric percentage

Where trigger event appears in plot, specified as the comma-separated pair consisting of 'Position' and a numeric percentage. By default, the trigger event appears in the middle of the plot, with a position of 0.5, or at the 50% position within the time span.

Example: 'Position', .3 positions the trigger event at the 30% point within the time span.

**Type — Type of trigger to add to signal**

Edge (default) | PulseWidth | Transition | Runt | Window | Timeout

Type of trigger to add to signal, specified as the comma-separated pair consisting of 'Type' and one of these options:

- **Edge** — Trigger when the signal crosses a threshold.
- **PulseWidth** — Trigger when the signal crosses twice between a low threshold and high threshold within a specified time.
- **Transition** — Trigger when the signal crosses a high threshold and a low threshold within a specified time.
- **Runt** — Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.
- **Window** — Trigger when a signal stays within or outside a range defined by a high threshold and a low threshold for a specified time.
- **Timeout** — Trigger when a signal stays above or below a threshold longer than a specified time.

For details regarding options for each type of trigger, see “Scope Triggers Panel”.

Example: 'Type', 'PulseWidth' configures a pulse width trigger.

**Polarity — Direction of signal value change that causes trigger event**

valid polarity for trigger type

Direction of signal value change that causes trigger event, specified as the comma-separated pair consisting of 'Polarity' and a valid polarity for the trigger type.

| Trigger Type | Polarity Options                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Edge         | <ul style="list-style-type: none"> <li>• <b>Rising</b> — Trigger when the signal crosses the threshold while increasing in value.</li> <li>• <b>Falling</b> — Trigger when the signal crosses the threshold while decreasing in value.</li> <li>• <b>Either</b> — Trigger when the signal crosses the threshold while increasing or decreasing in value.</li> </ul>                                                                                                       |
| PulseWidth   | <ul style="list-style-type: none"> <li>• <b>Positive</b> — Trigger on a rising pulse when the signal crosses the low threshold for a second time.</li> <li>• <b>Negative</b> — Trigger on a falling pulse when the signal crosses the high threshold for a second time.</li> <li>• <b>Either</b> — Trigger on both rising and falling pulses.</li> </ul>                                                                                                                  |
| Transition   | <ul style="list-style-type: none"> <li>• <b>RiseTime</b> — Trigger when the signal increases to cross from the low to the high threshold within the specified time.</li> <li>• <b>FallTime</b> — Trigger when the signal decreases to cross from the high threshold to the low threshold within the specified time.</li> <li>• <b>Either</b> — Trigger when the signal increases or decreases to cross the low and high thresholds within the specified time.</li> </ul>  |
| Runt         | <ul style="list-style-type: none"> <li>• <b>Positive</b> — Trigger on a rising pulse when the signal crosses the low threshold for a second time without crossing the high threshold.</li> <li>• <b>Negative</b> — Trigger on a falling pulse when the signal crosses the high threshold for a second time without crossing the low threshold.</li> <li>• <b>Either</b> — Trigger on rising or falling pulses that stay within the specified value thresholds.</li> </ul> |

| Trigger Type | Polarity Options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Window       | <ul style="list-style-type: none"> <li>• <b>Inside</b> — Trigger when a signal stays within the specified value range for a duration between the <code>MinTime</code> and <code>MaxTime</code>. The trigger event occurs when the signal exits the specified value range.</li> <li>• <b>Outside</b> — Trigger when a signal is outside the specified value range for a duration between the <code>MinTime</code> and the <code>MaxTime</code>. The trigger event occurs when the signal reenters the specified value range.</li> <li>• <b>Either</b> — Trigger when the signal is inside or outside of the specified value range for a duration between the <code>MinTime</code> and the <code>MaxTime</code>.</li> </ul> |
| Timeout      | <ul style="list-style-type: none"> <li>• <b>Rising</b> — Trigger when the signal remains above the threshold for longer than the specified time.</li> <li>• <b>Falling</b> — Trigger when the signal remains below the threshold for longer than the specified time.</li> <li>• <b>Either</b> — Trigger when the signal remains either above or below the threshold for longer than the specified time.</li> </ul>                                                                                                                                                                                                                                                                                                        |

Example: `'Type', 'Edge', 'Polarity', 'Rising'` configures a rising-edge trigger.

### AutoLevel — Whether to automatically determine trigger levels

`true` or `1` (default) | `false` or `0`

Whether to automatically determine trigger levels, specified as the comma-separated pair consisting of `'AutoLevel'` and `true` or `false`.

When you want to specify thresholds for the trigger, specify `'AutoLevel'` as `false`.

Example: `'AutoLevel', false` configures a trigger to use a user-specified level.

### Level — Threshold for trigger events

numeric scalar

Threshold for trigger events, specified as the comma-separated pair consisting of `'Level'` and a numeric scalar.

You can only specify the `'Level'` name-value pair when you specify the `'Type'` name-value pair as `'Edge'` or `'Timeout'`.

Example: `'Type', 'Timeout', 'Level', '0.5'` configures a timeout trigger with a threshold of `0.5`.

### Hysteresis — Signal value change required around threshold to cause trigger event

numeric scalar

Signal value change required around threshold to cause trigger event, specified as the comma-separated pair consisting of 'Hysteresis' and a numeric scalar. Specifying a hysteresis for the trigger results in noise rejection for trigger events.

You can only specify the 'Hysteresis' name-value pair when you specify the 'Type' name-value pair as 'Edge' or 'Timeout'.

Example: 'Type', 'Timeout', 'Hysteresis', '0.05' configures a timeout trigger that requires the signal value to change by more than 0.05 around the threshold to cause a trigger event.

### **UpperLevel — Upper threshold for trigger event**

numeric scalar

Upper threshold for trigger event, specified as the comma-separated pair consisting of 'UpperLevel' and a numeric scalar.

You can only specify the 'UpperLevel' name-value pair when you specify the 'Type' name-value pair as 'PulseWidth', 'Transition', 'Runt', or 'Window'.

Example: 'Type', 'PulseWidth', 'UpperLevel', '0.9' configures a pulse width trigger with an upper threshold of 0.9.

### **LowerLevel — Lower threshold for trigger event**

numeric scalar

Lower threshold for trigger event, specified as the comma-separated pair consisting of 'LowerLevel' and a numeric scalar.

You can only specify the 'LowerLevel' name-value pair when you specify the 'Type' name-value pair as 'PulseWidth', 'Transition', 'Runt', or 'Window'.

Example: 'Type', 'PulseWidth', 'LowerLevel', '0.1' configures a pulse width trigger with a lower threshold of 0.1.

### **MinTime — Lower time limit for trigger event**

numeric scalar

Lower time limit for trigger event, specified as the comma-separated pair consisting of 'MinTime' and a numeric scalar. You can only specify the 'MinTime' name-value pair when you specify the 'Type' name-value pair as 'PulseWidth', 'Transition', 'Runt', or 'Window'. The significance of the lower time limit depends on the type of trigger.

- 'PulseWidth' — Minimum pulse width for trigger event.
- 'Transition' — Minimum rise or fall time for trigger event.
- 'Runt' — Minimum pulse width for trigger event.
- 'Window' — Minimum time spent within or outside value range for trigger event.

Example: 'Type', 'PulseWidth', 'MinTime', '0.1' configures a pulse width trigger with a minimum pulse width of 100ms.

### **MaxTime — Upper time limit for trigger event**

numeric scalar

Upper time limit for trigger event, specified as the comma-separated pair consisting of 'MaxTime' and a numeric scalar. You can only specify the 'MaxTime' name-value pair when you specify the

'Type' name-value pair as 'PulseWidth', 'Transition', 'Runt', or 'Window'. The significance of the upper time limit depends on the type of trigger.

- 'PulseWidth' — Maximum pulse width for trigger event.
- 'Transition' — Maximum rise or fall time for trigger event.
- 'Runt' — Maximum pulse width for trigger event.
- 'Window' — Maximum time spent within or outside value range for trigger event.

Example: 'Type', 'PulseWidth', 'MaxTime', '0.5' configures a pulse width trigger with a maximum pulse width of 500ms.

### **Timeout — Time threshold for timeout trigger**

numeric scalar

Time threshold for timeout trigger, specified as the comma-separated pair consisting of 'Timeout' and a numeric scalar.

You can only specify the 'Timeout' name-value pair when you specify the 'Type' name-value pair as 'Timeout'.

Example: 'Type', 'Timeout', 'Timeout', '0.5' configures a timeout trigger that causes an event when a signal is above or below the value threshold for longer than 500ms.

### **Delay — Trigger event offset from trigger position**

numeric scalar

Trigger event offset from trigger position, specified as the comma-separated pair consisting of 'Delay' and a numeric scalar.

Example: 'Type', 'Edge', 'Delay', '0.1' configures an edge trigger where the trigger position marker is displayed 100ms after the trigger event.

### **Holdoff — Minimum time between trigger events**

numeric scalar

Minimum time between trigger events, specified as the comma-separated pair consisting of 'Holdoff' and a numeric scalar. After a trigger event, the display does not update again for at least the holdoff time.

Example: 'Type', 'Edge', 'Holdoff', '1' configures an edge trigger with a holdoff of 1s. After a trigger event, the display does not update for at least 1s.

## **Alternative Functionality**

You can add a trigger to a signal and configure the trigger options using the Simulation Data Inspector UI. For details, see “Control Display of Streaming Data Using Triggers”.

## **Version History**

## Simulink.sdi.cleanupWorkerResources

Clean up worker repositories

### Syntax

```
Simulink.sdi.cleanupWorkerResources
```

### Description

`Simulink.sdi.cleanupWorkerResources` removes redundant data from each parallel worker repository file used by the Simulation Data Inspector. Call this function while worker pools are running. The Simulation Data Inspector automatically cleans up repository files when you close the worker pool.

### Examples

#### Access Data from a Parallel Simulation

This example executes parallel simulations of the model `slexAircraftExample` with different input filter time constants and shows several ways to access the data using the Simulation Data Inspector programmatic interface.

#### Setup

Start by ensuring the Simulation Data Inspector is empty and Parallel Computing Toolbox support is configured to import runs created on local workers automatically. Then, create a vector of filter parameter values to use in each simulation.

```
% Make sure the Simulation Data Inspector is empty, and PCT support is
% enabled.
Simulink.sdi.clear
Simulink.sdi.enablePCTSupport('local')

% Define Ts values
Ts_vals = [0.01, 0.02, 0.05, 0.1, 0.2, 0.5, 1];
```

#### Initialize Parallel Workers

Use `gcp` to create a pool of local workers to run parallel simulations if you don't already have one. In an `spm` code block, load the `slexAircraftExample` model and select signals to log. To avoid data concurrency issues using `sim` in `parfor`, create a temporary directory for each worker to use during simulations.

```
p = gcp;
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 4 workers.
```

```
spm
```

```
 % Load system and select signals to log
```

```

load_system('slexAircraftExample')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, 'on')

% Create temporary directory on each worker
workDir = pwd;
addpath(workDir)
tempDir = tempname;
mkdir(tempDir)
cd(tempDir)

```

```
end
```

### Run Parallel Simulations

Use `parfor` to run the seven simulations in parallel. Select the value for `Ts` for each simulation, and modify the value of `Ts` in the model workspace. Then, run the simulation and build an array of `Simulink.sdi.WorkerRun` objects to access the data with the Simulation Data Inspector. After the `parfor` loop, use another `spmd` segment to remove the temporary directories from the workers.

```

parfor index = 1:7

 % Select value for Ts
 Ts_val = Ts_vals(index);

 % Change the filter time constant and simulate
 modelWorkspace = get_param('slexAircraftExample','modelworkspace');
 modelWorkspace.assignin('Ts',Ts_val)
 sim('slexAircraftExample')

 % Create a worker run for each simulation
 workerRun(index) = Simulink.sdi.WorkerRun.getLatest

```

```
end
```

```
spmd
```

```

% Remove temporary directories
cd(workDir)
rmdir(tempDir, 's')
rmpath(workDir)

```

```
end
```

### Get Dataset Objects from Parallel Simulation Output

The `getDataset` method puts the data from a `WorkerRun` into a `Dataset` object so you can easily post-process.

```

ds(7) = Simulink.SimulationData.Dataset;

for a = 1:7
 ds(a) = workerRun(a).getDataset;
end
ds(1)

ans =
Simulink.SimulationData.Dataset '' with 2 elements

```

|                | Name       | BlockPath                                |
|----------------|------------|------------------------------------------|
| 1 [1x1 Signal] | alpha, rad | ...rcraftExample/Aircraft Dynamics Model |
| 2 [1x1 Signal] | Stick      | slexAircraftExample/Pilot                |

- Use braces { } to access, modify, or add elements using index.

### Get DatasetRef Objects from Parallel Simulation Output

For big data workflows, use the `getDatasetRef` method to reference the data associated with the `WorkerRun`.

```
for b = 1:7
 datasetRef(b) = workerRun(b).getDatasetRef;
end
```

```
datasetRef(1)
```

```
ans =
 DatasetRef with properties:
 Name: 'Run 3: slexAircraftExample'
 Run: [1x1 Simulink.sdi.Run]
 numElements: 2
```

### Process Parallel Simulation Data in the Simulation Data Inspector

You can also create local Run objects to analyze and visualize your data using the Simulation Data Inspector API. This example adds a tag indicating the filter time constant value for each run.

```
for c = 1:7
 Runs(c) = workerRun(c).getLocalRun;
 Ts_val_str = num2str(Ts_vals(c));
 desc = strcat('Ts = ', Ts_val_str);
 Runs(c).Description = desc;
 Runs(c).Name = strcat('slexAircraftExample run Ts=', Ts_val_str);
end
```

### Clean Up Worker Repositories

Clean up the files used by the workers to free up disk space for other simulations you want to run on your worker pool.

```
Simulink.sdi.cleanupWorkerResources
```

## Version History

Introduced in R2017b

### See Also

`Simulink.sdi.isPCTSupportEnabled` | `Simulink.sdi.WorkerRun`

## Simulink.sdi.clear

**Package:** Simulink.sdi

Clear all data from the Simulation Data Inspector

### Syntax

```
Simulink.sdi.clear
```

### Description

`Simulink.sdi.clear` clears all plotted signals and deletes all data from the Simulation Data Inspector. The `Simulink.sdi.clear` function does not affect preferences or settings you have configured in the Simulation Data Inspector. Use the `Simulink.sdi.clearPreferences` function to reset the Simulation Data Inspector preferences to their default values. Use the `Simulink.sdi.clearAllSubPlots` function to clear all plotted signals without deleting any data from the Simulation Data Inspector.

### Examples

#### Save a Simulation Data Inspector Session

This example creates, saves, and loads a Simulation Data Inspector session. The example logs data in the model `slexAircraftExample` and visualizes the logged data in a Simulation Data Inspector session. Each time you use the Simulation Data Inspector, you create and modify a session. You can save the data and associated visualization settings for a session in an MLDATX file using the `Simulink.sdi.save` function. When you want to review the data later, you can load the session using the `Simulink.sdi.load` function.

#### Log Data to the Simulation Data Inspector

This example logs data from a simulation of the model `slexAircraftExample` to the Simulation Data Inspector. The model is not configured to log data. Load the model and mark the `Stick`, the `alpha`, `rad`, and the `q`, `rad/sec` signals for logging.

```
load_system('slexAircraftExample')

Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot',1,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',3,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')
```

For this example, run two simulations of the model. In the first simulation, use the sine wave output from the `Pilot` block, and in the second, use the square wave output.

```
set_param('slexAircraftExample/Pilot','WaveForm','sine')
sim('slexAircraftExample')

set_param('slexAircraftExample/Pilot','WaveForm','square')
sim('slexAircraftExample')
```

## Visualize the Logged Data

You can use the Simulation Data Inspector programmatic interface to access the logged data from the simulations. When you access data using the Simulation Data Inspector programmatic interface, you can use functions to create plots in the Simulation Data Inspector.

To start, access the run IDs for the most recent two runs and then get the corresponding `Simulink.sdi.Run` object. The Run objects allow you to access the logged data for the simulations.

```
runIDs = Simulink.sdi.getAllRunIDs;
sineRunID = runIDs(end-1);
squareRunID = runIDs(end);

sineRun = Simulink.sdi.getRun(sineRunID);
squareRun = Simulink.sdi.getRun(squareRunID);
```

Suppose you want to analyze the relationship between the input and output for the model. Get the `Simulink.sdi.Signal` objects for the input and output signals from the two simulation runs.

```
sineOut = getSignalByIndex(sineRun,1);
sineIn = getSignalByIndex(sineRun,3);

squareOut = getSignalByIndex(squareRun,1);
squareIn = getSignalByIndex(squareRun,3);
```

Change the subplot layout in the Simulation Data Inspector to 2-by-1 and plot the signals from the first simulation run on the top plot and the signals from the second run on the bottom plot.

```
Simulink.sdi.setSubPlotLayout(2,1)

plotOnSubPlot(sineIn,1,1,true)
plotOnSubPlot(sineOut,1,1,true)

plotOnSubPlot(squareIn,2,1,true)
plotOnSubPlot(squareOut,2,1,true)
```

## Save the Simulation Data Inspector Session

To view the plotted data in the Simulation Data Inspector, enter `Simulink.sdi.view` in the command window.

Then, save the Simulation Data Inspector session as an MLDATX file.

```
Simulink.sdi.save('myData.mldatx')
```

## Load the Simulation Data Inspector Session

To mimic a scenario where you want to return to looking at the same data at a later point, clear the data from the Simulation Data Inspector and reset the subplot layout to 1-by-1.

```
Simulink.sdi.clear
Simulink.sdi.setSubPlotLayout(1,1)
```

Load the session file and resume working with the data. You can open the Simulation Data Inspector and view the results using the `Simulink.sdi.view` function.

```
Simulink.sdi.load('myData.mldatx');
```

## Version History

Introduced in R2011b

# Simulink.sdi.clearAllSubPlots

Clear plotted signals from all subplots in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.clearAllSubPlots
```

## Description

`Simulink.sdi.clearAllSubPlots` clears plotted signals from all subplots in the Simulation Data Inspector, including any subplots with plotted data that are not visible in the current layout. Clearing plotted signals using the `Simulink.sdi.clearAllSubPlots` function does not delete data from the Simulation Data Inspector. To clear plotted signals and delete data from the Simulation Data Inspector, use the `Simulink.sdi.clear` function.

## Examples

### Clear Plotted Signals from All Subplots

You can programmatically clear plotted signals from all subplots in the Simulation Data Inspector. For example, clear plotted data at the start of a script that creates plots.

```
Simulink.sdi.clearAllSubPlots
```

### Plot Signals from Simulation Run

This example demonstrates how to access the `Simulink.sdi.Run` object for a Simulation Data Inspector run created by logging signals. From the `Simulink.sdi.Run` object you can get `Simulink.sdi.Signal` objects that contain the logged signal data and metadata. You can use the `Signal` objects and the `plotOnSubPlot` function to plot the data in the Simulation Data Inspector.

### Create a Simulation Run and Access the Run Object

The `ex_vdp` model logs two signals. To create a simulation run containing the logged data, simulate the model.

```
sim('ex_vdp');
```

The Simulation Data Inspector keeps track of runs by assigning a unique numeric run ID to each run created by simulation, importing data, or opening a session. To access the run object for the simulation you just performed, use the `Simulink.sdi.getAllRunIDs` function and take the last run ID in the returned vector.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

Once you have the run ID for the run, you can use the `Simulink.sdi.getRun` function to get the `Simulink.sdi.Run` object that corresponds to the run. You can use the Run object to check the metadata associated with the run, including the number of signals in the run.

```
vdpRun = Simulink.sdi.getRun(runID);

vdpRun.SignalCount

ans = int32
 2
```

### **Plot Data Using Signal Objects**

Use the `getSignalByIndex` function to access signals from the Run object, `vdpRun`.

```
signal1 = getSignalByIndex(vdpRun,1);
signal2 = getSignalByIndex(vdpRun,2);
```

Use the `Simulink.sdi.setSubPlotLayout` function to specify a 2-by-1 layout.

```
Simulink.sdi.setSubPlotLayout(2,1)
```

Before plotting the data, use the `Simulink.sdi.clearAllSubPlots` function to clear any data that is already plotted.

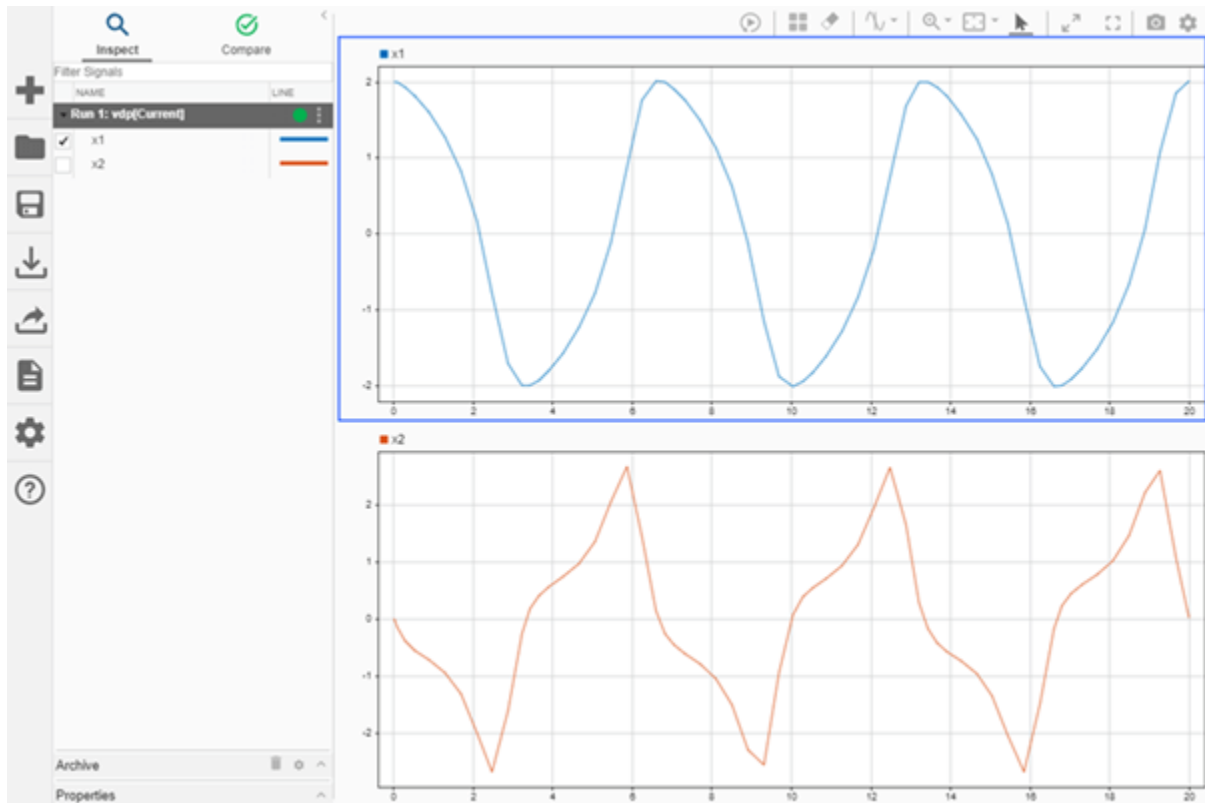

```
Simulink.sdi.clearAllSubPlots
```

Plot one signal on each subplot. To plot signals on the first subplot, you can set the checked property for the signal. To plot signals on subplots other than the first subplot, use the `plotOnSubPlot` function.

```
signal1.Checked = true;
plotOnSubPlot(signal2,2,1,true);
```

### **View the Plotted Data**

To view the plots you just created, open the Simulation Data Inspector using the `Simulink.sdi.view` function.

## Version History

Introduced in R2019b

## Simulink.sdi.clearPreferences

Restore Simulation Data Inspector preferences to default settings

### Syntax

```
Simulink.sdi.clearPreferences
```

### Description

`Simulink.sdi.clearPreferences` restores all Simulation Data Inspector preferences to their default values.

You can configure these preferences in the Simulation Data Inspector programmatically:

- Preferences:
  - Run naming rule — `Simulink.sdi.setRunNamingRule`
  - Subplot layout — `Simulink.sdi.setSubPlotLayout`
  - Signal grouping within a run — `Simulink.sdi.setTableGrouping`
- Time plot settings:
  - Border display — `Simulink.sdi.setBorderOn`
  - Grid display — `Simulink.sdi.setGridOn`
  - Data markers display — `Simulink.sdi.setMarkersOn`
  - Tick mark labels display — `Simulink.sdi.setTickLabelsDisplay`
  - Tick mark position — `Simulink.sdi.setTicksPosition`
- Archive preferences:
  - Archive behavior — `Simulink.sdi.setAutoArchiveMode`
  - Archive size limit — `Simulink.sdi.setArchiveRunLimit`

### Examples

#### Restore All Simulation Data Inspector Preferences to Default Values

You can restore default values to all Simulation Data Inspector preferences programmatically using the `Simulink.sdi.clearPreferences` function.

```
Simulink.sdi.clearPreferences
```

#### Modify Run Naming Rule Then Restore Default

This example shows how to use the Simulation Data Inspector API to modify the Simulation Data Inspector run naming rule, check a run's name, restore default preferences, and check the run naming rule.

```
% Load model
load_system('sldemo_fuelsys')

% Modify run naming rule
Simulink.sdi.setRunNamingRule('<model_name> Run <run_index>')

% Simulate system
sim('sldemo_fuelsys')

% Check run name
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelRun = Simulink.sdi.getRun(runID);
fuelRun.name

ans =
'sldemo_fuelsys Run 1'

% Clear preferences to reset the run naming rule
Simulink.sdi.clearPreferences

% Check run naming rule
Simulink.sdi.getRunNamingRule

ans =
'Run <run_index>: <model_name>'
```

## Version History

Introduced in R2017a

### Topics

“Configure the Simulation Data Inspector”

“Inspect and Compare Data Programmatically”

## Simulink.sdi.close

**Package:** Simulink.sdi

Close the Simulation Data Inspector

### Syntax

```
Simulink.sdi.close
Simulink.sdi.close('filename')
```

### Description

`Simulink.sdi.close` closes the **Simulation Data Inspector**.

`Simulink.sdi.close('filename')` closes the Simulation Data Inspector and saves the data in the file, `filename`.

### Examples

#### Close the Simulation Data Inspector from the Command Line

You can close the Simulation Data Inspector from the MATLAB command line when you have finished inspecting and analyzing your data.

```
Simulink.sdi.close
```

#### Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

##### Create Data for the Run

Create `timeseries` objects to contain data for a sine signal and a cosine signal. Give each `timeseries` object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

##### Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the Run object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun,'vars',sine_ts,cos_ts);
```

### Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';

cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubPlot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);

plotOnSubPlot(sine_sig,1,1,true);
plotOnSubPlot(cos_sig,2,1,true);
```

### Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an MLDATX file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

## Version History

Introduced in R2013b

“Save and Share Simulation Data Inspector Data and Views”

# Simulink.sdi.compareRuns

**Package:** Simulink.sdi

Compare data in two simulation runs

## Syntax

```
diffResult = Simulink.sdi.compareRuns(runID1,runID2)
diffResult = Simulink.sdi.compareRuns(runID1,runID2,Name=Value)
```

## Description

`diffResult = Simulink.sdi.compareRuns(runID1,runID2)` compares the data in the runs that correspond to `runID1` and `runID2` and returns the result in the `Simulink.sdi.DiffRunResult` object `diffResult`. For more information about the comparison algorithm, see “How the Simulation Data Inspector Compares Data”.

`diffResult = Simulink.sdi.compareRuns(runID1,runID2,Name=Value)` compares the simulation runs that correspond to `runID1` and `runID2` using the options specified by one or more name-value arguments. For more information about comparison options, see “How the Simulation Data Inspector Compares Data”.

## Examples

### Compare Runs with Global Tolerance

You can specify global tolerance values to use when comparing two simulation runs. Global tolerance values are applied to all signals within the run. This example shows how to specify global tolerance values for a run comparison and how to analyze and save the comparison results.

First, load the session file that contains the data to compare. The session file contains data for four simulations of an aircraft longitudinal controller. This example compares data from two runs that use different input filter time constants.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

To access the run data to compare, use the `Simulink.sdi.getAllRunIDs` function to get the run IDs that correspond to the last two simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);
```

Use the `Simulink.sdi.compareRuns` function to compare the runs. Specify a global relative tolerance value of `0.2` and a global time tolerance value of `0.5`.

```
runResult = Simulink.sdi.compareRuns(runID1,runID2,'reltol',0.2,'timetol',0.5);
```

Check the `Summary` property of the returned `Simulink.sdi.DiffRunResult` object to see whether signals were within the tolerance values or out of tolerance.

```
runResult.Summary
ans = struct with fields:
 OutOfTolerance: 0
 WithinTolerance: 3
 Unaligned: 0
 UnitsMismatch: 0
 Empty: 0
 Canceled: 0
 EmptySynced: 0
 DataTypeMismatch: 0
 TimeMismatch: 0
 StartStopMismatch: 0
 Unsupported: 0
```

All three signal comparison results fell within the specified global tolerance.

You can save the comparison results to an MLDATX file using the `saveResult` function.

```
saveResult(runResult, 'InputFilterComparison');
```

### Analyze Simulation Data Using Signal Tolerances

You can programmatically specify signal tolerance values to use in comparisons performed using the Simulation Data Inspector. In this example, you compare data collected by simulating a model of an aircraft longitudinal flight control system. Each simulation uses a different value for the input filter time constant and logs the input and output signals. You analyze the effect of the time constant change by comparing results using the Simulation Data Inspector and signal tolerances.

First, load the session file that contains the simulation data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

The session file contains four runs. In this example, you compare data from the first two runs in the file. Access the `Simulink.sdi.Run` objects for the first two runs loaded from the file.

```
runIDs = Simulink.sdi.getAllRunIDs;
runIDTs1 = runIDs(end-3);
runIDTs2 = runIDs(end-2);
```

Now, compare the two runs without specifying any tolerances.

```
noTolDiffResult = Simulink.sdi.compareRuns(runIDTs1, runIDTs2);
```

Use the `getResultByIndex` function to access the comparison results for the `q` and `alpha` signals.

```
qResult = getResultByIndex(noTolDiffResult, 1);
alphaResult = getResultByIndex(noTolDiffResult, 2);
```

Check the `Status` of each signal result to see whether the comparison result fell within our out of tolerance.

```
qResult.Status
ans =
 ComparisonSignalStatus enumeration
```

```
 OutOfTolerance
```

```
alphaResult.Status
```

```
ans =
 ComparisonSignalStatus enumeration

 OutOfTolerance
```

The comparison used a value of 0 for all tolerances, so the `OutOfTolerance` result means the signals are not identical.

You can further analyze the effect of the time constant by specifying tolerance values for the signals. Specify the tolerances by setting the properties for the `Simulink.sdi.Signal` objects that correspond to the signals being compared. Comparisons use tolerances specified for the baseline signals. This example specifies a time tolerance and an absolute tolerance.

To specify a tolerance, first access the `Signal` objects from the baseline run.

```
runTs1 = Simulink.sdi.getRun(runIDTs1);
qSig = getSignalsByName(runTs1,'q, rad/sec');
alphaSig = getSignalsByName(runTs1,'alpha, rad');
```

Specify an absolute tolerance of 0.1 and a time tolerance of 0.6 for the `q` signal using the `AbsTol` and `TimeTol` properties.

```
qSig.AbsTol = 0.1;
qSig.TimeTol = 0.6;
```

Specify an absolute tolerance of 0.2 and a time tolerance of 0.8 for the `alpha` signal.

```
alphaSig.AbsTol = 0.2;
alphaSig.TimeTol = 0.8;
```

Compare the results again. Access the results from the comparison and check the `Status` property for each signal.

```
tolDiffResult = Simulink.sdi.compareRuns(runIDTs1,runIDTs2);
qResult2 = getResultByIndex(tolDiffResult,1);
alphaResult2 = getResultByIndex(tolDiffResult,2);
```

```
qResult2.Status
```

```
ans =
 ComparisonSignalStatus enumeration

 WithinTolerance
```

```
alphaResult2.Status
```

```
ans =
 ComparisonSignalStatus enumeration

 WithinTolerance
```

## Configure Comparisons to Check Metadata

You can use the `Simulink.sdi.compareRuns` function to compare signal data and metadata, including data type and start and stop times. A single comparison may check for mismatches in one or more pieces of metadata. When you check for mismatches in signal metadata, the `Summary` property of the `Simulink.sdi.DiffRunResult` object may differ from a basic comparison because the `Status` property for a `Simulink.sdi.DiffSignalResult` object can indicate the metadata mismatch. You can configure comparisons using the `Simulink.sdi.compareRuns` function for imported data and for data logged from a simulation.

This example configures a comparison of runs created from workspace data three ways to show how the `Summary` of the `DiffSignalResult` object can provide specific information about signal mismatches.

### Create Workspace Data

The `Simulink.sdi.compareRuns` function compares time series data. Create data for a sine wave to use as the baseline signal, using the `timeseries` format. Give the `timeseries` the name `Wave Data`.

```
time = 0:0.1:20;
sig1vals = sin(2*pi/5*time);
sig1_ts = timeseries(sig1vals,time);
sig1_ts.Name = 'Wave Data';
```

Create a second sine wave to compare against the baseline signal. Use a slightly different time vector and attenuate the signal so the two signals are not identical. Cast the signal data to the `single` data type. Also name this `timeseries` object `Wave Data`. The Simulation Data Inspector comparison algorithm will align these signals for comparison using the name.

```
time2 = 0:0.1:22;
sig2vals = single(0.98*sin(2*pi/5*time2));
sig2_ts = timeseries(sig2vals,time2);
sig2_ts.Name = 'Wave Data';
```

### Create and Compare Runs in the Simulation Data Inspector

The `Simulink.sdi.compareRuns` function compares data contained in `Simulink.sdi.Run` objects. Use the `Simulink.sdi.createRun` function to create runs in the Simulation Data Inspector for the data. The `Simulink.sdi.createRun` function returns the run ID for each created run.

```
runID1 = Simulink.sdi.createRun('Baseline Run','vars',sig1_ts);
runID2 = Simulink.sdi.createRun('Compare to Run','vars',sig2_ts);
```

You can use the `Simulink.sdi.compareRuns` function to compare the runs. The comparison algorithm converts the signal data to the `double` data type and synchronizes the signal data before computing the difference signal.

```
basic_DRR = Simulink.sdi.compareRuns(runID1,runID2);
```

Check the `Summary` property of the returned `Simulink.sdi.DiffRunResult` object to see the result of the comparison.

**basic\_DRR.Summary**

```
ans = struct with fields:
 OutOfTolerance: 1
 WithinTolerance: 0
 Unaligned: 0
 UnitsMismatch: 0
 Empty: 0
 Canceled: 0
 EmptySynced: 0
 DataTypeMismatch: 0
 TimeMismatch: 0
 StartStopMismatch: 0
 Unsupported: 0
```

The difference between the signals is out of tolerance.

**Compare Runs and Check for Data Type Match**

Depending on your system requirements, you may want the data types for signals you compare to match. You can use the `Simulink.sdi.compareRuns` function to configure the comparison algorithm to check for and report data type mismatches.

```
dataType_DRR = Simulink.sdi.compareRuns(runID1,runID2,'DataType','MustMatch');
dataType_DRR.Summary
```

```
ans = struct with fields:
 OutOfTolerance: 0
 WithinTolerance: 0
 Unaligned: 0
 UnitsMismatch: 0
 Empty: 0
 Canceled: 0
 EmptySynced: 0
 DataTypeMismatch: 1
 TimeMismatch: 0
 StartStopMismatch: 0
 Unsupported: 0
```

The result of the signal comparison is now `DataTypeMismatch` because the data for the baseline signal is double data type, while the data for the signal compared to the baseline is single data type.

**Compare Runs and Check for Start and Stop Time Match**

You can use the `Simulink.sdi.compareRuns` function to configure the comparison algorithm to check whether the aligned signals have the same start and stop times.

```
startStop_DRR = Simulink.sdi.compareRuns(runID1,runID2,'StartStop','MustMatch');
startStop_DRR.Summary
```

```
ans = struct with fields:
 OutOfTolerance: 0
 WithinTolerance: 0
 Unaligned: 0
 UnitsMismatch: 0
```

```

 Empty: 0
 Canceled: 0
 EmptySynced: 0
 DataTypeMismatch: 0
 TimeMismatch: 0
 StartStopMismatch: 1
 Unsupported: 0

```

The signal comparison result is now `StartStopMismatch` because the signals created in the workspace have different stop times.

### Compare Runs with Alignment Criteria

When you compare runs using the Simulation Data Inspector, you can specify alignment criteria that determine how signals are paired with each other for comparison. This example compares data from simulations of a model of an aircraft longitudinal control system. The simulations used a square wave input. The first simulation used an input filter time constant of `0.1s` and the second simulation used an input filter time constant of `0.5s`.

First, load the simulation data from the session file that contains the data for this example.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

The session file contains data for four simulations. This example compares data from the first two runs. Access the run IDs for the first two runs loaded from the session file.

```
runIDs = Simulink.sdi.getAllRunIDs;
runIDTs1 = runIDs(end-3);
runIDTs2 = runIDs(end-2);
```

Before running the comparison, define how you want the Simulation Data Inspector to align the signals between the runs. This example aligns signals by their name, then by their block path, and then by their Simulink identifier.

```
alignMethods = [Simulink.sdi.AlignType.SignalName
 Simulink.sdi.AlignType.BlockPath
 Simulink.sdi.AlignType.SID];
```

Compare the simulation data in your two runs, using the alignment criteria you specified. The comparison uses a small time tolerance to account for the effect of differences in the step size used by the solver on the transition of the square wave input.

```
diffResults = Simulink.sdi.compareRuns(runIDTs1,runIDTs2,'align',alignMethods,...
 'timetol',0.005);
```

You can use the `getResultByIndex` function to access the comparison results for the aligned signals in the runs you compared. You can use the `Count` property of the `Simulink.sdi.DiffRunResult` object to set up a `for` loop to check the `Status` property for each `Simulink.sdi.DiffSignalResult` object.

```
numComparisons = diffResults.count;
for k = 1:numComparisons
 resultAtIdx = getResultByIndex(diffResults,k);
```

```

sigID1 = resultAtIdx.signalID1;
sigID2 = resultAtIdx.signalID2;

sig1 = Simulink.sdi.getSignal(sigID1);
sig2 = Simulink.sdi.getSignal(sigID2);

displayStr = 'Signals %s and %s: %s \n';
fprintf(displayStr,sig1.Name,sig2.Name,resultAtIdx.Status);
end

```

```

Signals q, rad/sec and q, rad/sec: OutOfTolerance
Signals alpha, rad and alpha, rad: OutOfTolerance
Signals Stick and Stick: WithinTolerance

```

## Input Arguments

### runID1 — Baseline run identifier

integer

Numeric identifier for the baseline run in the comparison, specified as a run ID that corresponds to a run in the Simulation Data Inspector. The Simulation Data Inspector assigns run IDs when runs are created. You can get the run ID for a run by using the ID property of the `Simulink.sdi.Run` object, the `Simulink.sdi.getAllRunIDs` function, or the `Simulink.sdi.getRunIDByIndex` function.

### runID2 — Identifier for run to compare

integer

Numeric identifier for the run to compare, specified as a run ID that corresponds to a run in the Simulation Data Inspector. The Simulation Data Inspector assigns run IDs when runs are created. You can get the run ID for a run by using the ID property of the `Simulink.sdi.Run` object, the `Simulink.sdi.getAllRunIDs` function, or the `Simulink.sdi.getRunIDByIndex` function.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `AbsTol=x,Align=alignOpts`

### Align — Signal alignment options

`Simulink.sdi.AlignType` scalar | `Simulink.sdi.AlignType` vector

Signal alignment options, specified as a `Simulink.sdi.AlignType` scalar or vector. The `Simulink.sdi.AlignType` enumeration includes a value for each option available for pairing each signal in the baseline run with a signal in the comparison run. You can specify one or more alignment options for the comparison. To use more than one alignment option, specify an array. When you specify multiple alignment options, the Simulation Data Inspector aligns signals first by the option in the first element of the array, then by the option in the second element array, and so on. For more information, see “Signal Alignment”.

| Value                                          | Aligns By                                    |
|------------------------------------------------|----------------------------------------------|
| <code>Simulink.sdi.AlignType.BlockPath</code>  | Path to the source block for the signal      |
| <code>Simulink.sdi.AlignType.SID</code>        | Automatically assigned Simulink identifier   |
| <code>Simulink.sdi.AlignType.SignalName</code> | Signal name                                  |
| <code>Simulink.sdi.AlignType.DataSource</code> | Path of the variable in the MATLAB workspace |

Example: `[Simulink.sdi.AlignType.SignalName, Simulink.sdi.AlignType.BlockPath]` specifies signal alignment by signal name and then by block path.

### **AbsTol — Global absolute tolerance for comparison**

0 (default) | positive-valued scalar

Global absolute tolerance for comparison, specified as a positive-valued scalar.

Global tolerances apply to all signals in the run comparison. To use a different tolerance value for a signal in the comparison, specify the tolerance you want to use on the `Simulink.sdi.Signal` object in the baseline run and set the `OverrideGlobalTol` property for that signal to `true`.

For more information about how tolerances are used in comparisons, see “Tolerance Specification”.

Example: 0.5

Data Types: `double`

### **RelTol — Global relative tolerance for comparison**

0 (default) | positive-valued scalar

Global relative tolerance for comparison, specified as a positive-valued scalar. The relative tolerance is expressed as a fractional multiplier. For example, 0.1 specifies a 10 percent tolerance.

Global tolerances apply to all signals in the run comparison. To use a different tolerance value for a signal in the comparison, specify the tolerance you want to use on the `Simulink.sdi.Signal` object in the baseline run and set the `OverrideGlobalTol` property for that signal to `true`.

For more information about how tolerances are used in comparisons, see “Tolerance Specification”.

Example: 0.1

Data Types: `double`

### **TimeTol — Global time tolerance for comparison**

0 (default) | positive-valued scalar

Global time tolerance for comparison, specified as a positive-valued scalar, using units of seconds.

Global tolerances apply to all signals in the run comparison. To use a different tolerance value for a signal in the comparison, specify the tolerance you want to use on the `Simulink.sdi.Signal` object in the baseline run and set the `OverrideGlobalTol` property for that signal to `true`.

For more information about tolerances in the Simulation Data Inspector, see “Tolerance Specification”.

Example: 0.2

Data Types: `double`

**DataType — Comparison sensitivity to signal data types**`"MustMatch"`

Comparison sensitivity to signal data types, specified as `"MustMatch"`. Specify `DataType="MustMatch"` when you want the comparison to be sensitive to numeric data type mismatches in compared signals.

When signal data types do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `DataTypeMismatch`.

The `Simulink.sdi.compareRuns` function compares the data types for aligned signals before synchronizing and comparing the signal data. When you do not specify this name-value argument, the comparison checks data types only to detect a comparison between string and numeric data. For a comparison between string and numeric data, results are not computed, and the status for the result is `DataTypeMismatch`. For aligned signals that have different numeric data types, the comparison computes results.

When you configure the comparison to stop on the first mismatch, a data type mismatch stops the comparison. A stopped comparison may not compute results for all signals.

**Time — Comparison sensitivity to signal time vectors**`"MustMatch"`

Comparison sensitivity to signal time vectors, specified as `"MustMatch"`. Specify `Time="MustMatch"` when you want the comparison to be sensitive to mismatches in the time vectors of compared signals. When you specify this name-value argument, the algorithm compares the time vectors of aligned signals before synchronizing and comparing the signal data.

When the time vectors for signals do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `TimeMismatch`.

Comparisons are not sensitive to differences in signal time vectors unless you specify this name-value argument. For comparisons that are not sensitive to differences in the time vectors, the comparison algorithm synchronizes the signals prior to the comparison. For more information about how synchronization works, see ["How the Simulation Data Inspector Compares Data"](#).

When you specify that time vectors must match and configure the comparison to stop on the first mismatch, a time vector mismatch stops the comparison. A stopped comparison may not compute results for all signals.

**StartStop — Comparison sensitivity to signal start and stop times**`"MustMatch"`

Comparison sensitivity to signal start and stop times, specified as `"MustMatch"`. Specify `StartStop="MustMatch"` when you want the comparison to be sensitive to mismatches in signal start and stop times. When you specify this name-value argument, the algorithm compares the start and stop times for aligned signals before synchronizing and comparing the signal data.

When the start times and stop times do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `StartStopMismatch`.

When you specify that start and stop times must match and configure the comparison to stop on the first mismatch, a start or stop time mismatch stops the comparison. A stopped comparison may not compute results for all signals.

**StopOnFirstMismatch — Whether comparison stops on first detected mismatch**`"Metadata" | "Any"`

Whether comparison stops on first detected mismatch without comparing remaining signals, specified as `"Metadata"` or `"Any"`. A stopped comparison may not compute results for all signals, and can return a mismatched result more quickly.

- `"Metadata"` — A mismatch in metadata for aligned signals stops the comparison. Metadata comparisons happen before comparing signal data.

The Simulation Data Inspector always aligns signals and compares signal units. When you configure the comparison to stop on the first mismatch, an unaligned signal or mismatched units always stop the comparison. You can specify additional name-value arguments to configure the comparison to check and stop on the first mismatch for additional metadata, such as signal data type, start and stop times, and time vectors.

- `"Any"` — A mismatch in metadata or signal data for aligned signals stops the comparison.

**ExpandChannels — Whether to compute comparison results for each channel in multidimensional signals**`true or 1 (default) | false or 0`

Whether to compute comparison results for each channel in multidimensional signals, specified as logical `true` (1) or `false` (0).

- `true` or `1` — Comparison expands multidimensional signals represented as a single signal with nonscalar sample values to a set of signals with scalar sample values and computes a comparison result for each signal.

The representation of the multidimensional signal in the Simulation Data Inspector as a single signal with nonscalar sample values does not change.

- `false` or `0` — Comparison does not compute results for multidimensional signals represented as a single signal with nonscalar sample values.

**Output Arguments****diffResult — Comparison results**`Simulink.sdi.DiffRunResult` object

Comparison results, returned as a `Simulink.sdi.DiffRunResult` object.

**Limitations**

The Simulation Data Inspector does not support comparing:

- Signals of data types `int64` or `uint64`.
- Variable-size signals.

**Version History****Introduced in R2011b**

## Simulink.sdi.compareSignals

**Package:** Simulink.sdi

Compare data in two Simulink.sdi.Signal objects

### Syntax

```
diff = Simulink.sdi.compareSignals(sigID1,sigID2)
diff = Simulink.sdi.compareSignals(sigID1,sigID2,Name=Value)
```

### Description

`diff = Simulink.sdi.compareSignals(sigID1,sigID2)` compares the signals that correspond to the signal IDs `sigID1` and `sigID2` and returns the results in a `Simulink.sdi.DiffSignalResult` object. For more information on how the comparison results are computed, see “How the Simulation Data Inspector Compares Data”.

`diff = Simulink.sdi.compareSignals(sigID1,sigID2,Name=Value)` compares the signals that correspond to the signal IDs `sigID1` and `sigID2` using the options specified by one or more name-value arguments.

### Examples

#### Compare Two Signals in the Same Run

You can use the Simulation Data Inspector programmatic interface to compare signals within a single run. This example compares the input and output signals of an aircraft longitudinal controller.

First, load the session that contains the data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

Use the `Simulink.sdi.Run.getLatest` function to access the latest run in the data.

```
aircraftRun = Simulink.sdi.Run.getLatest;
```

Then, you can use the `Simulink.sdi.getSignalsByName` function to access the `Stick` signal, which represents the input to the controller, and the `alpha, rad` signal that represents the output.

```
stick = getSignalsByName(aircraftRun,'Stick');
alpha = getSignalsByName(aircraftRun,'alpha, rad');
```

Before you compare the signals, you can specify a tolerance value to use for the comparison. Comparisons use tolerance values specified for the baseline signal in the comparison, so set an absolute tolerance value of `0.1` on the `Stick` signal.

```
stick.AbsTol = 0.1;
```

Now, compare the signals using the `Simulink.sdi.compareSignals` function. The `Stick` signal is the baseline, and the `alpha, rad` signal is the signal to compare against the baseline.

```

comparisonResults = Simulink.sdi.compareSignals(stick.ID,alpha.ID);
match = comparisonResults.Status

match =
 ComparisonSignalStatus enumeration
 OutOfTolerance

```

The comparison result is out of tolerance. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector to view and analyze the comparison results.

## Compare Signals from Different Runs

This example shows how to compare signals from different simulation runs using the Simulation Data Inspector's `Simulink.sdi.compareSignals` function. When you only have one signal of interest to compare, using a signal comparison returns the `Simulink.sdi.diffSignalResult` object with the comparison data directly.

### Generate Simulation Data

Use the `slexAircraftExample` model to generate simulation runs. Between the runs, change the time constant of the input filter.

```

% Load example model
load_system('slexAircraftExample')

% Mark the alpha, rad signal for streaming
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')

% Simulate system
out_1 = sim('slexAircraftExample');

% Change input filter time constant
modelWorkspace = get_param('slexAircraftExample','modelworkspace');
assignin(modelWorkspace,'Ts',0.2)

% Simulate again
out_2 = sim('slexAircraftExample');

```

### Get Signal IDs for the Signal Comparison

Create run objects using the run IDs, and then use `getSignalIDByIndex` to get the signal IDs to pass to `Simulink.sdi.compareSignals`.

```

% Get run data
runIDs = Simulink.sdi.getAllRunIDs;

runID1 = runIDs(end-1);
runID2 = runIDs(end);

run1 = Simulink.sdi.getRun(runID1);
run2 = Simulink.sdi.getRun(runID2);

sigID1 = getSignalIDByIndex(run1,1);
sigID2 = getSignalIDByIndex(run2,1);

```

## Compare Signals

Compare the signals, and open the Simulation Data Inspector to view the results.

```
diffResult = Simulink.sdi.compareSignals(sigID1,sigID2);

Simulink.sdi.view
```

## Input Arguments

### **sigID1 — Signal ID of baseline signal**

integer

Signal ID of baseline signal, specified as an integer. The Simulation Data Inspector assigns a signal ID to each signal when a run is created. You can get the signal ID for a signal using one of these functions:

- `getAllSignalIDs`
- `getSignalIDByIndex`
- `getSignalIDsByName`
- `Simulink.sdi.createRun`

### **sigID2 — Signal ID of signal to compare**

integer

Signal ID of signal to compare, specified as an integer. The Simulation Data Inspector assigns a signal ID to each signal when a run is created. You can get the signal ID for a signal using one of these functions:

- `getAllSignalIDs`
- `getSignalIDByIndex`
- `getSignalIDsByName`
- `Simulink.sdi.createRun`

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

```
Example: diff = Simulink.sdi.compareSignals(sigID1,sigID2,DataType="MustMatch")
```

### **DataType — Comparison sensitivity to signal data types**

"MustMatch"

Comparison sensitivity to signal data types, specified as "MustMatch". Specify `DataType="MustMatch"` when you want the comparison to be sensitive to numeric data type mismatches in compared signals.

When signal data types do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `DataTypeMismatch`.

The `Simulink.sdi.compareSignals` function compares the data types before synchronizing and comparing the signal data. When you do not specify this name-value argument, the comparison checks data types only to detect a comparison between string and numeric data. For a comparison between string and numeric data, results are not computed, and the status for the result is `DataTypeMismatch`. For signals that have different numeric data types, the comparison computes results.

When you configure the comparison to stop on the first mismatch, a data type mismatch stops the comparison.

### **Time — Comparison sensitivity to signal time vectors**

"MustMatch"

Comparison sensitivity to signal time vectors, specified as "MustMatch". Specify `Time="MustMatch"` when you want the comparison to be sensitive to mismatches in the time vectors of compared signals. When you specify this name-value argument, the algorithm compares the time vectors before synchronizing and comparing the signal data.

When the time vectors do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `TimeMismatch`.

Comparisons are not sensitive to differences in signal time vectors unless you specify this name-value argument. For comparisons that are not sensitive to differences in the time vectors, the comparison algorithm synchronizes the signals prior to the comparison. For more information about how synchronization works, see "How the Simulation Data Inspector Compares Data".

When you specify that time vectors must match and configure the comparison to stop on the first mismatch, a time vector mismatch stops the comparison.

### **StartStop — Comparison sensitivity to signal start and stop times**

"MustMatch"

Comparison sensitivity to signal start and stop times, specified as "MustMatch". Specify `StartStop="MustMatch"` when you want the comparison to be sensitive to mismatches in signal start and stop times. When you specify this name-value argument, the algorithm compares the start and stop times for each signal before synchronizing and comparing the signal data.

When the start times and stop times do not match, the `Status` property of the `Simulink.sdi.DiffSignalResult` object for the result is set to `StartStopMismatch`.

When you specify that start and stop times must match and configure the comparison to stop on the first mismatch, a start or stop time mismatch stops the comparison.

### **StopOnFirstMismatch — Whether comparison stops on first detected mismatch**

"Metadata" | "Any"

Whether comparison stops on first detected mismatch, specified as "Metadata" or "Any". A stopped comparison may not compute results for all channels when comparing multidimensional signals and can return a mismatched result more quickly.

- "Metadata" — A mismatch in metadata stops the comparison. Metadata comparisons happen before signal data comparisons.

The Simulation Data Inspector always compares signal units. When you configure the comparison to stop on the first mismatch, mismatched units always stop the comparison. You can specify

additional name-value arguments to configure the comparison to check and stop on the first mismatch for additional metadata, such as signal data type, start and stop times, and time vectors.

- "Any" — A mismatch in metadata or signal data stops the comparison.

### **ExpandChannels — Whether to compute comparison results for each channel in multidimensional signals**

`false` or `0` (default) | `true` or `1`

Whether to compute comparison results for each channel in multidimensional signals, specified as logical `true` (`1`) or `false` (`0`).

- `true` or `1` — Comparison expands multidimensional signals represented as a single signal with nonscalar sample values to a set of signals with scalar sample values and computes a comparison result for each signal.

The representation of the multidimensional signal in the Simulation Data Inspector as a single signal with nonscalar sample values does not change.

- `false` or `0` — Comparison does not compute results for multidimensional signals represented as a single signal with nonscalar sample values.

## **Output Arguments**

### **diff — Signal comparison result**

`Simulink.sdi.diffSignalResult` | array of `Simulink.sdi.diffSignalResult` objects

Signal comparison result, returned as a `Simulink.sdi.DiffSignalResult` object. Complex signal comparison results are returned as an array of two `DiffSignalResult` objects. One `DiffSignalResult` object contains the real data and the other contains the imaginary data. Check the `Name` property of the `DiffSignalResult` object to determine whether it contains real or imaginary data.

## **Limitations**

The Simulation Data Inspector does not support comparing:

- Signals of data types `int64` or `uint64`.
- Variable-size signals.

If you perform multiple signal comparisons or run comparisons, only the latest `DiffSignalResult` object has visible properties.

## **Version History**

Introduced in R2011b

## Simulink.sdi.copyRun

Copy a Simulation Data Inspector run

### Syntax

```
newRunID = Simulink.sdi.copyRun(runID)
[newRunID,runIndex] = Simulink.sdi.copyRun(runID)
[newRunID,runIndex,signalIDs] = Simulink.sdi.copyRun(runID)
```

### Description

`newRunID = Simulink.sdi.copyRun(runID)` copies the run corresponding to `runID` and returns the run ID for the new run. The new run includes all the simulation data and metadata from the original run. You can modify the copy of the run by adding or deleting signals and metadata while still retaining the original run.

`[newRunID,runIndex] = Simulink.sdi.copyRun(runID)` copies the run corresponding to `runID` and returns the run ID and index in the Simulation Data Inspector repository for the new run. The new run includes all the simulation data and metadata from the original run.

`[newRunID,runIndex,signalIDs] = Simulink.sdi.copyRun(runID)` copies the run corresponding to `runID` and returns the signal IDs for the signals in the new run along with its run ID and index in the Simulation Data Inspector repository. The new run includes all the simulation data and metadata from the original run.

### Examples

#### Compare a Subset of Signals

This example shows how to use `Simulink.sdi.copyRun` and `Simulink.sdi.deleteSignal` to create a copy of a run that contains a subset of the signals from the original run. You can use the copy to analyze and run comparisons on a subset of signals while still holding onto the original run that has all of the signals. For example, the model `sldemo_fuelsys` is configured to log ten signals. To compare the system's responses to different types of failures, you don't need to run the comparison on all of the logged signals. Deleting signals that do not represent the system's response before running the comparison saves processing time and simplifies the view of the results.

#### Create Runs

Load the model `sldemo_fuelsys` and run simulations to create runs in the Simulation Data Inspector. The first run simulates a failure of the throttle angle sensor, and the second run simulates a failure of the exhaust gas oxygen sensor.

```
load_system('sldemo_fuelsys')
modelWorkspace = get_param('sldemo_fuelsys','modelworkspace');
modelWorkspace.assignin('throttle_sw',0)
modelWorkspace.assignin('ego_sw',1)
sim('sldemo_fuelsys')
```

```
modelWorkspace.assignin('throttle_sw',1)
modelWorkspace.assignin('ego_sw',0)
sim('sldemo_fuelsys')
```

## Copy the Run

Use the Simulation Data Inspector's programmatic interface to get `Simulink.sdi.Run` objects for the simulations, and then create copies of the runs.

```
% Get runs
runIDs = Simulink.sdi.getAllRunIDs;

runID1 = runIDs(end-1);
runID2 = runIDs(end);

run1 = Simulink.sdi.getRun(runID1);
run2 = Simulink.sdi.getRun(runID2);

% Create a copy of each run, truncRun
[truncRun1,runIndex1,signalIDs1] = Simulink.sdi.copyRun(runID1);
[truncRun2,runIndex2,signalIDs2] = Simulink.sdi.copyRun(runID2);
```

## Delete Signals in Run Copy

The `sldemo_fuelsys` model is configured to log the values of the fault switches along with several signals representing the system's response. When you compare the system's response when a throttle angle sensor fails to its response when an exhaust gas oxygen sensor fails, comparing the fault switch states does not provide new information. Therefore, delete the switch signals before running the comparison to eliminate unnecessary computations.

```
Simulink.sdi.deleteSignal(signalIDs1(1))
Simulink.sdi.deleteSignal(signalIDs1(3))
Simulink.sdi.deleteSignal(signalIDs1(5))
Simulink.sdi.deleteSignal(signalIDs1(8))

Simulink.sdi.deleteSignal(signalIDs2(1))
Simulink.sdi.deleteSignal(signalIDs2(3))
Simulink.sdi.deleteSignal(signalIDs2(5))
Simulink.sdi.deleteSignal(signalIDs2(8))
```

## Compare Truncated Runs

You can use the truncated runs you created with `Simulink.sdi.copyRun` and `Simulink.sdi.deleteSignal` to perform a comparison of the system's response to different types of failures. Then, open the Simulation Data Inspector to view the comparison results.

```
truncRunDiff = Simulink.sdi.compareRuns(truncRun1,truncRun2);

Simulink.sdi.view
```

## Input Arguments

**runID** — Numeric run identifier

scalar

Run ID for the run you want to copy. The Simulation Data Inspector assigns run IDs when it creates runs. You can get the run ID for your run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

## Output Arguments

### **newRunID** — Run ID for the copy

scalar

Run ID for the copy of the run.

### **runIndex** — Run index for the copy

scalar

Index of the copy in the Simulation Data Inspector repository.

### **signalIDs** — Numeric identifiers for the signals in the copy

matrix

Matrix containing the signal IDs for the copies of signals created in the copy of the run.

## Version History

**Introduced in R2011b**

# Simulink.sdi.copyRunViewSettings

Copy line style and color for signals from one run to another

## Syntax

```
sigIDs = Simulink.sdi.copyRunViewSettings(run1,run2,plot)
```

## Description

`sigIDs = Simulink.sdi.copyRunViewSettings(run1,run2,plot)` copies the line style and color specifications from `runID1` to `runID2` for matched signals. You can specify `run1` and `run2` with their run ID or as a `Simulink.sdi.Run` object. If `plot` is specified as `true`, `Simulink.sdi.copyRunViewSettings` also changes signal parameters in both runs so that aligned signals that are plotted come from the `run2`. The function returns an array of signal identifiers for the signals that the Simulation Data Inspector aligned between the two runs. To learn more about how the Simulation Data Inspector aligns signals between runs, see “How the Simulation Data Inspector Compares Data”.

## Examples

### Copy View Settings to Run

Copy view settings from one run to another and create figures using the `Simulink.sdi.CustomSnapshot` object.

### Simulate Model and Get Run Object

Configure the `vdp` model to save output data. Run a simulation to create data.

```
load_system("vdp")
set_param("vdp","SaveFormat","Dataset","SaveOutput","on")
set_param("vdp/Mu","Gain","1");
sim("vdp");
```

Use the Simulation Data Inspector programmatic interface to access the run data.

```
runIndex = Simulink.sdi.getRunCount;
runID = Simulink.sdi.getRunIDByIndex(runIndex);
vdpRun = Simulink.sdi.getRun(runID);
```

### Modify Signal View Settings

Use the `Simulink.sdi.Run` object to access signals in the run. Then, modify the signal view settings. This example specifies the line color and style for each signal. The view settings for the run comprise the view settings for each signal and view settings specified for the plot area.

```
sig1 = getSignalByIndex(vdpRun,1);
sig2 = getSignalByIndex(vdpRun,2);

sig1.LineColor = [0 0 1];
```

```
sig1.LineDashed = "-.";
sig2.LineColor = [1 0 0];
sig2.LineDashed = ":";
```

### Capture Snapshot from Simulation Data Inspector

Create a `Simulink.sdi.CustomSnapshot` object and use the `Simulink.sdi.snapshot` function to programmatically capture a snapshot of the contents of the Simulation Data Inspector.

```
snap = Simulink.sdi.CustomSnapshot;
```

You can use properties of the `Simulink.sdi.CustomSnapshot` object to configure the plot settings, such as the subplot layout and axis limits, and to plot signals. When you use a `Simulink.sdi.CustomSnapshot` object to create your figure, these plot settings do not affect the Simulation Data Inspector.

```
snap.Rows = 2;
snap.YRange = {[-2.25 2.25], [-3 3]};
plotOnSubPlot(snap,1,1,sig1,true)
plotOnSubPlot(snap,2,1,sig2,true)
```

Use the `Simulink.sdi.snapshot` function to generate the figure you specified in the properties of the `Simulink.sdi.CustomSnapshot` object.

```
fig = Simulink.sdi.snapshot("From","custom","To","figure","Settings",snap);
```

### Copy View Settings to New Simulation Run

Simulate the model again, with a different Mu value. Use the Simulation Data Inspector programmatic interface to access the simulation data.

```
set_param("vdp/Mu", "Gain", "5")
sim("vdp");

runIndex2 = Simulink.sdi.getRunCount;
runID2 = Simulink.sdi.getRunIDByIndex(runIndex2);
run2 = Simulink.sdi.getRun(runID2);
```

To create a plot of the new output data that looks like the one you created in the previous step, you can copy the view settings to the run in a single line of code using the `Simulink.sdi.copyRunViewSettings` function. This function does not automatically update plot settings in `Simulink.sdi.CustomSnapshot` objects, so specify the input that determines whether the plot updates as `false`.

```
sigIDs = Simulink.sdi.copyRunViewSettings(runID, runID2, false);
```

### Capture Snapshot of New Simulation Run

Use the `Simulink.sdi.CustomSnapshot` object to capture a snapshot of the new simulation run. First, clear the signals from the subplots. Then, plot the signals from the new run and capture another snapshot.

```
clearSignals(snap)
snap.YRange = {[-2.25 2.25], [-8 8]};
plotOnSubPlot(snap, 1, 1, sigIDs(1), true)
plotOnSubPlot(snap, 2, 1, sigIDs(2), true)

fig = snapshot(snap, "To", "figure");
```

## Input Arguments

### run1 — Simulation Data Inspector run ID for source run

scalar | 'Simulink.sdi.Run' object

Run with the view settings you want to copy specified with its run ID or `Simulink.sdi.Run` object. The Simulation Data Inspector assigns run IDs when it creates runs. You can get the run ID for your run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

### run2 — Simulation Data Inspector run ID for destination run

scalar | 'Simulink.sdi.Run' object

Run you want to copy the view settings to, specified with its run ID or `Simulink.sdi.Run` object. The Simulation Data Inspector assigns run IDs when it creates runs. You can get the run ID for your run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

### plot — Specify whether to update plotted signals

true | false

Specifies whether the Simulation Data Inspector changes the plot settings in the runs corresponding to `run1` and `run2`.

- When `plot` is `true`, the Simulation Data Inspector modifies the signal parameters so that the aligned signals that are plotted come from `run2`.

- When `plot` is `false`, the Simulation Data Inspector does not change which signals are plotted.

Data Types: `logical`

## Output Arguments

### **sigIDs** — Signal IDs for aligned signals

matrix

Matrix containing the signal IDs for signals in `run2` that aligned with signals in `run1` and had view settings modified.

## Version History

Introduced in R2016a

### See Also

### Topics

“Inspect and Compare Data Programmatically”

“Create Plots Using the Simulation Data Inspector”

## Simulink.sdi.createRun

Import data into new run in Simulation Data Inspector and return run ID

### Syntax

```
runID = Simulink.sdi.createRun
runID = Simulink.sdi.createRun(runName)

runID = Simulink.sdi.createRun(var)
runID = Simulink.sdi.createRun(runName, 'vars', var, var2, ..., varn)
runID = Simulink.sdi.createRun(runName, 'namevalue', sourceNames, sigValues)

runID = Simulink.sdi.createRun(runName, 'file', filename)
runID = Simulink.sdi.createRun(runName, 'file', filename, Name=Value)

[runID, runIndex] = Simulink.sdi.createRun(____)
[runID, runIndex, sigIDs] = Simulink.sdi.createRun(____)
```

### Description

#### Create Empty Run

`runID = Simulink.sdi.createRun` creates an empty, unnamed run in the Simulation Data Inspector and returns the run ID for the created run.

You can use the `Simulink.sdi.getRun` function to access the `Simulink.sdi.Run` object that corresponds to the run. Set the properties on the Run object to add metadata to the run. Use the `Simulink.sdi.addToRun` function or the `add` function to add data to the run.

`runID = Simulink.sdi.createRun(runName)` creates an empty run named `runName`.

#### Import Data from Workspace

`runID = Simulink.sdi.createRun(var)` imports data from the scalar variable `var` into a new run in the Simulation Data Inspector. The run is named according to the input variable. For example, when `var` is a `timeseries` object, the run name comes from the `Name` property on the `timeseries` object.

`runID = Simulink.sdi.createRun(runName, 'vars', var, var2, ..., varn)` imports data from one or more variables into a new run in the Simulation Data Inspector named `runName`.

Use this syntax to import data from multiple variables or from a variable that represents an array of objects, such as an array of `Simulink.SimulationOutput` or `Simulink.SimulationData.Dataset` objects.

`runID = Simulink.sdi.createRun(runName, 'namevalue', sourceNames, sigValues)` imports data from one or more variables into a new run in the Simulation Data Inspector named `runName`. The cell array `sourceNames` specifies the names used to set the `RootSource`, `TimeSource`, and `DataSource` properties for the signals imported from the `sigValues` cell array.

### Import Data from File

`runID = Simulink.sdi.createRun(runName, 'file', filename)` imports data from a file into a new run in the Simulation Data Inspector. You can use a built-in file reader to import data from a MAT file, CSV file, Microsoft Excel file, or an MDF file.

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class.

`runID = Simulink.sdi.createRun(runName, 'file', filename, Name=Value)` imports data from a file into a new run in the Simulation Data Inspector according to options specified using one or more name-value arguments. For example, `sheets=["sheet1" "sheet2"]` specifies the sheets from which to import data when importing data from an Excel file.

### Return Additional Run Information

`[runID,runIndex] = Simulink.sdi.createRun( ___ )` returns the run ID and the run index in the Simulation Data Inspector for the created run.

`[runID,runIndex,sigIDs] = Simulink.sdi.createRun( ___ )` returns the run ID, run index in the Simulation Data Inspector, and the signal IDs for the signals in the created run.

## Examples

### Create Run in Simulation Data Inspector

You can programmatically import data into the Simulation Data Inspector by creating a run from data in the base workspace or a file. This example creates data in the workspace and then illustrates several methods of creating a Simulation Data Inspector run containing the data.

#### Create Data

Create data in the workspace. The Simulation Data Inspector supports timeseries data in many formats. This example creates data using the `timeseries` and `Simulink.SimulationData.Dataset` formats and saves the data in a MAT-file.

Create a sine signal and a cosine signal. Store the data for each signal in a `timeseries` object with a descriptive name.

```
time = 0:0.2:20;

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = "Sine, T=5";

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = "Cosine, T=8";
```

You can use the `Dataset` format to group related signal data together in a single object. The `Dataset` format is the default format for logged data and is supported for loading simulation input data. Create a `Dataset` object that contains the sinusoid `timeseries` data.

```
sinusoids_ds = Simulink.SimulationData.Dataset;
sinusoids_ds = addElement(sinusoids_ds,cos_ts);
sinusoids_ds = addElement(sinusoids_ds,sine_ts);
```

Scale each signal by a factor of 2 and create a `Dataset` object to contain the signal data for the results.

```
doubSine = 2*sine_ts;
doubCos = 2*cos_ts;

doubSinusoids_ds = Simulink.SimulationData.Dataset;
doubSinusoids_ds = addElement(doubSinusoids_ds,doubSine);
doubSinusoids_ds = addElement(doubSinusoids_ds,doubCos);
```

Finally, save the timeseries data to a MAT-file.

```
save sinusoids.mat sine_ts cos_ts
```

### Open Simulation Data Inspector

To view the runs you create in each section, open the Simulation Data Inspector by entering `Simulink.sdi.view` in the MATLAB™ Command Window.

### Create Run Using `Simulink.sdi.Run` Object

You can import your data into a run in the Simulation Data Inspector by creating an empty run and then adding data to the run from the workspace or a file. Depending on your task, use the `Simulink.sdi.Run.create` function or the `Simulink.sdi.createRun` function to create the empty run. The `Simulink.sdi.Run.create` function returns the `Simulink.sdi.Run` object for the new run. The `Simulink.sdi.createRun` function returns the run ID for the new run.

This example creates an empty run using the `Simulink.sdi.Run.create` function, gives the run a meaningful name and description, and then adds the sine and cosine timeseries data using the `add` function.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = "Sinusoids";
sinusoidsRun.Description = "Sine and cosine signals of different frequencies";

add(sinusoidsRun,'vars',sine_ts,cos_ts)
```

This example uses the `Simulink.sdi.createRun` function to create a new run in the Simulation Data Inspector called `My Waves` and then uses the `Simulink.sdi.addToRun` function to add the sine and cosine timeseries data to the run.

```
runID = Simulink.sdi.createRun("My Waves");
signalID = Simulink.sdi.addToRun(runID,'vars',sine_ts,cos_ts);
```

### Create Run from Workspace Variable

You can create a run from a single variable in the workspace. After creating the run, you can add additional data or create another run to contain your other data. The variable you use to create the run can be a `timeseries` object with data that corresponds to only one signal or a `Dataset` object that contains several signals.

When you use this syntax to create a run from a single workspace variable, the run takes the same name as the object used to create it.

```
runID = Simulink.sdi.createRun(sine_ts);
```

The `Simulink.sdi.createRun` function returns the run ID for the run the function creates. You can use the `Simulink.sdi.getRun` function to access the Run object for the run.

```
sineRun = Simulink.sdi.getRun(runID);
sineRun.Name
```

```
ans =
'Sine, T=5'
```

### Create Run from Multiple Workspace Variables

When your data exists in multiple variables in your workspace, you can use the `Simulink.sdi.createRun` function with the `vars` option to import the data from multiple variables into a single run in the Simulation Data Inspector. You can also use this syntax to create a run for a single variable that uses a name you specify.

This example creates a run called `My Sinusoids` that contains data for the sine and cosine timeseries objects.

```
runID = Simulink.sdi.createRun("My Sinusoids", 'vars', sine_ts, cos_ts);
```

### Create Run and Specify Source Names

You can use the `namevalue` option of the `Simulink.sdi.createRun` function to create a run and specify names for the signals in the run. This syntax can be helpful when you import individual leaf signals from hierarchical data.

This example creates a run containing the data for both the `Dataset` objects. Each `Dataset` object contains data for more than one signal, so the imported run data has hierarchy. The name-value syntax in this example specifies a name for the hierarchical node that corresponds to each `Dataset` object.

```
runID = Simulink.sdi.createRun("Waves", 'namevalue', {'Sinusoids', ...
 'BigSinusoids'}, {sinusoids_ds, doubSinusoids_ds});
```

### Create Run from File Data

You can also use the `Simulink.sdi.createRun` function to import data into the Simulation Data Inspector from a file. Use the `file` option to import the data in the `sinusoids.mat` file.

```
runID = Simulink.sdi.createRun("Wave Data", 'file', "sinusoids.mat");
```

### Create a Simulation Data Inspector Run and Access Signal Data

This example shows how to access signal data when you create a run in the Simulation Data Inspector.

#### Generate Data for Run

For this example, create timeseries data for sine and cosine signals.

```
% Create timeseries workspace data
time = linspace(0, 20, 101);
```

```
sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';
```

```
cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

### Create a Run and Return Signal IDs

You can use the `Simulink.sdi.createRun` syntax with multiple return arguments to get the signal IDs more directly instead of accessing the signal IDs through a `Simulink.sdi.Run` object.

```
[runID,runIndex,sigIDs] = Simulink.sdi.createRun('Sinusoids','vars',...
 sine_ts,cos_ts);
```

```
cosID = sigIDs(2);
cosSig = Simulink.sdi.getSignal(cosID);
```

### Modify Signal Properties and View in the Simulation Data Inspector

You can use the `Simulink.sdi.Signal` object to view and modify signal properties and to plot signals in the Simulation Data Inspector.

```
cosSig.Checked = true;
cosSig.AbsTol = 0.05;
Simulink.sdi.view
cosSig.Name
```

## Input Arguments

### runName — Name for run

string | character vector

Name for run in Simulation Data Inspector, specified as a string or a character vector.

Example: 'Baseline Simulation'

### var — Data to import

variable

Data to import, specified as a variable. The Simulation Data Inspector supports time-based data in which sample values are associated with sample times. The Simulation Data Inspector supports all loading and logging data formats, including `timeseries` and `Simulink.SimulationData.Dataset`.

Example: `myData`

### sourceNames — Source names for imported data

cell array of character vectors

Source names for imported data, specified as a cell array of character vectors. The source name is used to set the `RootSource`, `TimeSource`, and `DataSource` properties of the `Simulink.sdi.Signal` objects created from the data specified by the `sigValues` input.

Provide a `sourceNames` input when you specify 'namevalue' for the second argument.

Example: {'sig1','sig2'}

### **sigValues – Data to import**

cell array of variables

Data to import, specified as a cell array of variables.

Provide a `sigValues` input when you specify 'namevalue' for the second argument.

Example: {var1,var2}

### **filename – Name of file with data to import**

character vector

Name of file with data to import, specified as a character vector. Provide a `filename` input when you specify 'file' for the second argument.

You can create a run from these types of files using file readers built into the Simulation Data Inspector:

- MAT-file
- CSV file
- Microsoft Excel file that contains data formatted according to “Microsoft Excel Import, Export, and Logging Format”.
- MDF file with one of these extensions:
  - .mdf
  - .mf4
  - .mf3
  - .data
  - .dat

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class. You can also write a custom reader to use instead of the built-in reader for any file extension. For an example, see “Import Data Using a Custom File Reader”.

Example: 'simulation.mat'

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `sheets=["sheet1" "sheet2"]`

### **reader – File reader to use to import data**

string | character vector

File reader to use to import data, specified as a string or character vector.

The Simulation Data Inspector prioritizes using a registered custom reader when one is available for the file. When you do not specify a reader, the Simulation Data Inspector uses the first custom reader

registered for the file. If no custom readers are registered, the data is imported using the built-in reader.

Specify the reader input when:

- You want to use the built-in reader to import data for a file that is also supported by a custom reader.
- Multiple registered custom readers support the file.

To determine which readers are available to import your file, use the `io.reader.getSupportedReadersForFile` function.

Example: "MyExcelReader"

Example: "built-in"

### **sheets — Sheets in Excel file from which to import data**

string array | cell array of character vectors

Sheets in Excel file from which to import data, specified as a string array or a cell array of character vectors. By default, the Simulation Data Inspector imports data from all sheets. Use the `sheets` name-value argument when you do not want to import data from all sheets in the Excel file.

When the data in the file does not include simulation numbers and source information, the data on each sheet is imported into a separate run. For more information about formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: ["sheet1" "sheet2"]

### **model — Model with definitions of user-defined data types**

string | character vector

Model with definitions of user-defined data types, specified as a string or character vector.

When you load data from an Excel file that defines signal data types using user-defined data types, such as enumerations, buses, or aliases, the Simulation Data Inspector needs access to the type definition to import the data. You can provide access to the type definitions by:

- Loading the associated object into the MATLAB workspace.
- Specifying the `model` name-value argument to use type definitions saved in the model workspace or a data dictionary.

For more information on formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: "myModel.slx"

## **Output Arguments**

### **runID — Run ID for run that contains imported data**

scalar

Run ID for run that contains imported data, returned as a scalar.

### **runIndex — Run index in Simulation Data Inspector for run that contains imported data**

scalar

Run index in Simulation Data Inspector for run that contains imported data, returned as a scalar.

### **sigIDs — Signal IDs for signals created from imported data**

scalar | vector

Signal IDs for signals created from imported data, returned as a scalar or a vector.

## **Version History**

## Simulink.sdi.createRunOrAddToStreamedRun

**Package:** Simulink.sdi

Create a single run for all simulation outputs

### Syntax

```
runID = Simulink.sdi.createRunOrAddToStreamedRun mdl, runName, varSources, varValues)
```

### Description

`runID = Simulink.sdi.createRunOrAddToStreamedRun mdl, runName, varSources, varValues)` creates a run with the data `varValues` if no run exists in the Simulation Data Inspector repository for the model `mdl`. If one or more runs for the model `mdl` exist in the Simulation Data Inspector repository, the function adds `varValues` to the most recent run associated with `mdl`. The run is named according to `runName`, and the sources for the data in `varValues` are named according to `varSources`.

### Examples

#### Add Signals to a Run

This example shows how to use `Simulink.sdi.createRunOrAddToStreamedRun` to add data to an existing run for a model. In this example, you add data logged using the `Structure with Time` format to a run that contains logged signal data.

#### Simulate the Model

Open the `slexAircraftExample` model and mark the output of the Pilot block for logging. The logged signal data uses the `Dataset` format and streams to the Simulation Data Inspector during simulation. The model is configured to log outputs, states, and time as well as signals. Simulate the model and return a single output in the workspace with all the logged data. Use the `Structure with Time` format for logged states and outputs.

```
load_system('slexAircraftExample')

Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot',1,1)

out = sim('slexAircraftExample','ReturnWorkspaceOutputs','on',...
 'SaveFormat','StructureWithTime');
```

#### Add Logged States Data to Run

The Simulation Data Inspector automatically created a run for the logged signal data. Add the logged states and outputs data to the existing run using `Simulink.sdi.createRunOrAddToStreamedRun`.

```
Simulink.sdi.createRunOrAddToStreamedRun('slexAircraftExample','Run 1',...
 {'out'},{out});
```

## Open the Simulation Data Inspector to View Results

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector and view the results.

Using `Simulink.sdi.createRunOrAddToStreamedRun` avoids redundancy in the data shown in the Simulation Data Inspector. When you use the `Simulink.sdi.createRun` function to import the output and states data, the Simulation Data Inspector creates a second run. When you use the `Simulink.sdi.addToRun` function to add the logged states and output data to the run, the Simulation Data Inspector imports a duplicate of the Pilot block output signal. Using `Simulink.sdi.createRunOrAddToStreamedRun`, you can include all simulation data in a single run without duplicating any signals.

## Input Arguments

### **mdl** — Name of model that created simulation data

character vector

Name of the model the simulation data is from, specified as a character vector.

Example: `'my_model'`

### **runName** — Name for the run

character vector

Name for the new or augmented run. If `Simulink.sdi.createRunOrAddToStreamedRun` adds data to an existing run, the run is renamed according to `runName`.

Example: `'Run 1'`

### **varSources** — Names to use for the sources of data

cell array of character vectors

Names for the sources of the data in `varValues`.

Example: `{'sig1','sig2'}`

### **varValues** — Data to add to run

cell array

Cell array of data to incorporate into the run. `Simulink.sdi.createRunOrAddToStreamedRun` supports data in all logging and loading formats, including `timeseries` and `Simulink.SimulationData.Dataset`.

Example: `{sig1,sig2}`

## Output Arguments

### **runID** — Run identifier

scalar

Run identifier for the new or augmented run.

## Version History

Introduced in R2017a

“View Data in the Simulation Data Inspector”

# Simulink.sdi.deleteRun

**Package:** Simulink.sdi

Delete a run from the Simulation Data Inspector repository

## Syntax

```
Simulink.sdi.deleteRun(runID)
```

## Description

`Simulink.sdi.deleteRun(runID)` deletes the run corresponding to `runID`. When you delete a run, the indices of all runs following the deleted run change to account for the change in the run count. Deleting a run does not change any run IDs.

## Examples

### Delete a Run

You can delete a run from the Simulation Data Inspector repository to free up memory space or to declutter your workspace from data you do not need.

```
% Load and simulate sldemo_fuelsys model
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')

% Get the run ID for the run
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);

% Delete the run
Simulink.sdi.deleteRun(runID)
```

## Input Arguments

### runID — Run identifier

scalar

Run ID for the run you want to delete. You can get the run ID for a run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

## Version History

Introduced in R2011b

## See Also

“Inspect and Compare Data Programmatically”

# Simulink.sdi.deleteSignal

**Package:** Simulink.sdi

Delete signal in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.deleteSignal(sigID)
```

## Description

`Simulink.sdi.deleteSignal(sigID)` deletes the specified signal or signals from the Simulation Data Inspector.

## Examples

### Compare a Subset of Signals

This example shows how to use `Simulink.sdi.copyRun` and `Simulink.sdi.deleteSignal` to create a copy of a run that contains a subset of the signals from the original run. You can use the copy to analyze and run comparisons on a subset of signals while still holding onto the original run that has all of the signals. For example, the model `sldemo_fuelsys` is configured to log ten signals. To compare the system's responses to different types of failures, you don't need to run the comparison on all of the logged signals. Deleting signals that do not represent the system's response before running the comparison saves processing time and simplifies the view of the results.

### Create Runs

Load the model `sldemo_fuelsys` and run simulations to create runs in the Simulation Data Inspector. The first run simulates a failure of the throttle angle sensor, and the second run simulates a failure of the exhaust gas oxygen sensor.

```
load_system('sldemo_fuelsys')
modelWorkspace = get_param('sldemo_fuelsys','modelworkspace');
modelWorkspace.assignin('throttle_sw',0)
modelWorkspace.assignin('ego_sw',1)
sim('sldemo_fuelsys')

modelWorkspace.assignin('throttle_sw',1)
modelWorkspace.assignin('ego_sw',0)
sim('sldemo_fuelsys')
```

### Copy the Run

Use the Simulation Data Inspector's programmatic interface to get `Simulink.sdi.Run` objects for the simulations, and then create copies of the runs.

```
% Get runs
runIDs = Simulink.sdi.getAllRunIDs;
```

```
runID1 = runIDs(end-1);
runID2 = runIDs(end);

run1 = Simulink.sdi.getRun(runID1);
run2 = Simulink.sdi.getRun(runID2);

% Create a copy of each run, truncRun
[truncRun1,runIndex1,signalIDs1] = Simulink.sdi.copyRun(runID1);
[truncRun2,runIndex2,signalIDs2] = Simulink.sdi.copyRun(runID2);
```

### Delete Signals in Run Copy

The `sldemo_fuelsys` model is configured to log the values of the fault switches along with several signals representing the system's response. When you compare the system's response when a throttle angle sensor fails to its response when an exhaust gas oxygen sensor fails, comparing the fault switch states does not provide new information. Therefore, delete the switch signals before running the comparison to eliminate unnecessary computations.

```
Simulink.sdi.deleteSignal(signalIDs1(1))
Simulink.sdi.deleteSignal(signalIDs1(3))
Simulink.sdi.deleteSignal(signalIDs1(5))
Simulink.sdi.deleteSignal(signalIDs1(8))

Simulink.sdi.deleteSignal(signalIDs2(1))
Simulink.sdi.deleteSignal(signalIDs2(3))
Simulink.sdi.deleteSignal(signalIDs2(5))
Simulink.sdi.deleteSignal(signalIDs2(8))
```

### Compare Truncated Runs

You can use the truncated runs you created with `Simulink.sdi.copyRun` and `Simulink.sdi.deleteSignal` to perform a comparison of the system's response to different types of failures. Then, open the Simulation Data Inspector to view the comparison results.

```
truncRunDiff = Simulink.sdi.compareRuns(truncRun1,truncRun2);

Simulink.sdi.view
```

## Input Arguments

### **sigID** — Signal or signals to delete

scalar | vector

Signal to delete, specified as a scalar signal ID or vector of signal IDs. The Simulation Data Inspector assigns a unique numeric signal ID to each signal when a run is created for logged or imported data.

You can get the signal ID for a signal using one of these functions:

- `getAllSignalIDs`
- `getSignalIDByIndex`
- `getSignalIDsByName`
- `Simulink.sdi.createRun`

## Version History

Introduced in R2016a

## Simulink.sdi.DiffRunResult.getLatest

Access results from most recent comparison

### Syntax

```
diffRes = Simulink.sdi.DiffRunResult.getLatest
```

### Description

`diffRes = Simulink.sdi.DiffRunResult.getLatest` returns the `Simulink.sdi.DiffRunResult` object `diffRes` for the most recent comparison performed using the Simulation Data Inspector UI or programmatic interface.

---

**Tip** When you compare data using the Simulation Data Inspector UI, results are not returned in the workspace. You can use the `Simulink.sdi.DiffRunResult.getLatest` function to access results for comparisons performed using the Simulation Data Inspector UI. When you compare data using the `Simulink.sdi.compareRuns` or `Simulink.sdi.compareSignals` functions, the function returns the data in a `Simulink.sdi.DiffRunResult` object or a `Simulink.sdi.DiffSignalResult` object.

---

### Examples

#### Access Results for a UI Comparison

Use the `Simulink.sdi.DiffRunResult.getLatest` function to access the results of the most recent comparison to save or process further. For more information about how to compare data using the Simulation Data Inspector UI, see “Compare Simulation Data”.

```
compResults = Simulink.sdi.DiffRunResult.getLatest;
```

#### Retrieve Comparison Results in a Workspace Variable

You can use the `Simulink.sdi.getCurrentComparison` function or the `Simulink.sdi.DiffRunResult.getResult` function to retrieve the results for the most recent comparison if you accidentally delete the returned results from the workspace using the `clear` function.

If you delete the contents of the Simulation Data Inspector using the `Simulink.sdi.clear` function, you cannot recover the results.

#### Compare Simulation Data

This example creates runs to compare by running two simulations of the model `ex_vdp` with different values for `Mu`.

```
load_system('ex_vdp')
```

```
set_param('ex_vdp/Mu', 'Gain', '2');
out1 = sim('ex_vdp');
```

```
set_param('ex_vdp/Mu', 'Gain', '5');
out2 = sim('ex_vdp');
```

Use the `Simulink.sdi.getAllRunIDs` function to access the run IDs for the runs created from the simulations. Then use the `Simulink.sdi.compareRuns` function to compare the data.

```
IDs = Simulink.sdi.getAllRunIDs;
runID1 = IDs(end-1);
runID2 = IDs(end);
```

```
diffRun = Simulink.sdi.compareRuns(runID1, runID2);
```

Suppose you clear the workspace and lose the `diffRun` variable with the comparison results.

```
clear diffRun
```

### Retrieve Comparison Data in the Workspace

Use the `Simulink.sdi.getCurrentComparison` function to recover the comparison results.

```
diffRun = Simulink.sdi.getCurrentComparison
```

```
diffRun =
 DiffRunResult with properties:

 MatlabVersion: '9.14.0.2206163 (R2023a)'
 RunID1: 362
 RunID2: 383
 BaselineRunName: 'Run 1: ex_vdp'
 CompareToRunName: 'Run 2: ex_vdp'
 Count: 2
 DateCreated: 04-Mar-2023 02:12:43
 GlobalTolerance: [1x1 struct]
 Summary: [1x1 struct]
 Options: {'Units' 'MustMatch'}
 Status: Completed
 StopReason: []
```

You could also use the `Simulink.sdi.DiffRunResult.getLatest` function to recover the results.

```
clear diffRun
```

```
diffRun = Simulink.sdi.DiffRunResult.getLatest
```

```
diffRun =
 DiffRunResult with properties:

 MatlabVersion: '9.14.0.2206163 (R2023a)'
 RunID1: 362
 RunID2: 383
 BaselineRunName: 'Run 1: ex_vdp'
 CompareToRunName: 'Run 2: ex_vdp'
 Count: 2
 DateCreated: 04-Mar-2023 02:12:43
 GlobalTolerance: [1x1 struct]
```

```
Summary: [1x1 struct]
Options: {'Units' 'MustMatch'}
Status: Completed
StopReason: []
```

## Output Arguments

### **diffRes** — Results of most recent comparison

`Simulink.sdi.DiffRunResult` object

Results of the most recent comparison, returned as a `Simulink.sdi.DiffRunResult` object.

## Version History

**Introduced in R2020a**

### See Also

“Compare Simulation Data”

# Simulink.sdi.enablePCTSupport

Control when to import data from parallel simulations into the Simulation Data Inspector

## Syntax

```
Simulink.sdi.enablePCTSupport(mode)
```

## Description

`Simulink.sdi.enablePCTSupport(mode)` configures data import into the Simulation Data Inspector from parallel workers according to the mode specified by `mode`. You can configure the Simulation Data Inspector to import only data from local workers, or data from local and remote workers. You can also set the mode to manual, which allows you to manually import runs into the Simulation Data Inspector using the `Simulink.sdi.sendWorkerRunToClient` function. By default, the Simulation Data Inspector is configured for the manual import mode.

## Examples

### Enable Automatic Data Import for All Parallel Workers

Configure Simulation Data Inspector parallel worker support to import the output automatically from both local and remote workers.

```
Simulink.sdi.enablePCTSupport('all')
```

### Disable Automatic Data Import from Parallel Workers

To prevent the output from Parallel Computing Toolbox workers from automatically importing into the Simulation Data Inspector, specify the manual support mode.

```
Simulink.sdi.enablePCTSupport('manual')
```

### Manually Send Runs from Parallel Workers to the Simulation Data Inspector

This example shows how to use `Simulink.sdi.sendWorkerRunToClient` to send runs created using parallel workers manually to the Simulation Data Inspector.

#### Setup

This example runs several simulations of the `vdp` model, varying the value of the gain, `Mu`. To set up for the parallel simulation, define a vector of `Mu` values and configure the Simulation Data Inspector for manual Parallel Computing Toolbox support.

```
% Enable manual Parallel Computing Toolbox support
Simulink.sdi.enablePCTSupport('manual');
```

```
% Choose several Mu values
MuVals = [1 2 3 4];
```

### Initialize Parallel Workers

Use `parpool` (Parallel Computing Toolbox) to start a pool of four parallel workers. This example calls `parpool` inside an if statement so you only create a parallel pool if you don't already have one. You can use `spmd` (Parallel Computing Toolbox) to run initialization code common to all workers. For example, load the `vdp` model and select signals to log to runs that we can send to the Simulation Data Inspector on the client MATLAB. To avoid data concurrency issues when simulating with `sim` in `parfor`, create a temporary directory on each worker. After the simulations complete, another `spmd` block deletes the temporary directories.

```
p = gcp('nocreate');
```

```
if isempty(p)
```

```
 parpool(4);
```

```
end
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 4 workers.
```

```
spmd
```

```
 % Load system and select signals to log
 load_system('vdp')
 Simulink.sdi.markSignalForStreaming('vdp/x1',1,'on')
 Simulink.sdi.markSignalForStreaming('vdp/x2',1,'on')

 % Create temporary directory for simulation on worker
 workDir = pwd;
 addpath(workDir)
 tempDir = tempname;
 mkdir(tempDir)
 cd(tempDir)
```

```
end
```

### Run Parallel Simulations with parfor

To stream data from parallel workers to the Simulation Data Inspector, you have to run parallel simulations using `parfor` (Parallel Computing Toolbox). Each worker runs a `vdp` simulation with a different value of `Mu`. Simulink cannot access the contents of the `parfor` loop, so the variable `MuVal` is defined in the worker's workspace, where the `vdp` model can see it, using `assignin`.

```
parfor (index = 1:4)
```

```
 % Set value of Mu in the worker's base workspace
 assignin('base','MuVal',MuVals(index));

 % Modify the value of Mu in the model and simulate
 set_param('vdp/Mu','Gain','MuVal')
 sim('vdp')
```

## Access Data and Send Run to Client MATLAB

You can use the Simulation Data Inspector programmatic interface on the worker the same way you would in the client MATLAB. This example creates a `Simulink.sdi.Run` object and attaches the value of `Mu` used in the simulation with the `Tag` property.

```
% Attach metadata to the run
IDs = Simulink.sdi.getAllRunIDs;
lastIndex = length(IDs);
runID = Simulink.sdi.getRunIDByIndex(lastIndex);
parRun = Simulink.sdi.getRun(runID);
parRun.Tag = strcat('Mu = ', num2str(MuVals(index)));

% Send the run to the Simulation Data Inspector on the client MATLAB
Simulink.sdi.sendWorkerRunToClient
```

```
end
```

## Close Temporary Directories and View Runs in the Simulation Data Inspector

Use another `spm` section to delete the temporary directories created on the workers once the simulations complete. In each simulation, `Simulink.sdi.sendWorkerRunToClient` imported runs from all the workers into the Simulation Data Inspector. You can view the data and check the run properties to see the value of `Mu` used during simulation.

```
spmd
```

```
% Remove temporary directories
cd(workDir)
rmdir(tempDir, 's')
rmpath(workDir)
```

```
end
```

```
Simulink.sdi.view
```

## Access Data from a Parallel Simulation

This example executes parallel simulations of the model `slexAircraftExample` with different input filter time constants and shows several ways to access the data using the Simulation Data Inspector programmatic interface.

### Setup

Start by ensuring the Simulation Data Inspector is empty and Parallel Computing Toolbox support is configured to import runs created on local workers automatically. Then, create a vector of filter parameter values to use in each simulation.

```
% Make sure the Simulation Data Inspector is empty, and PCT support is
% enabled.
Simulink.sdi.clear
Simulink.sdi.enablePCTSupport('local')

% Define Ts values
Ts_vals = [0.01, 0.02, 0.05, 0.1, 0.2, 0.5, 1];
```

### Initialize Parallel Workers

Use `gcp` to create a pool of local workers to run parallel simulations if you don't already have one. In an `spmd` code block, load the `slexAircraftExample` model and select signals to log. To avoid data concurrency issues using `sim` in `parfor`, create a temporary directory for each worker to use during simulations.

```
p = gcp;
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 4 workers.
```

```
spmd
```

```
% Load system and select signals to log
load_system('slexAircraftExample')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, 'on')

% Create temporary directory on each worker
workDir = pwd;
addpath(workDir)
tempDir = tempname;
mkdir(tempDir)
cd(tempDir)
```

```
end
```

### Run Parallel Simulations

Use `parfor` to run the seven simulations in parallel. Select the value for `Ts` for each simulation, and modify the value of `Ts` in the model workspace. Then, run the simulation and build an array of `Simulink.sdi.WorkerRun` objects to access the data with the Simulation Data Inspector. After the `parfor` loop, use another `spmd` segment to remove the temporary directories from the workers.

```
parfor index = 1:7
```

```
% Select value for Ts
Ts_val = Ts_vals(index);

% Change the filter time constant and simulate
modelWorkspace = get_param('slexAircraftExample', 'modelworkspace');
modelWorkspace.assignin('Ts', Ts_val)
sim('slexAircraftExample')

% Create a worker run for each simulation
workerRun(index) = Simulink.sdi.WorkerRun.getLatest
```

```
end
```

```
spmd
```

```
% Remove temporary directories
cd(workDir)
rmdir(tempDir, 's')
rmpath(workDir)
```

```
end
```

## Get Dataset Objects from Parallel Simulation Output

The `getDataset` method puts the data from a `WorkerRun` into a `Dataset` object so you can easily post-process.

```
ds(7) = Simulink.SimulationData.Dataset;

for a = 1:7
 ds(a) = workerRun(a).getDataset;
end
ds(1)

ans =
Simulink.SimulationData.Dataset '' with 2 elements
```

|                | Name       | BlockPath                                |
|----------------|------------|------------------------------------------|
| 1 [1x1 Signal] | alpha, rad | ...rcraftExample/Aircraft Dynamics Model |
| 2 [1x1 Signal] | Stick      | slexAircraftExample/Pilot                |

- Use braces { } to access, modify, or add elements using index.

## Get DatasetRef Objects from Parallel Simulation Output

For big data workflows, use the `getDatasetRef` method to reference the data associated with the `WorkerRun`.

```
for b = 1:7
 datasetRef(b) = workerRun(b).getDatasetRef;
end

datasetRef(1)

ans =
DatasetRef with properties:
 Name: 'Run 3: slexAircraftExample'
 Run: [1x1 Simulink.sdi.Run]
 numElements: 2
```

## Process Parallel Simulation Data in the Simulation Data Inspector

You can also create local `Run` objects to analyze and visualize your data using the Simulation Data Inspector API. This example adds a tag indicating the filter time constant value for each run.

```
for c = 1:7

 Runs(c) = workerRun(c).getLocalRun;
 Ts_val_str = num2str(Ts_vals(c));
 desc = strcat('Ts = ', Ts_val_str);
 Runs(c).Description = desc;
 Runs(c).Name = strcat('slexAircraftExample run Ts=', Ts_val_str);

end
```

## Clean Up Worker Repositories

Clean up the files used by the workers to free up disk space for other simulations you want to run on your worker pool.

```
Simulink.sdi.cleanupWorkerResources
```

## Input Arguments

### mode — Parallel worker data import mode

```
'manual' (default) | 'local' | 'all'
```

Simulation Data Inspector data import mode for data logged on parallel workers, specified as one of these options:

- 'manual' — Do not automatically import runs created on parallel workers. You can manually import runs created on parallel workers using the `Simulink.sdi.sendWorkerRunToClient` function.
- 'local' — Automatically import runs created on local workers.
- 'all' — Automatically import runs created on local and remote workers.

Data Types: char | string

## Alternative Functionality

You can modify the parallel computing support mode in the Simulation Data Inspector by selecting **Preferences > Parallel**.

## Version History

Introduced in R2017b

**R2020a: 'none' input is no longer supported***Errors starting in R2020a*

Starting in R2020a, the `Simulink.sdi.enablePCTSupport` function no longer supports the 'none' input option. To disable automatic import of data logged on parallel workers into the Simulation Data Inspector, use the 'manual' option.

**R2020a: Logical inputs are ignored***Behavior changed in R2020a*

Starting in R2020a, the `Simulink.sdi.enablePCTSupport` function ignores logical inputs. In scripts that specify a logical input for the `Simulink.sdi.enablePCTSupport` function, replace a `0` or `false` input with the 'manual' input option and a `1` or `true` input with the 'all' option to achieve equivalent behavior.

**R2018a: Input values have changed***Behavior changed in R2018a*

Starting in R2018a, the `Simulink.sdi.enablePCTSupport` input values changed to:

- 'local'
- 'none'
- 'all'
- 'manual'

In R2017b, the `Simulink.sdi.enablePCTSupport` function accepted a logical input to enable or disable Simulation Data Inspector support for data logged in parallel simulations.

- `true` or `1` enables support for automatically importing data from all parallel workers into the Simulation Data Inspector.

In R2018a, use the 'all' option for the same behavior. You can also use the new 'local' input when you want to automatically import data only from local workers.

- `false` or `0` disables all support for importing data logged on parallel workers.

In R2018a, use the 'none' option for the same behavior. You can also use the new 'manual' option when you want to analyze data on the worker to determine whether you want to import individual runs into the Simulation Data Inspector from a parallel worker.

## Simulink.sdi.exportRun

Export Simulation Data Inspector run data to the workspace or a file

### Syntax

```
dataset = Simulink.sdi.exportRun(runID)
Simulink.sdi.exportRun(runID,Name,Value)
```

### Description

`dataset = Simulink.sdi.exportRun(runID)` creates a `Simulink.SimulationData.Dataset` object in the base workspace with the data in the Simulation Data Inspector run identified by `runID`.

`Simulink.sdi.exportRun(runID,Name,Value)` exports the data in the run corresponding to `runID` to the base workspace or a file according to the options specified by one or more name-value pair arguments. You can export data for one or more runs to a MAT, MLDATX, or Microsoft Excel file. To export data for multiple runs to a file, you can specify the `runIDs` input as a vector of run IDs.

### Examples

#### Export Run Data

This example shows how to export data from a run in the Simulation Data Inspector to a `Simulink.SimulationData.Dataset` object in the base workspace that you can use to further process your data. The method you choose to export your run depends on the processing you do in your script. If you have a run object for the run, you can use the `export` method to create a `Simulink.SimulationData.Dataset` object with the run data in the base workspace. If you do not have a run object, use the `Simulink.sdi.exportRun` function to export the run to the workspace.

#### Export Run Using Simulink.sdi.exportRun

Use the `Simulink.sdi.export` function to export run data to the workspace or a file when your workflow does not include creating a run object.

To create a run of simulation data, open the `vdp` model, mark signals for logging, and run a simulation.

```
load_system('vdp')

SignalHandles = get_param('vdp', 'Lines');

Simulink.sdi.markSignalForStreaming(SignalHandles(5).Handle, 'on')
Simulink.sdi.markSignalForStreaming(SignalHandles(6).Handle, 'on')

out = sim('vdp');
```

Use the `Simulink.sdi.getAllRunIDs` function to access the most recently created run.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

Use the `Simulink.sdi.exportRun` function to export the run data to a `Dataset` object in the workspace.

```
simDataset = Simulink.sdi.exportRun(runID);
```

### Export Run Using the export Function

When your task involves creating a Run object, you can use the `export` function to create a `Simulink.SimulationData.Dataset` object in the base workspace to further process the run data. For example, suppose you need to access Run objects for simulation runs with signal data you want to compare using the `Simulink.sdi.compareSignals` function.

Load a model and mark signals for logging. Then simulate the model to create run data.

```
load_system('vdp')

SignalHandles = get_param('vdp', 'Lines');

Simulink.sdi.markSignalForStreaming(SignalHandles(5).Handle, 'on')
Simulink.sdi.markSignalForStreaming(SignalHandles(6).Handle, 'on')

sim('vdp');
```

Use the `Simulink.sdi.getAllRunIDs` function to access the run ID for the most recently created run. Then, use the `Simulink.sdi.getRun` function to access the Run object corresponding to the run.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
vdpRun = Simulink.sdi.getRun(runID);
```

Use the `export` function to export the run data to a `Dataset` object in the workspace.

```
simDataset = export(vdpRun);
```

## Input Arguments

### runID — Run identifier

scalar | vector

Run identifier for the run you want to export to the workspace or a file. When you export data to a file, you can export more than one run by specifying the `runID` input as a vector of Simulation Data Inspector run IDs.

The Simulation Data Inspector assigns a unique run ID to each run. You can get the run ID for one or more runs using `Simulink.sdi.getAllRunIDs` and `Simulink.sdi.getRunIDByIndex`.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'to', 'file'

### **to — Where to export data**

'variable' (default) | 'file'

Where to export data, specified as the comma-separated pair consisting of 'to' and 'variable' or 'file'.

When you export data to a file, you must also specify a file name using the 'filename' name-value pair argument. You can specify a file name with a .mat, .mlatx, or .xlsx extension.

When you export a run to a MAT-file, the data is saved in a `Simulink.SimulationData.Dataset` object. When you export more than one run to a MAT-file using the `Simulink.sdi.exportRun` function, the data is saved in a `Dataset` object, where each element is a `Dataset` object that contains the data for one exported run.

Data exported to a Microsoft Excel file is saved using the format described in “Microsoft Excel Import, Export, and Logging Format”.

When you export data to a Microsoft Excel file, you can specify additional options using the 'overwrite', 'metadata', and 'sharetimecolumn' name-value pairs.

Example: 'to', 'file'

### **filename — Name of file to contain exported data**

string | character array

Name of the file to contain the exported data, specified as the comma-separated pair consisting of 'filename' and a string or character array. Include a .mat, .mlatx, or .xlsx extension in the file name to specify whether to export the data to a MAT-file, MLATX file, or a Microsoft Excel file. When you do not specify an extension with a file name, the data exports to a MAT-file.

Use the 'filename' name-value pair argument when you specify the 'to' name-value pair argument with the value 'file'.

When you export data to a Microsoft Excel file, you can specify additional options using the 'overwrite', 'metadata', and 'sharetimecolumn' name-value pair arguments.

Example: 'filename', "mySpreadsheet.xlsx"

### **overwrite — Data to overwrite in existing Microsoft Excel file**

'file' (default) | 'sheetonly'

Data to overwrite in existing Microsoft Excel file, specified as the comma-separated pair consisting of 'overwrite' and 'file' or 'sheetonly'.

- 'file' — Overwrite the entire file with the exported data.
- 'sheetonly' — Only overwrite sheets of the Microsoft Excel file with data that corresponds to the exported data.

When you export data to an existing MAT-file or MLATX file, the exported data overwrites the entire file.

Example: 'overwrite', 'sheetonly'

**metadata — Metadata to include in exported Microsoft Excel file**

[] (default) | string array

Metadata to include in the exported Microsoft Excel file, specified as the comma-separated pair consisting of 'metadata' and a string array. By default, the export operation does not include any metadata. You can export this metadata to the Microsoft Excel file:

- `dataType` — Signal data type
- `units` — Signal units
- `blockPath` — Path to the source block for logged signals
- `interp` — Signal interpolation method
- `portIndex` — Index of the port on the source block for logged signals

You can specify the desired metadata in any order you choose in the string array. The order of the metadata in the string array does not affect the format in the exported file, which always matches the description in “Microsoft Excel Import, Export, and Logging Format”.

Example: 'metadata', ["units", "dataType"]

**sharetimecolumn — Whether signals share time columns in exported Microsoft Excel file**

'on' (default) | 'off'

Whether signals that have identical time data share time columns in the exported Microsoft Excel file, specified as the comma-separated pair consisting of 'sharetimecolumn' and 'on' or 'off'. By default, signals with the same time data share a time column in the exported file. When you specify the value as 'off', each signal in the exported file has its own time column.

Example: 'sharetimecolumn', 'off'

## Output Arguments

**dataset — Dataset containing run data**

Simulink.SimulationData.Dataset

Simulink.SimulationData.Dataset object containing the data from the run identified by runID.

## Version History

Introduced in R2017a

“Save and Share Simulation Data Inspector Data and Views”

## Simulink.sdi.getAllRunIDs

**Package:** Simulink.sdi

Get all Simulation Data Inspector run identifiers

### Syntax

```
runIDs = Simulink.sdi.getAllRunIDs
```

### Description

`runIDs = Simulink.sdi.getAllRunIDs` returns a matrix of the run identifiers for all runs in the Simulation Data Inspector repository.

### Examples

#### Get Simulation Data Inspector Run IDs

Many tasks performed using the Simulation Data Inspector programmatic interface start with obtaining the run ID for a simulation run. This example illustrates several methods to get the run ID for a run. You can use the run ID to access the `Simulink.sdi.Run` object that contains the run data and metadata and perform run comparisons using the `Simulink.sdi.compareRuns` function.

#### Create a Run

The model `sldemo_fuelsys` is already configured for logging. When you simulate the model, the Simulation Data Inspector automatically creates a run and assigns it a run ID.

```
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

#### Get Run ID Using Simulink.sdi.getAllRunIDs

The `Simulink.sdi.getAllRunIDs` function returns an array of all run IDs for the runs in the Simulation Data Inspector repository, in order, with the most recently created run at the end.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

#### Get Run ID Using Simulink.sdi.getRunIDByIndex

You can also use the `Simulink.sdi.getRunCount` and `Simulink.sdi.getRunIDByIndex` functions to get the run ID for a run. This method is useful if you also want to use `count` as a counting variable to index through the runs in the Simulation Data Inspector repository.

```
count = Simulink.sdi.getRunCount;
runID = Simulink.sdi.getRunIDByIndex(count);
```

#### Get Run ID from a Simulink.sdi.Run Object

You can also get the run ID from the `Simulink.sdi.Run` object that corresponds to the run. This example uses the `Simulink.sdi.getCurrentSimulationRun` function to get the Run object that

corresponds to the most recent simulation of the `sldemo_fuelsys` model. You can also use the `Simulink.sdi.Run.getLatest` function to access the most recently created Run object.

```
fuelsysRun = Simulink.sdi.getCurrentSimulationRun('sldemo_fuelsys');
runID = fuelsysRun.ID;
```

## Output Arguments

### **runIDs** — Matrix of Simulation Data Inspector run IDs

matrix

Matrix of run IDs in the Simulation Data Inspector repository.

## Version History

Introduced in R2017a

### See Also

## Simulink.sdi.appendRunToTop

Get order in which Simulation Data Inspector appends run in work area or archive

### Syntax

```
ord = Simulink.sdi.appendRunToTop
```

### Description

`ord = Simulink.sdi.appendRunToTop` returns a logical value that indicates whether the Simulation Data Inspector appends a new run above or below prior runs in the archive or work area.

- 1 — New runs are placed above prior runs in the work area or archive.
- 0 — New runs are placed below prior runs in the work area or archive.

Whether the `Simulink.sdi.appendRunToTop` function gets the order of simulations in the archive or the work area is determined by the **Automatically archive** setting:

- When **Automatically archive** is enabled, the setting applies to runs in the archive.
- When **Automatically archive** is disabled, the setting applies to runs in the work area.

By default, new runs are placed below prior runs in the archive. For more information about configuring the archive behavior, see `Simulink.sdi.setAutoArchiveMode`.

### Examples

#### Change Order and Location of Runs

First, determine the order that runs are currently stored in the archive.

```
ord = Simulink.sdi.appendRunToTop
```

```
ord = logical
 0
```

By default, runs moved into the archive are placed below runs already in the archive. To have runs placed above the runs already in the archive, change the value of the `Simulink.sdi.appendRunToTop` function.

```
Simulink.sdi.appendRunToTop(true)
```

You can restore the original placement of runs as they move to the archive by passing `ord` back to the set function.

```
Simulink.sdi.appendRunToTop(ord)
```

## Output Arguments

**ord** — Whether Simulation Data Inspector appends new runs to top of work area or archive

true or 1 | false or 0

Whether Simulation Data Inspector appends new runs to top of work area or archive, returned as logical 1 (true) or 0 (false).

## Version History

Introduced in R2022b

### See Also

[Simulink.sdi.appendRunToTop](#) | [Simulink.sdi.setAutoArchiveMode](#) | [Simulink.sdi.setAutoArchiveMode](#)

### Topics

“Configure the Simulation Data Inspector”

## Simulink.sdi.getArchiveRunLimit

Get limit for number of runs to retain in Simulation Data Inspector archive

### Syntax

```
limit = Simulink.sdi.getArchiveRunLimit
```

### Description

`limit = Simulink.sdi.getArchiveRunLimit` returns the limit on the number of runs the Simulation Data Inspector retains in the archive. A return of -1 indicates no limit on the number of runs.

When you run multiple simulations in a single MATLAB session, the Simulation Data Inspector retains results from each simulation so you can analyze the results together. Use the Simulation Data Inspector archive to manage the number of runs the Simulation Data Inspector retains and to visually manage runs in the user interface.

---

**Tip** To automatically limit the number of runs, configure the Simulation Data Inspector to automatically move prior runs into the archive using the `Simulink.sdi.setAutoArchiveMode` function and specify the archive run limit.

For information about how to control the amount of data logged from simulation, see “Limit the Size of Logged Data”.

---

### Examples

#### Stop Retaining Data in Simulation Data Inspector

You can configure the Simulation Data Inspector to retain only the logged data for your current simulation. In iterative design and debugging workflows, this configuration helps prevent the accumulation of unwanted logged data on disk.

First, check the configuration of the Simulation Data Inspector archive. Save the archive preference values to restore your preferences after you finish designing or debugging.

```
limit = Simulink.sdi.getArchiveRunLimit;
mode = Simulink.sdi.getAutoArchiveMode;
```

Configure the Simulation Data Inspector to automatically move runs into the archive. Then, set the archive run limit to 0.

```
Simulink.sdi.setAutoArchiveMode(true)
Simulink.sdi.setArchiveRunLimit(0)
```

When you simulate your model, the Simulation Data Inspector deletes the previous run and updates the view to show signals from the current simulation.

When you finish designing or debugging your model, you can restore the Simulation Data Inspector archive to the previous configuration.

```
Simulink.sdi.setArchiveRunLimit(limit)
Simulink.sdi.setAutoArchiveMode(mode)
```

## Output Arguments

**limit** — Maximum number of runs to store in Simulation Data Inspector archive

numeric scalar

Maximum number of runs to store in Simulation Data Inspector archive, returned as a numeric scalar. A value of -1 indicates no limit on the number of runs to retain in the archive.

## Version History

**Introduced in R2018b**

### See Also

`Simulink.sdi.setArchiveRunLimit` | `Simulink.sdi.setAutoArchiveMode` | `Simulink.sdi.getAutoArchiveMode`

### Topics

“Limit the Size of Logged Data”

“Configure the Simulation Data Inspector”

## Simulink.sdi.getAutoArchiveMode

Get Simulation Data Inspector run management mode

### Syntax

```
archive = Simulink.sdi.getAutoArchiveMode
```

### Description

`archive = Simulink.sdi.getAutoArchiveMode` returns a logical value that indicates whether the Simulation Data Inspector automatically manages runs using the archive.

- 1 — When you start a new simulation, the Simulation Data Inspector automatically moves the prior simulation run into the archive. In the user interface, the run moves into the collapsible **Archive** pane, and plots update to show data from the current simulation.
- 0 — The Simulation Data Inspector does not manage runs automatically with the archive or update plots.

### Examples

#### Stop Retaining Data in Simulation Data Inspector

You can configure the Simulation Data Inspector to retain only the logged data for your current simulation. In iterative design and debugging workflows, this configuration helps prevent the accumulation of unwanted logged data on disk.

First, check the configuration of the Simulation Data Inspector archive. Save the archive preference values to restore your preferences after you finish designing or debugging.

```
limit = Simulink.sdi.getArchiveRunLimit;
mode = Simulink.sdi.getAutoArchiveMode;
```

Configure the Simulation Data Inspector to automatically move runs into the archive. Then, set the archive run limit to 0.

```
Simulink.sdi.setAutoArchiveMode(true)
Simulink.sdi.setArchiveRunLimit(0)
```

When you simulate your model, the Simulation Data Inspector deletes the previous run and updates the view to show signals from the current simulation.

When you finish designing or debugging your model, you can restore the Simulation Data Inspector archive to the previous configuration.

```
Simulink.sdi.setArchiveRunLimit(limit)
Simulink.sdi.setAutoArchiveMode(mode)
```

## Output Arguments

**archive** — Whether Simulation Data Inspector automatically manages runs using archive

true or 1 | false or 0

Whether Simulation Data Inspector automatically manages runs using archive, returned as logical 1 (true) or 0 (false).

## Version History

Introduced in R2018b

## Simulink.sdi.getBorderOn

Get border display setting for time plots

### Syntax

```
border = Simulink.sdi.getBorderOn
```

### Description

`border = Simulink.sdi.getBorderOn` returns the current setting for whether borders are displayed on time plots in the Simulation Data Inspector. The return value corresponds to the value of the **Show border** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector displays the border on time plots.

### Examples

#### Configure Time Plot Border Display

You can use the `Simulink.sdi.setBorderOn` function to show or hide the border on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector shows the border on time plots.

This example starts by showing how to use the `Simulink.sdi.getBorderOn` function to determine whether the border is currently displayed. Subsequent sections show the code to hide and show the border. To show the result, the example generates an image using the `Simulink.sdi.snapshot` function with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

#### Get Current Border Display Setting

Before modifying the border display setting for time plots, you can save the current setting to a variable in the workspace in case you want to restore the preference later.

```
border = Simulink.sdi.getBorderOn;
```

#### Hide the Border on Time Plots

```
Simulink.sdi.setBorderOn(false)
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Show the Border on Time Plots

```
Simulink.sdi.setBorderOn(true)
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Output Arguments

### **border** — Border display setting for time plots

true or 1 | false or 0

Border display setting for time plots in the Simulation Data Inspector, returned as true (1) or false (0).

- true or 1 — Border displayed for time plots.
- false or 0 — Border hidden for time plots.

## Version History

Introduced in R2019b

# Simulink.sdi.getCurrentComparison

Access results from most recent comparison

## Syntax

```
diffRes = Simulink.sdi.getCurrentComparison
```

## Description

`diffRes = Simulink.sdi.getCurrentComparison` returns the `Simulink.sdi.DiffRunResult` object `diffRes` for the most recent comparison performed using the Simulation Data Inspector UI or programmatic interface.

---

**Tip** When you compare data using the Simulation Data Inspector UI, results are not returned in the workspace. You can use the `Simulink.sdi.getCurrentComparison` function to access results for comparisons performed using the Simulation Data Inspector UI. When you compare data using the `Simulink.sdi.compareRuns` or `Simulink.sdi.compareSignals` functions, the function returns the data in a `Simulink.sdi.DiffRunResult` object or a `Simulink.sdi.DiffSignalResult` object.

---

## Examples

### Access Results for a UI Comparison

Use the `Simulink.sdi.getCurrentComparison` function to access the results of the most recent comparison to save or process further. For more information about how to compare data using the Simulation Data Inspector UI, see “Compare Simulation Data”.

```
compResults = Simulink.sdi.getCurrentComparison;
```

### Retrieve Comparison Results in a Workspace Variable

You can use the `Simulink.sdi.getCurrentComparison` function or the `Simulink.sdi.DiffRunResult.getResult` function to retrieve the results for the most recent comparison if you accidentally delete the returned results from the workspace using the `clear` function.

If you delete the contents of the Simulation Data Inspector using the `Simulink.sdi.clear` function, you cannot recover the results.

### Compare Simulation Data

This example creates runs to compare by running two simulations of the model `ex_vdp` with different values for `Mu`.

```
load_system('ex_vdp')
```

```
set_param('ex_vdp/Mu', 'Gain', '2');
out1 = sim('ex_vdp');

set_param('ex_vdp/Mu', 'Gain', '5');
out2 = sim('ex_vdp');
```

Use the `Simulink.sdi.getAllRunIDs` function to access the run IDs for the runs created from the simulations. Then use the `Simulink.sdi.compareRuns` function to compare the data.

```
IDs = Simulink.sdi.getAllRunIDs;
runID1 = IDs(end-1);
runID2 = IDs(end);

diffRun = Simulink.sdi.compareRuns(runID1, runID2);
```

Suppose you clear the workspace and lose the `diffRun` variable with the comparison results.

```
clear diffRun
```

### Retrieve Comparison Data in the Workspace

Use the `Simulink.sdi.getCurrentComparison` function to recover the comparison results.

```
diffRun = Simulink.sdi.getCurrentComparison

diffRun =
 DiffRunResult with properties:

 MatlabVersion: '9.14.0.2206163 (R2023a)'
 RunID1: 362
 RunID2: 383
 BaselineRunName: 'Run 1: ex_vdp'
 CompareToRunName: 'Run 2: ex_vdp'
 Count: 2
 DateCreated: 04-Mar-2023 02:12:43
 GlobalTolerance: [1x1 struct]
 Summary: [1x1 struct]
 Options: {'Units' 'MustMatch'}
 Status: Completed
 StopReason: []
```

You could also use the `Simulink.sdi.DiffRunResult.getLatest` function to recover the results.

```
clear diffRun

diffRun = Simulink.sdi.DiffRunResult.getLatest

diffRun =
 DiffRunResult with properties:

 MatlabVersion: '9.14.0.2206163 (R2023a)'
 RunID1: 362
 RunID2: 383
 BaselineRunName: 'Run 1: ex_vdp'
 CompareToRunName: 'Run 2: ex_vdp'
 Count: 2
 DateCreated: 04-Mar-2023 02:12:43
 GlobalTolerance: [1x1 struct]
```

```
Summary: [1x1 struct]
Options: {'Units' 'MustMatch'}
Status: Completed
StopReason: []
```

## Output Arguments

### **diffRes** — Results of most recent comparison

`Simulink.sdi.DiffRunResult` object

Results of the most recent comparison, returned as a `Simulink.sdi.DiffRunResult` object.

## Version History

**Introduced in R2020a**

### See Also

`Simulink.sdi.DiffRunResult` | `Simulink.sdi.DiffSignalResult` |  
`Simulink.sdi.compareRuns`

### Topics

“Compare Simulation Data”

## Simulink.sdi.getCurrentSimulationRun

Access data for in-progress or most recently completed simulation

### Syntax

```
runObj = Simulink.sdi.getCurrentSimulationRun mdl
```

### Description

`runObj = Simulink.sdi.getCurrentSimulationRun(mdl)` returns the `Simulink.sdi.Run` object that corresponds to the in-progress or most recently completed simulation of the model specified by `mdl`. If you delete the Run object that corresponds to the most recently completed simulation, the `Simulink.sdi.getCurrentSimulationRun` function returns empty.

### Examples

#### Access Simulation Data Inspector Runs

Many tasks performed using the Simulation Data Inspector programmatic interface start by accessing the `Simulink.sdi.Run` object that corresponds to the logged or imported data you want to analyze. For example, you can use the Run object to access the `Simulink.sdi.Signal` objects that correspond to individual signals in the run.

This example shows how to access Run objects by using the `Simulink.sdi.Run.getLatest` function, the `Simulink.sdi.getCurrentSimulationRun` function, or the `Simulink.sdi.getRun` function.

#### Create a Run

The model `sldemo_fuelsys` is already configured for logging. When you simulate the model, the Simulation Data Inspector automatically creates a run and assigns it a run ID.

```
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

#### Get Run Object Using Simulink.sdi.Run.getLatest

In this example, the run created when you simulated the model is the most recently created run in the Simulation Data Inspector. When you want to access the most recently created run, use the `Simulink.sdi.Run.getLatest` function.

```
fuelsysRun = Simulink.sdi.Run.getLatest;
```

#### Get Run Object Using Simulink.sdi.getCurrentSimulationRun

The run you want to access may not be the most recently created run in the Simulation Data Inspector. If the run corresponds to the most recent simulation of a model, you can use the `Simulink.sdi.getCurrentSimulationRun` function to access the Run object. You can also use the `Simulink.sdi.getCurrentSimulationRun` function to access data for an in-progress

simulation when the simulation streams data to the Simulation Data Inspector. This function can be useful when you are working with multiple models.

In this example, the run created when you simulated the model is the current simulation run for the `sldemo_fuelsys` model.

```
fuelsysRun = Simulink.sdi.getCurrentSimulationRun('sldemo_fuelsys');
```

### Get Run Object from a Run ID

When your task also requires the run ID, you can use the `Simulink.sdi.getRun` function to get the corresponding `Simulink.sdi.Run` object that contains the run data and metadata.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelsysRun = Simulink.sdi.getRun(runID);
```

## Input Arguments

### `mdl` — Model name

string | character vector

Name of the model that created the simulation data you want to access, specified as a string or character array.

Example: `'vdp'`

Data Types: `char` | `string`

## Output Arguments

### `runObj` — `Simulink.sdi.Run` object for the in-progress or most recently completed simulation

`Simulink.sdi.Run` object

`Simulink.sdi.Run` object that corresponds to the in-progress or most recently completed simulation.

## Tips

- You can use the `Simulink.sdi.getCurrentSimulationRun` function to access logged data in a `StopFcn` model callback function. Workspace variable data is not available when the `StopFcn` callback executes, but the `Run` object is available because data streams to the Simulation Data Inspector.
- You can use the `Simulink.sdi.getCurrentSimulationRun` function to analyze run data on parallel workers to determine whether to send the run data to the Simulation Data Inspector.

## Version History

Introduced in R2020a

“Inspect and Compare Data Programmatically”

# Simulink.sdi.getCursorPositions

Get position for active cursors in the Simulation Data Inspector

## Syntax

```
t1 = Simulink.sdi.getCursorPositions
t1 = Simulink.sdi.getCursorPositions(view)
[t1,t2] = Simulink.sdi.getCursorPositions
[t1,t2] = Simulink.sdi.getCursorPositions(view)
```

## Description

`t1 = Simulink.sdi.getCursorPositions` returns the value of the leftmost active cursor in the **Inspect** pane of the Simulation Data Inspector. Assign the return to a single output when one cursor is active.

`t1 = Simulink.sdi.getCursorPositions(view)` returns the value of the leftmost active cursor in the **Inspect** or **Compare** pane of the Simulation Data Inspector according to `view`. Assign the return to a single output when one cursor is active.

`[t1,t2] = Simulink.sdi.getCursorPositions` returns the positions of the active cursors in the **Inspect** pane of the Simulation Data Inspector.

`[t1,t2] = Simulink.sdi.getCursorPositions(view)` returns the positions of the active cursors in the **Inspect** or **Compare** pane of the Simulation Data Inspector according to `view`.

## Examples

### Programmatically Interact with Cursors in the Simulation Data Inspector

You can use the Simulation Data Inspector programmatic interface to specify the position of cursors on time plots or sparklines and to access the time that corresponds to the current cursor position.

Open the session file `vdp_mu.mldatx` to add plot data in the Simulation Data Inspector. The session file contains data for a 20-second simulation of a model of the Van Der Pol equation, with signals `x1` and `x2` plotted on separate subplots in a 2-by-1 subplot layout.

```
open vdp_mu.mldatx;
```

Use the `Simulink.sdi.setNumCursors` function to add one cursor to the plot.

```
Simulink.sdi.setNumCursors(1);
```

Suppose you want to know the signal values 5 seconds into the simulation. Use the `Simulink.sdi.setCursorPositions` function to move the cursor to `t=5s` and read the signal values off from the cursor on each subplot. The asterisk next to the value in the cursor label indicates that the value is interpolated because the simulation did not include a calculation for a simulation time of exactly 5s.

```
Simulink.sdi.setCursorPositions('left',5);
```

Suppose you want to calculate the time between two peaks in the x2 signal. Add a second cursor using the `Simulink.sdi.setNumCursors` function or by using Show/hide data cursors  in the Simulation Data Inspector.

```
numCursors = Simulink.sdi.getNumCursors;
if(numCursors < 2)
 Simulink.sdi.setNumCursors(2);
end
```

Drag the cursors so the left cursor is positioned at the first peak in the x2 signal and the right cursor is positioned at the second peak. Alternatively, you can run this code that positions the cursors for you.

```
Simulink.sdi.setCursorPositions('left',5.921998549931304,...
 'right',12.378442136906246);
```

The Simulation Data Inspector displays the difference between the two cursors in seconds. However, the cursor position and difference values are both rounded. Use the `Simulink.sdi.getCursorPositions` function to programmatically retrieve the exact time values that correspond to the cursor positions. Then, compute the difference between the times.

```
[t1,t2] = Simulink.sdi.getCursorPositions;
T = t2 - t1
```

```
T = 6.4564
```

## Input Arguments

**view** — Plot area on which to return cursor positions

'inspect' (default) | 'compare'

Plot area for which to return cursor positions, specified as 'inspect' or 'compare'.

Example: `[t1,t2] = Simulink.sdi.getCursorPositions('compare')` returns the positions of two cursors on the **Compare** pane of the Simulation Data Inspector.

Data Types: char | string

## Output Arguments

### **t1 — Left cursor position**

scalar

Left cursor position, returned as a scalar. When no cursors are active in the plot area specified by `view`, the value for `t1` is returned as `NaN`.

Cursor identities are relative, not absolute. If the left cursor moves to the right of the right cursor, the left cursor becomes the right cursor and vice versa.

### **t2 — Right cursor position**

scalar

Right cursor position, returned as a scalar. When fewer than two cursors are active in the plot area specified by `view`, the value for `t1` is returned as `NaN`.

Cursor identities are relative, not absolute. If the left cursor moves to the right of the right cursor, the left cursor becomes the right cursor and vice versa.

# Simulink.sdi.getDeleteRunsOnLowSpace

Get configured behavior when size of logged data approaches configured limits

## Syntax

```
deleteRuns = Simulink.sdi.getDeleteRunsOnLowSpace
```

## Description

`deleteRuns = Simulink.sdi.getDeleteRunsOnLowSpace` returns the configured behavior for when the size of logged data approaches a configured size limit or free disk space requirement. When `deleteRuns` is `true`, logged data from prior simulations is deleted first to free space for continued logging in the current simulation. If deleting prior simulation data does not free enough disk space to continue logging through the end of the current simulation, recording data is disabled. When `deleteRuns` is `false`, recording data from the current simulation is disabled and no logged data from prior simulations is deleted.

## Examples

### Get Configured Logging Size Limits

You can limit the size of logged data by specifying a maximum size for the data or a minimum amount of disk space to leave empty. This example uses several functions to get the current configuration of logging size limits.

Use the `Simulink.sdi.getRequiredFreeSpace` function to get the configured minimum free disk space requirement. The returned value uses units of GB.

```
minDiskSpace = Simulink.sdi.getRequiredFreeSpace;
```

Use the `Simulink.sdi.getMaxDiskUsage` function to get the configured maximum size for data logged to disk. The returned value uses units of GB.

```
maxSize = Simulink.sdi.getMaxDiskUsage;
```

Use the `Simulink.sdi.getDeleteRunsOnLowSpace` function to get the configured behavior when approaching the logging limits. When `deleteRuns` is `true`, data from prior simulations is deleted first to free disk space for continued logging in the current simulation. If deleting runs does not free up enough space, recording logged data is disabled for the current simulation. When `deleteRuns` is `false`, recording logged data is disabled for the current simulation and data from prior simulations is retained.

```
deleteRuns = Simulink.sdi.getDeleteRunsOnLowSpace;
```

## Output Arguments

**deleteRuns** — Behavior when logged data size approaches configured limits

1 | 0

Behavior when logged data size approaches configured limits, returned as 1 (`true`) or 0 (`false`).

- `true` — First delete data logged from prior simulations. If deleting prior simulation data does not free enough space, disable recording data.
- `false` — Disable recording data for current simulation. Do not delete prior simulation data.

When recording is disabled due to configured disk space requirements or logged data size limits, you need to enable recording again to log data in subsequent simulations. You can configure the record mode in the Simulation Data Inspector preferences or by using the `Simulink.sdi.setRecordData` function.

## Version History

Introduced in R2021a

# Simulink.sdi.getGridOn

**Package:** Simulink.sdi

Determine grid configuration for time plots

## Syntax

```
grid = Simulink.sdi.getGridOn
```

## Description

`grid = Simulink.sdi.getGridOn` returns the grid configuration for time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector shows horizontal and vertical grid lines.

## Examples

### Configure Grid for Time Plots in the Simulation Data Inspector

You can use `Simulink.sdi.setGridOn` to configure the appearance of the grid for time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector shows horizontal and vertical grid lines.

This example starts by showing how to use `Simulink.sdi.getGridOn` to access the current grid configuration. The subsequent sections show the code for each configuration option for time plot grid in the Simulation Data Inspector. To see the result, the example uses a `Simulink.sdi.CustomSnapshot` object to specify settings for the output of the `Simulink.sdi.snapshot` function.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

### Get Initial Grid Setting

Before modifying the grid display preferences, you can save the current configuration to a variable in the workspace in case you want to restore the preferences later.

```
gridInit = Simulink.sdi.getGridOn;
```

### Configure Horizontal Grid Lines

Show only horizontal grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('horizontal')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

### **Configure Vertical Grid Lines**

Show only vertical grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('vertical')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

### Configure No Grid Lines

Show no grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('off')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Configure Horizontal and Vertical Grid Lines

Show horizontal and vertical grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('on')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Output Arguments

### **grid** — Time plot grid configuration

'on' (default) | 'horizontal' | 'vertical' | 'off'

Grid configuration for time plots in the Simulation Data Inspector.

- 'on' — Horizontal and vertical grid lines are shown on time plots in the Simulation Data Inspector.
- 'horizontal' — Only horizontal grid lines are shown on time plots in the Simulation Data Inspector.
- 'vertical' — Only vertical grid lines are shown on time plots in the Simulation Data Inspector.
- 'off' — No grid lines are shown on time plots in the Simulation Data Inspector.

## Version History

**Introduced in R2019a**

### **R2019b: Simulink.sdi.getGridOn return values have changed**

*Behavior changed in R2019b*

Starting in R2019b, the `Simulink.sdi.getGridOn` return values changed to:

- 'on'
- 'horizontal'

- 'vertical'
- 'off'

In R2019a, the `Simulink.sdi.getGridOn` returned a logical value:

- `true` or `1` — Horizontal and vertical grid lines are shown on time plots in the Simulation Data Inspector.
- `false` or `0` — Horizontal and vertical grid lines are hidden on time plots in the Simulation Data Inspector.

Starting in R2019b, the 'on' return value is equivalent to the `true` or `1` return, and the 'off' return value is equivalent to the `false` or `0` return.

# Simulink.sdi.getMarkersOn

**Package:** Simulink.sdi

Determine if data markers are shown in the Simulation Data Inspector

## Syntax

```
markersOn = Simulink.sdi.getMarkersOn
```

## Description

`markersOn = Simulink.sdi.getMarkersOn` returns a logical value indicating whether data markers are displayed on plots in the Simulation Data Inspector.

## Examples

### Store Marker State

You can check and store the value of the **Show markers** setting in the Simulation Data Inspector from the command window or in a script.

```
markersOn = Simulink.sdi.getMarkersOn;
```

## Output Arguments

**markersOn** — Logical indication of marker state

false or 0 (default) | true or 1

Logical indication of whether markers are displayed on plots in the Simulation Data Inspector.

- true or 1 indicates that markers are displayed.
- false or 0 indicates that markers are not displayed.

## Version History

Introduced in R2017b

## Simulink.sdi.getMaxDiskUsage

Get configured maximum size for data logged to disk

### Syntax

```
maxSize = Simulink.sdi.getMaxDiskUsage
```

### Description

`maxSize = Simulink.sdi.getMaxDiskUsage` returns the maximum size configured for data logged to disk, in units of GB.

### Examples

#### Get Configured Logging Size Limits

You can limit the size of logged data by specifying a maximum size for the data or a minimum amount of disk space to leave empty. This example uses several functions to get the current configuration of logging size limits.

Use the `Simulink.sdi.getRequiredFreeSpace` function to get the configured minimum free disk space requirement. The returned value uses units of GB.

```
minDiskSpace = Simulink.sdi.getRequiredFreeSpace;
```

Use the `Simulink.sdi.getMaxDiskUsage` function to get the configured maximum size for data logged to disk. The returned value uses units of GB.

```
maxSize = Simulink.sdi.getMaxDiskUsage;
```

Use the `Simulink.sdi.deleteRunsOnLowSpace` function to get the configured behavior when approaching the logging limits. When `deleteRuns` is true, data from prior simulations is deleted first to free disk space for continued logging in the current simulation. If deleting runs does not free up enough space, recording logged data is disabled for the current simulation. When `deleteRuns` is false, recording logged data is disabled for the current simulation and data from prior simulations is retained.

```
deleteRuns = Simulink.sdi.deleteRunsOnLowSpace;
```

### Output Arguments

**maxSize** — Maximum size configured for data logged to disk

scalar

Maximum size configured for data logged to disk, returned as a scalar, in units of GB.

## Version History

Introduced in R2021a

## Simulink.sdi.getNumCursors

Check number of cursors active in the Simulation Data Inspector

### Syntax

```
num = Simulink.sdi.getNumCursors
num = Simulink.sdi.getNumCursors(view)
```

### Description

`num = Simulink.sdi.getNumCursors` returns the number of active cursors in the **Inspect** pane of the Simulation Data Inspector.

`num = Simulink.sdi.getNumCursors(view)` returns the number of active cursors in the **Inspect** or **Compare** pane of the Simulation Data Inspector, as specified by `view`.

### Examples

#### Programmatically Interact with Cursors in the Simulation Data Inspector

You can use the Simulation Data Inspector programmatic interface to specify the position of cursors on time plots or sparklines and to access the time that corresponds to the current cursor position.

Open the session file `vdp_mu.mldatx` to add plot data in the Simulation Data Inspector. The session file contains data for a 20-second simulation of a model of the Van Der Pol equation, with signals `x1` and `x2` plotted on separate subplots in a 2-by-1 subplot layout.

```
open vdp_mu.mldatx;
```

Use the `Simulink.sdi.setNumCursors` function to add one cursor to the plot.

```
Simulink.sdi.setNumCursors(1);
```

Suppose you want to know the signal values 5 seconds into the simulation. Use the `Simulink.sdi.setCursorPositions` function to move the cursor to `t=5s` and read the signal values off from the cursor on each subplot. The asterisk next to the value in the cursor label indicates that the value is interpolated because the simulation did not include a calculation for a simulation time of exactly 5s.

```
Simulink.sdi.setCursorPositions('left',5);
```

Suppose you want to calculate the time between two peaks in the x2 signal. Add a second cursor using the `Simulink.sdi.setNumCursors` function or by using Show/hide data cursors  in the Simulation Data Inspector.

```
numCursors = Simulink.sdi.getNumCursors;
if(numCursors < 2)
 Simulink.sdi.setNumCursors(2);
end
```

Drag the cursors so the left cursor is positioned at the first peak in the x2 signal and the right cursor is positioned at the second peak. Alternatively, you can run this code that positions the cursors for you.

```
Simulink.sdi.setCursorPositions('left',5.921998549931304,...
 'right',12.378442136906246);
```

The Simulation Data Inspector displays the difference between the two cursors in seconds. However, the cursor position and difference values are both rounded. Use the `Simulink.sdi.getCursorPosition` function to programmatically retrieve the exact time values that correspond to the cursor positions. Then, compute the difference between the times.

```
[t1,t2] = Simulink.sdi.getCursorPosition;
T = t2 - t1
```

```
T = 6.4564
```

## Input Arguments

**view** — Plot area for which to return number of active cursors

'inspect' (default) | 'compare'

Plot area for which to return number of active cursors, specified as 'inspect' or 'compare'.

Data Types: char | string

## Output Arguments

**num** — Number of active cursors

0 | 1 | 2

Number of active cursors, returned as 0, 1, or 2.

## Version History

Introduced in R2021a

## Simulink.sdi.getPosition

Get position and size of Simulation Data Inspector

### Syntax

```
pos = Simulink.sdi.getPosition
```

### Description

`pos = Simulink.sdi.getPosition` returns a four-element vector in the form `[left bottom width height]` indicating the position and size of the Simulation Data Inspector window. If the Simulation Data Inspector is not open, `Simulink.sdi.getPosition` returns `[0 0 0 0]`.

### Examples

#### Change Position of Simulation Data Inspector

This example shows you how to change the position and size of the Simulation Data Inspector window. First, open the Simulation Data Inspector.

```
Simulink.sdi.view
```

Set the Simulation Data Inspector window to be:

- 800 pixels wide
- 500 pixels high
- 200 pixels from the left edge of your primary display
- 60 pixels from the bottom of your primary display

```
pos = [200 60 800 500];
Simulink.sdi.setPosition(pos)
```

Alternatively, you can move and resize the Simulation Data Inspector manually. To use this placement in future simulations, retrieve the position vector using the function `Simulink.sdi.getPosition`.

```
newPos = Simulink.sdi.getPosition
```

```
newPos = 1×4
```

```
 200 60 800 500
```

### Output Arguments

**pos** — Position and size of Simulation Data Inspector  
`[left bottom width height]`

Position and size of the Simulation Data Inspector window, specified as a four-element vector in the form [left bottom width height]. All measurements have units of pixels.

| Element | Description                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| left    | Distance from the left edge of the primary display to the inner-left edge of the window. This value can be negative on systems that have more than one monitor.     |
| bottom  | Distance from the bottom edge of the primary display to the inner-bottom edge of the window. This value can be negative on systems that have more than one monitor. |
| width   | Distance between the right and left inner edges of the window.                                                                                                      |
| height  | Distance between the top and bottom inner edges of the window.                                                                                                      |

## Simulink.sdi.getRecordData

Check record mode for logging

### Syntax

```
record = Simulink.sdi.getRecordData
```

### Description

`record = Simulink.sdi.getRecordData` returns the currently configured value for the **Record mode** in the Simulation Data Inspector preferences. When `record` is `true` or `1`, logged data is available to view during simulation and is recorded to the Simulation Data Inspector and workspace for analysis after simulation. When `record` is `false` or `0`, logged data is not recorded and is only available to view during simulation.

### Examples

#### Check Record Mode for Logging

You can use the `Simulink.sdi.getRecordData` function to check the configuration before starting a simulation to ensure you record data you want to save.

```
record = Simulink.sdi.getRecordData
```

```
record =
```

```
 logical
```

```
 1
```

The **Record mode** setting is restored to **View and record data** at the start of each MATLAB session.

### Output Arguments

**record** — Record mode

1 | 0

Record mode, returned as 1 (true) or 0 (false).

- 1 — Logged data is stored on disk and available in the workspace and Simulation Data Inspector after simulation.
- 0 — Logged data is not stored on disk and is only available to view during simulation. After simulation, no logged data is available in the Simulation Data Inspector or workspace. For more information, see “View Data Only During Simulation”.

## Simulink.sdi.getRequiredFreeSpace

Get configured minimum disk space requirement for logging

### Syntax

```
minDiskSpace = Simulink.sdi.getRequiredFreeSpace
```

### Description

`minDiskSpace = Simulink.sdi.getRequiredFreeSpace` returns the minimum free disk space requirement configured for logging, in units of GB.

### Examples

#### Get Configured Logging Size Limits

You can limit the size of logged data by specifying a maximum size for the data or a minimum amount of disk space to leave empty. This example uses several functions to get the current configuration of logging size limits.

Use the `Simulink.sdi.getRequiredFreeSpace` function to get the configured minimum free disk space requirement. The returned value uses units of GB.

```
minDiskSpace = Simulink.sdi.getRequiredFreeSpace;
```

Use the `Simulink.sdi.getMaxDiskUsage` function to get the configured maximum size for data logged to disk. The returned value uses units of GB.

```
maxSize = Simulink.sdi.getMaxDiskUsage;
```

Use the `Simulink.sdi.deleteRunsOnLowSpace` function to get the configured behavior when approaching the logging limits. When `deleteRuns` is true, data from prior simulations is deleted first to free disk space for continued logging in the current simulation. If deleting runs does not free up enough space, recording logged data is disabled for the current simulation. When `deleteRuns` is false, recording logged data is disabled for the current simulation and data from prior simulations is retained.

```
deleteRuns = Simulink.sdi.deleteRunsOnLowSpace;
```

### Output Arguments

**minDiskSpace** — Minimum free disk space requirement for logging

scalar

Minimum free disk space requirement for logging, returned as a scalar, in units of GB.

## Simulink.sdi.getRun

**Package:** Simulink.sdi

Access data for a Simulation Data Inspector run

### Syntax

```
run = Simulink.sdi.getRun(runID)
```

### Description

`run = Simulink.sdi.getRun(runID)` returns a `Simulink.sdi.Run` object that provides access to the data in the run corresponding to the `runID`. The Simulation Data Inspector assigns run IDs when it creates a run. You can get the run ID for your run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

### Examples

#### Access Simulation Data Inspector Runs

Many tasks performed using the Simulation Data Inspector programmatic interface start by accessing the `Simulink.sdi.Run` object that corresponds to the logged or imported data you want to analyze. For example, you can use the Run object to access the `Simulink.sdi.Signal` objects that correspond to individual signals in the run.

This example shows how to access Run objects by using the `Simulink.sdi.Run.getLatest` function, the `Simulink.sdi.getCurrentSimulationRun` function, or the `Simulink.sdi.getRun` function.

#### Create a Run

The model `sldemo_fuelsys` is already configured for logging. When you simulate the model, the Simulation Data Inspector automatically creates a run and assigns it a run ID.

```
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

#### Get Run Object Using Simulink.sdi.Run.getLatest

In this example, the run created when you simulated the model is the most recently created run in the Simulation Data Inspector. When you want to access the most recently created run, use the `Simulink.sdi.Run.getLatest` function.

```
fuelsysRun = Simulink.sdi.Run.getLatest;
```

#### Get Run Object Using Simulink.sdi.getCurrentSimulationRun

The run you want to access may not be the most recently created run in the Simulation Data Inspector. If the run corresponds to the most recent simulation of a model, you can use the `Simulink.sdi.getCurrentSimulationRun` function to access the Run object. You can also use

the `Simulink.sdi.getCurrentSimulationRun` function to access data for an in-progress simulation when the simulation streams data to the Simulation Data Inspector. This function can be useful when you are working with multiple models.

In this example, the run created when you simulated the model is the current simulation run for the `sldemo_fuelsys` model.

```
fuelsysRun = Simulink.sdi.getCurrentSimulationRun('sldemo_fuelsys');
```

### Get Run Object from a Run ID

When your task also requires the run ID, you can use the `Simulink.sdi.getRun` function to get the corresponding `Simulink.sdi.Run` object that contains the run data and metadata.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelsysRun = Simulink.sdi.getRun(runID);
```

### Plot Signals from Simulation Run

This example demonstrates how to access the `Simulink.sdi.Run` object for a Simulation Data Inspector run created by logging signals. From the `Simulink.sdi.Run` object you can get `Simulink.sdi.Signal` objects that contain the logged signal data and metadata. You can use the `Signal` objects and the `plotOnSubPlot` function to plot the data in the Simulation Data Inspector.

### Create a Simulation Run and Access the Run Object

The `ex_vdp` model logs two signals. To create a simulation run containing the logged data, simulate the model.

```
sim('ex_vdp');
```

The Simulation Data Inspector keeps track of runs by assigning a unique numeric run ID to each run created by simulation, importing data, or opening a session. To access the run object for the simulation you just performed, use the `Simulink.sdi.getAllRunIDs` function and take the last run ID in the returned vector.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

Once you have the run ID for the run, you can use the `Simulink.sdi.getRun` function to get the `Simulink.sdi.Run` object that corresponds to the run. You can use the `Run` object to check the metadata associated with the run, including the number of signals in the run.

```
vdpRun = Simulink.sdi.getRun(runID);
```

```
vdpRun.SignalCount
```

```
ans = int32
 2
```

### Plot Data Using Signal Objects

Use the `getSignalByIndex` function to access signals from the `Run` object, `vdpRun`.

```
signal1 = getSignalByIndex(vdpRun,1);
signal2 = getSignalByIndex(vdpRun,2);
```

Use the `Simulink.sdi.setSubPlotLayout` function to specify a 2-by-1 layout.

```
Simulink.sdi.setSubPlotLayout(2,1)
```

Before plotting the data, use the `Simulink.sdi.clearAllSubPlots` function to clear any data that is already plotted.

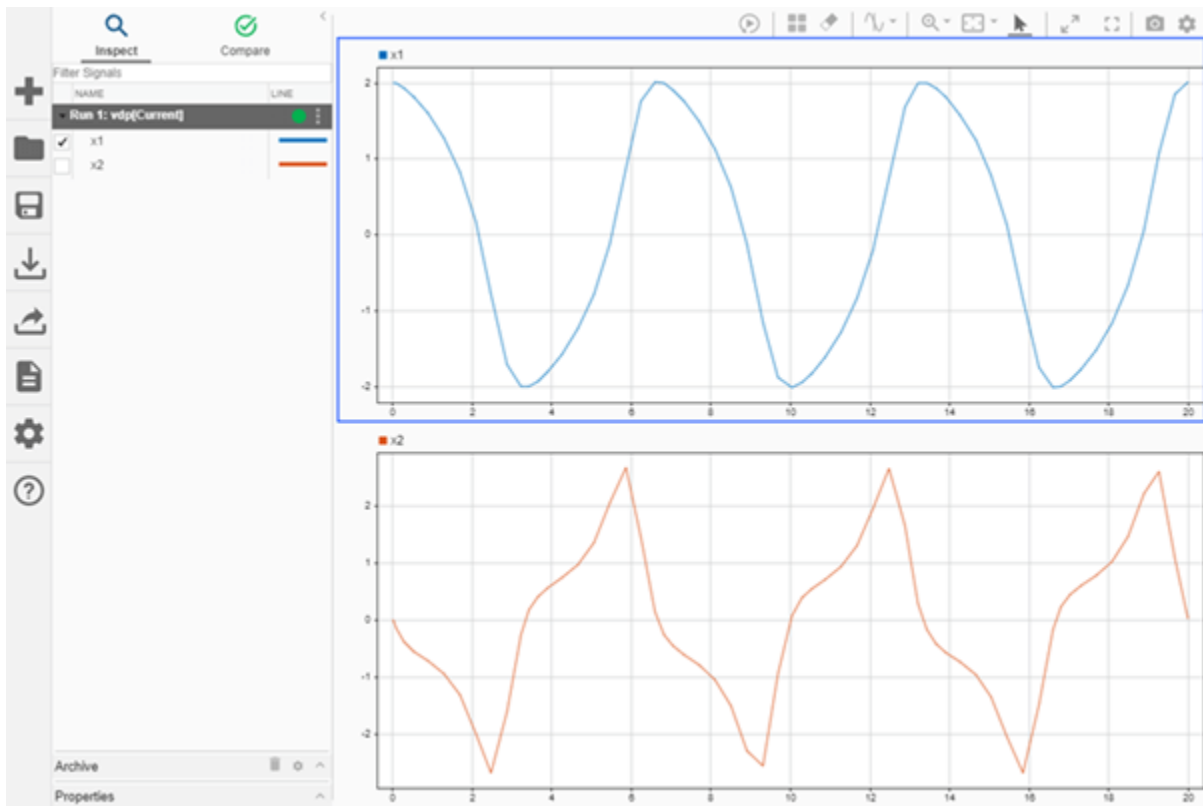

```
Simulink.sdi.clearAllSubPlots
```

Plot one signal on each subplot. To plot signals on the first subplot, you can set the checked property for the signal. To plot signals on subplots other than the first subplot, use the `plotOnSubPlot` function.

```
signal1.Checked = true;
plotOnSubPlot(signal2,2,1,true);
```

### View the Plotted Data

To view the plots you just created, open the Simulation Data Inspector using the `Simulink.sdi.view` function.

### Input Arguments

**runID** — Numeric run identifier

scalar

Run ID for the run you want a `Simulink.sdi.Run` object for. The Simulation Data Inspector assigns run IDs when it creates runs. You can get the run ID for a run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

## Output Arguments

**run** — `Simulink.sdi.Run` object

'`Simulink.sdi.Run`'

`Simulink.sdi.Run` object for the run corresponding to the run ID.

## Version History

Introduced in R2011b

# Simulink.sdi.getRunCount

**Package:** Simulink.sdi

Get number of runs in Simulation Data Inspector repository

## Syntax

```
count = Simulink.sdi.getRunCount
```

## Description

`count = Simulink.sdi.getRunCount` returns the number of runs in the Simulation Data Inspector repository. You can use the run count to loop over all runs in the Simulation Data Inspector repository to modify run or signal properties. For example, you could add an absolute tolerance to a signal in every run.

## Examples

### Apply a Tolerance to a Signal in Multiple Runs

You can use the Simulation Data Inspector programmatic interface to modify a parameter for the same signal in multiple runs. This example adds an absolute tolerance of `0.1` to a signal in all four runs of data.

First, clear the workspace and load the Simulation Data Inspector session with the data. The session includes logged data from four simulations of a Simulink® model of a longitudinal controller for an aircraft.

```
Simulink.sdi.clear
Simulink.sdi.load('AircraftExample.mldatx');
```

Use the `Simulink.sdi.getRunCount` function to get the number of runs in the Simulation Data Inspector. You can use this number as the index for a for loop that operates on each run.

```
count = Simulink.sdi.getRunCount;
```

Then, use a for loop to assign the absolute tolerance of `0.1` to the first signal in each run.

```
for a = 1:count
 runID = Simulink.sdi.getRunIDByIndex(a);
 aircraftRun = Simulink.sdi.getRun(runID);
 sig = getSignalByIndex(aircraftRun,1);
 sig.AbsTol = 0.1;
end
```

## Output Arguments

**count** — Number of runs

scalar

Number of runs in the Simulation Data Inspector repository.

## **Version History**

**Introduced in R2011b**

### **See Also**

### **Topics**

“Inspect and Compare Data Programmatically”

## Simulink.sdi.getRunIDByIndex

**Package:** Simulink.sdi

Use Simulation Data Inspector run index to get run ID

### Syntax

```
runID = Simulink.sdi.getRunIDByIndex(index)
```

### Description

`runID = Simulink.sdi.getRunIDByIndex(index)` returns the run ID for the run with the specified index in the Simulation Data Inspector repository.

### Examples

#### Get Simulation Data Inspector Run IDs

Many tasks performed using the Simulation Data Inspector programmatic interface start with obtaining the run ID for a simulation run. This example illustrates several methods to get the run ID for a run. You can use the run ID to access the `Simulink.sdi.Run` object that contains the run data and metadata and perform run comparisons using the `Simulink.sdi.compareRuns` function.

#### Create a Run

The model `sldemo_fuelsys` is already configured for logging. When you simulate the model, the Simulation Data Inspector automatically creates a run and assigns it a run ID.

```
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

#### Get Run ID Using Simulink.sdi.getAllRunIDs

The `Simulink.sdi.getAllRunIDs` function returns an array of all run IDs for the runs in the Simulation Data Inspector repository, in order, with the most recently created run at the end.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

#### Get Run ID Using Simulink.sdi.getRunIDByIndex

You can also use the `Simulink.sdi.getRunCount` and `Simulink.sdi.getRunIDByIndex` functions to get the run ID for a run. This method is useful if you also want to use `count` as a counting variable to index through the runs in the Simulation Data Inspector repository.

```
count = Simulink.sdi.getRunCount;
runID = Simulink.sdi.getRunIDByIndex(count);
```

#### Get Run ID from a Simulink.sdi.Run Object

You can also get the run ID from the `Simulink.sdi.Run` object that corresponds to the run. This example uses the `Simulink.sdi.getCurrentSimulationRun` function to get the Run object that

corresponds to the most recent simulation of the `sldemo_fuelsys` model. You can also use the `Simulink.sdi.Run.getLatest` function to access the most recently created Run object.

```
fuelsysRun = Simulink.sdi.getCurrentSimulationRun('sldemo_fuelsys');
runID = fuelsysRun.ID;
```

## Input Arguments

### **index** — Run index in Simulation Data Inspector

integer

Positive, whole number index of the run in the Simulation Data Inspector repository.

Example: 3

## Output Arguments

### **runID** — Numeric run identifier

scalar

Numeric run identification assigned by the Simulation Data Inspector.

## Version History

Introduced in R2011b

## Simulink.sdi.getRunNamingRule

**Package:** Simulink.sdi

Get the Simulation Data Inspector rule for naming runs

### Syntax

```
namingRule = Simulink.sdi.getRunNamingRule
```

### Description

`namingRule = Simulink.sdi.getRunNamingRule` returns the run naming rule as a character vector. The run naming rule can contain one or more tokens that update for each run, for example, `<run_index>`. The run naming rule applies to runs automatically created through simulating a model in Simulink.

### Examples

#### Modify Run Naming Rule Then Restore Default

This example shows how to use the Simulation Data Inspector API to modify the Simulation Data Inspector run naming rule, check a run's name, restore default preferences, and check the run naming rule.

```
% Load model
load_system('sldemo_fuelsys')

% Modify run naming rule
Simulink.sdi.setRunNamingRule('<model_name> Run <run_index>')

% Simulate system
sim('sldemo_fuelsys')

% Check run name
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelRun = Simulink.sdi.getRun(runID);
fuelRun.name

ans =
'sldemo_fuelsys Run 1'

% Clear preferences to reset the run naming rule
Simulink.sdi.clearPreferences

% Check run naming rule
Simulink.sdi.getRunNamingRule

ans =
'Run <run_index>: <model_name>'
```

## Output Arguments

### **namingRule** — Naming rule for Simulation Data Inspector runs

character vector

Character vector that specifies the naming rule the Simulation Data Inspector uses to name the runs automatically created through simulating a Simulink model. The run naming rule can contain any of the following tokens that represent information pulled for each run:

- `<run_index>` - Run's index in the Simulation Data Inspector repository.
- `<model_name>` - Name of the model simulated to create the run.
- `<time_stamp>` - Start time for the simulation that created the run.
- `<sim_mode>` - Simulation mode used for the simulation that created the run.

## Alternatives

You can view the run naming rule using the Simulation Data Inspector UI. You can find the **New Run** options under the Simulation Data Inspector **Preferences** menu.

## Version History

Introduced in R2015a

## See Also

[Simulink.sdi.setRunNamingRule](#) | [Simulink.sdi.resetRunNamingRule](#) | [Simulink.sdi.Run](#) | [Simulink.sdi.clearPreferences](#)

# Simulink.sdi.getSignal

**Package:** Simulink.sdi

Get Simulink.sdi.Signal object for a signal

## Syntax

```
signalObj = Simulink.sdi.getSignal(sigID)
```

## Description

`signalObj = Simulink.sdi.getSignal(sigID)` returns a `Simulink.sdi.Signal` object for the signal in the Simulation Data Inspector that corresponds to the signal ID, `sigID`.

## Examples

### Create a Simulation Data Inspector Run and Access Signal Data

This example shows how to access signal data when you create a run in the Simulation Data Inspector.

#### Generate Data for Run

For this example, create timeseries data for sine and cosine signals.

```
% Create timeseries workspace data
time = linspace(0, 20, 101);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

#### Create a Run and Return Signal IDs

You can use the `Simulink.sdi.createRun` syntax with multiple return arguments to get the signal IDs more directly instead of accessing the signal IDs through a `Simulink.sdi.Run` object.

```
[runID,runIndex,sigIDs] = Simulink.sdi.createRun('Sinusoids','vars',...
 sine_ts,cos_ts);

cosID = sigIDs(2);
cosSig = Simulink.sdi.getSignal(cosID);
```

#### Modify Signal Properties and View in the Simulation Data Inspector

You can use the `Simulink.sdi.Signal` object to view and modify signal properties and to plot signals in the Simulation Data Inspector.

```
cosSig.Checked = true;
cosSig.AbsTol = 0.05;
Simulink.sdi.view
cosSig.Name
```

## Input Arguments

### **sigID** — Signal ID

scalar

Unique, numeric signal identifier, specified as an integer. The Simulation Data Inspector assigns a signal ID to each signal when a run is created. You can get the signal ID for a signal using one of these functions:

- `getAllSignalIDs`
- `getSignalIDByIndex`
- `getSignalIDsByName`
- `Simulink.sdi.createRun`

## Output Arguments

### **signalObj** — `Simulink.sdi.Signal` object

`Simulink.sdi.Signal` object

Signal that corresponds to the signal ID, `sigID`, returned as a `Simulink.sdi.Signal` object.

## Version History

Introduced in R2011b

## See Also

## Simulink.sdi.getSignalInputProcessingMode

Get value of Input Processing signal property

### Syntax

```
inputMode = Simulink.sdi.getSignalInputProcessingMode(blkPath,port)
inputMode = Simulink.sdi.getSignalInputProcessingMode(h)
```

### Description

`inputMode = Simulink.sdi.getSignalInputProcessingMode(blkPath,port)` returns the value of the **Input Processing** property for the signal produced by the specified block and port. The **Input Processing** property specifies whether to log the signal as sample-based or frame-based.

`inputMode = Simulink.sdi.getSignalInputProcessingMode(h)` returns the value of the **Input Processing** property for the signal that corresponds to the specified line handle, `h`.

### Examples

#### Check Signal Input Processing Setting Using Block Path

Check the value of the **Input Processing** property for the output signal of the Gain block **Mu** in the model `vdp` using the block path and the index of the output port that produces the signal.

```
open_system('vdp')
MuInputProc = Simulink.sdi.getSignalInputProcessingMode('vdp/Mu',1);
```

#### Check Signal Input Processing Setting Using Line Handle

Check the value of the **Input Processing** property for the output signal of the Gain block **Mu** in the model `vdp` using the line handle for the signal.

```
open_system('vdp')
MuLineHandles = get_param('vdp/Mu','LineHandles');
MuOutputHandle = MuLineHandles.Outputport;
MuInputProc = Simulink.sdi.getSignalInputProcessingMode(MuOutputHandle);
```

### Input Arguments

#### **blkPath** — Block path for block that produces signal

string | character vector

Block path for the block that produces the signal, specified as a string or a character vector.

Example: "vdp/Mu"

#### **port** — Index of block output port that produces signal

scalar

Index of block output port that produces signal, specified as a numeric scalar.

Example: 1

### **h** — Signal

line handle

Signal, specified as a line handle. To get the line handle for a signal, use the `get_param` function with the 'LineHandles' option. For example, to access the line handle for the output of the Mu block in the model `vdp`, use:

```
MuLineHandles = get_param('vdp/Mu', 'LineHandles');
MuOutputLineHandle = MuLineHandles.Output;
```

## **Output Arguments**

### **inputMode** — Input processing used for signal

'sample' | 'frame'

Input processing used for signal, returned as 'sample' or 'frame'.

Signal **Input Processing** setting.

- 'sample' — Each element in a sample is treated as a channel.
- frame — Each column in a sample is treated as a channel.

## **Version History**

## Simulink.sdi.getStorageLocation

Get path to custom storage location for data logged to disk

### Syntax

```
storagePath = Simulink.sdi.getStorageLocation
```

### Description

`storagePath = Simulink.sdi.getStorageLocation` returns the configured custom location to store data logged to disk. When data logs to the temporary directory on your computer, the `Simulink.sdi.getStorageLocation` function returns an empty character array.

---

**Note** The location returned by the `Simulink.sdi.getStorageLocation` function applies for data logged to the workspace and Simulation Data Inspector and is *not* the location of the file created for data logged to a file.

---

### Examples

#### Check Custom Storage Location

By default, data logged to the workspace and the Simulation Data Inspector is stored in the temporary directory on your computer. You may want to change the location of logged data when you need to log large amounts of data and a secondary drive provides more storage capacity. When you specify a custom storage location for logged data, you can use the `Simulink.sdi.getStorageLocation` function to access the path to the temporary file that contains the logged data.

```
storagePath = Simulink.sdi.getStorageLocation;
```

```
storagePath =
```

```
 'C:\Users\username\LoggedData'
```

### Output Arguments

#### **storagePath** — Location of data logged to disk

character vector

Location of data logged to disk, returned as a character vector. An empty character vector indicates that the data is logged to the temporary directory on your computer.

### Version History

Introduced in R2021a

## Simulink.sdi.getStorageMode

Check if logging is configured to log data to disk or memory

### Syntax

```
storageMode = Simulink.sdi.getStorageMode
```

### Description

`storageMode = Simulink.sdi.getStorageMode` returns the configured logging storage mode as 'disk' or 'memory'. By default, data logged to the workspace and the Simulation Data Inspector is logged to disk.

### Examples

#### Check Whether Data Logs to Disk or Memory

You can configure whether data logged in simulation logs to memory or to disk. By default, data is logged to disk and brought into memory on demand. If your machine has more RAM than disk space, you may want to log data to memory instead.

Use the `Simulink.sdi.getStorageMode` function to check whether logging is configured to store logged data on disk or in memory.

```
storageMode = Simulink.sdi.getStorageMode
```

```
storageMode =
```

```
 'disk'
```

### Output Arguments

**storageMode** — Where logged simulation data is stored on your machine

'disk' | 'memory'

Where logged simulation data is stored on your machine, returned as 'disk' or 'memory'.

## Version History

Introduced in R2021a

## Simulink.sdi.getSubplotLimits

Get  $t$ - and  $y$ -axis limits for time plot in the Simulation Data Inspector

### Syntax

```
[tMin,tMax,yMin,yMax] = Simulink.sdi.getSubplotLimits(r,c)
```

### Description

`[tMin,tMax,yMin,yMax] = Simulink.sdi.getSubplotLimits(r,c)` returns the  $t$ - and  $y$ -axis limits for the subplot at the specified location in the Simulation Data Inspector subplot layout.

### Examples

#### Copy y-Axis Range from One Subplot to Another

You can use the `Simulink.sdi.getSubplotLimits` and `Simulink.sdi.setSubplotLimits` functions to copy the axis limits from one subplot to another. For example, you can specify the same  $y$ -axis limits for two subplots that display the same signal from simulations that used different values of a model parameter. This example copies the  $y$ -axis settings from one subplot to another to analyze the effect of changing the value of  $\mu$  in the model `vdp`.

Create the data in the Simulation Data Inspector by simulating the model `vdp` twice. The first time, specify the value of  $\mu$  as 1. For the second simulation, set the value of  $\mu$  to 2. The model logs data for the signals `x1` and `x2`.

```
open_system("vdp");
set_param("vdp/Mu","Gain","1")
sim("vdp");

set_param("vdp/Mu","Gain","2")
sim("vdp");
```

Open the Simulation Data Inspector.

```
Simulink.sdi.view
```

Create plots in the Simulation Data Inspector to show the results from each simulation. Configure a 2x2 subplot layout so you can plot one signal on each plot, side by side.

```
Simulink.sdi.setSubPlotLayout(2,2)
```

Get the `Simulink.sdi.Signal` objects that correspond to each signal from each run, and plot one signal on each subplot. Plot the signals from the first simulation on the subplots in the first column and the signals from the second simulation on the subplots in the second column.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);
```

```
runMu1 = Simulink.sdi.getRun(runID1);
runMu2 = Simulink.sdi.getRun(runID2);

sig1 = getSignalByIndex(runMu1,1);
sig2 = getSignalByIndex(runMu1,2);
sig3 = getSignalByIndex(runMu2,1);
sig4 = getSignalByIndex(runMu2,2);

plotOnSubPlot(sig1,1,1,true);
plotOnSubPlot(sig2,2,1,true);
plotOnSubPlot(sig3,1,2,true);
plotOnSubPlot(sig4,2,2,true);
```

The signals in the first column of plots look similar to those in the second column. However, the y-axis limits for the plots of the x2 signal are different.

Use the `Simulink.sdi.getSubplotLimits` function to copy the limits used for the subplot with the `x2` signal from the second simulation.

```
[~,~,ymin,ymax] = Simulink.sdi.getSubplotLimits(2,2);
```

Use the `Simulink.sdi.setSubplotLimits` function to apply the same y-axis limits to the subplot with the `x2` signal from the first run.

```
Simulink.sdi.setSubplotLimits(2,1,'yRange',[ymin,ymax]);
```

With the updated y-axis limits, the difference in the `x2` signal is more apparent.

## Input Arguments

### **r** — Subplot row index

integer

Subplot row index, specified as an integer between 1 and 8, inclusive. Use the *r* and *c* inputs together to specify the location of the subplot for which you want the axis limits.

Example: `[~,~,yMin,yMax] = Simulink.sdi.setSubplotLimits(2,2)` returns y-axis limits for the time plot in the second row of the second column of the subplot layout in the Simulation Data Inspector.

### **c** — Subplot column index

integer

Subplot column index, specified as an integer value between 1 and 8, inclusive. Use the *r* and *c* inputs together to specify the location of the subplot for which you want the axis limits.

Example: `[~,~,yMin,yMax] = Simulink.sdi.setSubplotLimits(2,2)` returns the y-axis limits for the time plot in the second row of the second column of the subplot layout in the Simulation Data Inspector.

## Output Arguments

### **tMin** — t-axis minimum

double

t-axis minimum, returned as a double and the first element in a 1-by-4 vector of the form `[tMin, tMax, yMin, yMax]`.

### **tMax** — t-axis maximum

double

t-axis maximum, returned as a double and the second element in a 1-by-4 vector of the form `[tMin, tMax, yMin, yMax]`.

### **yMin** — y-axis minimum

double

y-axis minimum, returned as a double and the third element in a 1-by-4 vector of the form `[tMin, tMax, yMin, yMax]`.

### **yMax** — y-axis maximum

double

y-axis maximum, returned as a double and the last element in a 1-by-4 vector of the form `[tMin, tMax, yMin, yMax]`.

# Simulink.sdi.getTickLabelsDisplay

Get tick mark label setting for time plots

## Syntax

```
tickLabels = Simulink.sdi.getTickLabelsDisplay
```

## Description

`tickLabels = Simulink.sdi.getTickLabelsDisplay` returns the current setting for displayed tick mark labels on time plots in the Simulation Data Inspector. The return value corresponds to the value of the **Tick labels** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector displays tick mark labels for both axes on time plots.

## Examples

### Configure Tick Mark Label Visibility for Time Plots

You can use the `Simulink.sdi.setTickLabelsDisplay` function to configure the visibility of tick mark labels for the *t*- and *y*-axes on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector displays tick marks for both axes.

This example starts by showing how to use the `Simulink.sdi.getTickLabelsDisplay` function to access the current tick mark label visibility. Subsequent sections show the code to specify each available option for tick mark label visibility on time plots in the Simulation Data Inspector. To see the result of each configuration, the example generates an image using the `Simulink.sdi.snapshot` function with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

### Get Current Tick Mark Label Visibility

Before modifying the visibility of the tick mark labels on time plots, you can save the current configuration to a variable in the workspace in case you want to restore the preference later.

```
initTickLabels = Simulink.sdi.getTickLabelsDisplay;
```

### Show Only *t*-Axis Tick Mark Labels

Show the tick mark labels for the *t*-Axis.

```
Simulink.sdi.setTickLabelsDisplay('t-axis')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Show Only y-Axis Tick Mark Labels

Show the tick mark labels for the y-axis.

```
Simulink.sdi.setTickLabelsDisplay('y-axis')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Hide Tick Mark Labels

You can hide the tick mark labels for both axes.

```
Simulink.sdi.setTickLabelsDisplay('none')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Show All Tick Mark Labels

By default, the Simulation Data Inspector shows tick mark labels for both axes on time plots.

```
Simulink.sdi.setTickLabelsDisplay('all')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

## Output Arguments

### **tickLabels** — Time plot axes that display tick mark labels

'all' | 't-axis' | 'y-axis' | 'none'

Time plot axes that display tick mark labels in the Simulation Data Inspector, returned as one of these options:

- 'all' — Tick mark labels displayed for both time plot axes.
- 't-axis' — Tick mark labels displayed only on the *t*-axis for time plots.
- 'y-axis' — Tick mark labels displayed only on the *y*-axis for time plots.
- 'none' — No tick mark labels displayed on time plots.

## Version History

**Introduced in R2019b**

# Simulink.sdi.getTicksPosition

Get tick mark position setting for time plots

## Syntax

```
ticksPos = Simulink.sdi.getTicksPosition
```

## Description

`ticksPos = Simulink.sdi.getTicksPosition` returns the current setting for the position of tick marks on time plots in the Simulation Data Inspector. The return value corresponds to the value of the **Ticks** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector displays tick marks on the outside of the plot area for time plots.

## Examples

### Configure Position for Tick Marks on Time Plots

You can use `Simulink.sdi.setTicksPosition` function to specify the position for tick marks on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector displays tick marks outside of the plot area for time plots.

This example starts by showing how to use the `Simulink.sdi.getTicksPosition` function to access the current position of tick marks. Subsequent sections show the code to specify each configuration option for the position of tick marks on time plots in the Simulation Data Inspector. To see the result, the example generates an image using `Simulink.sdi.snapshot` with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

### Get Current Tick Mark Position

Before modifying the position of tick marks on time plots, you can save the current configuration to a variable in the workspace in case you want to restore the preference later.

```
initTickPos = Simulink.sdi.getTicksPosition;
```

### Position Tick Marks Inside Plot Area

Position the tick marks inside the plot area to increase the amount of space used by the plot area.

```
Simulink.sdi.setTicksPosition('inside')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Hide Tick Marks on Time Plots

You can hide the tick marks for time plots in the Simulation Data Inspector. Hiding the tick marks expands the plot area.

```
Simulink.sdi.setTicksPosition('none')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Position Tick Marks Outside Plot Area

By default, the Simulation Data Inspector displays tick marks outside of the plot area for time plots.

```
Simulink.sdi.setTicksPosition('outside')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Output Arguments

**ticksPos** — Current setting for tick mark position on time plots

'outside' | 'inside' | 'none'

Current setting for the position of tick marks on time plots in the Simulation Data Inspector, returned as 'inside' or 'outside'.

## Version History

Introduced in R2019b

# Simulink.sdi.getTrigger

Get signal and trigger options for trigger configured in the Simulation Data Inspector

## Syntax

```
sig = Simulink.sdi.getTrigger
[sig,opts] = Simulink.sdi.getTrigger
```

## Description

`sig = Simulink.sdi.getTrigger` returns the `Simulink.sdi.Signal` object for the signal used to trigger display updates in the Simulation Data Inspector.

`[sig,opts] = Simulink.sdi.getTrigger` returns the trigger options configured for the trigger in the Simulation Data Inspector.

## Examples

### Programmatically Configure Triggers in the Simulation Data Inspector

Add a trigger to a signal in the Simulation Data Inspector to specify criteria that determine when to update plots to display fresh data. Triggers can allow you to capture transient signal behavior and can help stabilize the display of periodic signals so you can take measurements.

Simulate the `Triggers` model. Data in the model logs to the Simulation Data Inspector.

```
open_system('Triggers');
out = sim('Triggers');
```

Then, add a trigger to the `Pulse` signal. Configure the trigger as a falling-edge trigger with a threshold of 0.5.

```
trigRun = Simulink.sdi.getCurrentSimulationRun('Triggers');
pulseSig = getSignalsByName(trigRun,'Pulse');
Simulink.sdi.addTrigger(pulseSig,'Type','Edge','Level',0.5);
```

You can verify that the trigger was added and configured correctly by opening the Simulation Data Inspector using `Simulink.sdi.view` and clicking the trigger icon next to the `Pulse` signal to check the configuration. You can also use the `Simulink.sdi.getTrigger` function to check which signal is used to generate trigger events and the trigger configuration.

```
[sig,trigOpts] = Simulink.sdi.getTrigger;
```

```
sig.Name
```

```
ans =
'Pulse'
```

```
trigOpts
```

```
trigOpts = struct with fields:
 Mode: 'Auto'
```

```

 Type: 'Edge'
 Position: 0.5000
 Delay: 0
 SourceChannelComplexity: 'Scalar'
 Polarity: 'Positive'
 AutoLevel: 1
 Level: 0.5000
 UpperLevel: 0
 LowerLevel: 1.2252e-311
 Hysteresis: 0
 MinTime: 0
 MaxTime: Inf
 Timeout: 0
 Holdoff: 0

```

When you do not want to use a trigger to control when the Simulation Data Inspector updates the plots with fresh data, you can remove the trigger using the `Simulink.sdi.removeTrigger` function.

```
Simulink.sdi.removeTrigger
```

You can verify that the trigger was removed in the Simulation Data Inspector UI or using the `Simulink.sdi.getTrigger` function. The `Simulink.sdi.getTrigger` function returns an empty array of `Simulink.sdi.Signal` objects when no trigger is configured in the Simulation Data Inspector.

```
sig = Simulink.sdi.getTrigger;
size(sig)
```

```
ans = 1×2
 0 0
```

## Output Arguments

### **sig** — Signal used to trigger display updates in the Simulation Data Inspector

`Simulink.sdi.Signal` object

Signal used to trigger display updates in the Simulation Data Inspector, returned as a `Simulink.sdi.Signal` object.

### **opts** — Configuration of trigger in the Simulation Data Inspector

structure

Configuration of trigger in the Simulation Data Inspector, returned as a structure that contains these fields:

- Mode
- Type
- Position
- Delay

- SourceChannelComplexity
- Polarity
- AutoLevel
- Level
- UpperLevel
- LowerLevel
- Hysteresis
- MinTime
- MaxTime
- Timeout
- Holdoff

For details on trigger configuration, see “Scope Triggers Panel” and `Simulink.sdi.addTrigger`.

## Simulink.sdi.getUnitSystem

Get current unit system configured in Simulation Data Inspector preferences

### Syntax

```
unitSystem = Simulink.sdi.getUnitSystem
[unitSystem,overrideUnits] = Simulink.sdi.getUnitSystem
```

### Description

`unitSystem = Simulink.sdi.getUnitSystem` returns the unit system configured in the Simulation Data Inspector preferences. For more information about unit preferences, see “Signal Display Units”. To specify unit preferences for the Simulation Data Inspector, use the `Simulink.sdi.setUnitSystem` function.

`[unitSystem,overrideUnits] = Simulink.sdi.getUnitSystem` returns the unit system and override units configured in the Simulation Data Inspector preferences.

### Examples

#### Configure Unit Preferences in the Simulation Data Inspector

To specify a system of units to use for plotting signals in the Simulation Data Inspector, use the `Simulink.sdi.setUnitSystem` function. When you choose to display signals using the SI or US Customary unit system, the Simulation Data Inspector automatically changes the **Display Units** property for logged or imported signals that use units that are not part of the specified unit system. The signal data stored on disk does not change. Signals also have a **Stored Units** property, and the Simulation Data Inspector converts the data to plot the signal when the **Stored Units** and **Display Units** differ.

#### Specify a System of Units

By default, the Simulation Data Inspector displays signals using the units assigned to the signal during simulation or in the imported data. To facilitate analyzing multiple signals and data sets together, you can specify a system of units as a preference. The Simulation Data Inspector automatically updates the **Display Units** for logged or imported signals that use units that are invalid in the specified unit system. For example, a signal logged in a model using units of ft could be updated to use units of m when the system of units is specified as SI.

Use the `Simulink.sdi.setUnitSystem` function to configure the Simulation Data Inspector to display signals using units in the US Customary unit system.

```
Simulink.sdi.setUnitSystem('USCustomary');
```

#### Specify Override Units

When you want all signals that represent the same type of measurement to use the same **Display Units**, you can also specify override units. For example, to plot all signals that represent length using units of ft, specify ft as an override unit.

```
Simulink.sdi.setUnitSystem('USCustomary','Overrides','ft');
```

### Check Unit Configuration

Use the `Simulink.sdi.getUnitSystem` function to check the current unit preferences configured in the Simulation Data Inspector.

```
[unitSystem,overrideUnits] = Simulink.sdi.getUnitSystem
```

```
unitSystem =
'USCustomary'
```

```
overrideUnits =
"ft"
```

### Output Arguments

#### **unitSystem** — System of units used to define signal display units

character vector

System of units used to define signal display units, returned as a character vector.

#### **overrideUnits** — Units to override signal display units

string | string array

Units to override signal display units, returned as a string or string array. The Simulation Data Inspector displays all signals that represent a measurement type using specified override units. For example, if override units of `in` are specified, the Simulation Data Inspector displays all signals that represent length using units of `in`.

Determine status and mode for Parallel Computing Toolbox support

### Syntax

```
[enabled,mode] = Simulink.sdi.isPCTSupportEnabled
```

### Description

`[enabled,mode] = Simulink.sdi.isPCTSupportEnabled` returns `enabled`, a logical indication of whether support for the Parallel Computing Toolbox is enabled, and `mode`, the mode of support enabled.

### Examples

#### Check Status of Parallel Worker Support

Before running code that depends on whether automatic import of runs created by parallel workers is enabled, you can use the `Simulink.sdi.isPCTSupportEnabled` function to check the support status. The default behavior for the Simulation Data Inspector enables parallel worker support in `local` mode. In `local` mode, only runs created on local workers automatically import into the Simulation Data Inspector.

```
[enabled, mode] = Simulink.sdi.isPCTSupportEnabled
```

```
enabled =
```

```
 logical
```

```
 1
```

```
mode =
```

```
 'local'
```

### Output Arguments

#### **enabled** — Logical indicator of parallel worker support

logical

Logical indication of parallel worker support.

- 1 indicates that support for parallel workers is enabled.
- 0 indicates that support for parallel workers is not enabled.

#### **mode** — Parallel worker support mode

local (default)

Mode of Parallel Computing Toolbox support.

- 'local' — Runs generated on local workers automatically import to the Simulation Data Inspector.
- 'none' — Parallel worker support is disabled.
- 'all' — Runs created from local and remote workers automatically import to the Simulation Data Inspector.
- 'manual' — Support for manual import of runs created by parallel workers using the `Simulink.sdi.sendWorkerRunToClient` function.

## Version History

Introduced in R2017b

### See Also

`Simulink.sdi.enablePCTSupport` | `Simulink.sdi.WorkerRun` | `Simulink.sdi.sendWorkerRunToClient`

### Topics

“Inspect and Compare Data Programmatically”

## Simulink.sdi.isValidRunID

**Package:** Simulink.sdi

Determine whether a run ID is valid

### Syntax

```
valid = Simulink.sdi.isValidRunID(runID)
```

### Description

`valid = Simulink.sdi.isValidRunID(runID)` returns `true` if `runID` corresponds to a run in the Simulation Data Inspector repository.

### Examples

#### Check Run ID Validity

This example shows how to check whether a run ID is valid. You can use `Simulink.sdi.isValidRunID` to ensure you have valid data throughout your script.

#### Create a Simulation Run

Simulate the model `sldemo_fuelsys` to create a run in the Simulation Data Inspector, and use `Simulink.sdi.getAllRunIDs` to get its run ID.

```
% Simulate model
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')

% Get run ID
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
```

#### Check Run ID Validity

Check to verify that the Simulation Data Inspector has a run corresponding to the run ID.

```
Simulink.sdi.isValidRunID(runID)

ans = logical
 1
```

#### Delete the Run and Check Validity

You can delete runs to clear out memory space or clean up the Simulation Data Inspector UI. When you delete a run, the run ID for that run becomes invalid.

```
Simulink.sdi.deleteRun(runID)

Simulink.sdi.isValidRunID(runID)
```

```
ans = logical
 0
```

## Input Arguments

### **runID** — Simulation Data Inspector run identifier

scalar

Unique numeric identification for the run. The Simulation Data Inspector assigns run IDs when it creates runs. You can get the run ID for your run using `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`.

## Output Arguments

### **valid** — Run validity indicator

logical

Run validity indicator. When `valid` is `true`, the `runID` is valid. When `valid` is `false`, the `runID` is invalid.

## Version History

**Introduced in R2011b**

## See Also

`Simulink.sdi.getAllRunIDs` | `Simulink.sdi.getRunIDByIndex` |  
`Simulink.sdi.createRun` | `Simulink.sdi.deleteRun` | `Simulink.sdi.compareRuns`

## Topics

“Inspect and Compare Data Programmatically”

## Simulink.sdi.load

**Package:** Simulink.sdi

Load a Simulation Data Inspector session or view

### Syntax

```
valid = Simulink.sdi.load(fileName)
```

### Description

`valid = Simulink.sdi.load(fileName)` loads the data and visualization settings in the Simulation Data Inspector session file or MAT file specified by `fileName` and returns 1 when `fileName` is a valid session file or a MAT file that contains data the Simulation Data Inspector supports.

Simulation Data Inspector views are also saved as MLDATX files. To load a view file, use the `Simulink.sdi.loadView` function.

### Examples

#### Save a Simulation Data Inspector Session

This example creates, saves, and loads a Simulation Data Inspector session. The example logs data in the model `slexAircraftExample` and visualizes the logged data in a Simulation Data Inspector session. Each time you use the Simulation Data Inspector, you create and modify a session. You can save the data and associated visualization settings for a session in an MLDATX file using the `Simulink.sdi.save` function. When you want to review the data later, you can load the session using the `Simulink.sdi.load` function.

#### Log Data to the Simulation Data Inspector

This example logs data from a simulation of the model `slexAircraftExample` to the Simulation Data Inspector. The model is not configured to log data. Load the model and mark the `Stick`, the `alpha`, `rad`, and the `q`, `rad/sec` signals for logging.

```
load_system('slexAircraftExample')

Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot',1,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',3,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')
```

For this example, run two simulations of the model. In the first simulation, use the sine wave output from the `Pilot` block, and in the second, use the square wave output.

```
set_param('slexAircraftExample/Pilot','WaveForm','sine')
sim('slexAircraftExample')

set_param('slexAircraftExample/Pilot','WaveForm','square')
sim('slexAircraftExample')
```

## Visualize the Logged Data

You can use the Simulation Data Inspector programmatic interface to access the logged data from the simulations. When you access data using the Simulation Data Inspector programmatic interface, you can use functions to create plots in the Simulation Data Inspector.

To start, access the run IDs for the most recent two runs and then get the corresponding `Simulink.sdi.Run` object. The Run objects allow you to access the logged data for the simulations.

```
runIDs = Simulink.sdi.getAllRunIDs;
sineRunID = runIDs(end-1);
squareRunID = runIDs(end);

sineRun = Simulink.sdi.getRun(sineRunID);
squareRun = Simulink.sdi.getRun(squareRunID);
```

Suppose you want to analyze the relationship between the input and output for the model. Get the `Simulink.sdi.Signal` objects for the input and output signals from the two simulation runs.

```
sineOut = getSignalByIndex(sineRun,1);
sineIn = getSignalByIndex(sineRun,3);

squareOut = getSignalByIndex(squareRun,1);
squareIn = getSignalByIndex(squareRun,3);
```

Change the subplot layout in the Simulation Data Inspector to 2-by-1 and plot the signals from the first simulation run on the top plot and the signals from the second run on the bottom plot.

```
Simulink.sdi.setSubPlotLayout(2,1)

plotOnSubPlot(sineIn,1,1,true)
plotOnSubPlot(sineOut,1,1,true)

plotOnSubPlot(squareIn,2,1,true)
plotOnSubPlot(squareOut,2,1,true)
```

## Save the Simulation Data Inspector Session

To view the plotted data in the Simulation Data Inspector, enter `Simulink.sdi.view` in the command window.

Then, save the Simulation Data Inspector session as an MLDATX file.

```
Simulink.sdi.save('myData.mldatx')
```

## Load the Simulation Data Inspector Session

To mimic a scenario where you want to return to looking at the same data at a later point, clear the data from the Simulation Data Inspector and reset the subplot layout to 1-by-1.

```
Simulink.sdi.clear
Simulink.sdi.setSubPlotLayout(1,1)
```

Load the session file and resume working with the data. You can open the Simulation Data Inspector and view the results using the `Simulink.sdi.view` function.

```
Simulink.sdi.load('myData.mldatx');
```

## Input Arguments

### **fileName** — Name of session file or MAT file

string | character vector

Name of the session file or MAT file to load, specified as a string or character vector. You must specify the file extension to load data from an MLDATX file.

Example: 'myData.mldatx'

Example: 'myData.mat'

## Output Arguments

### **valid** — File validity indicator

logical

File validity indicator, returned as 1 (true) or 0 (false). A return value of 0 indicates that the Simulation Data Inspector did not load the session file or did not import data from the MAT file.

## Version History

**Introduced in R2011b**

## See Also

[Simulink.sdi.save](#) | [Simulink.sdi.close](#) | [Simulink.sdi.saveView](#) | [Simulink.sdi.loadView](#)

## Topics

“Inspect and Compare Data Programmatically”

“View Data in the Simulation Data Inspector”

# Simulink.sdi.loadView

Load a view file to visualize data in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.loadView(filename)
```

## Description

`Simulink.sdi.loadView(filename)` applies the visualization information in the view file, `filename`, to the data in the Simulation Data Inspector.

A view contains information about the layout and plots in the graphical viewing area as well as properties of plotted signals. When you load a view, the Simulation Data Inspector uses the properties and preferences in the file to display data currently in the Simulation Data Inspector. Signals in the Simulation Data Inspector that align with the signals in the view are plotted in the graphical viewing area. Use a view to apply a consistent set of visualization settings to multiple sets of similar data.

The view file includes the following information:

- Subplot layout and visualization type
- Settings for each visualization type in the layout
- Signal selection mode
- Replay controls visibility
- Metadata displayed in the work area
- Settings for signal grouping in the work area
- Plotted signals and the line style and color for each plotted signal

A view file does not contain data. To load a session file that contains data and visualization information, use the `Simulink.sdi.load` function.

## Examples

### Save and Use a View

This example visualizes the output from the `ex_vdp` model, saves the configuration as a view, and then uses the view to visualize the output from another simulation of the same model.

To generate data to plot in the Simulation Data Inspector, simulate the model.

```
open_system('ex_vdp')
set_param('ex_vdp/Mu', 'Gain', '1')
sim('ex_vdp');
```

### Programmatically Configure and Save a View

The `ex_vdp` model is configured to log two signals, `x1` and `x2`. Plot each signal on a subplot in a 2-by-1 layout.

```
Simulink.sdi.setSubPlotLayout(2,1)
```

To plot one signal on each subplot, first access the `Simulink.sdi.Run` object for the simulation.

```
runIDs = Simulink.sdi.getAllRunIDs;
ex_vdpRunID = runIDs(end);
ex_vdpRun = Simulink.sdi.getRun(ex_vdpRunID);
```

Then, you can access the data for each signal in a `Simulink.sdi.Signal` object and use the `plotOnSubPlot` function to specify where to plot each signal.

```
x1 = getSignalByIndex(ex_vdpRun,1);
x2 = getSignalByIndex(ex_vdpRun,2);
```

```
plotOnSubPlot(x1,1,1,true)
plotOnSubPlot(x2,2,1,true)
```

To view the result in the Simulation Data Inspector, enter `Simulink.sdi.view` in the command window.

Then, save the view.

```
Simulink.sdi.saveView('ex_vdpView.mldatx')
```

## Use the View

To mimic a situation where the Simulation Data Inspector is configured differently and contains data from another simulation, this example clears data from the Simulation Data Inspector, loads a view that represents the default visualization configuration, and runs another simulation of the `ex_vdp` model.

```
Simulink.sdi.clear
Simulink.sdi.loadView('default.mldatx');
set_param('ex_vdp/Mu', 'Gain', '2')
sim('ex_vdp');
```

Use the `Simulink.sdi.loadView` function to apply the saved view from the previous simulation.

```
Simulink.sdi.loadView('ex_vdpView.mldatx')
```

You can open the Simulation Data Inspector to view the results using the `Simulink.sdi.view` function. The saved view includes information regarding the axes limits. When you use a view to apply visualization settings, you may need to adjust axes limits or zoom levels to fit data from a modified simulation.

## Input Arguments

**filename** — Name of the view file  
string | character vector

Name of the view file, specified as a string or character vector. You can specify `filename` as only the file name when the file is on the MATLAB path, or you can specify a full path to the file.

Example: `'myView.mldatx'`

Data Types: `char` | `string`

## **Version History**

# Simulink.sdi.markSignalForStreaming

**Package:** Simulink.sdi

Turn logging on or off for a signal

## Syntax

```
Simulink.sdi.markSignalForStreaming(block,portIndex,log)
Simulink.sdi.markSignalForStreaming(portHandle,log)
Simulink.sdi.markSignalForStreaming(lineHandle,log)
```

## Description

`Simulink.sdi.markSignalForStreaming(block,portIndex,log)` marks the signal on the specified `portIndex` of the specified block for logging when you specify `log` as 'on'. To stop logging a signal, specify `log` as 'off'.

`Simulink.sdi.markSignalForStreaming(portHandle,log)` marks the signal on the port specified by `portHandle` for logging when you specify `log` as 'on'. To stop logging a signal, specify `log` as 'off'.

`Simulink.sdi.markSignalForStreaming(lineHandle,log)` marks the signal with the specified `lineHandle` for logging when you specify `log` as 'on'. To stop logging a signal, specify `log` as 'off'.

## Examples

### Mark Signals for Logging with Port Handles

This example shows how to mark signals for logging using port handles.

#### Load Model and Mark Signals for Streaming

User `get_param` to get the port handles for the blocks with your signals of interest. Then, use the handle to mark the desired signals for logging.

```
load_system('vdp')

% Get port handles
x1_handles = get_param('vdp/x1','PortHandles');
x1 = x1_handles.Outputport(1);
x2_handles = get_param('vdp/x2','PortHandles');
x2 = x2_handles.Outputport(1);

% Mark signals for streaming
Simulink.sdi.markSignalForStreaming(x1,'on');
Simulink.sdi.markSignalForStreaming(x2,'on');
```

#### Simulate Model and View Signals in the Simulation Data Inspector

Simulate the model and then open the Simulation Data Inspector to view the logged signals.

```
sim('vdp');
Simulink.sdi.view
```

### Mark Signals for Logging Using Line Handles

Load the model `slexAircraftExample`, and use `get_param` to get handles for the signals in the model. Then, use the line handles to mark signals of interest for logging.

```
load_system('slexAircraftExample')
```

Use the `get_param` function to get the line handles for the signals in the model.

```
lines = get_param('slexAircraftExample','Lines');
```

Use the `Simulink.sdi.markSignalForStreaming` function to mark two of the signals for logging using the line handles.

```
sig1handle = lines(1).Handle;
sig2handle = lines(2).Handle;

Simulink.sdi.markSignalForStreaming(sig1handle,'on')
Simulink.sdi.markSignalForStreaming(sig2handle,'on')
```

Simulate the model then open the Simulation Data Inspector to view the logged signal data.

```
out = sim('slexAircraftExample');
Simulink.sdi.view
```

## Input Arguments

### **block** — Source block path or handle

character vector

Block path for the block with the desired signal connected to one of its outputs.

Example: `'slexAircraftExample/Pilot'`

### **portIndex** — Source block output port index

integer

Index of the port connected to the signal you want to mark for streaming.

Example: `1`

### **log** — Logging state

'on' | 'off'

Logging state desired for signal.

- 'on' -- Turn logging on for a signal.
- 'off' -- Turn logging off for a signal.

**portHandle — Source block output port handle**

handle

Port handle for the source block's output port that connects to the signal.

Example: `x1_handles.Outputport(1)`

**lineHandle — Signal line handle**

handle

Line handle for the signal.

Example: `lines(1).Handle`

## Version History

**Introduced in R2015b**

## Simulink.sdi.registerCursorCallback

Register callback for cursor movements in the Simulation Data Inspector

### Syntax

```
callbackID = Simulink.sdi.registerCursorCallback(func)
callbackID = Simulink.sdi.registerCursorCallback(func,view)
```

### Description

`callbackID = Simulink.sdi.registerCursorCallback(func)` registers the callback function associated with the function handle `func` with the Simulation Data Inspector. The Simulation Data Inspector executes the callback when you move a cursor or change the number of cursors displayed on the **Inspect** pane.

`callbackID = Simulink.sdi.registerCursorCallback(func,view)` registers the callback function associated with the function handle `func` with the Simulation Data Inspector. The Simulation Data Inspector executes the callback when you move a cursor or change the number of cursors displayed on the pane specified by `view`.

### Examples

#### Use Simulation Data Inspector Cursor Callback in App Designer App

You can use a Simulation Data Inspector cursor callback function to send cursor position data to an app you build using the App Designer. This example shows how to add a property to the app to store the callback ID and where to register and unregister the cursor callback. For an example of an App Designer app that uses a cursor callback, see “Synchronize Cursors in the Simulation Data Inspector with an App Designer App”.

Add a `callbackID` property to the app object.

```
properties (Access = private)
 callbackID
end
```

Define the behavior of the cursor callback function.

```
methods (Access = public)
 function myCursorCallback(app,~,~)
 if isvalid(app)
 ...
 end
 end
end
```

Register the cursor callback in the app `startupFcn`. This example registers the same callback on the **Inspect** pane and the **Compare** pane.

```
function startupFcn(app)
 app.callbackID = Simulink.sdi.registerCursorCallback(...
```

```

 @(t1,t2)myCursorCallback(app,t1,t2));
 app.callbackID(2) = Simulink.sdi.registerCursorCallback(...
 @(t1,t2)myCursorCallback(app,t1,t2), 'compare');
 ...
end

```

Unregister the cursor callback in the app UIFigureCloseRequest function.

```

function myAppUIFigureCloseRequest(app, event)
 Simulink.sdi.unregisterCursorCallback(app.callbackID(1));
 Simulink.sdi.unregisterCursorCallback(app.callbackID(2));
end

```

## Input Arguments

### func — Cursor callback to register

function handle

Cursor callback to register, specified as a function handle. The function that corresponds to the function handle must accept two input arguments, `t1` and `t2`, that correspond to the left and right cursor positions. When no cursors are displayed, `t1` and `t2` are NaN. When only one cursor is displayed, `t2` is NaN.

Example: `id = Simulink.sdi.registerCursorCallback(@(t1,t2)myFunc(t1,t2))` registers the function `myFunc` as the callback for cursor events on the **Inspect** pane of the Simulation Data Inspector.

Data Types: `function_handle`

### view — Cursor event source

'inspect' (default) | 'compare'

Cursor event source, specified as 'inspect' or 'compare'.

- 'inspect' — Register callback for cursor events on the **Inspect** pane.
- 'compare' — Register callback for cursor events on the **Compare** pane.

The registered cursor callback executes for each cursor event. Cursor events occur when you move cursors or change the number of visible cursors.

Data Types: `char` | `string`

## Output Arguments

### callbackID — Registered callback ID

scalar

Registered callback ID, returned as a scalar. Use the callback ID to unregister the callback.

## Version History

Introduced in R2021a

## **See Also**

### **Functions**

`Simulink.sdi.unregisterCursorCallback` | `Simulink.sdi.setCursorPositions` |  
`Simulink.sdi.setCursorPositions` | `Simulink.sdi.setNumCursors` |  
`Simulink.sdi.getNumCursors`

### **Topics**

“Synchronize Cursors in the Simulation Data Inspector with an App Designer App”

# Simulink.sdi.removeTrigger

Remove trigger from signal in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.removeTrigger
```

## Description

`Simulink.sdi.removeTrigger` removes the trigger from a signal in the Simulation Data Inspector. If a trigger exists in the Simulation Data Inspector, adding a trigger to a different signal also removes the existing trigger.

## Examples

### Programmatically Configure Triggers in the Simulation Data Inspector

Add a trigger to a signal in the Simulation Data Inspector to specify criteria that determine when to update plots to display fresh data. Triggers can allow you to capture transient signal behavior and can help stabilize the display of periodic signals so you can take measurements.

Simulate the Triggers model. Data in the model logs to the Simulation Data Inspector.

```
open_system('Triggers');
out = sim('Triggers');
```

Then, add a trigger to the Pulse signal. Configure the trigger as a falling-edge trigger with a threshold of 0.5.

```
trigRun = Simulink.sdi.getCurrentSimulationRun('Triggers');
pulseSig = getSignalsByName(trigRun,'Pulse');
Simulink.sdi.addTrigger(pulseSig,'Type','Edge','Level',0.5);
```

You can verify that the trigger was added and configured correctly by opening the Simulation Data Inspector using `Simulink.sdi.view` and clicking the trigger icon next to the Pulse signal to check the configuration. You can also use the `Simulink.sdi.getTrigger` function to check which signal is used to generate trigger events and the trigger configuration.

```
[sig,trigOpts] = Simulink.sdi.getTrigger;
```

```
sig.Name
```

```
ans =
'Pulse'
```

```
trigOpts
```

```
trigOpts = struct with fields:
 Mode: 'Auto'
 Type: 'Edge'
 Position: 0.5000
```

```
 Delay: 0
SourceChannelComplexity: 'Scalar'
 Polarity: 'Positive'
 AutoLevel: 1
 Level: 0.5000
UpperLevel: 0
LowerLevel: 1.2252e-311
Hysteresis: 0
 MinTime: 0
 MaxTime: Inf
 Timeout: 0
 Holdoff: 0
```

When you do not want to use a trigger to control when the Simulation Data Inspector updates the plots with fresh data, you can remove the trigger using the `Simulink.sdi.removeTrigger` function.

```
Simulink.sdi.removeTrigger
```

You can verify that the trigger was removed in the Simulation Data Inspector UI or using the `Simulink.sdi.getTrigger` function. The `Simulink.sdi.getTrigger` function returns an empty array of `Simulink.sdi.Signal` objects when no trigger is configured in the Simulation Data Inspector.

```
sig = Simulink.sdi.getTrigger;
size(sig)
```

```
ans = 1×2
```

```
 0 0
```

## Alternative Functionality

To remove a trigger from a signal using the Simulation Data Inspector UI, click the trigger symbol next to the signal, then click **Remove**.

## Version History

Introduced in R2020b

## Simulink.sdi.report

**Package:** Simulink.sdi

Generate a Simulation Data Inspector report

### Syntax

```
Simulink.sdi.report
Simulink.sdi.report(Name,Value)
```

### Description

`Simulink.sdi.report` creates a report that contains plot snapshots and metadata for signals plotted in the **Inspect** pane of the Simulation Data Inspector.

`Simulink.sdi.report(Name,Value)` creates a report as specified by one or more `Name,Value` pair arguments. Using this syntax, you can create a report of data plotted in the **Inspect** pane or a report of comparison results. You can specify details for each report.

### Examples

#### Create a Report for Plotted Signals

Create a report that contains information about and plots of the signals plotted in the **Inspect** pane of the Simulation Data Inspector. By default, the report contains the metadata displayed for signals in the table on the **Inspect** pane. This example shows how to specify which metadata to include in the report.

#### Load the Session File

This example populates the Simulation Data Inspector with data and plotted signals by loading a saved session file. A session file contains the signal data as well as information about plotted signals and plot layout. Load the session file.

```
Simulink.sdi.load('ex_sl-demo_absbrake_slp_Ww.mldatx');
```

## Create a Report for Plotted Signals

The report includes plots and metadata for the plotted signals. By default, the report includes the metadata that corresponds to the columns displayed in the signals table on the **Inspect** pane. You can include more data in the report by displaying more columns in the **Inspect** pane. You can also specify the information you want in the report programmatically using the 'ColumnsToReport' name-value pair and the enumeration class `Simulink.sdi.SignalMetaData`.

```
signalMetadata = [Simulink.sdi.SignalMetaData.Run, ...
 Simulink.sdi.SignalMetaData.Line, ...
 Simulink.sdi.SignalMetaData.BlockName, ...
 Simulink.sdi.SignalMetaData.SignalName];

Simulink.sdi.report('ReportType','Inspect', 'ReportOutputFile', ...
 'absbrake_slp_report.html', 'ColumnsToReport', signalMetadata);
```

The report shows tables of the metadata for plotted signals, organized by run, above a snapshot of the plot.

## Create a Report for Comparison Results

Use the `Simulink.sdi.report` function to create a report of comparison results. The report is web-based and interactive, and you can switch between the interactive view and a printable view.

## Load Comparison Results

This example loads previously computed comparison results that were saved in an MLDATX file using the `saveResult` function. The data came from two simulations of the `slexAircraftExample` model that used different time constant values for the input filter.

```
Simulink.sdi.load('slexAircraftExampleTsComparison.mldatx');
```

## Create Comparison Report

Create a report that contains the comparison results using the `Simulink.sdi.report` function. You can specify a title and author for the report that display in the report header.

```
Simulink.sdi.report('ReportType','Compare','ReportTitle',...
 'Compare: Ts = 0.1 vs Ts = 1','ReportAuthor','Jane Smith');
```

The report opens in the system browser once it is generated. Select signals to see the results displayed in the plot and the metadata for the signals in the **Properties** pane. The report HTML file is in the `sdireports` folder in the working directory.

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'ReportType','Compare','ShortenBlockPath',true`

### ReportType — Type of report to create

`'Inspect'` (default) | `'Compare'`

Type of report to create, specified as the comma-separated pair consisting of `'ReportType'` and `'Inspect'` or `'Compare'`.

- `'Inspect'` -- Create a report that contains plot snapshots and metadata for signals plotted in the **Inspect** pane of the Simulation Data Inspector.
- `'Compare'` -- Create a report that summarizes comparison results. The comparison report is interactive and includes plot snapshots of comparison results as well as metadata for the compared signals.

Example: `'ReportType','Compare'`

### ReportTitle — Report title displayed in header for comparison report

`'Compare: <Baseline Run> vs. <Compare To Run>'` (default) | character vector

Report title displayed in header for comparison report, specified as the comma-separated pair consisting of `'ReportTitle'` and a character vector.

You can only specify a report title for a comparison report.

Example: `'ReportTitle','Trial 1 vs. Trial 2'`

**ReportAuthor — Report author displayed in header for comparison report**

'<username>' (default) | character vector

Report author displayed in header for comparison report, specified as the comma-separated pair consisting of 'ReportAuthor' and a character vector.

You can only specify a report author for a comparison report.

Example: 'ReportAuthor','John Smith'

**ReportOutputFolder — Folder where report is saved**

'<current working folder>/sdireports' (default) | path

Folder where report is saved, specified as the comma-separated pair consisting of 'ReportOutputFolder' and a character vector.

Example: 'ReportOutputFolder','C:\Users\user1\Desktop'

**ReportOutputFile — Report file name**

'SDI\_report.html' (default) | character vector

Report file name, specified as the comma-separated pair consisting of 'ReportOutputFile' and a character vector.

Example: 'ReportOutputFile','MyReport.html'

**PreventOverwritingFile — Whether to prevent overwriting report files**

true (default) | false

Whether to prevent overwriting report files, specified as the comma-separated pair consisting of 'PreventOverwritingFile' and true or false.

- true enables file overwrite protection.
- false disables file overwrite protection.

File overwrite protection prevents the Simulation Data Inspector from overwriting an existing file by appending the file name with a number that increments each time you generate a report. When you disable file overwrite protection, the Simulation Data Inspector overwrites the existing report file unless you specify a unique file name.

Example: 'PreventOverwritingFile',false

**ColumnsToReport — Signal metadata to include in report for plotted signals**

array

Signal metadata to include in the report of signals plotted in the **Inspect** pane of the Simulation Data Inspector, specified as the comma-separated pair consisting of 'ColumnsToReport' and an array. By default, the **Inspect** report includes the block path, name, line style and color, and data source parameters for each plotted signal.

---

**Note** The `ColumnsToReport` input does not affect comparison reports. The comparison report always includes all signal metadata, and the summary at the top of the comparison report always includes the signal name, absolute tolerance, relative tolerance, maximum difference, and result for each signal comparison.

---

Specify metadata to include as an array, using the enumeration class `Simulink.sdi.SignalMetaData`. For example, to include the name of the simulation run and signal name:

```
signal_metadata = [Simulink.sdi.SignalMetaData.Run,...
 Simulink.sdi.SignalMetaData.SignalName];
```

Then, specify `ColumnsToReport` as `signal_metadata` in the name-value pair:

```
Simulink.sdi.report('ColumnsToReport',signal_metadata)
```

The table summarizes the metadata available for Inspect report.

| Column Value         | Description                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------|
| SignalName (default) | Signal name                                                                                    |
| Line (default)       | Signal line style and color                                                                    |
| SID                  | Automatically assigned Simulink identifier                                                     |
| Units                | Signal measurement units                                                                       |
| SigDataType          | Signal data type                                                                               |
| SigSampleTime        | Method used to sample the signal                                                               |
| Model                | Name of the model that generated the signal                                                    |
| BlockName            | Name of the source block for the signal                                                        |
| BlockPath            | Path to the source block for the signal                                                        |
| Port                 | Index of the signal on the output port of its block                                            |
| Dimensions           | Dimensions of the matrix containing the signal                                                 |
| Channel              | Index of signal within matrix                                                                  |
| Run                  | Name of the simulation run containing the signal                                               |
| AbsTol               | Absolute tolerance for the signal                                                              |
| RelTol               | Relative tolerance for the signal                                                              |
| OverrideGlobalTol    | Property that specifies whether signal tolerances take priority over global tolerances         |
| TimeTol              | Time tolerance for the signal                                                                  |
| InterpMethod         | Interpolation method                                                                           |
| SyncMethod           | Synchronization method used to coordinate signals for comparison                               |
| TimeSeriesRoot       | Name of the variable associated with the signal for signals imported from the MATLAB workspace |
| TimeSource           | Name of the array containing the time data for signals imported from the MATLAB workspace      |
| DataSource           | Name of the array containing the signal data for signals imported from the MATLAB workspace    |

Example: `'ColumnsToReport',metadata`

### ShortenBlockPath — Whether to shorten block path in report

`true` (default) | `false`

Whether to shorten block path in report, specified as the comma-separated pair consisting of 'ShortenBlockPath' and true or false.

- `true` -- Use the shortened block path in the report.
- `false` -- Include the full block path in the report.

Example: 'ShortenBlockPath', false

### **LaunchReport — Whether to open report when created**

true (default) | false

Whether to open the report when it is created, specified as the comma-separated pair consisting of 'LaunchReport' and true or false.

- `true` -- Open the report when it is created.
- `false` -- Do not open the report automatically.

Example: 'LaunchReport', false

### **SignalsToReport — Signals to include in comparison report**

'ReportOnlyMismatchedSignals' (default) | 'ReportAllSignals'

Signals to include in a comparison report, specified as the comma-separated pair consisting of 'SignalsToReport' and 'ReportOnlyMismatchedSignals' or 'ReportAllSignals'.

- `ReportOnlyMismatchedSignals` -- Include only signals with out of tolerance comparison results.
- `ReportAllSignals` -- Include all signals.

Example: 'SignalsToReport', 'ReportAllSignals'

## **Version History**

### **Introduced in R2011b**

#### **R2020b: ReportStyle input ignored**

*Behavior changed in R2020b*

Starting in R2020b, the `ReportStyle` name-value pair input is ignored.

In R2020a, you could use the `Simulink.sdi.report` function to create two separate types of comparison report, and you could use the `ReportStyle` name-value pair to indicate the type of report to create.

From R2020b, the Simulation Data Inspector only produces one comparison report. You can switch between the interactive and printable view within the report.

# Simulink.sdi.resetRunNamingRule

**Package:** Simulink.sdi

Revert the Simulation Data Inspector run naming rule to default

## Syntax

Simulink.sdi.resetRunNamingRule

## Description

Simulink.sdi.resetRunNamingRule resets the run naming rule the Simulation Data Inspector uses to assign a name to runs created through simulating a Simulink model to its default 'Run <run\_index>: <model\_name>'.

## Examples

### Modify then Reset Run Naming Rule

This example shows how to use the Simulation Data Inspector API to modify the Simulation Data Inspector run naming rule, check a run's name, reset the run naming rule to its default, and check the run naming rule.

```
% Load model
load_system('sldemo_fuelsys')

% Modify run naming rule
Simulink.sdi.setRunNamingRule('<model_name> Run <run_index>')

% Simulate system
sim('sldemo_fuelsys')

% Check run name
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
run = Simulink.sdi.getRun(runID);
run.name

ans =
'sldemo_fuelsys Run 1'

% Reset the run naming rule
Simulink.sdi.resetRunNamingRule

% Check run naming rule
Simulink.sdi.getRunNamingRule

ans =
'Run <run_index>: <model_name>'
```

## Alternatives

You can reset the run naming rule to its default using the Simulation Data Inspector UI. Use the **Restore Defaults** button on the **New Run** tab under Simulation Data Inspector **Preferences**.

`Simulink.sdi.clearPreferences` restores the run naming rule, along with all other Simulation Data Inspector preferences.

## Version History

Introduced in R2015a

# Simulink.sdi.Run.create

Import data into new run in Simulation Data Inspector and return `Simulink.sdi.Run` object

## Syntax

```
runObj = Simulink.sdi.Run.create
runObj = Simulink.sdi.Run.create(runName)

runObj = Simulink.sdi.Run.create(var)
runObj = Simulink.sdi.Run.create(runName, 'vars', var, var2, ..., varn)
runObj = Simulink.sdi.Run.create(runName, 'namevalue', sourceNames, sigValues)

runObj = Simulink.sdi.Run.create(runName, 'file', filename)
runObj = Simulink.sdi.Run.create(runName, 'file', filename, Name=Value)
```

## Description

### Create Empty Run

`runObj = Simulink.sdi.Run.create` creates the empty `Simulink.sdi.Run` object, `runObj`. You can add signals to the Run object using the `add` function or the `Simulink.sdi.addToRun` function.

`runObj = Simulink.sdi.Run.create(runName)` creates an empty run named `runName`.

### Import Data from Workspace

`runObj = Simulink.sdi.Run.create(var)` imports data from the scalar variable `var` into a new run in the Simulation Data Inspector. The run is named according to the input variable. For example, when `var` is a `timeseries` object, the run name comes from the `Name` property on the `timeseries` object.

`runObj = Simulink.sdi.Run.create(runName, 'vars', var, var2, ..., varn)` imports data from one or more variables into a new run in the Simulation Data Inspector named `runName`.

Use this syntax to import data from multiple variables or from a variable that represents an array of objects, such as an array of `Simulink.SimulationOutput` or `Simulink.SimulationData.Dataset` objects.

`runObj = Simulink.sdi.Run.create(runName, 'namevalue', sourceNames, sigValues)` imports data from one or more variables into a new run in the Simulation Data Inspector named `runName`. The cell array `sourceNames` specifies the names used to set the `RootSource`, `TimeSource`, and `DataSource` properties for the signals imported from the `sigValues` cell array.

### Import Data from File

`runObj = Simulink.sdi.Run.create(runName, 'file', filename)` imports data from a file into a new run in the Simulation Data Inspector named `runName`. You can use a built-in file reader to import data from a MAT file, CSV file, Microsoft Excel file, or an MDF file.

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class.

`runObj = Simulink.sdi.Run.create(runName, 'file', filename, Name=Value)` imports data from a file into a new run in the Simulation Data Inspector according to options specified using one or more name-value arguments. For example, `sheets=["sheet1" "sheet2"]` specifies the sheets from which to import data when importing data from an Excel file.

## Examples

### Create Run in Simulation Data Inspector

You can programmatically import data into the Simulation Data Inspector by creating a run from data in the base workspace or a file. This example creates data in the workspace and then illustrates several methods of creating a Simulation Data Inspector run containing the data.

#### Create Data

Create data in the workspace. The Simulation Data Inspector supports timeseries data in many formats. This example creates data using the `timeseries` and `Simulink.SimulationData.Dataset` formats and saves the data in a MAT-file.

Create a sine signal and a cosine signal. Store the data for each signal in a `timeseries` object with a descriptive name.

```
time = 0:0.2:20;

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = "Sine, T=5";

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = "Cosine, T=8";
```

You can use the `Dataset` format to group related signal data together in a single object. The `Dataset` format is the default format for logged data and is supported for loading simulation input data. Create a `Dataset` object that contains the sinusoid `timeseries` data.

```
sinusoids_ds = Simulink.SimulationData.Dataset;
sinusoids_ds = addElement(sinusoids_ds,cos_ts);
sinusoids_ds = addElement(sinusoids_ds,sine_ts);
```

Scale each signal by a factor of 2 and create a `Dataset` object to contain the signal data for the results.

```
doubSine = 2*sine_ts;
doubCos = 2*cos_ts;

doubSinusoids_ds = Simulink.SimulationData.Dataset;
doubSinusoids_ds = addElement(doubSinusoids_ds,doubSine);
doubSinusoids_ds = addElement(doubSinusoids_ds,doubCos);
```

Finally, save the `timeseries` data to a MAT-file.

```
save sinusoids.mat sine_ts cos_ts
```

## Open Simulation Data Inspector

To view the runs you create in each section, open the Simulation Data Inspector by entering `Simulink.sdi.view` in the MATLAB™ Command Window.

## Create Run Using Simulink.sdi.Run Object

You can import your data into a run in the Simulation Data Inspector by creating an empty run and then adding data to the run from the workspace or a file. Depending on your task, use the `Simulink.sdi.Run.create` function or the `Simulink.sdi.createRun` function to create the empty run. The `Simulink.sdi.Run.create` function returns the `Simulink.sdi.Run` object for the new run. The `Simulink.sdi.createRun` function returns the run ID for the new run.

This example creates an empty run using the `Simulink.sdi.Run.create` function, gives the run a meaningful name and description, and then adds the sine and cosine timeseries data using the `add` function.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = "Sinusoids";
sinusoidsRun.Description = "Sine and cosine signals of different frequencies";

add(sinusoidsRun, 'vars', sine_ts, cos_ts)
```

This example uses the `Simulink.sdi.createRun` function to create a new run in the Simulation Data Inspector called `My Waves` and then uses the `Simulink.sdi.addToRun` function to add the sine and cosine timeseries data to the run.

```
runID = Simulink.sdi.createRun("My Waves");
signalID = Simulink.sdi.addToRun(runID, 'vars', sine_ts, cos_ts);
```

## Create Run from Workspace Variable

You can create a run from a single variable in the workspace. After creating the run, you can add additional data or create another run to contain your other data. The variable you use to create the run can be a `timeseries` object with data that corresponds to only one signal or a `Dataset` object that contains several signals.

When you use this syntax to create a run from a single workspace variable, the run takes the same name as the object used to create it.

```
runID = Simulink.sdi.createRun(sine_ts);
```

The `Simulink.sdi.createRun` function returns the run ID for the run the function creates. You can use the `Simulink.sdi.getRun` function to access the Run object for the run.

```
sineRun = Simulink.sdi.getRun(runID);
sineRun.Name
```

```
ans =
'Sine, T=5'
```

## Create Run from Multiple Workspace Variables

When your data exists in multiple variables in your workspace, you can use the `Simulink.sdi.createRun` function with the `vars` option to import the data from multiple variables into a single run in the Simulation Data Inspector. You can also use this syntax to create a run for a single variable that uses a name you specify.

This example creates a run called `My Sinusoids` that contains data for the sine and cosine timeseries objects.

```
runID = Simulink.sdi.createRun("My Sinusoids", 'vars', sine_ts, cos_ts);
```

### Create Run and Specify Source Names

You can use the `namevalue` option of the `Simulink.sdi.createRun` function to create a run and specify names for the signals in the run. This syntax can be helpful when you import individual leaf signals from hierarchical data.

This example creates a run containing the data for both the `Dataset` objects. Each `Dataset` object contains data for more than one signal, so the imported run data has hierarchy. The name-value syntax in this example specifies a name for the hierarchical node that corresponds to each `Dataset` object.

```
runID = Simulink.sdi.createRun("Waves", 'namevalue', {'Sinusoids', ...
 'BigSinusoids'}, {sinusoids_ds, doubSinusoids_ds});
```

### Create Run from File Data

You can also use the `Simulink.sdi.createRun` function to import data into the Simulation Data Inspector from a file. Use the `file` option to import the data in the `sinusoids.mat` file.

```
runID = Simulink.sdi.createRun("Wave Data", 'file', "sinusoids.mat");
```

### Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

#### Create Data for the Run

Create timeseries objects to contain data for a sine signal and a cosine signal. Give each timeseries object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

#### Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the `Run` object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun,'vars',sine_ts,cos_ts);
```

### Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';

cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubplot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);

plotOnSubPlot(sine_sig,1,1,true);
plotOnSubPlot(cos_sig,2,1,true);
```

### Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an MLDATX file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

## Input Arguments

### runName — Name for run

string | character vector

Name for run in Simulation Data Inspector, specified as a string or a character vector.

Example: 'Baseline Simulation'

### var — Data to import

variable

Data to import, specified as a variable. The Simulation Data Inspector supports time-based data in which sample values are associated with sample times. The Simulation Data Inspector supports all loading and logging data formats, including `timeseries` and `Simulink.SimulationData.Dataset`.

Example: `myData`

**sourceNames — Source names for imported data**

cell array of character vectors

Source names for imported data, specified as a cell array of character vectors. The source name is used to set the `RootSource`, `TimeSource`, and `DataSource` properties of the `Simulink.sdi.Signal` objects created from the data specified by the `sigValues` input.

Provide a `sourceNames` input when you specify 'namevalue' for the second argument.

Example: {'sig1','sig2'}

**sigValues — Data to import**

cell array of variables

Data to import, specified as a cell array of variables.

Provide a `sigValues` input when you specify 'namevalue' for the second argument.

Example: {var1,var2}

**filename — Name of file with data to import**

character vector

Name of file with data to import, specified as a character vector. Provide a `filename` input when you specify 'file' for the second argument.

You can create a run from these types of files using file readers built into the Simulation Data Inspector:

- MAT-file
- CSV file
- Microsoft Excel file that contains data formatted according to “Microsoft Excel Import, Export, and Logging Format”.
- MDF file with one of these extensions:
  - .mdf
  - .mf4
  - .mf3
  - .data
  - .dat

When you need to import data from a file that the built-in readers do not support, you can write your own reader using the `io.reader` class. You can also write a custom reader to use instead of the built-in reader for any file extension. For an example, see “Import Data Using a Custom File Reader”.

Example: 'simulation.mat'

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: sheets=["sheet1" "sheet2"]

**reader — File reader to use to import data**

string | character vector

File reader to use to import data, specified as a string or character vector.

The Simulation Data Inspector prioritizes using a registered custom reader when one is available for the file. When you do not specify a reader, the Simulation Data Inspector uses the first custom reader registered for the file. If no custom readers are registered, the data is imported using the built-in reader.

Specify the reader input when:

- You want to use the built-in reader to import data for a file that is also supported by a custom reader.
- Multiple registered custom readers support the file.

To determine which readers are available to import your file, use the `io.reader.getSupportedReadersForFile` function.

Example: "MyExcelReader"

Example: "built-in"

**sheets — Sheets in Excel file from which to import data**

string array | cell array of character vectors

Sheets in Excel file from which to import data, specified as a string array or a cell array of character vectors. By default, the Simulation Data Inspector imports data from all sheets. Use the `sheets` name-value argument when you do not want to import data from all sheets in the Excel file.

When the data in the file does not include simulation numbers and source information, the data on each sheet is imported into a separate run. For more information about formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: ["sheet1" "sheet2"]

**model — Model with definitions of user-defined data types**

string | character vector

Model with definitions of user-defined data types, specified as a string or character vector.

When you load data from an Excel file that defines signal data types using user-defined data types, such as enumerations, buses, or aliases, the Simulation Data Inspector needs access to the type definition to import the data. You can provide access to the type definitions by:

- Loading the associated object into the MATLAB workspace.
- Specifying the `model` name-value argument to use type definitions saved in the model workspace or a data dictionary.

For more information on formatting data to import from an Excel file, see "Microsoft Excel Import, Export, and Logging Format".

Example: "myModel.slx"

## Output Arguments

### **runObj** — Imported data

`Simulink.sdi.Run` object

Imported data, returned as a `Simulink.sdi.Run` object. When you create an empty Run object, import data into the run using the `add` function or the `Simulink.sdi.addToRun` function.

# Simulink.sdi.Run.getLatest

Get the most recently created Simulation Data Inspector run

## Syntax

```
runObj = Simulink.sdi.Run.getLatest
```

## Description

`runObj = Simulink.sdi.Run.getLatest` returns the most recently created run in the Simulation Data Inspector repository. A run is created when you simulate a model that logs data or when you import data into the Simulation Data Inspector.

## Examples

### Access Simulation Data Inspector Runs

Many tasks performed using the Simulation Data Inspector programmatic interface start by accessing the `Simulink.sdi.Run` object that corresponds to the logged or imported data you want to analyze. For example, you can use the Run object to access the `Simulink.sdi.Signal` objects that correspond to individual signals in the run.

This example shows how to access Run objects by using the `Simulink.sdi.Run.getLatest` function, the `Simulink.sdi.getCurrentSimulationRun` function, or the `Simulink.sdi.getRun` function.

### Create a Run

The model `sldemo_fuelsys` is already configured for logging. When you simulate the model, the Simulation Data Inspector automatically creates a run and assigns it a run ID.

```
load_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

### Get Run Object Using `Simulink.sdi.Run.getLatest`

In this example, the run created when you simulated the model is the most recently created run in the Simulation Data Inspector. When you want to access the most recently created run, use the `Simulink.sdi.Run.getLatest` function.

```
fuelsysRun = Simulink.sdi.Run.getLatest;
```

### Get Run Object Using `Simulink.sdi.getCurrentSimulationRun`

The run you want to access may not be the most recently created run in the Simulation Data Inspector. If the run corresponds to the most recent simulation of a model, you can use the `Simulink.sdi.getCurrentSimulationRun` function to access the Run object. You can also use the `Simulink.sdi.getCurrentSimulationRun` function to access data for an in-progress simulation when the simulation streams data to the Simulation Data Inspector. This function can be useful when you are working with multiple models.

In this example, the run created when you simulated the model is the current simulation run for the `sldemo_fuelsys` model.

```
fuelsysRun = Simulink.sdi.getCurrentSimulationRun('sldemo_fuelsys');
```

### **Get Run Object from a Run ID**

When your task also requires the run ID, you can use the `Simulink.sdi.getRun` function to get the corresponding `Simulink.sdi.Run` object that contains the run data and metadata.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelsysRun = Simulink.sdi.getRun(runID);
```

## **Output Arguments**

### **runObj — Simulink.sdi.Run object**

`Simulink.sdi.Run` object

`Simulink.sdi.Run` object for the most recently created run in the Simulation Data Inspector.

## **Version History**

**Introduced in R2020a**

### **See Also**

`Simulink.sdi.Run` | `Simulink.sdi.getCurrentSimulationRun` | `Simulink.sdi.getRun` |  
`Simulink.sdi.getRunCount` | `Simulink.sdi.getRunIDByIndex` |  
`Simulink.sdi.getAllRunIDs`

# Simulink.sdi.save

**Package:** Simulink.sdi

Save Simulation Data Inspector session

## Syntax

```
Simulink.sdi.save(fileName)
```

## Description

`Simulink.sdi.save(fileName)` saves all runs, signals, and visualization settings as a Simulation Data Inspector session in the file `fileName`.

A session file includes data as well as visualization information. Use the `Simulink.sdi.load` function to open a session file in the Simulation Data Inspector. When the session file opens, you can choose to add the data to existing data in the Simulation Data Inspector or clear the existing data.

You can also save only the visualization information to apply to other sets of data. Save visualization information for reuse in a view file using the `Simulink.sdi.saveView` function.

## Examples

### Save a Simulation Data Inspector Session

This example creates, saves, and loads a Simulation Data Inspector session. The example logs data in the model `slexAircraftExample` and visualizes the logged data in a Simulation Data Inspector session. Each time you use the Simulation Data Inspector, you create and modify a session. You can save the data and associated visualization settings for a session in an MLDATX file using the `Simulink.sdi.save` function. When you want to review the data later, you can load the session using the `Simulink.sdi.load` function.

### Log Data to the Simulation Data Inspector

This example logs data from a simulation of the model `slexAircraftExample` to the Simulation Data Inspector. The model is not configured to log data. Load the model and mark the `Stick`, the `alpha`, `rad`, and the `q`, `rad/sec` signals for logging.

```
load_system('slexAircraftExample')

Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot',1,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',3,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')
```

For this example, run two simulations of the model. In the first simulation, use the sine wave output from the `Pilot` block, and in the second, use the square wave output.

```
set_param('slexAircraftExample/Pilot','WaveForm','sine')
sim('slexAircraftExample')
```

```
set_param('slexAircraftExample/Pilot','WaveForm','square')
sim('slexAircraftExample')
```

### Visualize the Logged Data

You can use the Simulation Data Inspector programmatic interface to access the logged data from the simulations. When you access data using the Simulation Data Inspector programmatic interface, you can use functions to create plots in the Simulation Data Inspector.

To start, access the run IDs for the most recent two runs and then get the corresponding `Simulink.sdi.Run` object. The Run objects allow you to access the logged data for the simulations.

```
runIDs = Simulink.sdi.getAllRunIDs;
sineRunID = runIDs(end-1);
squareRunID = runIDs(end);

sineRun = Simulink.sdi.getRun(sineRunID);
squareRun = Simulink.sdi.getRun(squareRunID);
```

Suppose you want to analyze the relationship between the input and output for the model. Get the `Simulink.sdi.Signal` objects for the input and output signals from the two simulation runs.

```
sineOut = getSignalByIndex(sineRun,1);
sineIn = getSignalByIndex(sineRun,3);

squareOut = getSignalByIndex(squareRun,1);
squareIn = getSignalByIndex(squareRun,3);
```

Change the subplot layout in the Simulation Data Inspector to 2-by-1 and plot the signals from the first simulation run on the top plot and the signals from the second run on the bottom plot.

```
Simulink.sdi.setSubPlotLayout(2,1)

plotOnSubPlot(sineIn,1,1,true)
plotOnSubPlot(sineOut,1,1,true)

plotOnSubPlot(squareIn,2,1,true)
plotOnSubPlot(squareOut,2,1,true)
```

### Save the Simulation Data Inspector Session

To view the plotted data in the Simulation Data Inspector, enter `Simulink.sdi.view` in the command window.

Then, save the Simulation Data Inspector session as an MLDATX file.

```
Simulink.sdi.save('myData.mldatx')
```

### Load the Simulation Data Inspector Session

To mimic a scenario where you want to return to looking at the same data at a later point, clear the data from the Simulation Data Inspector and reset the subplot layout to 1-by-1.

```
Simulink.sdi.clear
Simulink.sdi.setSubPlotLayout(1,1)
```

Load the session file and resume working with the data. You can open the Simulation Data Inspector and view the results using the `Simulink.sdi.view` function.

```
Simulink.sdi.load('myData.mldatx');
```

## Input Arguments

### **fileName** — File name

character vector

Name for the session file.

Example: 'myData.mldatx'

## Version History

**Introduced in R2011b**

## See Also

## Topics

“Inspect and Compare Data Programmatically”

“Save and Share Simulation Data Inspector Data and Views”

## Simulink.sdi.saveView

Save visualization settings to apply to other data

### Syntax

```
Simulink.sdi.saveView(filename)
```

### Description

`Simulink.sdi.saveView(filename)` saves the current view in the Simulation Data Inspector to the file, `filename`.

A view contains information about the layout and plots in the graphical viewing area as well as properties of plotted signals. When you load a view, the Simulation Data Inspector uses the properties and preferences in the file to display data currently in the Simulation Data Inspector. Signals in the Simulation Data Inspector that align with the signals in the view are plotted in the graphical viewing area. Use a view to apply a consistent set of visualization settings to multiple sets of similar data.

The view file saves the following information:

- Subplot layout and visualization type
- Settings for each visualization type in the layout
- Signal selection mode
- Replay controls visibility
- Metadata displayed in the work area
- Settings for signal grouping in the work area
- Plotted signals and the line style and color for each plotted signal

A view file does not contain data. To save run data, export the data or save a session using the `Simulink.sdi.save` function.

### Examples

#### Save and Use a View

This example visualizes the output from the `ex_vdp` model, saves the configuration as a view, and then uses the view to visualize the output from another simulation of the same model.

To generate data to plot in the Simulation Data Inspector, simulate the model.

```
open_system('ex_vdp')
set_param('ex_vdp/Mu', 'Gain', '1')
sim('ex_vdp');
```

#### Programmatically Configure and Save a View

The `ex_vdp` model is configured to log two signals, `x1` and `x2`. Plot each signal on a subplot in a 2-by-1 layout.

```
Simulink.sdi.setSubPlotLayout(2,1)
```

To plot one signal on each subplot, first access the `Simulink.sdi.Run` object for the simulation.

```
runIDs = Simulink.sdi.getAllRunIDs;
ex_vdpRunID = runIDs(end);
ex_vdpRun = Simulink.sdi.getRun(ex_vdpRunID);
```

Then, you can access the data for each signal in a `Simulink.sdi.Signal` object and use the `plotOnSubPlot` function to specify where to plot each signal.

```
x1 = getSignalByIndex(ex_vdpRun,1);
x2 = getSignalByIndex(ex_vdpRun,2);
```

```
plotOnSubPlot(x1,1,1,true)
plotOnSubPlot(x2,2,1,true)
```

To view the result in the Simulation Data Inspector, enter `Simulink.sdi.view` in the command window.

Then, save the view.

```
Simulink.sdi.saveView('ex_vdpView.mldatx')
```

## Use the View

To mimic a situation where the Simulation Data Inspector is configured differently and contains data from another simulation, this example clears data from the Simulation Data Inspector, loads a view that represents the default visualization configuration, and runs another simulation of the `ex_vdp` model.

```
Simulink.sdi.clear
Simulink.sdi.loadView('default.mldatx');
set_param('ex_vdp/Mu', 'Gain', '2')
sim('ex_vdp');
```

Use the `Simulink.sdi.loadView` function to apply the saved view from the previous simulation.

```
Simulink.sdi.loadView('ex_vdpView.mldatx')
```

You can open the Simulation Data Inspector to view the results using the `Simulink.sdi.view` function. The saved view includes information regarding the axes limits. When you use a view to apply visualization settings, you may need to adjust axes limits or zoom levels to fit data from a modified simulation.

## Input Arguments

**filename** — Name of view file

string | character array

Name of the view file, specified as a string or character array.

Example: 'myView.mldatx'

Data Types: char | string

## Version History

Introduced in R2020a

# Simulink.sdi.sendWorkerRunToClient

**Package:** Simulink.sdi

Send run created on parallel workers to the Simulation Data Inspector

## Syntax

```
Simulink.sdi.sendWorkerRunToClient
Simulink.sdi.sendWorkerRunToClient(run)
```

## Description

`Simulink.sdi.sendWorkerRunToClient` sends the run most recently generated by the worker to the client MATLAB and imports the run to the Simulation Data Inspector.

`Simulink.sdi.sendWorkerRunToClient(run)` sends the run corresponding to `run` to the client MATLAB and imports the run to the Simulation Data Inspector.

## Examples

### Manually Send Runs from Parallel Workers to the Simulation Data Inspector

This example shows how to use `Simulink.sdi.sendWorkerRunToClient` to send runs created using parallel workers manually to the Simulation Data Inspector.

#### Setup

This example runs several simulations of the `vdp` model, varying the value of the gain, `Mu`. To set up for the parallel simulation, define a vector of `Mu` values and configure the Simulation Data Inspector for manual Parallel Computing Toolbox support.

```
% Enable manual Parallel Computing Toolbox support
Simulink.sdi.enablePCTSupport('manual');
```

```
% Choose several Mu values
MuVals = [1 2 3 4];
```

#### Initialize Parallel Workers

Use `parpool` (Parallel Computing Toolbox) to start a pool of four parallel workers. This example calls `parpool` inside an `if` statement so you only create a parallel pool if you don't already have one. You can use `spmd` (Parallel Computing Toolbox) to run initialization code common to all workers. For example, load the `vdp` model and select signals to log to runs that we can send to the Simulation Data Inspector on the client MATLAB. To avoid data concurrency issues when simulating with `sim` in `parfor`, create a temporary directory on each worker. After the simulations complete, another `spmd` block deletes the temporary directories.

```
p = gcp('nocreate');

if isempty(p)
```

```

 parpool(4);

end

Starting parallel pool (parpool) using the 'local' profile ...
connected to 4 workers.

spmd

 % Load system and select signals to log
 load_system('vdp')
 Simulink.sdi.markSignalForStreaming('vdp/x1',1,'on')
 Simulink.sdi.markSignalForStreaming('vdp/x2',1,'on')

 % Create temporary directory for simulation on worker
 workDir = pwd;
 addpath(workDir)
 tempDir = tempname;
 mkdir(tempDir)
 cd(tempDir)

end

```

### Run Parallel Simulations with parfor

To stream data from parallel workers to the Simulation Data Inspector, you have to run parallel simulations using `parfor` (Parallel Computing Toolbox). Each worker runs a `vdp` simulation with a different value of `Mu`. Simulink cannot access the contents of the `parfor` loop, so the variable `MuVal` is defined in the worker's workspace, where the `vdp` model can see it, using `assignin`.

```

parfor (index = 1:4)

 % Set value of Mu in the worker's base workspace
 assignin('base','MuVal',MuVals(index));

 % Modify the value of Mu in the model and simulate
 set_param('vdp/Mu','Gain','MuVal')
 sim('vdp')

```

### Access Data and Send Run to Client MATLAB

You can use the Simulation Data Inspector programmatic interface on the worker the same way you would in the client MATLAB. This example creates a `Simulink.sdi.Run` object and attaches the value of `Mu` used in the simulation with the `Tag` property.

```

 % Attach metadata to the run
 IDs = Simulink.sdi.getAllRunIDs;
 lastIndex = length(IDs);
 runID = Simulink.sdi.getRunIDByIndex(lastIndex);
 parRun = Simulink.sdi.getRun(runID);
 parRun.Tag = strcat('Mu = ',num2str(MuVals(index)));

 % Send the run to the Simulation Data Inspector on the client MATLAB
 Simulink.sdi.sendWorkerRunToClient

end

```

### **Close Temporary Directories and View Runs in the Simulation Data Inspector**

Use another `spmd` section to delete the temporary directories created on the workers once the simulations complete. In each simulation, `Simulink.sdi.sendWorkerRunToClient` imported runs from all the workers into the Simulation Data Inspector. You can view the data and check the run properties to see the value of `Mu` used during simulation.

```
spmd
```

```
 % Remove temporary directories
 cd(workDir)
 rmdir(tempDir, 's')
 rmpath(workDir)
```

```
end
```

```
Simulink.sdi.view
```

### **Input Arguments**

**run** — Run ID or `Simulink.sdi.Run` object

runID | `Simulink.sdi.Run` object

Run ID or `Simulink.sdi.Run` object corresponding to the run you want to import into the Simulation Data Inspector.

### **Version History**

**Introduced in R2018a**

### **See Also**

# Simulink.sdi.setAppendRunToTop

Specify order in which Simulation Data Inspector appends new run in work area or archive

## Syntax

```
Simulink.sdi.setAppendRunToTop(ord)
```

## Description

`Simulink.sdi.setAppendRunToTop(ord)` configures the order in which the Simulation Data Inspector appends new runs in the work area or archive.

- 1 — New runs are added to the top of the archive or work area.
- 0 — New runs are added to the bottom of the archive or work area.

Whether the `Simulink.sdi.getAppendRunToTop` function sets the order of simulations in the archive or the work area is determined by the **Automatically archive** setting:

- When **Automatically archive** is enabled, the setting applies to runs in the archive.
- When **Automatically archive** is disabled, the setting applies to runs in the work area.

By default, new runs are placed below prior runs in the archive. For more information about configuring the archive behavior, see `Simulink.sdi.setAutoArchiveMode`.

## Examples

### Change Order and Location of Runs

First, determine the order that runs are currently stored in the archive.

```
ord = Simulink.sdi.getAppendRunToTop
```

```
ord = logical
 0
```

By default, runs moved into the archive are placed below runs already in the archive. To have runs placed above the runs already in the archive, change the value of the `Simulink.sdi.setAppendRunToTop` function.

```
Simulink.sdi.setAppendRunToTop(true)
```

You can restore the original placement of runs as they move to the archive by passing `ord` back to the set function.

```
Simulink.sdi.setAppendRunToTop(ord)
```

## Input Arguments

**ord** — **Whether Simulation Data Inspector appends new run to top of work area or archive**  
false or 0 (default) | true or 1

Whether Simulation Data Inspector appends new run to top of work area or archive, specified by true (1) or false (0).

Data Types: logical

## Version History

**Introduced in R2022b**

### Topics

“Configure the Simulation Data Inspector”

# Simulink.sdi.setArchiveRunLimit

Specify number of runs to retain in Simulation Data Inspector archive

## Syntax

```
Simulink.sdi.setArchiveRunLimit(limit)
```

## Description

`Simulink.sdi.setArchiveRunLimit(limit)` sets the limit `limit` for the number of runs to retain in the Simulation Data Inspector archive. When the number of runs in the archive reaches the specified limit, the Simulation Data Inspector deletes runs from the archive on a first-in, first-out basis.

---

**Tip** To automatically limit the number of runs, configure the Simulation Data Inspector to automatically move prior runs into the archive using the `Simulink.sdi.setAutoArchiveMode` function and specify the archive run limit.

For information about how to control the amount of data logged from simulation, see “Limit the Size of Logged Data”.

---

## Examples

### Limit Number of Runs Retained in Simulation Data Inspector

Configure the Simulation Data Inspector to automatically move prior simulation runs into the archive.

```
Simulink.sdi.setAutoArchiveMode(true)
```

Specify the number of runs to retain in the Simulation Data Inspector by setting the archive run limit. For example, specify the archive run limit as 5 to only retain five prior runs in addition to the current run.

```
Simulink.sdi.setArchiveRunLimit(5)
```

The Simulation Data Inspector automatically moves prior runs into the archive. Once the archive contains five runs, the Simulation Data Inspector deletes run data from the archive on a first-in, first-out basis.

### Stop Retaining Data in Simulation Data Inspector

You can configure the Simulation Data Inspector to retain only the logged data for your current simulation. In iterative design and debugging workflows, this configuration helps prevent the accumulation of unwanted logged data on disk.

First, check the configuration of the Simulation Data Inspector archive. Save the archive preference values to restore your preferences after you finish designing or debugging.

```
limit = Simulink.sdi.getArchiveRunLimit;
mode = Simulink.sdi.getAutoArchiveMode;
```

Configure the Simulation Data Inspector to automatically move runs into the archive. Then, set the archive run limit to 0.

```
Simulink.sdi.setAutoArchiveMode(true)
Simulink.sdi.setArchiveRunLimit(0)
```

When you simulate your model, the Simulation Data Inspector deletes the previous run and updates the view to show signals from the current simulation.

When you finish designing or debugging your model, you can restore the Simulation Data Inspector archive to the previous configuration.

```
Simulink.sdi.setArchiveRunLimit(limit)
Simulink.sdi.setAutoArchiveMode(mode)
```

## Input Arguments

### **limit** — Maximum number of runs to store in Simulation Data Inspector archive

numeric scalar

Maximum number of runs to store in Simulation Data Inspector archive, specified as a whole numeric scalar. To configure no limit, specify -1.

#### **Tips**

To retain simulation results for only the current run, configure the Simulation Data Inspector to automatically archive simulation runs, and specify the archive run limit as 0.

```
Simulink.sdi.setAutoArchiveMode(true)
Simulink.sdi.setArchiveRunLimit(0)
```

## Version History

**Introduced in R2018b**

### **See Also**

#### **Topics**

“Limit the Size of Logged Data”

“Configure the Simulation Data Inspector”

# Simulink.sdi.setAutoArchiveMode

Specify how Simulation Data Inspector manages simulation runs

## Syntax

```
Simulink.sdi.setAutoArchiveMode(archive)
```

## Description

`Simulink.sdi.setAutoArchiveMode(archive)` configures the Simulation Data Inspector to manage simulation runs according to `archive`.

When you run multiple simulations in a single MATLAB session, the Simulation Data Inspector retains results from each simulation so you can analyze the results together. Use the Simulation Data Inspector archive to manage the number of runs the Simulation Data Inspector retains and to visually manage runs in the user interface.

With automatic archiving enabled, when you start a simulation, the Simulation Data Inspector moves the prior run into the archive. In the user interface, prior runs automatically move into the collapsible **Archive** pane, and plots automatically update to show data from the current simulation.

With automatic archiving disabled, the Simulation Data Inspector does not move runs to the archive or automatically update plots.

---

**Tip** When you enable automatic archiving and specify an archive run limit, the Simulation Data Inspector automatically manages the number of runs it retains. Once the number of runs reaches the specified limit, the Simulation Data Inspector deletes runs from the archive on a first-in, first-out basis.

For more information about how to control the amount of data logged from simulation, see “Limit the Size of Logged Data”.

---

## Examples

### Limit Number of Runs Retained in Simulation Data Inspector

Configure the Simulation Data Inspector to automatically move prior simulation runs into the archive.

```
Simulink.sdi.setAutoArchiveMode(true)
```

Specify the number of runs to retain in the Simulation Data Inspector by setting the archive run limit. For example, specify the archive run limit as 5 to only retain five prior runs in addition to the current run.

```
Simulink.sdi.setArchiveRunLimit(5)
```

The Simulation Data Inspector automatically moves prior runs into the archive. Once the archive contains five runs, the Simulation Data Inspector deletes run data from the archive on a first-in, first-out basis.

## Stop Retaining Data in Simulation Data Inspector

You can configure the Simulation Data Inspector to retain only the logged data for your current simulation. In iterative design and debugging workflows, this configuration helps prevent the accumulation of unwanted logged data on disk.

First, check the configuration of the Simulation Data Inspector archive. Save the archive preference values to restore your preferences after you finish designing or debugging.

```
limit = Simulink.sdi.getArchiveRunLimit;
mode = Simulink.sdi.getAutoArchiveMode;
```

Configure the Simulation Data Inspector to automatically move runs into the archive. Then, set the archive run limit to 0.

```
Simulink.sdi.setAutoArchiveMode(true)
Simulink.sdi.setArchiveRunLimit(0)
```

When you simulate your model, the Simulation Data Inspector deletes the previous run and updates the view to show signals from the current simulation.

When you finish designing or debugging your model, you can restore the Simulation Data Inspector archive to the previous configuration.

```
Simulink.sdi.setArchiveRunLimit(limit)
Simulink.sdi.setAutoArchiveMode(mode)
```

## Input Arguments

### **archive** — Whether Simulation Data Inspector manages runs using archive

true or 1 (default) | false or 0

Whether Simulation Data Inspector manages runs using archive, specified as logical true (1) or false (0).

Data Types: logical

## Version History

Introduced in R2018b

# Simulink.sdi.setBorderOn

Display or hide border on time plots

## Syntax

```
Simulink.sdi.setBorderOn(border)
```

## Description

`Simulink.sdi.setBorderOn(border)` displays or hides the border on time plots in the Simulation Data Inspector according to the logical input, `border`. The function sets the value of the **Show border** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector shows the border on time plots.

## Examples

### Configure Time Plot Border Display

You can use the `Simulink.sdi.setBorderOn` function to show or hide the border on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector shows the border on time plots.

This example starts by showing how to use the `Simulink.sdi.getBorderOn` function to determine whether the border is currently displayed. Subsequent sections show the code to hide and show the border. To show the result, the example generates an image using the `Simulink.sdi.snapshot` function with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

### Get Current Border Display Setting

Before modifying the border display setting for time plots, you can save the current setting to a variable in the workspace in case you want to restore the preference later.

```
border = Simulink.sdi.getBorderOn;
```

### Hide the Border on Time Plots

```
Simulink.sdi.setBorderOn(false)
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Show the Border on Time Plots

```
Simulink.sdi.setBorderOn(true)
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Input Arguments

### **border** — Whether border is visible on time plots

`true` or `1` (default) | `false` or `0`

Whether the border is visible on time plots in the Simulation Data Inspector, specified as `true` (1) or `false` (0).

- `true` or `1` — Display border for time plots.
- `false` or `0` — Hide border for time plots.

## Version History

**Introduced in R2019b**

“Create Plots Using the Simulation Data Inspector”

# Simulink.sdi.setCursorOptions

Configure shading options for cursors in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.setCursorOptions(Name,Value)
```

## Description

`Simulink.sdi.setCursorOptions(Name,Value)` configures shading options for cursors in the Simulation Data Inspector according to one or more name-value pair arguments. For example, `'ShadeArea', 'InBetween'` configures the Simulation Data Inspector to apply shading to the area between two cursors. You can specify name-value pair arguments to configure the area to shade, the color and opacity of the shaded region, and whether signal data is emphasized in the shaded region.

## Examples

### Configure Shading Options for Cursors in the Simulation Data inspector

You can configure shading options for cursors to draw attention to a region of interest in a time plot. You can choose to emphasize or de-emphasize the signal data in the shaded region, and you can specify the shading color and opacity. By default, the Simulation Data Inspector shades areas gray with an opacity of 0.7 to de-emphasize signal data and shades areas light blue with an opacity of 0.7 when signal data is emphasized.

Suppose you want to highlight a signal transition by shading the area where the transition occurs a light yellow. Configure the cursors to highlight the area between the cursors a light yellow color.

```
Simulink.sdi.setCursorOptions('Emphasize',true,...
 'ShadeArea','InBetween','ShadeColor',[1 1 0.6]);
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'ShadeArea', 'Lead', 'ShadeOpacity', 0.5` configures cursors to shade the area that leads the left-most cursor with an opacity of 0.5.

### Type — Where to apply cursor options

'Inspect' (default) | 'Compare'

Where to apply cursor options, specified as the name-value pair consisting of 'Type' and 'Inspect' or 'Compare'. You can configure independent cursor options for the **Inspect** and **Compare** panes in the Simulation Data Inspector.

Example: 'Type', 'Compare' configures cursor options for the **Compare** pane.

### **Emphasize — Whether signal data is emphasized in the shaded region**

true or 1 (default) | false or 0

Whether signal data is emphasized in shaded region, specified as the name-value pair consisting of 'Emphasize' and true or false. When emphasized, the signal data is plotted on top of the cursor shading.

Example: 'Emphasize', false configures cursor options to plot signal data under shaded region.

### **ShadeArea — Area to shade relative to cursors**

'lead' (default) | 'lag' | 'leadandlag' | 'inbetween' | 'none'

Area to shade relative to cursors, specified as the name-value pair consisting of 'ShadeArea' and one of these options:

- 'lead' — Shade the plot area that leads the left-most cursor.
- 'lag' — Shade the plot area that lags the right-most cursor.
- 'leadandlag' — Shade the plot area outside of the cursors, when two cursors are displayed.
- 'inbetween' — Shade the plot area between the cursors, when two cursors are displayed.
- 'none' — Do not shade any plot area.

Example: 'ShadeArea', 'none' configures cursor options to not shade any region relative to the cursors.

### **ShadeColor — Color of the shaded area**

[r g b] vector

Color of the shaded area, specified as the name-value pair consisting of 'ShadeColor' and an r g b vector with values between 0 and 1.

Example: 'ShadeColor', [0 0 1] configures the color of the shaded area as blue.

### **ShadeOpacity — Opacity of the shaded area**

percentage value between 0 and 1

Opacity of the shaded area, specified as the name-value pair consisting of 'ShadeOpacity' and a percentage value between 0 and 1.

Example: 'ShadeOpacity', 0.5 configures the opacity of the shaded area as 0.5.

## **Version History**

“Create Plots Using the Simulation Data Inspector”

# Simulink.sdi.setCursorPositions

Specify active cursor positions in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.setCursorPositions(Name,Value)
```

## Description

`Simulink.sdi.setCursorPositions(Name,Value)` configures the position for active cursors in the Simulation Data Inspector as specified by one or more name-value pair arguments.

## Examples

### Programmatically Interact with Cursors in the Simulation Data Inspector

You can use the Simulation Data Inspector programmatic interface to specify the position of cursors on time plots or sparklines and to access the time that corresponds to the current cursor position.

Open the session file `vdp_mu.mldatx` to add plot data in the Simulation Data Inspector. The session file contains data for a 20-second simulation of a model of the Van Der Pol equation, with signals `x1` and `x2` plotted on separate subplots in a 2-by-1 subplot layout.

```
open vdp_mu.mldatx;
```

Use the `Simulink.sdi.setNumCursors` function to add one cursor to the plot.

```
Simulink.sdi.setNumCursors(1);
```

Suppose you want to know the signal values 5 seconds into the simulation. Use the `Simulink.sdi.setCursorPositions` function to move the cursor to `t=5s` and read the signal values off from the cursor on each subplot. The asterisk next to the value in the cursor label indicates that the value is interpolated because the simulation did not include a calculation for a simulation time of exactly 5s.

```
Simulink.sdi.setCursorPositions('left',5);
```

Suppose you want to calculate the time between two peaks in the x2 signal. Add a second cursor using the `Simulink.sdi.setNumCursors` function or by using Show/hide data cursors  in the Simulation Data Inspector.

```
numCursors = Simulink.sdi.getNumCursors;
if(numCursors < 2)
 Simulink.sdi.setNumCursors(2);
end
```

Drag the cursors so the left cursor is positioned at the first peak in the x2 signal and the right cursor is positioned at the second peak. Alternatively, you can run this code that positions the cursors for you.

```
Simulink.sdi.setCursorPositions('left',5.921998549931304,...
 'right',12.378442136906246);
```

The Simulation Data Inspector displays the difference between the two cursors in seconds. However, the cursor position and difference values are both rounded. Use the `Simulink.sdi.getCursorPosition` function to programmatically retrieve the exact time values that correspond to the cursor positions. Then, compute the difference between the times.

```
[t1,t2] = Simulink.sdi.getCursorPosition;
T = t2 - t1
```

```
T = 6.4564
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Simulink.sdi.setCursorPositions('right',10,'view','compare')` moves the right cursor on the **Compare** pane to 10s.

**left — Left cursor position**

scalar

Left cursor position, specified as a finite scalar using units of s. Use the 'left' name-value pair argument to specify the position for a single active cursor.

Cursor identities are relative, not absolute. If you specify a value for the left cursor that moves it to the right of the right cursor, the left cursor becomes the right cursor and vice versa.

Example: `Simulink.sdi.setCursorPositions('left',0.5)` moves the left cursor to 500ms.

Data Types: double

**right — Right cursor position**

scalar

Right cursor position, specified as a finite scalar using units of s.

Cursor identities are relative, not absolute. If you specify a value for the left cursor that moves it to the right of the right cursor, the left cursor becomes the right cursor and vice versa.

Example: `Simulink.sdi.setCursorPositions('right',10)` moves the right cursor to 10s.

**Tips**

Use the 'left' name-value pair argument to specify the position for a single active cursor.

Data Types: double

**view — Plot area on which to move cursors**

'inspect' (default) | 'compare'

Plot area on which to move cursors, specified as 'inspect' or 'compare'.

Example: `Simulink.sdi.setCursorPositions('right',10,'view','compare')` moves the right cursor on the **Compare** pane to 10s.

Data Types: char | string

# Simulink.sdi.setDeleteRunsOnLowSpace

Specify behavior when logged data size approaches configured limits

## Syntax

```
Simulink.sdi.setDeleteRunsOnLowSpace(deleteRuns)
```

## Description

`Simulink.sdi.setDeleteRunsOnLowSpace(deleteRuns)` configures the action to take when the size of logged data approaches the configured maximum size or minimum free disk space requirement. When `deleteRuns` is `true`, logged data from prior simulations is deleted first to free space for continued logging in the current simulation. If deleting prior simulation data does not free enough disk space to continue logging through the end of the current simulation, recording data is disabled. When `deleteRuns` is `false`, recording data from the current simulation is disabled and no logged data from prior simulations is deleted.

## Examples

### Configure Logged Data Size Limits

Logging data from simulation can produce large amounts of data that may fill up disk space. To mitigate issues related to filing disk space, you can specify a minimum disk space requirement, a maximum size for logged data, or both. To ensure the logged data does not exceed the specified maximum size or use enough disk space to violate the disk space requirement, prior run data may be deleted and recording logged data may be disabled. You can specify whether to prioritize continuing to log data in the current simulation or retaining prior simulation data.

Use the `Simulink.sdi.setRequiredFreeSpace` function to configure logging to leave at least 1 GB of disk space empty.

```
Simulink.sdi.setRequiredFreeSpace(1);
```

Use the `Simulink.sdi.setMaxDiskUsage` function to specify a maximum logged data size of 100 GB.

```
Simulink.sdi.setMaxDiskUsage(100);
```

When you configure logging size limits, you can also specify what to do when the logging limits are approached. You can choose whether to prioritize retaining data from prior runs or data in the current run.

By default, current simulation data is prioritized. If the size of logged data approaches configured limits, data from prior simulations is deleted. If deleting run data does not free enough space, recording logged data is disabled and no more data from the current simulation is saved. When you choose to prioritize logged data from prior simulations instead, recording is disabled as soon as the size of logged data approaches configured limits. You see a warning when run data is deleted and when recording is disabled.

Use the `Simulink.sdi.setDeleteRunsOnLowSpace` function to configure logging to prioritize retaining prior run data.

```
Simulink.sdi.setDeleteRunsOnLowSpace(false);
```

If recording is disabled due to the size of logged data, you need to enable recording again to save data from future simulations. Use the `Simulink.sdi.setRecordData` function to enable recording.

```
Simulink.sdi.setRecordData(true);
```

## Input Arguments

### **deleteRuns** — Behavior when logged data size approaches configured limits

`true` or `1` (default) | `false` or `0`

Behavior when logged data size approaches configured limits, specified as numeric or logical `1` (`true`) or `0` (`false`).

- `true` — First delete data logged from prior simulations. If deleting prior simulation data does not free enough space, disable recording data.
- `false` — Disable recording data for current simulation. Do not delete prior simulation data.

When recording is disabled due to configured disk space requirements or logged data size limits, you need to enable recording again to log data in subsequent simulations. You can configure the record mode in the Simulation Data Inspector preferences or using the `Simulink.sdi.setRecordData` function.

Data Types: `logical`

# Simulink.sdi.setGridOn

**Package:** Simulink.sdi

Configure grid lines for time plots in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.setGridOn(grid)
```

## Description

`Simulink.sdi.setGridOn(grid)` configures the grid lines for time plots in the Simulation Data Inspector according to the input, `grid`. The function configures the **Horizontal** and **Vertical** options on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The settings apply to the session and configure the grids for all time plots. By default, the Simulation Data Inspector shows horizontal and vertical grid lines.

## Examples

### Configure Grid for Time Plots in the Simulation Data Inspector

You can use `Simulink.sdi.setGridOn` to configure the appearance of the grid for time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector shows horizontal and vertical grid lines.

This example starts by showing how to use `Simulink.sdi.getGridOn` to access the current grid configuration. The subsequent sections show the code for each configuration option for time plot grid in the Simulation Data Inspector. To see the result, the example uses a `Simulink.sdi.CustomSnapshot` object to specify settings for the output of the `Simulink.sdi.snapshot` function.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

### Get Initial Grid Setting

Before modifying the grid display preferences, you can save the current configuration to a variable in the workspace in case you want to restore the preferences later.

```
gridInit = Simulink.sdi.getGridOn;
```

### Configure Horizontal Grid Lines

Show only horizontal grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('horizontal')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Configure Vertical Grid Lines

Show only vertical grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('vertical')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

### Configure No Grid Lines

Show no grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('off')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Configure Horizontal and Vertical Grid Lines

Show horizontal and vertical grid lines in the Simulation Data Inspector.

```
Simulink.sdi.setGridOn('on')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Input Arguments

### grid — Visible grid lines

'on' (default) | 'horizontal' | 'vertical' | 'off'

Grid lines to show on time plots in the Simulation Data Inspector, specified as one of these options:

- 'on' — Horizontal and vertical grid lines
- 'horizontal' — Only horizontal grid lines
- 'vertical' — Only vertical grid lines
- 'off' — No grid lines

## Version History

Introduced in R2019a

### R2019b: Specifying the input as a logical value is not recommended

Starting in R2019b, the `Simulink.sdi.setGridOn` input values changed to:

- 'on'
- 'horizontal'
- 'vertical'

- 'off'

In R2019a, the `Simulink.sdi.setGridOn` accepted a logical input to show or hide the grid on time plots in the Simulation Data Inspector:

- `true` or `1` shows horizontal and vertical grid lines on time plots in the Simulation Data Inspector.
- `false` or `0` hides horizontal and vertical grid lines on time plots in the Simulation Data Inspector.

Starting in R2019b, use the 'on' input value for the same behavior as the `true` or `1` input, and use the 'off' input value for the same behavior as the `false` or `0` input.

# Simulink.sdi.setMarkersOn

**Package:** Simulink.sdi

Show or hide markers for plotted signals

## Syntax

```
Simulink.sdi.setMarkersOn(value)
```

## Description

`Simulink.sdi.setMarkersOn(value)` shows or hides markers on signals plotted in the Simulation Data Inspector according to the logical input, `value`. The function configures the **Show markers** setting in the Simulation Data Inspector. The setting applies to the session and shows or hides markers for all signals plotted in the Simulation Data Inspector. By default, markers are hidden in the Simulation Data Inspector.

## Examples

### Display Markers in the Simulation Data Inspector

```
Simulink.sdi.setMarkersOn(true);
```

## Input Arguments

### `value` — Logical input

false or 0 (default) | true or 1

Logical specification of whether markers are shown on plots in the Simulation Data Inspector.

- true or 1 shows markers on plots in the Simulation Data Inspector.
- false or 0 does not show markers on plots in the Simulation Data Inspector.

Data Types: logical

## Version History

# Simulink.sdi.setMaxDiskUsage

Specify maximum size for data logged to disk

## Syntax

```
Simulink.sdi.setMaxDiskUsage(maxSize)
```

## Description

`Simulink.sdi.setMaxDiskUsage(maxSize)` configures logging to use no more than the maximum amount of disk space specified by `maxSize`, in units of GB.

When you configure a maximum size for logged data, you can also configure the behavior when logged data approaches the maximum size using the `Simulink.sdi.setDeleteRunsOnLowSpace` function. For more information, see “Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data”.

## Examples

### Configure Logged Data Size Limits

Logging data from simulation can produce large amounts of data that may fill up disk space. To mitigate issues related to filing disk space, you can specify a minimum disk space requirement, a maximum size for logged data, or both. To ensure the logged data does not exceed the specified maximum size or use enough disk space to violate the disk space requirement, prior run data may be deleted and recording logged data may be disabled. You can specify whether to prioritize continuing to log data in the current simulation or retaining prior simulation data.

Use the `Simulink.sdi.setRequiredFreeSpace` function to configure logging to leave at least 1 GB of disk space empty.

```
Simulink.sdi.setRequiredFreeSpace(1);
```

Use the `Simulink.sdi.setMaxDiskUsage` function to specify a maximum logged data size of 100 GB.

```
Simulink.sdi.setMaxDiskUsage(100);
```

When you configure logging size limits, you can also specify what to do when the logging limits are approached. You can choose whether to prioritize retaining data from prior runs or data in the current run.

By default, current simulation data is prioritized. If the size of logged data approaches configured limits, data from prior simulations is deleted. If deleting run data does not free enough space, recording logged data is disabled and no more data from the current simulation is saved. When you choose to prioritize logged data from prior simulations instead, recording is disabled as soon as the size of logged data approaches configured limits. You see a warning when run data is deleted and when recording is disabled.

Use the `Simulink.sdi.setDeleteRunsOnLowSpace` function to configure logging to prioritize retaining prior run data.

```
Simulink.sdi.setDeleteRunsOnLowSpace(false);
```

If recording is disabled due to the size of logged data, you need to enable recording again to save data from future simulations. Use the `Simulink.sdi.setRecordData` function to enable recording.

```
Simulink.sdi.setRecordData(true);
```

## Input Arguments

### **maxSize** — Maximum size for data logged to disk

0 (default) | scalar

Maximum size for data logged to disk, specified as a scalar, in units of GB. To configure no limit on the size of logged data, specify 0.

Example: `Simulink.sdi.setMaxDiskUsage(500)` configures logging to use no more than 500 GB of disk space.

## Version History

Introduced in R2021a

# Simulink.sdi.setNumCursors

Configure number of cursors active in Simulation Data Inspector

## Syntax

```
Simulink.sdi.setNumCursors(num)
Simulink.sdi.setNumCursors(num,view)
```

## Description

`Simulink.sdi.setNumCursors(num)` configures the Simulation Data Inspector to display the number of cursors specified by `num` in the **Inspect** pane plots.

`Simulink.sdi.setNumCursors(num,view)` configures the Simulation Data Inspector to display the number of cursors specified by `num` in the **Inspect** or **Compare** plot area, as specified by `view`.

## Examples

### Programmatically Interact with Cursors in the Simulation Data Inspector

You can use the Simulation Data Inspector programmatic interface to specify the position of cursors on time plots or sparklines and to access the time that corresponds to the current cursor position.

Open the session file `vdp_mu.mldatx` to add plot data in the Simulation Data Inspector. The session file contains data for a 20-second simulation of a model of the Van Der Pol equation, with signals `x1` and `x2` plotted on separate subplots in a 2-by-1 subplot layout.

```
open vdp_mu.mldatx;
```

Use the `Simulink.sdi.setNumCursors` function to add one cursor to the plot.

```
Simulink.sdi.setNumCursors(1);
```

Suppose you want to know the signal values 5 seconds into the simulation. Use the `Simulink.sdi.setCursorPositions` function to move the cursor to `t=5s` and read the signal values off from the cursor on each subplot. The asterisk next to the value in the cursor label indicates that the value is interpolated because the simulation did not include a calculation for a simulation time of exactly 5s.

```
Simulink.sdi.setCursorPositions('left',5);
```

Suppose you want to calculate the time between two peaks in the x2 signal. Add a second cursor

using the `Simulink.sdi.setNumCursors` function or by using Show/hide data cursors  in the Simulation Data Inspector.

```
numCursors = Simulink.sdi.getNumCursors;
if(numCursors < 2)
 Simulink.sdi.setNumCursors(2);
end
```

Drag the cursors so the left cursor is positioned at the first peak in the x2 signal and the right cursor is positioned at the second peak. Alternatively, you can run this code that positions the cursors for you.

```
Simulink.sdi.setCursorPositions('left',5.921998549931304,...
 'right',12.378442136906246);
```

The Simulation Data Inspector displays the difference between the two cursors in seconds. However, the cursor position and difference values are both rounded. Use the `Simulink.sdi.getCursorPosition` function to programmatically retrieve the exact time values that correspond to the cursor positions. Then, compute the difference between the times.

```
[t1,t2] = Simulink.sdi.getCursorPosition;
T = t2 - t1
```

```
T = 6.4564
```

## Input Arguments

**num** — Number of cursors to display

0 | 1 | 2

Number of cursors to display, specified as 0, 1, or 2.

**view** — Plot area in which to display cursors

'inspect' (default) | 'compare'

Plot area in which to display cursors, specified as 'inspect' or 'compare'.

Data Types: char | string

# Simulink.sdi.setPosition

Set position and size of Simulation Data Inspector

## Syntax

```
Simulink.sdi.setPosition(pos)
```

## Description

`Simulink.sdi.setPosition(pos)` sets the position and size of the Simulation Data Inspector window based on the values in the vector, `pos`. The Simulation Data Inspector must be open before changing the position or size of the window.

## Examples

### Change Position of Simulation Data Inspector

This example shows you how to change the position and size of the Simulation Data Inspector window. First, open the Simulation Data Inspector.

```
Simulink.sdi.view
```

Set the Simulation Data Inspector window to be:

- 800 pixels wide
- 500 pixels high
- 200 pixels from the left edge of your primary display
- 60 pixels from the bottom of your primary display

```
pos = [200 60 800 500];
Simulink.sdi.setPosition(pos)
```

Alternatively, you can move and resize the Simulation Data Inspector manually. To use this placement in future simulations, retrieve the position vector using the function `Simulink.sdi.getPosition`.

```
newPos = Simulink.sdi.getPosition
```

```
newPos = 1×4
```

```
 200 60 800 500
```

## Input Arguments

**pos** — Position and size of Simulation Data Inspector  
numeric array (default)

Position and size of the Simulation Data Inspector window, specified as a four-element vector in the form [left bottom width height]. All measurements have units of pixels.

| <b>Element</b> | <b>Description</b>                                                                                                                                                  |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| left           | Distance from the left edge of the primary display to the inner-left edge of the window. This value can be negative on systems that have more than one monitor.     |
| bottom         | Distance from the bottom edge of the primary display to the inner-bottom edge of the window. This value can be negative on systems that have more than one monitor. |
| width          | Distance between the right and left inner edges of the window.                                                                                                      |
| height         | Distance between the top and bottom inner edges of the window.                                                                                                      |

# Simulink.sdi.setRecordData

Specify record mode for logging

## Syntax

```
Simulink.sdi.setRecordData(record)
```

## Description

`Simulink.sdi.setRecordData(record)` configures the logging **Record mode** according to the value of `record`. When `record` is `true`, logged data is available to view during simulation and for analysis after simulation. When `record` is `false`, data is only available for viewing during simulation and is not available after simulation in the workspace or the Simulation Data Inspector.

## Examples

### Configure Logging to View Data Only During Simulation

In certain scenarios, you may want to only view logged data during simulation and not save any data to disk. For example, when using the Simulation Data Inspector to visualize data streaming from hardware, you may only want to view the data live and not record it. Use the `Simulink.sdi.setRecordData` function to configure the **Record mode** setting in the Simulation Data Inspector programmatically. To view data only during simulation, specify the input as `false`.

```
Simulink.sdi.setRecordData(false)
```

When you want to record logged data on disk so that it is available for analysis after simulation, call the `Simulink.sdi.setRecordData` function with `true` as the input.

```
Simulink.sdi.setRecordData(true)
```

The **Record mode** setting is restored to **View and record data** at the start of each MATLAB session.

## Input Arguments

### record — Record mode

`true` or 1 (default) | `false` or 0

Record mode, specified as numeric or logical 1 (`true`) or 0 (`false`).

- `true` — Logged data is stored on disk and available in the workspace and the Simulation Data Inspector after simulation.
- `false` — Logged data is not stored on disk and is only available to view during simulation. After simulation, no logged data is available in the Simulation Data Inspector or workspace.

Specifying `record` as `false` can affect other applications. For more information, see “View Data Only During Simulation”.

Data Types: `logical`

# Simulink.sdi.setRequiredFreeSpace

Specify minimum disk space to leave free when logging data

## Syntax

```
Simulink.sdi.setRequiredFreeSpace(minDiskSpace)
```

## Description

`Simulink.sdi.setRequiredFreeSpace(minDiskSpace)` configures logging to leave at least the number of GB specified by `minDiskSpace` free when logging data.

When you configure a minimum amount of disk space to leave free, you can also configure the behavior when the free disk space limit is approached using the `Simulink.sdi.setDeleteRunsOnLowSpace` function. For more information, see “Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data”.

## Examples

### Configure Logged Data Size Limits

Logging data from simulation can produce large amounts of data that may fill up disk space. To mitigate issues related to filing disk space, you can specify a minimum disk space requirement, a maximum size for logged data, or both. To ensure the logged data does not exceed the specified maximum size or use enough disk space to violate the disk space requirement, prior run data may be deleted and recording logged data may be disabled. You can specify whether to prioritize continuing to log data in the current simulation or retaining prior simulation data.

Use the `Simulink.sdi.setRequiredFreeSpace` function to configure logging to leave at least 1 GB of disk space empty.

```
Simulink.sdi.setRequiredFreeSpace(1);
```

Use the `Simulink.sdi.setMaxDiskUsage` function to specify a maximum logged data size of 100 GB.

```
Simulink.sdi.setMaxDiskUsage(100);
```

When you configure logging size limits, you can also specify what to do when the logging limits are approached. You can choose whether to prioritize retaining data from prior runs or data in the current run.

By default, current simulation data is prioritized. If the size of logged data approaches configured limits, data from prior simulations is deleted. If deleting run data does not free enough space, recording logged data is disabled and no more data from the current simulation is saved. When you choose to prioritize logged data from prior simulations instead, recording is disabled as soon as the size of logged data approaches configured limits. You see a warning when run data is deleted and when recording is disabled.

Use the `Simulink.sdi.setDeleteRunsOnLowSpace` function to configure logging to prioritize retaining prior run data.

```
Simulink.sdi.setDeleteRunsOnLowSpace(false);
```

If recording is disabled due to the size of logged data, you need to enable recording again to save data from future simulations. Use the `Simulink.sdi.setRecordData` function to enable recording.

```
Simulink.sdi.setRecordData(true);
```

## Input Arguments

### **minDiskSpace** — Minimum amount of free disk space required

0.1 (default) | scalar

Minimum amount of free disk space required, specified as a scalar, in units of GB. The minimum disk space requirement is a way to limit the size of logged data. The **When low on disk space** setting specifies what happens when the minimum disk space requirement is approached. For more information, see “Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data”.

Example: `Simulink.sdi.setRequiredFreeSpace(0.5)` configures logging to leave at least half a gigabyte of free disk space.

## Version History

Introduced in R2021a

# Simulink.sdi.setRunNamingRule

**Package:** Simulink.sdi

Specify the Simulation Data Inspector run naming rule

## Syntax

```
Simulink.sdi.setRunNamingRule('rule')
```

## Description

`Simulink.sdi.setRunNamingRule('rule')` sets the Simulation Data Inspector rule for naming runs created by simulating a Simulink model.

## Examples

### Modify Run Naming Rule Then Restore Default

This example shows how to use the Simulation Data Inspector API to modify the Simulation Data Inspector run naming rule, check a run's name, restore default preferences, and check the run naming rule.

```
% Load model
load_system('sldemo_fuelsys')

% Modify run naming rule
Simulink.sdi.setRunNamingRule('<model_name> Run <run_index>')

% Simulate system
sim('sldemo_fuelsys')

% Check run name
runIDs = Simulink.sdi.getAllRunIDs;
runID = runIDs(end);
fuelRun = Simulink.sdi.getRun(runID);
fuelRun.name

ans =
'sldemo_fuelsys Run 1'

% Clear preferences to reset the run naming rule
Simulink.sdi.clearPreferences

% Check run naming rule
Simulink.sdi.getRunNamingRule

ans =
'Run <run_index>: <model_name>'
```

## Input Arguments

### 'rule' — Simulation Data Inspector run naming rule

Run <run\_index>: <model\_name> (default) | character vector

Simulation Data Inspector run naming rule for runs created by simulating a Simulink model. The character vector specifying the run naming rule can include plain text and any of the following tokens that represent data pulled from each run:

- <run\_index> - Run's index in the Simulation Data Inspector repository.
- <model\_name> - Name of the model simulated to create the run.
- <time\_stamp> - Start time for the simulation that created the run.
- <sim\_mode> - Simulation mode used for the simulation that created the run.

Example: '<time\_stamp> Simulation <run\_index>: <model\_name>'

Example: '<model\_name> - <run\_index>'

## Alternatives

You can modify the run naming rule using the Simulation Data Inspector UI in the **Preferences** menu. You can rename a run by modifying the Name property of its `Simulink.sdi.Run` object.

## Version History

**Introduced in R2011b**

# Simulink.sdi.setSignalInputProcessingMode

Specify value for Input Processing signal property

## Syntax

```
Simulink.sdi.setSignalInputProcessingMode(blkPath,port,mode)
Simulink.sdi.setSignalInputProcessingMode(h,mode)
```

## Description

`Simulink.sdi.setSignalInputProcessingMode(blkPath,port,mode)` specifies `mode` as the value of the **Input Processing** property for the signal at the specified block path and port. You can only specify the **Input Processing** property for logged signals.

The **Input Processing** setting affects the format of the logged data and how the Simulation Data Inspector and dashboard blocks display the signal. You can configure a signal for frame-based or sample-based input processing.

`Simulink.sdi.setSignalInputProcessingMode(h,mode)` specifies `mode` as the value of the **Input Processing** property for the signal that corresponds to the line handle, `h`.

## Examples

### Programmatically Specify Input Processing Setting to Log a Frame-Based Signal

Many signal processing applications process data using frames, rather than individual signal values. A frame consists of signal values for several sample times. To process signals as frame-based in your model, specify frame-based processing in the blocks. To log and visualize frame-based signals, set the **Input Processing** setting to `Columns as channels (frame based)` in the Instrumentation Properties for the signal.

This example uses a model from the DSP System Toolbox™ to show how to programmatically specify the **Input Processing** setting for signals in a model using the `Simulink.sdi.setSignalInputProcessingMode` function. The model uses frame-based signals and demonstrates single sideband (SSB) modulation.

### Configure Signal Logging

Open or load the model `ssbdemo_frame`. This example illustrates a scripting workflow and only loads the model.

```
load_system('ssbdemo_frame');
```

The model includes visualization blocks and does not use signal logging. Mark the signals that represent the upper sideband and lower sideband for logging.

```
upperSB_block = 'ssbdemo_frame/Up';
lowerSB_block = 'ssbdemo_frame/Down';
```

```
Simulink.sdi.markSignalForStreaming(upperSB_block,1,'on')
Simulink.sdi.markSignalForStreaming(lowerSB_block,1,'on')
```

If you simulate the model as-is, the signals would be logged as though they were sample-based, so each element in a sample would be treated as a separate channel. To log the signals as frame-based, specify the **Input Processing** setting for the signal as frame using the `Simulink.sdi.setSignalInputProcessingMode` function.

```
Simulink.sdi.setSignalInputProcessingMode(upperSB_block,1,'frame');
Simulink.sdi.setSignalInputProcessingMode(lowerSB_block,1,'frame');
```

After configuring the upper and lower sideband signals for logging and as frame-based, the data logs to the workspace and the Simulation Data Inspector in a frame-based format, so each column in a sample is treated as a channel in the signal. You can view and analyze the data in the Simulation Data Inspector or using its programmatic interface.

### Input Arguments

#### **blkPath** — Block path for block that produces signal

string | character array

Block path for the block that produces the signal, specified as a string or character array.

Example: "vdp/Mu"

**port — Number of block output port connected to signal**

scalar

Block output port number for the port that produces the signal, specified as a scalar.

Example: 1

**mode — Signal input processing setting**

"sample" (default) | "frame"

**Input Processing** property value for the signal, returned as "signal" or "frame".

- **sample** — Sample-based input processing, where each element in a sample is treated as a channel.
- **frame** — Frame-based input processing, where each column in a sample is treated as a channel.

**h — Signal line handle**

line handle

Line handle for the signal. You can get the line handle for a signal using the `get_param` function with the 'LineHandles' option. For example, to access the line handle for the output of the Mu block in the model vdp:

```
MuLineHandles = get_param('vdp/Mu','LineHandles');
MuOutputLineHandle = MuLineHandles.Outputport;
```

Example: MuOutputLineHandle

## Version History

Introduced in R2020a

# Simulink.sdi.setStorageLocation

Specify location for logged data on disk

## Syntax

```
Simulink.sdi.setStorageLocation(storagePath)
```

## Description

`Simulink.sdi.setStorageLocation(storagePath)` configures `storagePath` as the location for simulation data logged to disk. By default, data is logged to the temporary directory on your computer.

---

**Note** Logging data to a network location can degrade performance.

---

---

**Note** The `Simulink.sdi.setStorageLocation` function configures the location of data logged to the workspace and Simulation Data Inspector when you log data to disk. The `Simulink.sdi.setStorageLocation` function does *not* configure the location of data logged to a file.

---

## Examples

### Specify Location of Logged Data

By default, data logged to the workspace and Simulation Data Inspector is stored in the temporary directory on your computer. You may want to change the location of logged data when you need to log large amounts of data and a secondary drive provides more storage capacity.

Use the `Simulink.sdi.setStorageLocation` function to specify the location for the file that holds data logged to disk.

```
Simulink.sdi.setStorageLocation('C:/Users/username/LoggedData');
```

## Input Arguments

### **storagePath** — Location of data logged to disk

character vector | string

Location of data logged to disk, specified as a character vector or string. By default, data logs to the temporary directory on your computer.

You may want to change the location of logged data when you need to log large amounts and a network location provides more storage capacity than your local machine. However, logging data to a network location can degrade performance.

Example: 'C:/Users/username/LoggedData'

Data Types: char | string

## **Version History**

## Simulink.sdi.setStorageMode

Specify whether to log data to disk or memory

### Syntax

```
Simulink.sdi.setStorageMode(storageMode)
```

### Description

`Simulink.sdi.setStorageMode(storageMode)` configures logging to log data to disk or to memory according to `storageMode`. By default, data logged to the workspace and the Simulation Data Inspector is logged to disk.

---

**Note** When you change the logging storage mode, data from prior simulations is deleted. You cannot change the logging storage mode while a simulation is running.

---

### Examples

#### Log Simulation Data to Memory

You can configure whether data logged in simulation logs to memory or to disk. By default, data is logged to disk and brought into memory on demand. If your machine has more RAM than disk space, you may want to log data to memory instead.

Use the `Simulink.sdi.setStorageMode` function to configure logging to log data to memory.

```
Simulink.sdi.setStorageMode("memory");
```

### Input Arguments

#### **storageMode** — Where logged simulation data is stored on your machine

'disk' (default) | 'memory'

Where logged simulation data is stored on your machine, specified as 'disk' or 'memory'. By default, data logged to the workspace and the Simulation Data Inspector is logged to disk.

When you change the storage mode to log data to memory:

- Data logged from prior simulations is deleted.
- Configuring limits on the size of logged data is not supported.

You cannot change the storage mode while a simulation is running.

When you configure a parallel worker to log to memory, sending logged data to the client is not supported.

Logging data to memory is not supported for rapid accelerator simulations or models deployed using Simulink Compiler.

Data Types: char | string

“Configure the Simulation Data Inspector”

# Simulink.sdi.setSubPlotLayout

**Package:** Simulink.sdi

Set subplot layout in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.setSubPlotLayout(r,c)
```

## Description

`Simulink.sdi.setSubPlotLayout(r,c)` sets the grid layout of plots in the **Simulation Data Inspector** using the specified number of rows, `r`, and columns, `c`.

## Examples

### Change Subplot Layout

```
% Change subplot layout to 4 rows and 2 columns
Simulink.sdi.setSubPlotLayout(4,2);
```

### Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

#### Create Data for the Run

Create `timeseries` objects to contain data for a sine signal and a cosine signal. Give each `timeseries` object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

#### Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the Run object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun, 'vars', sine_ts, cos_ts);
```

### Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';

cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubplot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);

plotOnSubPlot(sine_sig,1,1,true);
plotOnSubPlot(cos_sig,2,1,true);
```

### Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an MLDATX file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

## Input Arguments

### **r** — Number of rows

integer

Number of rows in the subplot grid layout, specified as a whole number between 1 and 8, inclusive.

Example: 2

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

### **c** — Number of columns

integer

Number of columns in the subplot grid layout, specified as a whole number between 1 and 8, inclusive.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

## **Version History**

“Create Plots Using the Simulation Data Inspector”

# Simulink.sdi.setSubplotLimits

Specify subplot limits for time plots in the Simulation Data Inspector

## Syntax

```
Simulink.sdi.setSubplotLimits(r,c,Name,Value)
```

## Description

`Simulink.sdi.setSubplotLimits(r,c,Name,Value)` configures the time and y-axis limits for the subplot at the location specified by *r* and *c* according to the values specified by one or more name-value pair arguments. You can specify any combination of a *t*-axis minimum, *t*-axis maximum, *y*-axis minimum, and *y*-axis maximum using name-value pair arguments.

---

**Note** Limits for the *t*-axis apply to all linked time plots in the Simulation Data Inspector. For more information, see “Linked Subplots”.

---

## Examples

### Copy y-Axis Range from One Subplot to Another

You can use the `Simulink.sdi.getSubplotLimits` and `Simulink.sdi.setSubplotLimits` functions to copy the axis limits from one subplot to another. For example, you can specify the same *y*-axis limits for two subplots that display the same signal from simulations that used different values of a model parameter. This example copies the *y*-axis settings from one subplot to another to analyze the effect of changing the value of *Mu* in the model `vdp`.

Create the data in the Simulation Data Inspector by simulating the model `vdp` twice. The first time, specify the value of *Mu* as 1. For the second simulation, set the value of *Mu* to 2. The model logs data for the signals `x1` and `x2`.

```
open_system("vdp");
set_param("vdp/Mu","Gain","1")
sim("vdp");

set_param("vdp/Mu","Gain","2")
sim("vdp");
```

Open the Simulation Data Inspector.

```
Simulink.sdi.view
```

Create plots in the Simulation Data Inspector to show the results from each simulation. Configure a 2x2 subplot layout so you can plot one signal on each plot, side by side.

```
Simulink.sdi.setSubPlotLayout(2,2)
```

Get the `Simulink.sdi.Signal` objects that correspond to each signal from each run, and plot one signal on each subplot. Plot the signals from the first simulation on the subplots in the first column and the signals from the second simulation on the subplots in the second column.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);

runMu1 = Simulink.sdi.getRun(runID1);
runMu2 = Simulink.sdi.getRun(runID2);

sig1 = getSignalByIndex(runMu1,1);
sig2 = getSignalByIndex(runMu1,2);
sig3 = getSignalByIndex(runMu2,1);
sig4 = getSignalByIndex(runMu2,2);

plotOnSubPlot(sig1,1,1,true);
plotOnSubPlot(sig2,2,1,true);
plotOnSubPlot(sig3,1,2,true);
plotOnSubPlot(sig4,2,2,true);
```

The signals in the first column of plots look similar to those in the second column. However, the y-axis limits for the plots of the x2 signal are different.

Use the `Simulink.sdi.getSubplotLimits` function to copy the limits used for the subplot with the `x2` signal from the second simulation.

```
[~,~,ymin,ymax] = Simulink.sdi.getSubplotLimits(2,2);
```

Use the `Simulink.sdi.setSubplotLimits` function to apply the same y-axis limits to the subplot with the `x2` signal from the first run.

```
Simulink.sdi.setSubplotLimits(2,1, 'yRange', [ymin,ymax]);
```

With the updated y-axis limits, the difference in the `x2` signal is more apparent.

## Input Arguments

**r** — Subplot row index  
integer

Subplot row index, specified as an integer between 1 and 8, inclusive. Use the `r` and `c` inputs together to specify the location of the subplot for which you want to specify axis limits.

Example: `Simulink.sdi.setSubplotLimits(2,2,'yrange',[0,3])` configures y-axis limits for the time plot in the second row of the second column of the subplot layout in the Simulation Data Inspector.

**c — Subplot column index**

integer

Subplot column index, specified as an integer value between 1 and 8, inclusive. Use the `r` and `c` inputs together to specify the location of the subplot for which you want to specify axis limits.

Example: `Simulink.sdi.setSubplotLimits(2,2,'yrange',[0,3])` configures  $y$ -axis limits for the time plot in the second row of the second column of the subplot layout in the Simulation Data Inspector.

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Simulink.sdi.setSubplotLimits(2,2,'ymin',0,'ymax',3)` configures  $y$ -axis limits for the time plot in the second row of the second column of the subplot layout in the Simulation Data Inspector.

**View — Simulation Data Inspector view**

'Inspect' (default) | 'Compare'

Simulation Data Inspector view, specified as 'Inspect' or 'Compare'. Specify the view with the subplot for which you want to specify limits. When you omit the 'View' argument, the limits are applied to the specified subplot in the inspect view.

Example: `Simulink.sdi.setSubplotLimits(2,1,'View','Compare','yRange',[-2,2])` configures  $y$ -axis limits for the difference plot in the compare view of the Simulation Data Inspector.

Data Types: char | string

**tMin — t-axis minimum**

scalar

$t$ -axis minimum, specified as a scalar.

You can specify limits for the  $t$ -axis using the `tMin` and `tMax` name-value arguments, using the `tRange` argument, or using the `AllRange` argument. When you specify the `tMin` name-value pair argument, do not specify the `tRange` or `AllRange` arguments.

Data Types: double

**tMax — t-axis maximum**

scalar

$t$ -axis maximum, specified as a scalar.

You can specify limits for the  $t$ -axis using the `tMin` and `tMax` name-value arguments, the `tRange` argument, or the `AllRange` argument. When you specify the `tMax` name-value argument, do not specify the `tRange` or `AllRange` arguments.

Data Types: double

**yMin — y-axis minimum**

scalar

*y*-axis minimum, specified as a scalar.

You can specify limits for the *y*-axis using the `yMin` and `yMax` name-value arguments, the `yRange` argument, or the `AllRange` argument. When you specify the `yMin` name-value argument, do not specify the `yRange` or `AllRange` arguments.

Data Types: `double`

### **yMax — *y*-axis maximum**

scalar

*y*-axis maximum, specified as a scalar.

You can specify limits for the *y*-axis using the `yMin` and `yMax` name-value arguments, the `yRange` argument, or the `AllRange` argument. When you specify the `yMax` name-value argument, do not specify the `yRange` or `AllRange` arguments.

Data Types: `double`

### **tRange — *t*-axis range**

1-by-2 vector

*t*-axis range, specified as a 1-by-2 vector that contains scalar numeric values.

You can specify limits for the *t*-axis using the `tMin` and `tMax` name-value arguments, the `tRange` argument, or the `AllRange` argument. When you specify the `tRange` name-value argument, do not specify the `tMin`, `tMax`, or `AllRange` arguments.

Example: `Simulink.sdi.setSubplotLimits(1,1,'tRange',[-1,20])` configures the *t*-axis range for the subplot in the first row and first column of the Simulation Data Inspector subplot layout.

Data Types: `double`

### **yRange — *y*-axis range**

1-by-2 vector

*y*-axis range, specified as a 1-by-2 vector that contains scalar numeric values.

You can specify limits for the *y*-axis using the `yMin` and `yMax` name-value arguments, the `yRange` argument, or the `AllRange` argument. When you specify the `yRange` name-value argument, do not specify the `yMin`, `yMax`, or `AllRange` arguments.

Example: `Simulink.sdi.setSubplotLimits(1,1,'yRange',[-5,5])` configures the *y*-axis range for the subplot in the first row and first column of the Simulation Data Inspector subplot layout.

Data Types: `double`

### **AllRange — Ranges for *t*-axis and *y*-axis**

1-by-4 vector

Ranges for *t*-axis and *y*-axis, specified as a 1-by-4 vector that contains scalar numeric values. The values specified in the vector are mapped to the *t*- and *y*-axis limits in this order: `[tMin,tMax,yMin,yMax]`.

When you specify the `AllRange` name-value argument, do not specify the `tMin`, `tMax`, `yMin`, `yMax`, `tRange`, or `yRange` arguments.

Example: `Simulink.sdi.setSubplotLimits(1,1,'AllRange',[-1,20,-5,5])` configures the *t*-axis range and *y*-axis range for the subplot in the first row and first column of the Simulation Data Inspector subplot layout.

Data Types: `double`

# Simulink.sdi.setTableGrouping

Change signal grouping hierarchy in Inspect pane

## Syntax

```
Simulink.sdi.setTableGrouping
Simulink.sdi.setTableGrouping(group,group1,...,groupN)
```

## Description

`Simulink.sdi.setTableGrouping` removes grouping for signals in the Simulation Data Inspector.

`Simulink.sdi.setTableGrouping(group,group1,...,groupN)` groups signals in the Simulation Data Inspector according to one or more specified options. Signal grouping is the same on the **Inspect** and **Compare** panes. You can group signals by any combination of domain, physical system hierarchy, data hierarchy, and model hierarchy.

## Examples

### Group Data by Model Hierarchy Then by Data Hierarchy

To help organize and find signals in the Simulation Data Inspector, you can group the signals. For example, you could group signals according to their location within a model hierarchy and then by data hierarchy.

```
Simulink.sdi.setTableGrouping('Subsystems','DataHierarchy');
```

## Input Arguments

### group — Signal grouping

'Domain' | 'DataHierarchy' | 'Subsystems' | 'PhysmodHierarchy'

Signal grouping, specified as one or more of these values:

- **Domain** — Group signals by domain.
- **DataHierarchy** — Group signals according to data hierarchy, such as the hierarchy for a bus.
- **SubSystems** — Group signals according to their location within the model hierarchy.
- **PhysmodHierarchy** — Group signals according to the Simscape hierarchy. This option is only available when you have a Simscape license.

You can specify up to three grouping options unless you have a Simscape license, in which case you can specify up to four.

By default, the Simulation Data Inspector groups signals by domain, then by physical system hierarchy (if you have a Simscape license), and then by data hierarchy.

## **Version History**

**Introduced in R2016a**

## Simulink.sdi.setTickLabelsDisplay

Configure tick label visibility for time plot axes

### Syntax

```
Simulink.sdi.setTickLabelsDisplay(label)
```

### Description

`Simulink.sdi.setTickLabelsDisplay(label)` displays labels for the tick marks on axes of time plots in the Simulation Data Inspector according to the input, `label`. The function sets the value of the **Tick labels** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector displays tick mark labels for both axes.

### Examples

#### Configure Tick Mark Label Visibility for Time Plots

You can use the `Simulink.sdi.setTickLabelsDisplay` function to configure the visibility of tick mark labels for the *t*- and *y*-axes on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector displays tick marks for both axes.

This example starts by showing how to use the `Simulink.sdi.getTickLabelsDisplay` function to access the current tick mark label visibility. Subsequent sections show the code to specify each available option for tick mark label visibility on time plots in the Simulation Data Inspector. To see the result of each configuration, the example generates an image using the `Simulink.sdi.snapshot` function with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

#### Get Current Tick Mark Label Visibility

Before modifying the visibility of the tick mark labels on time plots, you can save the current configuration to a variable in the workspace in case you want to restore the preference later.

```
initTickLabels = Simulink.sdi.getTickLabelsDisplay;
```

#### Show Only *t*-Axis Tick Mark Labels

Show the tick mark labels for the *t*-Axis.

```
Simulink.sdi.setTickLabelsDisplay('t-axis')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

### Show Only y-Axis Tick Mark Labels

Show the tick mark labels for the y-axis.

```
Simulink.sdi.setTickLabelsDisplay('y-axis')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Hide Tick Mark Labels

You can hide the tick mark labels for both axes.

```
Simulink.sdi.setTickLabelsDisplay('none')
Simulink.sdi.snapshot('from','custom','settings',snapSettings);
```

### Show All Tick Mark Labels

By default, the Simulation Data Inspector shows tick mark labels for both axes on time plots.

```
Simulink.sdi.setTickLabelsDisplay('all')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Input Arguments

### label — Tick mark labels to display

'all' (default) | 't-axis' | 'y-axis' | 'none'

Tick mark labels to display on time plots in the Simulation Data Inspector, specified as one of these options:

- 'all' — Display tick mark labels for both time plot axes.
- 't-axis' — Display tick mark labels only on the *t*-axis for time plots.
- 'y-axis' — Display tick mark labels only on the *y*-axis for time plots.
- 'none' — Do not display tick mark labels.

## Version History

Introduced in R2019b

“Create Plots Using the Simulation Data Inspector”

## Simulink.sdi.setTicksPosition

Configure position for tick marks on time plots in the Simulation Data Inspector

### Syntax

```
Simulink.sdi.setTicksPosition(position)
```

### Description

`Simulink.sdi.setTicksPosition(position)` sets the location of tick marks on time plots in the Simulation Data Inspector according to the input, `position`. The function configures the **Ticks** setting on the **Time Plot** section of the **Visualization Settings** in the Simulation Data Inspector. The setting applies to all time plots in the layout. By default, the Simulation Data Inspector displays tick marks on the outside of the plot area.

### Examples

#### Configure Position for Tick Marks on Time Plots

You can use `Simulink.sdi.setTicksPosition` function to specify the position for tick marks on time plots in the Simulation Data Inspector. By default, the Simulation Data Inspector displays tick marks outside of the plot area for time plots.

This example starts by showing how to use the `Simulink.sdi.getTicksPosition` function to access the current position of tick marks. Subsequent sections show the code to specify each configuration option for the position of tick marks on time plots in the Simulation Data Inspector. To see the result, the example generates an image using `Simulink.sdi.snapshot` with settings specified by a `Simulink.sdi.CustomSnapshot` object.

```
snapSettings = Simulink.sdi.CustomSnapshot;
snapSettings.Width = 300;
snapSettings.Height = 300;
```

#### Get Current Tick Mark Position

Before modifying the position of tick marks on time plots, you can save the current configuration to a variable in the workspace in case you want to restore the preference later.

```
initTickPos = Simulink.sdi.getTicksPosition;
```

#### Position Tick Marks Inside Plot Area

Position the tick marks inside the plot area to increase the amount of space used by the plot area.

```
Simulink.sdi.setTicksPosition('inside')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Hide Tick Marks on Time Plots

You can hide the tick marks for time plots in the Simulation Data Inspector. Hiding the tick marks expands the plot area.

```
Simulink.sdi.setTicksPosition('none')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

### Position Tick Marks Outside Plot Area

By default, the Simulation Data Inspector displays tick marks outside of the plot area for time plots.

```
Simulink.sdi.setTicksPosition('outside')
Simulink.sdi.snapshot('from', 'custom', 'settings', snapSettings);
```

## Input Arguments

### **position** — Position of tick marks on time plots

'outside' (default) | 'inside' | 'none'

Position of tick marks on time plots in the Simulation Data Inspector, specified as 'inside' or 'outside'.

---

**Tip** Move tick marks to the inside of time plots to increase the space available for the plot area.

---

Example: 'inside'

## Version History

**Introduced in R2019b**

### Topics

“Create Plots Using the Simulation Data Inspector”

## Simulink.sdi.setUnitSystem

Specify system of units to define signal display units in the Simulation Data Inspector

### Syntax

```
Simulink.sdi.setUnitSystem(unitSystem)
Simulink.sdi.setUnitSystem(unitSystem,"Overrides",overrideUnits)
```

### Description

`Simulink.sdi.setUnitSystem(unitSystem)` configures the Simulation Data Inspector to use the specified unit system to define the display units for logged and imported signals.

The Simulation Data Inspector plots signals using the display units. The display units for a signal may differ from the stored units, which indicate units for the data as stored on disk. When you specify a system of units in the Simulation Data Inspector preferences, the Simulation Data Inspector automatically adjusts the display units for logged or imported signals that use units that are not valid in the specified system.

`Simulink.sdi.setUnitSystem(unitSystem,"Overrides",overrideUnits)` configures the Simulation Data Inspector to use the specified override units. Specify override units when you want a type of measurement, such as length, to use consistent units, such as m or ft, across all signals in the Simulation Data Inspector.

### Examples

#### Configure Unit Preferences in the Simulation Data Inspector

To specify a system of units to use for plotting signals in the Simulation Data Inspector, use the `Simulink.sdi.setUnitSystem` function. When you choose to display signals using the SI or US Customary unit system, the Simulation Data Inspector automatically changes the **Display Units** property for logged or imported signals that use units that are not part of the specified unit system. The signal data stored on disk does not change. Signals also have a **Stored Units** property, and the Simulation Data Inspector converts the data to plot the signal when the **Stored Units** and **Display Units** differ.

#### Specify a System of Units

By default, the Simulation Data Inspector displays signals using the units assigned to the signal during simulation or in the imported data. To facilitate analyzing multiple signals and data sets together, you can specify a system of units as a preference. The Simulation Data Inspector automatically updates the **Display Units** for logged or imported signals that use units that are invalid in the specified unit system. For example, a signal logged in a model using units of ft could be updated to use units of m when the system of units is specified as SI.

Use the `Simulink.sdi.setUnitSystem` function to configure the Simulation Data Inspector to display signals using units in the US Customary unit system.

```
Simulink.sdi.setUnitSystem('USCustomary');
```

## Specify Override Units

When you want all signals that represent the same type of measurement to use the same **Display Units**, you can also specify override units. For example, to plot all signals that represent length using units of ft, specify ft as an override unit.

```
Simulink.sdi.setUnitSystem('USCustomary','Overrides','ft');
```

## Check Unit Configuration

Use the `Simulink.sdi.getUnitSystem` function to check the current unit preferences configured in the Simulation Data Inspector.

```
[unitSystem,overrideUnits] = Simulink.sdi.getUnitSystem

unitSystem =
'USCustomary'

overrideUnits =
"ft"
```

## Input Arguments

### unitSystem — System of units used to define signal display units

'Default' (default) | 'SI' | 'USCustomary'

System of units used to define signal display units, specified as 'Default', 'SI', or 'USCustomary'.

- **Default** — Use signal stored units.
- **SI** — Use units from the SI unit system for signal display units.
- **USCustomary** — Use units from the US Customary unit system for signal display units.

### overrideUnits — Units to override signal display units

string | string array

Units to override signal display units, specified as a string or string array. Specify override units when you want all signals that represent the same measurement type to use consistent units. For example, specify override units of ft to display all signals that represent length measurements using units of ft.

Example: "Overrides",["in","lb"]

Data Types: string

## Version History

Introduced in R2020b

# Simulink.sdi.snapshot

**Package:** Simulink.sdi

Capture contents of Simulation Data Inspector plots

## Syntax

```
fig = Simulink.sdi.snapshot
[fig,image] = Simulink.sdi.snapshot
Simulink.sdi.snapshot(Name,Value)
Simulink.sdi.snapshot(Name,Value)
Simulink.sdi.snapshot(Name,Value)
```

## Description

`fig = Simulink.sdi.snapshot` creates a figure of the plotting area in the open Simulation Data Inspector session with the figure handle `fig`.

`[fig,image] = Simulink.sdi.snapshot` creates a figure of the plotting area in the open Simulation Data Inspector session with the figure handle `fig` and returns the image data in the array, `image`.

`Simulink.sdi.snapshot(Name,Value)` captures an image of the Simulation Data Inspector plots according to the options specified by name-value pairs.

`fig = Simulink.sdi.snapshot(Name,Value)` captures an image of the Simulation Data Inspector plots according to the options specified by name-value pairs. This syntax returns the figure handle, `fig`, if a figure is created.

`[fig, image] = Simulink.sdi.snapshot(Name,Value)` captures an image of the Simulation Data Inspector plots according to the options specified by name-value pairs. This syntax returns the figure handle, `fig`, and an array of image data, `image`, when appropriate for the specified options.

## Examples

### Copy View Settings to Run

Copy view settings from one run to another and create figures using the `Simulink.sdi.CustomSnapshot` object.

### Simulate Model and Get Run Object

Configure the `vdp` model to save output data. Run a simulation to create data.

```
load_system("vdp")
set_param("vdp","SaveFormat","Dataset","SaveOutput","on")
set_param("vdp/Mu","Gain","1");
sim("vdp");
```

Use the Simulation Data Inspector programmatic interface to access the run data.

```
runIndex = Simulink.sdi.getRunCount;
runID = Simulink.sdi.getRunIDByIndex(runIndex);
vdpRun = Simulink.sdi.getRun(runID);
```

### **Modify Signal View Settings**

Use the `Simulink.sdi.Run` object to access signals in the run. Then, modify the signal view settings. This example specifies the line color and style for each signal. The view settings for the run comprise the view settings for each signal and view settings specified for the plot area.

```
sig1 = getSignalByIndex(vdpRun,1);
sig2 = getSignalByIndex(vdpRun,2);

sig1.LineColor = [0 0 1];
sig1.LineDashed = "-.";

sig2.LineColor = [1 0 0];
sig2.LineDashed = ":";
```

### **Capture Snapshot from Simulation Data Inspector**

Create a `Simulink.sdi.CustomSnapshot` object and use the `Simulink.sdi.snapshot` function to programmatically capture a snapshot of the contents of the Simulation Data Inspector.

```
snap = Simulink.sdi.CustomSnapshot;
```

You can use properties of the `Simulink.sdi.CustomSnapshot` object to configure the plot settings, such as the subplot layout and axis limits, and to plot signals. When you use a `Simulink.sdi.CustomSnapshot` object to create your figure, these plot settings do not affect the Simulation Data Inspector.

```
snap.Rows = 2;
snap.YRange = {[-2.25 2.25],[-3 3]};
plotOnSubPlot(snap,1,1,sig1,true)
plotOnSubPlot(snap,2,1,sig2,true)
```

Use the `Simulink.sdi.snapshot` function to generate the figure you specified in the properties of the `Simulink.sdi.CustomSnapshot` object.

```
fig = Simulink.sdi.snapshot("From","custom","To","figure","Settings",snap);
```

### Copy View Settings to New Simulation Run

Simulate the model again, with a different Mu value. Use the Simulation Data Inspector programmatic interface to access the simulation data.

```
set_param("vdp/Mu", "Gain", "5")
sim("vdp");
```

```
runIndex2 = Simulink.sdi.getRunCount;
runID2 = Simulink.sdi.getRunIDByIndex(runIndex2);
run2 = Simulink.sdi.getRun(runID2);
```

To create a plot of the new output data that looks like the one you created in the previous step, you can copy the view settings to the run in a single line of code using the `Simulink.sdi.copyRunViewSettings` function. This function does not automatically update plot settings in `Simulink.sdi.CustomSnapshot` objects, so specify the input that determines whether the plot updates as `false`.

```
sigIDs = Simulink.sdi.copyRunViewSettings(runID, runID2, false);
```

### Capture Snapshot of New Simulation Run

Use the `Simulink.sdi.CustomSnapshot` object to capture a snapshot of the new simulation run. First, clear the signals from the subplots. Then, plot the signals from the new run and capture another snapshot.

```
clearSignals(snap)
snap.YRange = {[-2.25 2.25], [-8 8]};
```

```
plotOnSubPlot(snap,1,1,sigIDs(1),true)
plotOnSubPlot(snap,2,1,sigIDs(2),true)
```

```
fig = snapshot(snap,"To","figure");
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `'to','figure','props',{'Name','My Data'}`

### from — Content to include in the snapshot

`'opened'` (default) | `'active'` | `'comparison'` | `'custom'`

Content to include in the snapshot.

- `'opened'` — Include all subplots in the graphical viewing area of the open Simulation Data Inspector session.

- `'active'` — Include only the active (selected) subplot in the open Simulation Data Inspector session.
- `'comparison'` — Include the comparison plots for the selected comparison run or signal in the open Simulation Data Inspector session.
- `'custom'` — Include contents specified by the `settings` name-value pair `Simulink.sdi.CustomSnapshot` object. You can use the `'from'`, `'custom'` option to create a snapshot without opening the Simulation Data Inspector or affecting your open Simulation Data Inspector session. Include a `settings` name-value pair when you specify `'from'`, `'custom'`.

Example: `'from','comparison'`

Data Types: `char | string`

### To — Type of snapshot to create

`"image" (default) | "figure" | "file" | "clipboard"`

Type of snapshot to create, specified as:

- `"image"` — Create a figure and return the figure handle and an array of image data. When you specify `"To","image"`, the `fig` and `image` outputs both have value.
- `"figure"` — Create a figure and return the figure handle. When you specify `"To","figure"`, the `fig` output has value, and the `image` output is empty.
- `"file"` — Save to a PNG file with the name specified by the `Filename` name-value argument. If you do not specify a `Filename` name-value argument, the file is named `plots.png`. When you specify `"To","file"`, the `fig` and `image` outputs are both empty.
- `"clipboard"` — Copy the plots to your system clipboard. From the clipboard, you can paste the image into another program, such as Microsoft Word. When you specify `"To","clipboard"`, the `fig` and `image` outputs are both empty.

Example: `"To","file"`

Data Types: `char | string`

### Filename — Name for image file

`"plots.png" (default) | character array | string`

Name for image file to store the snapshot when you specify `"To","file"`, specified as a character array or string.

Example: `"Filename","MyImage.png"`

Data Types: `char | string`

### Props — Figure properties

cell array

Figure properties, specified as a cell array. To customize your figure, you can include settings for the figure properties described in Figure Properties.

Example: `"Props",{"Name","MyData","NumberTitle","off"}`

Data Types: `char | string`

### settings — Custom snapshot settings

`Simulink.sdi.CustomSnapshot`

`Simulink.sdi.CustomSnapshot` object specifying custom snapshot settings. You can use the `settings` name-value pair to specify the dimensions of the image in pixels, subplot layout, and limits for the x- and y-axes.

Example: `'settings', customSnap`

Data Types: `char` | `string`

## Output Arguments

### **fig** — Figure handle

figure handle

Figure handle, specified as a figure handle. When a figure is not created with your specified options, the `fig` output is empty.

### **image** — Image data

array

Image data, returned as an array. The `image` output has value when you use `Simulink.sdi.snapshot` without any input arguments or without a `To` name-value argument and when you specify `'To', 'image'`.

## Version History

Introduced in R2018a

# Simulink.sdi.unregisterCursorCallback

Unregister cursor callback function

## Syntax

```
Simulink.sdi.unregisterCursorCallback(callbackID)
```

## Description

`Simulink.sdi.unregisterCursorCallback(callbackID)` unregisters the cursor callback function that corresponds to `callbackID`.

## Examples

### Use Simulation Data Inspector Cursor Callback in App Designer App

You can use a Simulation Data Inspector cursor callback function to send cursor position data to an app you build using the App Designer. This example shows how to add a property to the app to store the callback ID and where to register and unregister the cursor callback. For an example of an App Designer app that uses a cursor callback, see “Synchronize Cursors in the Simulation Data Inspector with an App Designer App”.

Add a `callbackID` property to the app object.

```
properties (Access = private)
 callbackID
end
```

Define the behavior of the cursor callback function.

```
methods (Access = public)
 function myCursorCallback(app,~,~)
 if isvalid(app)
 ...
 end
 end
end
```

Register the cursor callback in the app `startupFcn`. This example registers the same callback on the **Inspect** pane and the **Compare** pane.

```
function startupFcn(app)
 app.callbackID = Simulink.sdi.registerCursorCallback(...
 @(t1,t2)myCursorCallback(app,t1,t2));
 app.callbackID(2) = Simulink.sdi.registerCursorCallback(...
 @(t1,t2)myCursorCallback(app,t1,t2), 'compare');
 ...
end
```

Unregister the cursor callback in the app `UIFigureCloseRequest` function.

```
function myAppUIFigureCloseRequest(app, event)
 Simulink.sdi.unregisterCursorCallback(app.callbackID(1));
 Simulink.sdi.unregisterCursorCallback(app.callbackID(2));

end
```

## Input Arguments

### **callbackID** — Registered callback ID

scalar

Registered callback ID, specified as a scalar. The callback ID is returned when you register the callback using the `Simulink.sdi.registerCursorCallback` function.

## Version History

**Introduced in R2021a**

## See Also

### **Functions**

`Simulink.sdi.registerCursorCallback` | `Simulink.sdi.setCursorPositions` |  
`Simulink.sdi.getCursorPositions` | `Simulink.sdi.setNumCursors` |  
`Simulink.sdi.getNumCursors`

# Simulink.sdi.view

**Package:** Simulink.sdi

Open the Simulation Data Inspector

## Syntax

```
Simulink.sdi.view
```

## Description

`Simulink.sdi.view` opens the **Simulation Data Inspector**. You can write a script to plot your data and customize the Simulation Data Inspector properties and then use `Simulink.sdi.view` to see the results.

## Examples

### Open the Simulation Data Inspector from the Command Line

You can open the Simulation Data Inspector from the MATLAB command line to visualize, inspect, and analyze your data.

```
Simulink.sdi.view
```

### Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

#### Create Data for the Run

Create `timeseries` objects to contain data for a sine signal and a cosine signal. Give each `timeseries` object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

#### Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the Run object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun,'vars',sine_ts,cos_ts);
```

### Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';

cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubplot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);

plotOnSubPlot(sine_sig,1,1,true);
plotOnSubPlot(cos_sig,2,1,true);
```

### Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an `MLDATX` file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

## Alternatives

You can open the Simulation Data Inspector from the Simulink Editor toolbar with the **Simulation**

**Data Inspector** button .

## Version History

## Simulink.SFunctionBuilder.add

Add input, output, parameter, library item, or state to S-Function Builder block

### Syntax

```
Simulink.SFunctionBuilder.add(blk,elem)
Simulink.SFunctionBuilder.add(blk,elem,Name=Value)
```

### Description

`Simulink.SFunctionBuilder.add(blk,elem)` adds the element `elem` with default options to the S-Function Builder block `blk`. Use the `Simulink.SFunctionBuilder.add` function to add:

- Input ports
- Output ports
- Parameters
- Library items
- Discrete states
- Continuous states

`Simulink.SFunctionBuilder.add(blk,elem,Name=Value)` adds the element `elem` with options specified using one or more name-value arguments to the S-Function Builder block `blk`. For example, to specify the data type for a port as `double`, set `DataType` to `double`.

The options you can specify depend on the type of element you add.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

#### **elem** — Type of element to add

'Input' | 'Output' | 'Parameter' | 'LibraryItem' | 'DiscreteState' | 'ContinuousState'

Type of element to add, specified as one of these options:

- 'Input'
- 'Output'

- 'Parameter'
- 'LibraryItem'
- 'DiscreteState'
- 'ContinuousState'

Data Types: char | string

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: Name="in1", DataType="single" specifies options to configure an input port with the name in1 and data type single.

### Name — Port or parameter name

string | character vector

Port or parameter name, specified as a string or a character vector. By default:

- Input ports are named u0, u1, ... un.
- Output ports are named y0, y1, ... ,yn.
- Parameters are named p0, p1, ... , pn.

Specify the Name name-value argument only when you add an input port, an output port, or a parameter.

Example: Name="inputSignal"

Data Types: char | string

### DataType — Port or parameter data type

'double' (default) | 'single' | 'boolean' | 'int8' | 'int16' | 'int32' | 'uint8' | 'uint16' | 'uint32' | 'Fixdt:binary(a,b,c)' | 'Fixdt:slope and bias(a,b,c,d)' | 'Bus: <object name>'

Port or parameter data type, specified as one of these options:

- 'double'
- 'single'
- 'boolean'
- 'int8'
- 'int16'
- 'int32'
- 'uint8'
- 'uint16'
- 'uint32'
- 'Fixdt:binary(a,b,c)'

- 'Fixdt:slope and bias(a,b,c,d)'
- 'Bus: <object name>'

Parameters do not support fixed-point or bus data types.

Specify the `DataType` name-value argument only when you add an input port, an output port, or a parameter.

Example: `DataType="single"`

Data Types: `char` | `string`

### **Complexity — Port or parameter complexity**

'real' (default) | 'complex'

Port or parameter complexity, specified as 'real' or 'complex'.

Specify the `Complexity` name-value argument only when you add an input port, an output port, or a parameter.

Example: `Complexity="complex"`

Data Types: `char` | `string`

### **Dimensions — Input or output port dimensions**

'[1,1]' (default) | string | character vector

Input or output port dimensions, specified as a string or a character vector that defines the port dimensions as a scalar or vector.

Specify the `Dimensions` name-value argument only when you add an input or output port.

Example: `Dimensions="2"`

Example: `Dimensions="[1,2]"`

Data Types: `char` | `string`

### **Value — Parameter value**

1 (default) | string | character vector

Parameter value, specified as a string or a character vector that defines the value of the parameter.

Specify the `Value` name-value argument only when you add a parameter.

Example: `Value="2"` specifies the parameter value as 2.

Example: `Value="[1 2]"` specifies the parameter value as [1 2].

Data Types: `char` | `string`

### **LibraryItemTag — Tag for library item**

'SRC\_PATH' (default) | 'LIB\_PATH' | 'INC\_PATH' | 'ENV\_PATH' | 'ENTRY'

Tag for library item, specified as one of these options:

- 'SRC\_PATH' — Object or library path
- 'LIB\_PATH' — Include search path for header files and source files

- 'INC\_PATH' — Search path for object files and source files
- 'ENV\_PATH' — Environment variable
- 'ENTRY' — Object, source, or library file name or preprocessor directive, such as -DDEBUG

When you add a library item to an S-Function Builder block, use the `LibraryItemTag` and `LibraryItemValue` name-value arguments together to define the library item.

Specify the `LibraryItemTag` name-value argument only when you add a library item.

Example: `LibraryItemTag="LIB_PATH",LibraryItemValue="$MATLABROOT\customobjs"`

Data Types: char | string

### **LibraryItemValue — Library item value**

string | character vector

Library item value, specified as a string or a character vector. The value you specify depends on the tag for the library item you add.

When you add a library item to an S-Function Builder block, use the `LibraryItemTag` and `LibraryItemValue` name-value arguments together to define the library item.

Example: `LibraryItemTag="LIB_PATH",LibraryItemValue="$MATLABROOT\customobjs"`

Data Types: char | string

### **InitialCondition — Initial condition for state**

'0' (default) | string | character vector

Initial condition for state, specified as a string or a character vector that defines the initial value for the state.

Specify the `InitialCondition` name-value argument only when you add a discrete or continuous state.

Example: `InitialCondition="1"` specifies the initial condition for the added state as 1.

Data Types: char | string

## **Version History**

## Simulink.SFunctionBuilder.build

Build S-function and generate MEX file for S-Function Builder block

### Syntax

```
Simulink.SFunctionBuilder.build(blk)
```

### Description

`Simulink.SFunctionBuilder.build(blk)` builds the S-function and generates the MEX file for the S-Function Builder block `blk`.

To build the S-function without generating the MEX file, use the `Simulink.SFunctionBuilder.generateCodeOnly` function.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

## Version History

Introduced in R2022a

# Simulink.SFunctionBuilder.delete

Remove input, output, parameter, library item, or state from S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.delete(blk,elem,Name=name)
Simulink.SFunctionBuilder.delete(blk,elem,Index=ind)
```

## Description

`Simulink.SFunctionBuilder.delete(blk,elem,Name=name)` deletes the item `item` with the specified name `name` from the S-Function Builder block `blk`. Use this syntax to delete input ports, output ports, and parameters.

`Simulink.SFunctionBuilder.delete(blk,elem,Index=ind)` deletes the item `item` at the specified index `ind` from the S-Function Builder block `blk`. Use this syntax to delete library items, discrete states, and continuous states.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### **elem** — Type of element to delete

'Input' | 'Output' | 'Parameter' | 'LibraryItem' | 'DiscreteState' | 'ContinuousState'

Type of element to delete, specified as one of these options:

- 'Input'
- 'Output'
- 'Parameter'
- 'LibraryItem'
- 'DiscreteState'
- 'ContinuousState'

### Tips

The way to specify which element to delete depends on the type of element you want to delete.

- To specify which input port, output port, or parameter to delete, specify the **Name** name-value argument.
- To specify which library item, discrete state, or continuous state to delete, specify the **Index** name-value argument.

Data Types: `char` | `string`

**name** — Name of input port, output port, or parameter to delete

`string` | character vector

Name of input port, output port, or parameter to delete, specified as a string or a character vector.

Example: `Name="in1"`

Data Types: `char` | `string`

**ind** — Index of library item, discrete state, or continuous state to delete

scalar

Index of library item, discrete state, or continuous state to delete, specified as a scalar.

Example: `Index=1`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

# Simulink.SFunctionBuilder.generateCodeOnly

Build S-function without generating MEX file for S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.generateCodeOnly(blk)
```

## Description

`Simulink.SFunctionBuilder.generateCodeOnly(blk)` builds the S-function for the specified S-Function Builder block `blk` without generating the MEX file.

To build the S-function and generate the MEX file, use the `Simulink.SFunctionBuilder.build` function.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

# Simulink.SFunctionBuilder.getBuildOptions

Get build options for S-Function Builder block

## Syntax

```
buildOpts = Simulink.SFunctionBuilder.getBuildOptions(blk)
```

## Description

`buildOpts = Simulink.SFunctionBuilder.getBuildOptions(blk)` returns a structure with fields that indicate which build options are enabled for the S-Function Builder block `blk`.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

## Output Arguments

### **buildOpts** — Build options for S-Function Builder block

structure

Build options for S-Function Builder block, returned as a structure that contains these fields:

- `ShowCompileSteps` — Option to log build steps
- `CreateDebuggableMEX` — Option to include debugging information in MEX file
- `GenerateWrapperTLC` — Option to generate TLC file
- `EnableSupportForCoverage` — Option to build S-function that supports model coverage
- `EnableSupportForDesignVerifier` — Option to build S-function that supports Simulink Design Verifier

The value of each field is a logical indication of whether that build option is enabled.

## Simulink.SFunctionBuilder.getSettings

Get settings for S-Function Builder block

### Syntax

```
sFunSettings = Simulink.SFunctionBuilder.getSettings(blk)
```

### Description

`sFunSettings = Simulink.SFunctionBuilder.getSettings(blk)` returns a structure with fields that indicate the value for each setting for the S-Function Builder block `blk`.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### Output Arguments

#### **sFunSettings** — S-Function Builder block settings

structure

S-Function Builder block settings, returned as a structure that contains these fields:

- `NumberDiscreteStates` — Number of discrete states
- `DiscreteStatesIC` — Initial conditions for discrete states
- `NumberContinuousStates` — Number of continuous states
- `ContinuousStatesIC` — Initial conditions for continuous states
- `ArrayLayout` — Array layout for code
- `SampleMode` — Sample mode for S-function
- `SampleTime` — Sample time for S-function
- `NumberOfPWorks` — Number of PWorks pointers for S-function
- `UseSimStruct` — Whether wrapper has access to SimStruct
- `DirectFeedthrough` — Whether S-function has direct feedthrough

## Simulink.SFunctionBuilder.getSFunctionName

Get name of S-function generated by S-Function Builder block

### Syntax

```
SFunName = Simulink.SFunctionBuilder.getSFunctionName(blk)
```

### Description

`SFunName = Simulink.SFunctionBuilder.getSFunctionName(blk)` returns the name for the S-function generated by the S-Function Builder block `blk`. The S-function name is used as a prefix for all wrapper functions built by the S-Function Builder block.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### Output Arguments

#### **SFunName** — S-function name

empty (default) | string | character vector

S-function name, returned as a string or a character vector.

Data Types: `char` | `string`

## Simulink.SFunctionBuilder.getTargetLanguage

Get language for S-function generated using S-Function Builder block

### Syntax

```
lang = Simulink.SFunctionBuilder.getTargetLanguage(blk)
```

### Description

`lang = Simulink.SFunctionBuilder.getTargetLanguage(blk)` returns the target language for the S-function built by the S-Function Builder block `blk`.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### Output Arguments

#### **lang** — S-function language

'inherit' | 'cpp' | 'c'

S-function language, returned as one of these values:

- 'inherit' — Language inherited from the **Language** model configuration parameter .
- 'cpp' — C++
- 'c' — C

## Simulink.SFunctionBuilder.getUserCode

Get code for method of S-function generated using S-Function Builder block

### Syntax

```
userCode = Simulink.SFunctionBuilder.getUserCode(blk,methodType)
```

### Description

`userCode = Simulink.SFunctionBuilder.getUserCode(blk,methodType)` returns the user code `userCode` specified for the method indicated by `methodType` of the S-Function Builder block `blk`.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

#### **methodType** — S-function method code to get

'includes' | 'externs' | 'start' | 'output' | 'update' | 'derivatives' | 'terminate'

S-function method code to get, specified as one of these options:

- 'includes' — Return S-function include statements.
- 'externs' — Return global variable declarations for S-function.
- 'start' — Return code defined for start method of S-function.
- 'output' — Return code defined for output method.
- 'update' — Return code defined for update method.
- 'derivatives' — Return code defined for derivatives method.
- 'terminate' — Return code defined for terminate method.

Data Types: char

### Output Arguments

#### **userCode** — Code for specified method of S-function

character vector

Code for specified method of S-function, returned as a character vector.

## Version History

Introduced in R2022a

## Simulink.SFunctionBuilder.list

List inputs, outputs, parameters, library items, and states for S-Function Builder block

### Syntax

```
elemList = Simulink.SFunctionBuilder.list(blk,elem)
elemList = Simulink.SFunctionBuilder.list(blk,elem,Format=listFormat)
```

### Description

`elemList = Simulink.SFunctionBuilder.list(blk,elem)` returns a structure that lists the items of type `elem` configured for the S-Function Builder block `blk`. Use the `Simulink.SFunctionBuilder.list` function to list configurations for:

- Input ports
- Output ports
- Parameters
- Library items
- States

`elemList = Simulink.SFunctionBuilder.list(blk,elem,Format=listFormat)` returns a list of the items of type `elem` configured for the S-Function Builder block `blk` using the format `listFormat`. You can return the list as a structure or a table.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

#### **elem** — Type of element to list

'Input' | 'Output' | 'Parameter' | 'LibraryItem' | 'States'

Type of element to list, specified as one of these options:

- 'Input' — Input ports
- 'Output' — Output ports
- 'Parameter' — Parameters
- 'LibraryItem' — Library items
- 'States' — States

Data Types: char | string

### **ListFormat — Format of list to return**

'Structure' (default) | 'Table'

Format of list to return, specified as 'Structure' or 'Table'. When you do not specify the Format name-value argument, the `Simulink.SFunctionBuilder.list` function returns a structure.

- 'Structure' — Return the list of elements configured for the S-Function Builder block as a structure. The fields in the structure depend on the type of element you specify.
- 'Table' — Return the list of elements configured for the S-Function Builder block as a MATLAB table. The columns in the table depend on the type of element you specify.

Data Types: char | string

## **Output Arguments**

### **elemList — List of elements configured for S-Function Builder block**

structure | MATLAB table

List of elements configured for S-Function Builder block, returned as a structure or a MATLAB table.

## **Version History**

**Introduced in R2022a**

## **See Also**

### **Blocks**

S-Function Builder

### **Topics**

“Build S-Functions Automatically Using S-Function Builder”

## Simulink.SFunctionBuilder.setBuildOptions

Set build options for S-Function Builder block

### Syntax

```
Simulink.SFunctionBuilder.setBuildOptions(blk,Name=Value)
```

### Description

`Simulink.SFunctionBuilder.setBuildOptions(blk,Name=Value)` sets build options specified using one or more name-value arguments for the S-Function Builder block `blk`. For example, to include debugging information in the generated MEX file, specify `CreateDebuggableMEX` as `true`.

To configure S-function settings such as access to the `SimStruct`, sample mode, and sample time, use the `Simulink.SFunctionBuilder.setSettings` function.

To specify the language for the S-function, use the `Simulink.SFunctionBuilder.setTargetLanguage` function.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

#### Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `CreateDebuggableMEX=true`

#### **ShowCompileSteps** — Option to log build steps

0 or false (default) | 1 or true

Option to log build steps, specified as logical 1 (true) or 0 (false).

Example: `ShowCompileSteps=true`

Data Types: `logical`

**CreateDebuggableMEX — Option to include debugging information in generated MEX file**

0 or false (default) | 1 or true

Option to include debugging information in generated MEX file, specified as logical 1 (true) or 0 (false).

Example: CreateDebuggableMEX=true

Data Types: logical

**GenerateWrapperTLC — Option to generate TLC file**

1 or true (default) | 0 or false

Option to generate TLC file, specified as logical 1 (true) or 0 (false).

Example: GenerateWrapperTLC=false

Data Types: logical

**EnableSupportForCoverage — Option to build S-function that supports model coverage**

0 or false (default) | 1 or true

Option to build S-function that supports model coverage, specified as logical 1 (true) or 0 (false).

Example: EnableSupportForCoverage=true

Data Types: logical

**EnableSupportForDesignVerifier — Option to build S-function that supports Simulink Design Verifier**

0 or false (default) | 1 or true

Option to build S-function that supports Simulink Design Verifier, specified as logical 1 (true) or 0 (false).

Example: EnableSupportForDesignVerifier=true

Data Types: logical

## Simulink.SFunctionBuilder.setSettings

Set settings for S-Function Builder block

### Syntax

```
Simulink.SFunctionBuilder.setSettings(blk,Name=Value)
```

### Description

`Simulink.SFunctionBuilder.setSettings(blk,Name=Value)` sets the settings specified using one or more name-value arguments for the S-Function Builder block `blk`. Use the `Simulink.SFunctionBuilder.setSettings` function to configure:

- The array layout for your code
- The sample mode for the S-function
- The sample time for the S-function
- The number of pointers used in the S-function code
- Whether to make the `SimStruct` available to the S-Function Builder wrapper functions
- Support for direct feedthrough.

To configure the build options for the S-Function Builder block, use the `Simulink.SFunctionBuilder.setBuildOptions` function.

To specify a name for the S-function, use the `Simulink.SFunctionBuilder.setSFunctionName` function.

To specify the language for the S-function, use the `Simulink.SFunctionBuilder.setTargetLanguage` function.

### Input Arguments

#### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

#### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

### **ArrayLayout — Array layout for code**

'Column' (default) | 'Row'

Array layout for code, specified as 'Column' or 'Row'.

Example: ArrayLayout="Row"

Data Types: char | string

### **SampleMode — Sample mode for S-function**

'Inherited' (default) | 'Continuous' | 'Discrete'

Sample mode for S-function, specified as 'Inherited', 'Continuous', or 'Discrete'. The sample mode for the block determines when the block computes a new output value.

- 'Inherited' — The S-Function Builder block inherits sample time from the block connected to the input port.
- 'Continuous' — The S-Function Builder block computes a new output value for every simulation time step.
- 'Discrete' — The S-Function Builder block computes a new output value at a fixed sample time you specify.

Example: SampleMode="Continuous"

Data Types: char | string

### **SampleTime — Discrete sample time for S-function**

'Inherited' (default) | scalar | string | character vector

Discrete sample time for S-function, specified as a scalar, a string, or a character vector. By default, the sample time for an S-Function Builder block is 'Inherited' because the default sample mode is 'Inherited'.

Specify the SampleTime name-value argument only when the SampleMode is set to Discrete.

Example: SampleMode="Discrete", SampleTime=0.2

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

### **NumberOfPWorks — Number of pointers used in S-function**

0 (default) | scalar | string | character vector

Number of pointers used in S-function, specified as a scalar, a string, or a character vector.

S-functions that use PWorks do not support model operating points.

Example: NumberOfPWorks=3

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

### **UseSimStruct — Option to enable access to SimStruct in wrapper functions**

0 or false (default) | 1 or true

Option to enable access to SimStruct in wrapper functions, specified as logical 0 (`false`) or 1 (`true`). When you enable access to the SimStruct, you can use SimStruct macros and functions in the code you write for the `Outputs_wrapper`, `Derivatives_wrapper`, and `Update_wrapper` functions.

Example: `UseSimStruct=true`

Data Types: `logical`

### **DirectFeedthrough — Whether S-function has direct feedthrough**

1 or `true` (default) | 0 or `false`

Whether S-function has direct feedthrough, specified as logical 1 (`true`) or 0 (`false`).

The direct feedthrough flag for the S-function affects block execution order and is used to detect algebraic loops.

For more information, see “S-Function Concepts”.

Example: `DirectFeedthrough=false`

Data Types: `logical`

# Simulink.SFunctionBuilder.setSFunctionName

Set name of S-function for S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.setSFunctionName(blk,SFunName)
```

## Description

`Simulink.SFunctionBuilder.setSFunctionName(blk,SFunName)` sets the name of the S-function built by the S-Function Builder block `blk` to the name specified by `SFunName`. The S-function name is used as a prefix for all wrapper functions built by the S-Function Builder block.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### **SFunName** — S-function name

empty (default) | string | character vector

S-function name, specified as a string or a character vector.

Example: "mySFunction"

Data Types: char | string

# Simulink.SFunctionBuilder.setTargetLanguage

Set language for S-function generated using S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.setTargetLanguage(blk, lang)
```

## Description

`Simulink.SFunctionBuilder.setTargetLanguage(blk, lang)` sets the target language for the S-function generated by the S-Function Builder block `blk` to the specified language `lang`.

To specify build options such as whether the MEX file includes debugging information, use the `Simulink.SFunctionBuilder.setBuildOptions` function.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### **lang** — S-function language

'inherited' (default) | 'cpp' | 'c'

S-function language, specified as one of these options:

- 'inherited' — Language inherited from the **Language** model configuration parameter
- 'cpp' — C++
- 'c' — C

Data Types: char | string

## Version History

Introduced in R2022a

`Simulink.SFunctionBuilder.setSettings`

### **Topics**

“Build S-Functions Automatically Using S-Function Builder”

# Simulink.SFunctionBuilder.setUserCode

Set code for methods of S-function generated using S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.setUserCode(blk,methodType,userCode)
```

## Description

`Simulink.SFunctionBuilder.setUserCode(blk,methodType,userCode)` specifies the code `userCode` as part of the S-function for the S-Function Builder block `blk`. Use this function to specify include statements, global variables, and code for the S-function methods.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### **methodType** — S-function method for which to specify code

'include' | 'externs' | 'start' | 'output' | 'update' | 'derivatives' | 'terminate'

S-function method for which to specify code, specified as one of these options:

- 'include' — Include statement
- 'externs' — Global variable declaration
- 'start' — Start method

Use the start method to allocate memory at the start of the simulation. Reference the allocated memory throughout the S-function code using `PWorks`.

- 'output' — Output method

The output method computes the block output values for each simulation time step.

- 'update' — Update method

The update method computes the value of discrete states for the next simulation time step. Only define the update method when the S-function has discrete states.

- 'derivatives' — Derivatives method

The derivatives method computes the value of state derivatives. Only define the derivatives method when the S-function has continuous states.

- 'terminate' — Terminate method

Use the terminate method to deallocate memory at the end of simulation.

Example: `Simulink.SFunctionBuilder.setUserCode(blk,"output", "*y0 = myCFunction(*u0);")`

**Tips**

- To specify include paths and library paths, add one or more library items using the `Simulink.SFunctionBuilder.add` function.
- To configure the number of PWorks, use the `Simulink.SFunctionBuilder.setSettings` function.
- To add discrete or continuous states, use the `Simulink.SFunctionBuilder.add` function.

Data Types: char | string

**userCode — Code for S-function method**

string | character vector

Code for S-function method, specified as a string or a character vector that defines C or C++ code for part of the S-function.

Example: `Simulink.SFunctionBuilder.setUserCode(blk,"output", "*y0 = myCFunction(*u0);")`

**Tips**

To specify the target language for the S-function, use the `Simulink.SFunctionBuilder.setTargetLanguage` function.

Data Types: char | string

# Simulink.SFunctionBuilder.update

Update attributes for input port, output port, or parameter of S-Function Builder block

## Syntax

```
Simulink.SFunctionBuilder.update(blk,elem,Name=elemName,FieldToUpdate=field,NewValue=newVal)
```

## Description

`Simulink.SFunctionBuilder.update(blk,elem,Name=elemName,FieldToUpdate=field,NewValue=newVal)` updates the value of the specified property for an input port, output port, or parameter of the S-Function Builder block `blk`.

To add a new input port, output port, or parameter to an S-Function Builder block, use the `Simulink.SFunctionBuilder.add` function.

## Input Arguments

### **blk** — S-Function Builder block

block handle | string | character vector

S-Function Builder block, specified as a block handle or as a string or a character vector that defines the block path.

### Tips

- To get the block handle for a block in your model, use the `getSimulinkBlockHandle` function.
- To get the block handle for the most recently selected or added block, use the `gcbh` function.

### **elem** — Type of element to update

'Input' | 'Output' | 'Parameter'

Type of element to update, specified as one of these options:

- 'Input' — Update property for input port on S-Function Builder block.
- 'Output' — Update property for output port on S-Function Builder block.
- 'Parameter' — Update property for parameter of S-Function Builder block.

Data Types: char | string

### **elemName** — Name of input port, output port, or parameter to update

string | character vector

Name of input port, output port, or parameter to update, specified as a string or a character vector.

Data Types: char | string

### **field** — Property of input port, output port, or parameter to update

'Name' | 'DataType' | 'Complexity' | 'Dimensions' | 'Value'

Property of input port, output port, or parameter to update, specified as one of these options:

- 'Name' — Update input port, output port, or parameter name.
- 'DataType' — Update input port, output port, or parameter data type.
- 'Complexity' — Update input port, output port, or parameter complexity.
- 'Dimensions' — Update input port or output port dimensions.

Do not specify `FieldToUpdate='Dimensions'` when you specify the second input argument as `'Parameter'`.

- 'Value' — Update parameter value.

Do not specify `FieldToUpdate='Value'` when you specify the second input argument as `'Input'` or `'Output'`.

Data Types: `char` | `string`

**newVal** — New value for property of input port, output port, or parameter

`string` | character vector

New value for property of input port, output port, or parameter, specified as a string or a character vector that contains the new value. The values you can specify depend on the property you want to update.

| Property to Update | Valid Values                                                                                                                                                                             |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name               | Valid port name                                                                                                                                                                          |

## Simulink.SimulationData.createStructOfTimeseries

Create structure of timeseries data to load as simulation input for bus

### Syntax

```
tsStruct = Simulink.SimulationData.createStructOfTimeseries(busObj,
tsStructIn)
tsStruct = Simulink.SimulationData.createStructOfTimeseries(busObj,
tsCellArray)
tsStructArray = Simulink.SimulationData.createStructOfTimeseries(busObj,
tsCellArray,dims)
tsStruct = Simulink.SimulationData.createStructOfTimeseries(tsArray)
```

### Description

`tsStruct = Simulink.SimulationData.createStructOfTimeseries(busObj, tsStructIn)` creates a structure with attributes that match those specified by the `Simulink.Bus` object, `busObj`, and data specified by the structure of timeseries objects, `tsStructIn`.

When the names in the input structure do not match the names specified by the bus object, the function renames the fields in the output structure to match the bus object specification. When other attributes such as data type and complexity do not match, the function returns an error.

You can use this syntax to create a simulation input that fully or partially specifies the data for a bus. You can also use this syntax to rename the structure elements to match the names in the `Simulink.Bus` object.

`tsStruct = Simulink.SimulationData.createStructOfTimeseries(busObj, tsCellArray)` creates a structure of timeseries objects with attributes that match those specified by the `Simulink.Bus` object, `busObj`, and data specified by the cell array of timeseries objects, `tsCellArray`.

When the names in the input structure do not match the names specified by the bus object, the function renames the fields in the output structure to match the bus object specification. When other attributes such as data type and complexity do not match, the function returns an error.

You can use this syntax to create simulation input that fully or partially specifies the data for a bus using a flat list of timeseries objects. The function maps the timeseries objects to the hierarchy specified by the `Simulink.Bus` object using a depth-first search.

`tsStructArray = Simulink.SimulationData.createStructOfTimeseries(busObj, tsCellArray,dims)` creates an array of timeseries structures where the attributes of each structure match those defined by the `Simulink.Bus` object, `busObj` with the data specified by the cell array of timeseries objects, `tsCellArray`. The input `dims` specifies the dimensions of the array.

`tsStruct = Simulink.SimulationData.createStructOfTimeseries(tsArray)` creates a structure of timeseries objects from the bus data stored in the `Simulink.TsArray` object, `tsArray`. In versions before R2016a, signal logging creates `Simulink.TsArray` objects to store

logged bus data. Use this syntax when you want to use bus data logged in a release before R2016a using ModelDataLogs format as simulation input.

## Examples

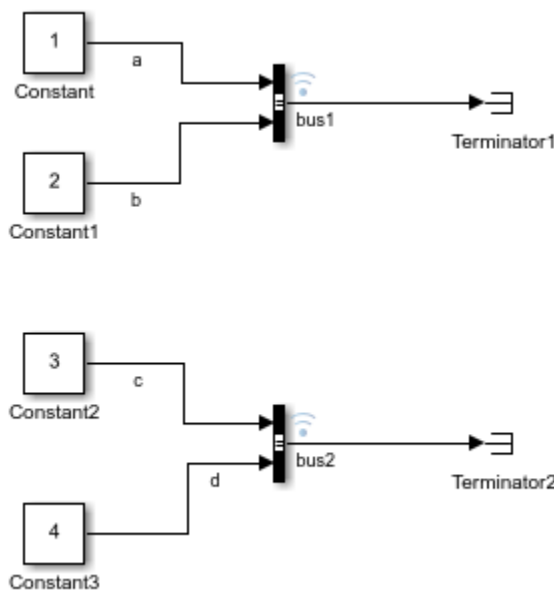

### Use Logged Bus Data as Simulation Input

You can use the `Simulink.SimulationData.createStructOfTimeseries` function to create structures of `timeseries` objects to use as simulation input for bus signals. This example shows you how to create a structure of timeseries to load into a model using timeseries data logged from a different simulation.

#### Create a Structure of Timeseries

Open the `ex_log_structtimeseries` model.

```
open_system('ex_log_structtimeseries')
```

The model uses Constant blocks and Bus Creator blocks to build two buses, `bus1` and `bus2`, with signals `a`, `b`, `c`, and `d`. The model uses signal logging to log the bus data. Create bus data by simulating the model.

```
out = sim('ex_log_structtimeseries');
```

View the data in the logging variable `logstdout`. Signal logging creates a `Simulink.SimulationData.Dataset` object with `Simulink.SimulationData.Signal` objects as elements.

```
logstdout = out.logstdout
```

```
logstdout =
```

```
Simulink.SimulationData.Dataset 'logout' with 2 elements
```

|   |              | Name | BlockPath                            |
|---|--------------|------|--------------------------------------|
| 1 | [1x1 Signal] | bus1 | ex_log_structtimeseries/Bus Creator  |
| 2 | [1x1 Signal] | bus2 | ex_log_structtimeseries/Bus Creator1 |

- Use braces { } to access, modify, or add elements using index.

You can use the `get` function to select the `Simulink.SimulationData.Signal` object for bus2. The bus data is in the `Values` property of the `Simulink.SimulationData.Signal` object. The data representing bus2 is logged in a structure containing `timeseries` objects named `c` and `d`.

```
logout.get(2).Values
```

```
ans =
```

```
struct with fields:
```

```
c: [1x1 timeseries]
d: [1x1 timeseries]
```

### Loading Model Configuration

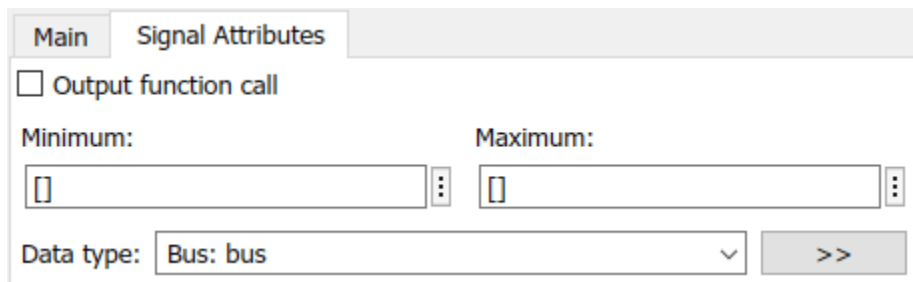

Open the `ex_load_structtimeseries` model, which uses the logged simulation data as input.

```
open_system('ex_load_structtimeseries')
```

The model uses the `InBus` Inport block to load input bus data. A `Bus Selector` block chooses signals from the bus to display on `Display` blocks.

Double-click the `InBus` block and check its **Data type** on the **Signal Attributes** tab of the dialog. The data type is specified by a `Simulink.Bus` object called `bus`.

Close the dialog and open the Model Explorer. On the **Callbacks** tab, you can see the model uses its `PreLoadFcn` to define the `Simulink.Bus` object that defines the data type for the Inport block.

Open the Configuration Parameters and view the specification for the **Input** parameter on the **Data Import/Export** pane. The model uses the variable `inputBus` for its **Input**.

### Create Simulation Input from the Structure of timeseries Data

To load the data logged for `bus1`, you only need to assign the structure data to the Input variable for the model.

```
inputBus = logout.get(1).Values
```

```
inputBus =
 struct with fields:
 a: [1x1 timeseries]
 b: [1x1 timeseries]
```

When you simulate the model, the Display blocks show the values 1 and 2 logged in `bus1` and loaded into the model.

To load the data logged for `bus2`, you need to use the `Simulink.Bus` object that defines the Inport block data type and `Simulink.SimulationData.createStructOfTimeseries` to create a structure of `timeseries` with names specified by the `Simulink.Bus` object.

```
inputBus = Simulink.SimulationData.createStructOfTimeseries('bus', ...
 logout.get(2).Values)
```

```
inputBus =
 struct with fields:
 a: [1x1 timeseries]
 b: [1x1 timeseries]
```

When you simulate the model, the Display blocks show the values 3 and 4 logged in `bus2` and loaded into the model.

### Partially Specify Simulation Input for a Bus

This example shows how to use the `Simulink.SimulationData.createStructOfTimeseries` function to create partially specified simulation input for a bus. This example logs data from `ex_log_structtimeseries` and then loads that data into `ex_load_structtimeseries`.

#### Create timeseries Data

First, open and simulate the `ex_log_structtimeseries` model. The model logs two bus signals, `bus1` and `bus2`, created using Constant blocks and Bus Creator blocks. Access the `logout` Dataset in the `Simulink.SimulationOutput` object, `out`.

```
open_system('ex_log_structtimeseries')
out = sim('ex_log_structtimeseries');
```

```
logcout = out.logcout;
```

You can use a structure of `timeseries` data or a cell array of `timeseries` data to partially specify simulation input for a bus.

### Partially Specify Bus Data with a Structure of `timeseries` Data

Open the model `ex_load_structtimeseries` that will load some of the data you logged in the previous section.

```
open_system('ex_load_structtimeseries')
```

Use the `get` function to access the structure of `timeseries` data logged for `bus1`.

```
bus1 = logcout.get(1).Values;
```

Then, replace the `b` data with `[]`.

```
bus1.b = [];
```

The `ex_load_structtimeseries` model uses the variable `inputBus` as its **Input**. The `Simulink.Bus` object, `bus`, that defines the data type for the Inport block is defined in the `PreLoadFcn` callback for the `ex_load_structtimeseries` model. Because the signal names in

bus1 match the `Simulink.Bus` object specification for the Inport block in the `ex_load_structtimeseries` model, you can use the logged structure without modification. To load the data for bus1, assign bus1 to the variable `inputBus`.

```
inputBus = bus1;
```

Simulate the model. The Display blocks show the logged value 1 for a and 0 for b. The simulation uses ground values when you do not specify data for the signal.

```
loadOut = sim('ex_load_structtimeseries');
```

Now, load the data logged for bus2. The signal names in bus2 do not match the `Simulink.Bus` object specification for the Inport block in the `ex_load_structtimeseries` model. Modify the data in the structure to partially specify input data for the bus. Then, use the `Simulink.SimulationData.createStructOfTimeseries` function to change the names in the structure to match the bus specification.

```
bus2 = logout.get(2).Values;
bus2.d = [];
inputBus = bus2;
inputBus = Simulink.SimulationData.createStructOfTimeseries('bus',inputBus);
```

Simulate the model. The Display blocks show the logged value 3 for a and 0 for b.

```
loadOut = sim('ex_load_structtimeseries');
```

### Partially Specify Bus Data with a Cell Array of Timeseries Data

When you have timeseries data, you can use `Simulink.SimulationData.createStructOfTimeseries` to partially specify simulation input for a bus using a cell array of the timeseries data. Load the timeseries data for signal d in bus2 as part of a partial bus specification for the Inport block in the `ex_load_structtimeseries` model. The `PreLoadFcn` callback for the `ex_load_structtimeseries` model defines the `Simulink.Bus` object, `bus`, that defines the data type for the Inport block.

```
d = logout.get(2).Values.d;
inputBus = Simulink.SimulationData.createStructOfTimeseries('bus',...
 {d, []});
```

Simulate the model. The Display block for signal a in the `ex_load_structtimeseries` model shows the data logged in signal d from the `ex_log_structtimeseries` model. The Display block for signal b shows 0.

```
loadOut = sim('ex_load_structtimeseries');
```

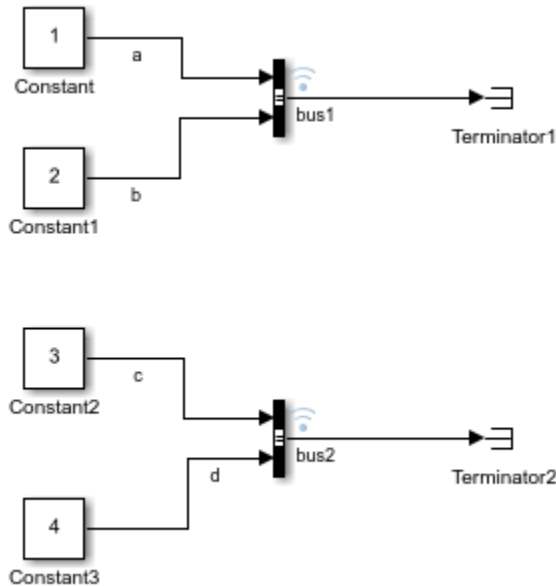

### Load Simulation Input Data for an Array of Buses

This example shows how to use the `Simulink.SimulationData.createStructOfTimeseries` function to generate simulation input for an array of buses. You create timeseries data by simulating one model. Then, you create an input structure using the logged data to load into an array of buses in another model.

### Create timeseries Data

To start, open the `ex_log_structtimeseries` model.

```
open_system('ex_log_structtimeseries')
```

The model creates two buses, `bus1` and `bus2`, using Constant blocks and Bus Creator blocks. The signals are named `a`, `b`, `c`, and `d`. Create logged bus data by simulating the model.

```
out = sim('ex_log_structtimeseries');
```

The output `out` contains a `Simulink.SimulationData.Dataset` object, `logouts`, with the logged data. You can access the `bus1` and `bus2` signals using the `get` function. The data for each signal is in the `Simulink.SimulationData.Signal` object `Values` parameter. You can access the bus elements using a dot followed by the signal name. `bus1` is the first signal in the `Dataset` object and contains signals `a` and `b`. `bus2` contains signals `c` and `d`.

```
logouts = out.logouts;
```

```
a = logouts.get(1).Values.a;
b = logouts.get(1).Values.b;
c = logouts.get(2).Values.c;
d = logouts.get(2).Values.d;
```

### Loading Model Configuration

Open the model `ex_structtimeseries_aob`, which uses an array of buses as input.

```
open_system('ex_load_structtimeseries_aob')
```

The model uses the InAoB Inport block to load simulation input. Selector blocks select a bus from the array of buses, and Bus Selector blocks select signals to show in the Display blocks.

Double-click the InAoB block and look at the **Signal Attributes** pane of the dialog. The **Data type** for the block is set to **Bus** with the type defined by the Simulink.Bus object, bus. The **Port dimensions** parameter is set to [2 1].

You can see the definition for the Simulink.Bus object, bus, in the **Callbacks** tab in the Model Explorer. This model uses the PreLoadFcn to define the bus object.

Open the Model Configuration Parameters and look at the **Input** parameter. The model uses the variable inputAoB as input.

### Create Array of Buses Simulation Input

Use Simulink.SimulationData.createStructOfTimeseries and the data logged in the first section to create a structure to load as simulation input for the array of buses. Specify the dimensions as [2 1] to match the dimensions of the InAoB block.

```
inputAoB = Simulink.SimulationData.createStructOfTimeseries('bus', ...
 {a,b,c,d}, [2 1]);
```

When you simulate the model, the Display blocks show the data for signals a, b, c, and d logged from the ex\_log\_structtimeseries model. The array of buses contains two buses with signals a and b. Simulink.SimulationData.createStructOfTimeseries renamed signals c and d to match the Simulink.Bus specification used by the array of buses.

```
inputAoB(2)
```

```
ans =
```

```
struct with fields:
 a: [1x1 timeseries]
 b: [1x1 timeseries]
```

Simulate the model. The display blocks show the logged values.

```
aob_out = sim('ex_load_structtimeseries_aob');
```

### Create a Structure of timeseries Objects from a Simulink.TsArray Object

In releases before R2016a, when you log simulation data using ModelDataLogs format, bus data is stored as a Simulink.TSArray object. You cannot log data using ModelDataLogs format using a release after R2016a. In this example, the logged data, log sout, was logged in ModelDataLogs format using a release before R2016a. The variable log sout contains data for a single bus, bus1.

```
log sout
```

```
log sout =
```

```
Simulink.ModelDataLogs (log_modeldatalogs):
 Name Elements Simulink Class
 bus1 2 TsArray
```

To load the logged data as simulation input for a bus, create a structure of timeseries objects from the data in bus1.

```
struct_of_ts = ...
Simulink.SimulationData.createStructOfTimeseries(logsout.bus1)

struct_of_ts =

 const1_sig: [1x1 timeseries]
 const2_sig: [1x1 timeseries]
```

## Input Arguments

### busObj — Name of Simulink.Bus object

character vector

Name of the Simulink.Bus object that specifies the attributes for the data in the output structure of timeseries objects. When you want to load the structure of timeseries objects as simulation input for a bus, the busObj is the bus that defines the data type for the root-level Inport block.

Simulink.SimulationData.createStructOfTimeseries validates the input timeseries attributes including data type and complexity against the Simulink.Bus object specification. When element names do not match between the Simulink.Bus specification and the input timeseries data, Simulink.SimulationData.createStructOfTimeseries renames the timeseries data to match the bus specification. When other attributes do not match, the function returns an error.

Example: 'MyInputBus'

### tsStructIn — Structure of timeseries objects

structure of timeseries data

Structure of timeseries data for use in creating the output structure of timeseries objects according to the Simulink.Bus object. The structure must have the same hierarchy as the Simulink.Bus object.

To partially specify data for a bus, use [] in the place of the bus element you want to use ground values.

**tsCellArray — Cell array of timeseries objects**cell array of `timeseries` objects

Cell array of `timeseries` objects specifying the data for the output structure of `timeseries` objects.

To partially specify data for a bus, use `[]` in the place of the bus element you want to use ground values.

The `Simulink.SimulationData.createStructOfTimeseries` function maps the `timeseries` elements of the cell array to the hierarchy specified by the `Simulink.Bus` object using a depth-first search.

Example: `{ts1,ts2,ts3}`

Example: `{ts1,[],ts3}`

**Dependencies**

When you specify the `dims` argument, the number of cells in the cell array must match the number of individual signal elements in the `Simulink.Bus` object multiplied by the product of the specified dimensions.

**dims — Dimensions for output array**

vector

Dimensions for the array of `timeseries` structures, specified as a vector.

When you specify the dimensions as a scalar, `n`, the function creates a 1-by-`n` array.

Example: `[2,1]`

**Dependencies**

When you specify the `dims` argument, the number of cells in the cell array must match the number of individual signal elements in the `Simulink.Bus` object multiplied by the product of the specified dimensions.

Data Types: `double`

**tsArray — Simulink.TsArray object**`Simulink.TsArray`

`Simulink.TsArray` object.

In versions prior to R2016a, signal logging creates `Simulink.TsArray` objects to store logged bus data. Use this syntax when you want to use data logged using `ModelDataLogs` format in a version before R2016a to create simulation input for a bus.

Example: `myTsArrayObj`

**Output Arguments****tsStruct — Structure of timeseries objects**

struct

Structure of `timeseries` objects with attributes specified by the `Simulink.TsArray` or `Simulink.Bus` input. You can load the structure of `timeseries` objects as simulation input for a bus.

**tsStructArray – Array of timeseries structures**

array

Array of structures of `timeseries` objects with dimensions specified by the `dims` input.

## Version History

Introduced in R2013a

“Load Bus Data to Root-Level Input Ports”

# Simulink.SimulationData.DatasetRef.getDatasetVariableNames

List names of variables in MAT file that contain `Simulink.SimulationData.Dataset` objects

## Syntax

```
dsNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames(
filename)
```

## Description

`dsNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames(filename)` returns the names of variables in the MAT file `filename` that contain `Simulink.SimulationData.Dataset` objects.

When you want to get the names of variables that contain `Dataset` objects, the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function runs faster than the `who` or `whos` functions.

Using the name of the MAT file and the name of a variable that contains a `Dataset` object, you can create a `Simulink.SimulationData.DatasetRef` object that references the data in the MAT file without loading the entire `Dataset` object into memory.

## Examples

### Stream Simulation Input Data Using DatasetRef Object

When your simulation input data is stored as a `Simulink.SimulationData.Dataset` object in a file that is too large to load into memory, you can create a `Simulink.SimulationData.DatasetRef` object to stream input data into your model during simulation. The `DatasetRef` object references the data in the `Dataset` object in the file and incrementally loads the data during simulation.

To create a `DatasetRef` object, you need the name of the file and the name of the variable in the file that contains the `Dataset` object. You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to see the names of all variables in a file that contain `Dataset` objects without loading the file into memory.

Get the names of variables in the file `aircraftData.mat` that contain `Dataset` objects.

```
datasetNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames("aircraftData.mat")
```

```
datasetNames = 1x3 cell
 {'logout'} {'xout'} {'yout'}
```

Create a reference to the data in the `Dataset` object `logout`.

```
logoutDSR = Simulink.SimulationData.DatasetRef("aircraftData.mat", "logout");
```

To stream the data stored in the `Dataset` object `logout` as input for simulation, specify the value for the **Input** parameter as `logoutDSR`. Loading data from a `DatasetRef` object works the same as loading data from a `Dataset` object except that the data is incrementally loaded into memory.

## Input Arguments

### **filename** — Name of MAT file

string | character vector

Name of MAT file, specified as a string or a character vector.

Example: "myMATFile.mat"

Data Types: char | string

## Output Arguments

### **dsNames** — Names of variables that contain Dataset objects

cell array of character vectors

Names of variables that contain `Dataset` objects, returned as a cell array of character vectors.

## Version History

**Introduced in R2016a**

# Simulink.SimulationData.forEachTimeseries

Apply function to data contained in set of timeseries objects

## Syntax

```
res = Simulink.SimulationData.forEachTimeseries(func,tsData)
```

## Description

`res = Simulink.SimulationData.forEachTimeseries(func,tsData)` applies the function `func` to each `timeseries` object in `tsData`. You can use this function to postprocess data logged from a bus or array of buses.

## Examples

### Find Minimum Values for Signals in Bus

Open the model `NonvirtualBusCreationModel`. The model groups the output signals from a Chirp block and a Sine block into a bus that is nested in another bus. The second bus also contains the output signal from a Step block.

Copyright 2019-2020 The MathWorks, Inc.

Mark the bus `TopBus` for logging.

```
Simulink.sdi.markSignalForStreaming("NonvirtualBusCreationModel/Bus Creator1",1,true);
```

Simulate the model.

```
out = sim("NonvirtualBusCreationModel");
```

The `Simulink.SimulationOutput` object contains simulation metadata and all simulation data logged to the workspace.

`out`

```
out =
 Simulink.SimulationOutput:

 logstdout: [1x1 Simulink.SimulationData.Dataset]
 tout: [53x1 double]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

The variable `logstdout` contains the data logged for the bus.

```
logstdout = out.logstdout
```

```
logstdout =
Simulink.SimulationData.Dataset 'logstdout' with 1 element
```

|                | Name   | BlockPath                               |
|----------------|--------|-----------------------------------------|
| 1 [1x1 Signal] | TopBus | NonvirtualBusCreationModel/Bus Creator1 |

- Use braces { } to access, modify, or add elements using index.

Access the signal that contains the data logged for the bus `TopBus`. The signal values are stored in the `Values` property for the `Simulink.SimulationData.Signal` object.

```
topBusSig = getElement(logstdout,1)
```

```
topBusSig =
 Simulink.SimulationData.Signal
 Package: Simulink.SimulationData
```

Properties:

```
 Name: 'TopBus'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'output'
 PortIndex: 1
 Values: [1x1 struct]
```

Methods, Superclasses

Access the structure that contains the values for the signals in the bus. The structure hierarchy and field names match the hierarchy and signal names for the bus. The data for each signal in the bus is stored as a `timeseries` object.

```
topBusData = topBusSig.Values
```

```
topBusData = struct with fields:
 NestedBus: [1x1 struct]
 Step: [1x1 timeseries]
```

Use the `Simulink.SimulationData.forEachTimeseries` function to find the minimum value for each signal in the bus. The minimum values are returned as a structure with the same fields and hierarchy as the input data.

```
topBusSigMins = Simulink.SimulationData.forEachTimeseries(@min,topBusData)
```

```
topBusSigMins = struct with fields:
 NestedBus: [1x1 struct]
 Step: 0
```

Check the minimum value for the output signal from the Chirp block.

```
chirpMin = topBusSigMins.NestedBus.Chirp
chirpMin = -0.9972
```

## Input Arguments

### **func** — Function to apply to data

function handle

Function to apply to data, specified as a function handle. For more information, see “Create Function Handle”.

The function that you specify must take at least one input argument and return a scalar. You can specify a handle for a built-in function, a function you create, or an anonymous function.

For example, you can use the built-in `min` function to compute the minimum value in each `timeseries` object.

```
res = Simulink.SimulationData.forEachTimeseries(@min,tsData);
```

When the function takes more than one input argument, only the argument for the `timeseries` object can change for each computation. The rest of the arguments must use the same values for each `timeseries` object.

For example, to apply the `resample` function to each `timeseries` object, specify the function as an anonymous function. Here, the variable `tsData` represents the `timeseries` objects. The other arguments for the `resample` function are passed as parameter values. The `Simulink.SimulationData.forEachTimeseries` function passes the `timeseries` data you specify in the second input argument to the anonymous function as the value for `tsData`.

```
res = Simulink.SimulationData.forEachTimeseries(@(tsData) resample(tsData,[2.5 3]),tsData);
```

Data Types: `function_handle`

### **tsData** — Data to process

scalar `timeseries` object | array of `timeseries` | structure of `timeseries` objects | array of structures of `timeseries` objects

Data to process, specified as one of these values:

- Scalar `timeseries` object

- Array of `timeseries` objects
- Structure of `timeseries` objects
- Array of structures of `timeseries` objects

## Output Arguments

### **res** — Results of processing data

scalar `timeseries` object | array of `timeseries` | structure of `timeseries` objects | array of structures of `timeseries` objects

Results of processing data, returned as one of these values:

- Scalar `timeseries` object
- Array of `timeseries` objects
- Structure of `timeseries` objects
- Array of structures of `timeseries` objects

Results are returned in the same form as the input data.

## Version History

Introduced in R2016b

# Simulink.SimulationData.ModelLoggingInfo.createFromModel

**Package:** Simulink.SimulationData

Create Simulink.SimulationData.ModelLoggingInfo object for top model with override settings for each logged signal in model

## Syntax

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl)
mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl,
Name,Value)
```

## Description

`mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl)` creates a model logging override object for the model `mdl` that includes logged signals for these kinds of systems:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

`mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl, Name,Value)` creates a Simulink.SimulationData.ModelLoggingInfo object for the model `mdl` with optional settings.

## Examples

### Create Model Logging Override Object with Logged Signals

You can create a model logging override object for the model `sldemo_mdhref_bus` and automatically add each logged signal in the model to that object. The model `sldemo_mdhref_bus` has four signals marked for logging.

```
mdl = 'sldemo_mdhref_bus';
open_system(mdl)
mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl)

mdlInfo =
 ModelLoggingInfo with properties:
 Model: 'sldemo_mdhref_bus'
 LoggingMode: 'OverrideSignals'
 LogAsSpecifiedByModels: {}
 Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `'OverrideSignals'`, which configures the model logging override object to log only the signals specified in the `Signals` property.

Apply the model override object settings. The software saves the settings when you save the model.

```
set_param mdl, 'DataLoggingOverride', mdlInfo;
```

## Specify How To Handle Variants

You can use the options in the `Simulink.SimulationData.ModelLoggingInfo.createFromModel` function to specify how model components like variants and model references should be handled. For example, use the `Variants` name-value argument to create a model logging override object that includes logged signals in all variants of the model `sldemo_variant_subsystems`.

By default, the `sldemo_variant_subsystems` model does not log any signals.

```
mdl = 'sldemo_variant_subsystems';
open_system(mdl)
```

Start by configuring the output signals from the Linear Controller and Nonlinear Controller subsystems for logging.

```
phLin = get_param("sldemo_variant_subsystems/Controller/Linear Controller",...
 "PortHandles");
set_param(phLin.Outport(1), 'DataLogging', 'on');
phNonlin = get_param("sldemo_variant_subsystems/Controller/Nonlinear Controller",...
 "PortHandles");
set_param(phNonlin.Outport(1), 'DataLogging', 'on');
```

Use the `Simulink.SimulationData.ModelLoggingInfo.createFromModel` function to create a model logging override object that includes the signals logged in all variant subsystems of the `sldemo_variant_subsystems` model.

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
mdl, 'Variants', 'AllVariants')
```

```
mdlInfo =
 ModelLoggingInfo with properties:

 Model: 'sldemo_variant_subsystems'
 LoggingMode: 'OverrideSignals'
 LogAsSpecifiedByModels: {}
 Signals: [1x2 Simulink.SimulationData.SignalLoggingInfo]
```

## Input Arguments

### **mdl** — Name of top model

character vector

Name of top model for which to create a `Simulink.SimulationData.ModelLoggingInfo` object, specified as a character vector.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

```
Example: mdlInfo =
Simulink.SimulationData.ModelLoggingInfo.createFromModel mdl, Variants =
'AllVariants')
```

If you select more than one option, then the created `Simulink.SimulationData.ModelLoggingInfo` object includes signals that fit the combinations of the specified options. For example, if you set `FollowLinks` to `on` and `RefModels` to `off`, then the model signal logging override object does not include signals from library links that exist inside of referenced models.

### FollowLinks — Option to follow links into library blocks

'on' (default) | 'off'

Option to follow links into library blocks, specified as 'on' or 'off'.

- 'on' — Include logged signals from inside of libraries.
- 'off' — Skip all libraries.

### LookUnderMasks — Option to include logged signals from masked systems

'all' (default) | 'none' | 'graphical' | 'functional'

Option to include logged signals from masked systems, specified as 'all', 'none', 'graphical', or 'functional'.

- 'all' — Include logged signals from all masked subsystems.
- 'none' — Skip all masked subsystems.
- 'graphical' — Include logged signals from masked subsystems that do not have a workspace or dialog box.
- 'functional' — Include logged signals from masked subsystems that do not have a dialog box.

### Variants — Option to include subsystem and model variants

'ActiveVariants' (default) | 'AllVariants'

Option to include subsystem and model variants, specified as 'ActiveVariants' or 'AllVariants'.

- 'ActiveVariants' — Include logged signals from only active subsystem and model variants.
- 'AllVariants' — Include logged signals from all subsystem and model variants.

### RefModels — Option to include logged signals from referenced models

'on' (default) | 'off'

Option to include logged signals from referenced models. specified as 'on' or 'off'.

- 'on' — Include logged signals from referenced models.

- 'off' — Skip all referenced models.

# Simulink.SubSystem.convertToModelReference

Convert subsystem to model reference

## Syntax

```
Simulink.SubSystem.convertToModelReference(gcf,'UseConversionAdvisor',true)
```

```
[tf,h] = Simulink.SubSystem.convertToModelReference(subsys,model)
```

```
[tf,h] = Simulink.SubSystem.convertToModelReference(subsys,model,Name,Value)
```

## Description

`Simulink.SubSystem.convertToModelReference(gcf,'UseConversionAdvisor',true)` opens the **Model Reference Conversion Advisor** for the selected Subsystem block.

`[tf,h] = Simulink.SubSystem.convertToModelReference(subsys,model)` converts the specified subsystems to referenced models.

For each subsystem that the function converts, it:

- Creates a model.
- Copies the contents of the subsystem into the new model.
- Updates any root-level input and output blocks and the configuration parameters of the model to match the compiled attributes of the original subsystem.
- Copies the contents of the model workspace of the original model to the new model.

Before you use this function, load the model containing the subsystem.

`[tf,h] = Simulink.SubSystem.convertToModelReference(subsys,model,Name,Value)` specifies options using one or more name-value arguments.

## Examples

### Open the Model Reference Conversion Advisor

Open the f14 model.

```
open_system('f14');
```

In the f14 model, select the Controller subsystem output signal and click **Log Signals**.

In the Simulink Editor, select the Controller subsystem. Open the **Model Reference Conversion Advisor** from the command window.

```
Simulink.SubSystem.convertToModelReference(gcf,'UseConversionAdvisor',true);
```

Perform the conversion using the advisor.

## Programmatically Convert Subsystem to Referenced Model

Convert the Bus Counter subsystem to a referenced model named `bus_counter_ref_model`.

```
open_system('sldemo_mdref_conversion');
Simulink.SubSystem.convertToModelReference(...
 'sldemo_mdref_conversion/Bus Counter', ...
 'bus_counter_ref_model', ...
 'AutoFix',true,...
 'ReplaceSubsystem',true,...
 'CheckSimulationResults',true);
```

### Successfully converted Subsystem block to Model block.

### Conversion to Model Reference Example

Double-click here to convert the Bus Counter subsystem to a referenced model.

Copyright 1990-2020 The MathWorks, Inc.

## Convert Multiple Subsystems to Referenced Models

Convert the two subsystems with one command.

```
open_system('f14');
set_param(gcs, 'SaveOutput', 'on', 'SaveFormat', 'Dataset');
set_param(gcs, 'SignalResolutionControl', 'UseLocalSettings');
Simulink.SubSystem.convertToModelReference(...
 {'f14/Controller', 'f14/Aircraft Dynamics Model'}, ...
 {'controller_ref_model', 'aircraft_dynamics_ref_model'}, ...
 'ReplaceSubsystem', true, ...
```

```
'AutoFix',true,...
'CheckSimulationResults',true)
```

## Input Arguments

### subsys — Subsystem names or handles

numeric array | character vector | cell array of character vectors | string array

Subsystem names or handles, specified as a numeric array, character vector, cell array of character vectors, or string array.

For information on which subsystems you can convert, see “Conditionally Execute Referenced Models”.

Data Types: double | char | string

### model — Referenced model names

character vector | cell array of character vectors | string array

Referenced model names, specified as a character vector, cell array of character vectors, or string array. Each model name must be 59 characters or less.

If you specify multiple subsystems to convert, specify the same number of referenced model names. Each model name corresponds to the specified subsystem, in the same order.

Data Types: char | string

## Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Simulink.SubSystem.convertToModelReference...  
(engineSubsys,engineModelRef,'ReplaceSubsystem',true)`

## Conversion

### AutoFix — Option to fix all conversion issues that can be fixed automatically

false (default) | true

Option to fix all conversion issues that can be fixed automatically, specified as true or false.

If you set `AutoFix` to true, the function fixes all conversion issues that it can fix. For issues that the function cannot fix, the conversion process generates error messages that you address by modifying the model.

---

**Note** If you set `Force` to true, then the function does not automatically fix conversion issues.

---

Data Types: logical

### Force — Option to complete conversion even with errors

false (default) | true

Option to complete conversion even with errors, specified as `true` or `false`.

If `true`, the function returns conversion errors as warnings and continues with the conversion without fixing the errors, even if you set `AutoFix` to `true`. The `Force` option allows you to use the function to do the initial steps of the conversion and then complete the conversion process yourself.

Data Types: `logical`

### **DataFileName — Name of file for storing conversion data**

character vector

Name of file for storing conversion data, specified as a character vector. You can specify an absolute or relative path.

You can save the conversion data in a MAT file (default) or a MATLAB file. If you use a `.m` file extension, the function serializes all variables to a MATLAB file.

By default, the function uses a file name consisting of the model name plus `_conversion_data.mat`.

Data Types: `char`

### **Model Interface**

### **CreateWrapperSubsystem — Option to insert wrapper subsystem to preserve model layout**

`false` (default) | `true`

Option to insert wrapper subsystem to preserve model layout, specified as `true` or `false`.

When you convert a subsystem to a referenced model, you can have the conversion process insert a wrapper subsystem to preserve the layout of the parent model. The subsystem wrapper contains the Model block from the conversion.

The conversion creates a wrapper subsystem automatically if the conversion modifies the Model block interface by adding ports.

Data Types: `logical`

### **CreateBusObjectsForAllBuses — Option to create bus objects for interface definition**

`false` (default) | `true`

Option to create bus objects for interface definition, specified as `true` or `false`.

Models require a defined interface, unlike subsystems. To define an interface that contains virtual buses, the new model must use either of these options:

- In Bus Element and Out Bus Element blocks
- Inport and Outport blocks that specify `Simulink.Bus` objects

By default, the conversion does not create Bus objects. Instead, the conversion uses In Bus Element and Out Bus Element blocks to support virtual buses at the model interface, and the new model contains the original subsystem.

When you set this parameter to `true`, the conversion creates Bus objects for all virtual buses connected to Inport and Outport blocks that do not specify Bus objects. The conversion keeps the Inport and Outport blocks at the model interface, and they specify the new Bus objects.

Data Types: `logical`

### **CopyCodeMappings — Option to copy code mappings from parent model to new model**

`false` (default) | `true`

Option to copy code mappings from parent model to the new model, specified as `true` or `false`.

If `true`, the function copies the existing code mapping configurations from the parent model to the new referenced model.

If `false`, the function does not copy the existing code mapping configurations from the parent model to the new model.

Data Types: `logical`

### **Model Implementation**

### **ReplaceSubsystem — Option to replace Subsystem blocks with Model blocks**

`false` (default) | `true`

Option to replace Subsystem blocks with Model blocks, specified as `true` or `false`.

If you set the value to `true`, consider making a backup of the original model before you convert the subsystems. If you want to undo the conversion, having a backup makes it easier to restore the model.

If you set `ReplaceSubsystem` to `true`, the conversion action depends on whether you use the automatic fix options.

- If you use the automatic fixes, then the conversion replaces the Subsystem block with a Model block unless the automatic fixes change the input or output ports. If the ports change, then the conversion includes the contents of the subsystem in a Model block that is inserted in the Subsystem block.
- If you do not use the automatic fixes, then the conversion replaces the Subsystem block with a Model block.

Data Types: `logical`

### **SimulationModes — Simulation mode for Model blocks**

`'Normal'` (default) | `'Accelerator'`

Simulation mode for Model blocks, specified as `'Normal'` or `'Accelerator'`. The simulation mode setting applies to the Model blocks that reference the models that the conversion creates.

Data Types: `char` | `string`

### **BuildTarget — Model reference targets to generate**

`'Sim'` | `'Coder'`

Model reference targets to generate, specified as `'Sim'` or `'Coder'`.

- `'Sim'` — Model reference simulation target
- `'Coder'` — Code generation target

Data Types: `char`

### Simulation Results Comparison

#### **CheckSimulationResults** — Option to check simulation results before and after conversion

`false` (default) | `true`

Option to check simulation results before and after conversion, specified as `true` or `false`.

Before performing the conversion:

- Enable signal logging for the subsystem output signals of interest in the model.
- Set `CheckSimulationResults` to `true`.
- Set `AbsoluteTolerance`.
- Set `RelativeTolerance`.
- Set `SimulationModes` to the simulation mode used by the original model.

If the difference between simulation results exceeds the tolerance level, the function displays a message.

Data Types: `logical`

#### **AbsoluteTolerance** — Absolute signal tolerance for comparison

`1e-06` (default) | numeric scalar

Absolute signal tolerance for comparison, specified as a numeric scalar.

Use this option only if you set `CheckSimulationResults` to `true`.

Data Types: `double`

#### **RelativeTolerance** — Relative signal tolerance for comparison

`1e-06` (default) | numeric scalar

Relative signal tolerance for comparison, specified as a numeric scalar.

Use this option only if you set `CheckSimulationResults` to `true`.

Data Types: `double`

## Output Arguments

#### **tf** — True or false result

`1` | `0` | logical array

True or false result, returned as `1` or `0` of data type `logical`.

A value of `1` indicates a successful conversion.

If you set `Force` to `true`, the function returns a value of `1` if the conversion completes. However, the simulation results can differ from the simulation results for the model before conversion.

#### **h** — Handles of created Model blocks

numeric array

Handles of the created Model blocks, returned as a numeric array.

Data Types: `double`

## Tips

- You cannot convert a parent subsystem and a child of that subsystem at the same time.
- Specifying multiple subsystems to convert with one command can save time compared to converting each subsystem separately. The multiple subsystem conversion process compiles the model once.
- If you specify multiple subsystems to convert, the conversion process attempts to convert each subsystem. Successfully converted subsystems produce referenced models, even if the conversions of other subsystems fail.
- If you specify multiple subsystems, consider:
  - In the input arguments, setting 'Autofix', 'ReplaceSubsystem', and 'CheckSimulationResults' to true.
  - In the model, setting a short simulation time.
- A data dictionary saves bus objects that it creates as part of the conversion process when both of these conditions exist:
  - The top model uses a data dictionary.
  - All changes to the top model are saved.
- To maintain the behavior of a masked subsystem, perform these additional tasks:
  - For masked callbacks, icons, ports, and documentation, create a backup copy of the masked subsystem before converting it to a referenced model. After conversion, copy the content from the Mask Editor of the backup masked subsystem to the Mask Editor of the new Model block.
  - Replace mask parameters with model arguments (see “Parameterize Instances of a Reusable Referenced Model”).

---

**Note** Referenced models do not support the functionality that you can achieve with mask initialization code to create masked parameters.

---

## Version History

### Introduced in R2006a

#### **R2019a: 'BuildTarget' argument value 'RTW' is not recommended**

*Not recommended starting in R2019a*

In R2019a, an argument value used with the `Simulink.SubSystem.convertToModelReference` function was updated. The legacy argument value is supported for backward compatibility.

To take advantage of the updated 'BuildTarget' argument value, use 'Coder' instead of 'RTW'.

#### **R2020b: Copy code mappings from parent model to referenced model**

Starting in R2020b, you can copy code mappings from the parent model to the newly created referenced model. To copy the code mappings, use the `Simulink.SubSystem.convertToModelReference` function with the `CopyCodeMappings` argument specified as true.

**R2023a: Copy service interface code mappings from parent model to referenced model**

Service interface code mappings were introduced in R2022b. Starting in R2023a, you can copy service interface code mappings from the parent model to the newly created referenced model. To copy the mappings, use the `Simulink.SubSystem.convertToModelReference` function with the `CopyCodeMappings` argument specified as `true`. To learn more about service interface mappings, see “C Service Interfaces” (Embedded Coder). To learn more about code mapping configurations, see “Define Service Interfaces, Storage Classes, Memory Sections, and Function Templates for Software Architecture” (Embedded Coder).

# Simulink.SubSystem.copyContentsToBlockDiagram

Copy graphical contents from subsystem to empty system

## Syntax

```
Simulink.SubSystem.copyContentsToBlockDiagram(subsys, sys)
```

## Description

`Simulink.SubSystem.copyContentsToBlockDiagram(subsys, sys)` copies the blocks, lines, and annotations of the specified subsystem to the top-level block diagram of the specified system. It does not affect nongraphical information such as configuration sets.

To use this function:

- The specified system must be loaded in memory.
- The specified subsystem must be loaded in memory.
- The specified system must not contain any blocks or lines. Other types of information can exist in the system and are unaffected by the function. To delete the graphical content of the system, use `Simulink.BlockDiagram.deleteContents`.

## Examples

### Copy Subsystem Contents to Model

Copy the graphical contents of a subsystem to a new model.

Open the f14 model.

```
open_system('f14');
```

Create an empty model named f14Controller.

```
model = new_system('f14Controller');
open_system(model)
```

Copy the graphical contents from the f14/Controller subsystem to the empty f14Controller model.

```
Simulink.SubSystem.copyContentsToBlockDiagram('f14/Controller', model)
```

## Input Arguments

### **subsys** — Subsystem block path or handle

character vector | string scalar | numeric scalar

Subsystem block path or handle, specified as a character vector, string scalar, or numeric scalar.

Example: 'model1/Subsystem'

Data Types: `double` | `char` | `string`

**sys** — System name or handle

character vector | string scalar | numeric scalar

System name or handle, specified as a character vector, string scalar, or numeric scalar.

A system name must not include a path or extension.

Example: `'model2'`

Data Types: `double` | `char` | `string`

## Tips

To flatten a model hierarchy by replacing a subsystem with its contents, use the `Simulink.BlockDiagram.expandSubsystem` function.

## Version History

Introduced in R2007a

“Expand Subsystem Contents”

# Simulink.SubSystem.deleteContents

Delete contents of subsystem

## Syntax

```
Simulink.SubSystem.deleteContents(subsys)
```

## Description

`Simulink.SubSystem.deleteContents(subsys)` deletes the blocks, lines, and annotations in the specified subsystem, which must be loaded in memory.

## Examples

### Delete Subsystem Contents

Open the f14 model.

```
open_system('f14')
```

Delete the graphical contents from the f14/Controller subsystem.

```
Simulink.SubSystem.deleteContents('f14/Controller')
```

## Input Arguments

**subsys** — Subsystem block path or handle

character vector | string scalar | numeric scalar

Subsystem block path or handle, specified as a character vector, string scalar, or numeric scalar.

Data Types: double | char | string

## Version History

Introduced in R2007a

## Simulink.SubSystem.getChecksum

Return checksum of nonvirtual subsystem

### Syntax

```
[checksum,details] = Simulink.SubSystem.getChecksum(subsys)
```

### Description

`[checksum,details] = Simulink.SubSystem.getChecksum(subsys)` returns the checksum of the specified nonvirtual subsystem. Simulink computes the checksum based on the subsystem parameter settings and the blocks the subsystem contains. Virtual subsystems do not have checksums.

One use of this command is to determine why code generated for a subsystem is not being reused.

---

**Note** `Simulink.SubSystem.getChecksum` compiles the model that contains the specified subsystem, if the model is not already in a compiled state. If you need to get the checksum for multiple subsystems and want to avoid multiple compiles, use the command `,model([], [], [], 'compile')` to place the model in a compiled state before using `Simulink.SubSystem.getChecksum`.

---

This command accepts the argument `subsys`, which is the full name or handle of the nonvirtual subsystem block for which you are returning checksum data.

### Examples

#### Run getChecksum on Model

Run the function `Simulink.SubSystem.getChecksum` on the model `rtwdemo_ssreuse`. In the MATLAB editor window, both output structures are displayed. In the workspace pane, double-click on either of the structures to view its contents.

Load the model `rtwdemo_ssreuse`.

```
rtwdemo_ssreuse
```

Select subsystem `SS1` and execute the follow line of code in the MATLAB editor to get the full name and path to the subsystem `SS1`:

```
path_ss1 = gcb
```

Run the function `getChecksum` on the subsystem with the following command:

```
[chksum1, chksum1_details] = Simulink.SubSystem.getChecksum(path_ss1)
```

The output structures `chksum1` and `chksum1_details` will store the output of the `getChecksum` function call.

```

checksum1 =
 struct with fields:
 Value: [4x1 uint32]
 MarkedUnique: 0

checksum1_details =
 struct with fields:
 ContentsChecksum: [1x1 struct]
 InterfaceChecksum: [1x1 struct]
 ContentsChecksumItems: [359x1 struct]
 InterfaceChecksumItems: [60x1 struct]

```

## Input Arguments

**subsys** — Name or handle of nonvirtual subsystem

character vector

Input the full name of the nonvirtual subsystem for which you want to calculate the checksum.

Data Types: char

## Output Arguments

**checksum** — A structure that stores the value of the checksum and indicates whether **subsys** contains unique block or subsystem properties which prevent generated code reuse

structure

Checksum information, returned as a structure with the fields:

**Value** - 4x1 uint32 - Array of four 32-bit integers that represents the subsystem's 128-bit checksum

**MarkedUnique** - bool - True if the subsystem or the blocks it contains have properties that would prevent the code generated for the subsystem from being reused; otherwise, false

**details** — A structure that stores checksum data on model contents and the interface

structure

Checksum information, returned as a structure with the fields:

**ContentsChecksum** - structure - A structure of the same form as **checksum**, representing a checksum that provides information about all blocks in the system.

**InterfaceChecksum** - structure - A structure of the same form as **checksum**, representing a checksum that provides information about the subsystem's block parameters and connections

**ContentsChecksumItems** — Structure array that Simulink uses to compute the checksum for **ContentsChecksum**

structure

Structure array returned with the following fields:

**Handle** - char array Object for which Simulink added an item to the checksum. For a block, the handle is a full block path. For a block port, the handle is the full block path and a character vector that identifies the port.

**Identifier** - char array - Descriptor of the item Simulink added to the checksum. If the item is a documented parameter, the identifier is the parameter name

**Value** - type - Value of the item Simulink added to the checksum. If the item is a parameter, Value is the value returned by `get_param(handle, identifier)`.

### **InterfaceChecksumItems — Structure array that Simulink uses to compute the checksum for InterfaceChecksum**

structure

Structure array returned with the following fields:

**Handle** - char array Object for which Simulink added an item to the checksum. For a block, the handle is a full block path. For a block port, the handle is the full block path and a character vector that identifies the port.

**Identifier** - char array - Descriptor of the item Simulink added to the checksum. If the item is a documented parameter, the identifier is the parameter name

**Value** - type - Value of the item Simulink added to the checksum. If the item is a parameter, Value is the value returned by `get_param(handle, identifier)`.

## **Version History**

# convertAllSubsystemReferenceBlocksToSubsystem

Converts all subsystem reference blocks to regular Subsystem blocks

## Syntax

```
Simulink.SubsystemReference.convertAllSubsystemReferenceBlocksToSubsystem(
path)
```

## Description

`Simulink.SubsystemReference.convertAllSubsystemReferenceBlocksToSubsystem(path)` converts all subsystem reference blocks inside a given block diagram to regular Subsystem blocks.

## Input Arguments

**path** — Path of the block diagram

string

The path of the block diagram specified as string. You can also specify handle as input argument

## Examples

```
>> Simulink.SubsystemReference.convertAllSubsystemReferenceBlocksToSubsystem('mdl1')
```

## Version History

Introduced in R2022a

## See Also

`Simulink.SubsystemReference`

## convertSubsystemReferenceBlockToSubsystem

Converts a subsystem reference block to a regular Subsystem block

### Syntax

```
Simulink.SubsystemReference.convertSubsystemReferenceBlockToSubsystem(path)
```

### Description

`Simulink.SubsystemReference.convertSubsystemReferenceBlockToSubsystem(path)` converts subsystem reference block to regular Subsystem block for a given block

### Input Arguments

**path** — Path of the subsystem reference block

(default) |

The path of the subsystem reference block that needs to be converted to Subsystem is specified. You can also specify the handle of the subsystem reference block.

### Examples

```
>> Simulink.SubsystemReference.convertSubsystemReferenceBlockToSubsystem('mdl1/Subsystem Reference')
```

### Version History

Introduced in R2022a

### See Also

`Simulink.SubsystemReference`

# convertSubsystemToSubsystemReference

Converts a Subsystem block to subsystem reference

## Syntax

```
Simulink.SubsystemReference.convertSubsystemToSubsystemReference(path, name)
```

## Description

`Simulink.SubsystemReference.convertSubsystemToSubsystemReference(path, name)` converts a Subsystem block to subsystem reference. The converted subsystem reference block takes the name given in `name`. It returns true, if the conversion is successful. False otherwise.

## Input Arguments

### **path** — Path of the subsystem

string

The path of the Subsystem that must be converted to subsystem reference is specified as string. You can also specify the handle of the Subsystem.

### **name** — Name for the converted subsystem

string

Name for the converted subsystem is specified as string.

## Examples

```
Simulink.SubsystemReference.convertSubsystemToSubsystemReference('mdl1/Subsystem2','ssref4')
```

```
ans =
 logical
 1
```

## Version History

**Introduced in R2022a**

# Simulink.SubsystemReference.generateSignatures

**Package:** Simulink.SubsystemReference

Generate unit test signatures of subsystem file

## Syntax

```
Simulink.SubsystemReference.generateSignatures(name)
Simulink.SubsystemReference.generateSignatures(name,testHarness)
Simulink.SubsystemReference.generateSignatures(name,
{testHarness1,...,testHarnessN})
```

## Description

`Simulink.SubsystemReference.generateSignatures(name)` generates signatures of the unit tests of the subsystem file name.

`Simulink.SubsystemReference.generateSignatures(name,testHarness)` generates the signature of the unit test `testHarness` of the subsystem file name.

`Simulink.SubsystemReference.generateSignatures(name, {testHarness1,...,testHarnessN})` generates the signatures of the unit tests `testHarness1,...,testHarnessN` of the subsystem file name.

## Examples

### Generate All Unit Test Signatures

Generate the signatures of all the unit tests of the subsystem file.

```
Simulink.SubsystemReference.generateSignatures('slexReusableSS')
```

### Generate Specific Unit Test Signatures

Generate the signatures of specified unit tests of the subsystem file.

```
Simulink.SubsystemReference.generateSignatures('slexReusableSS',{'ssref1_double','ssref1_int32'})
```

## Input Arguments

### **name** — Name of subsystem file

string | character vector

Name of the subsystem file, specified as a string or character vector. You can also specify the handle of the subsystem file.

Example: 'slexReusableSS'

Data Types: char | string

**testHarness — Name of unit test**

string | character vector

Name of the unit test, specified as a string or character vector.

Example: 'ssref1\_double'

Data Types: char | string

**{testHarness1, ..., testHarnessN} — Names of unit tests**

cell array

Names of the unit tests, specified as a cell array.

Example: {'ssref1\_double', 'ssref1\_int32'}

Data Types: cell

## getActiveInstances

Returns all the active instances of subsystem references

### Syntax

```
Simulink.SubsystemReference.getActiveInstances(path)
```

### Description

`Simulink.SubsystemReference.getActiveInstances(path)` returns all the active instances of subsystem reference blocks which point to the subsystem file.

### Input Arguments

**path** — Path of the subsystem reference file

string

The path of the subsystem reference file that is being referred in other Subsystem blocks. You can also specify the handle of the subsystem reference.

### Output Arguments

**path** — Path of the active instances

An array consisting of the path of all the active instances is returned.

### Examples

#### Get all active instances of the subsystem

```
Simulink.SubsystemReference.getActiveInstances('mdl2/Subsystem Reference')
```

```
ans =
```

```
4×1 cell array
```

```
 {'ssref1' }
 {'mdl1/Subsystem1' }
 {'mdl2/Subsystem Reference' }
 {'mdl1/Subsystem/Subsystem Reference' }
```

### Version History

Introduced in R2022a

**See Also**

Simulink.SubsystemReference

## getAllDirtyInstances

Returns child Subsystem block diagrams that are referred in the given block diagram and are also being edited

### Syntax

```
Simulink.SubsystemReference.getAllDirtyInstances(path)
```

### Description

`Simulink.SubsystemReference.getAllDirtyInstances(path)` returns all the child Subsystem block diagrams that are referred in the given block diagram and are also being edited.

### Input Arguments

**path** — Path of the block diagram

string

The path of the block diagram specified as string. You can also specify the handle of the block diagram.

### Output Arguments

**block name** — List of subsystem block diagrams that are being edited and referred in the given block diagram

It returns list of subsystem block diagrams that are being edited and referred in the given block diagram. It is not necessary that the subsystem block diagram is being edited directly. It might be edited through an instance.

### Examples

```
Simulink.SubsystemReference.getAllDirtyInstances('mdl1')
```

```
ans =
```

```
 'ssref1'
```

## Version History

Introduced in R2022a

`Simulink.SubsystemReference`

# getAllInstances

Returns all subsystem reference blocks inside a block diagram

## Syntax

```
Simulink.SubsystemReference.getAllInstances(path)
```

## Description

`Simulink.SubsystemReference.getAllInstances(path)` returns all subsystem reference blocks inside a block diagram.

## Input Arguments

**path** — System or model name  
(default) | string

The path of the system or model name specified as string. You can also specify the handle of the system or model name.

## Output Arguments

**path** — Path of all the subsystem reference blocks

It return an array consisting of the path of all the subsystem reference blocks that is inside a block diagram.

## Examples

```
>> Simulink.SubsystemReference.getAllInstances('mdl1')
```

```
ans =
```

```
2×1 cell array
```

```
 {'mdl1/Subsystem1' }
 {'mdl1/Subsystem/Subsystem Reference' }
```

## Version History

Introduced in R2022a

## See Also

`Simulink.SubsystemReference`

## getAllReferencedSubsystemBlockDiagrams

Returns all the child Subsystem block diagrams for a given block diagram

### Syntax

```
Simulink.SubsystemReference.getAllReferencedSubsystemBlockDiagrams(path)
```

### Description

`Simulink.SubsystemReference.getAllReferencedSubsystemBlockDiagrams(path)` returns all the child Subsystem block diagrams for a given block diagram.

### Input Arguments

**path — Path of the system or block diagram**

character vector (default) | string

The path of the system or block diagram is specified as string. You can also specify the handle of the system or block diagram.

### Output Arguments

**block name — Name of the block**

character vector (default)

An array consisting of the name of the child blocks is returned. The output doesn't contain duplicates. So, if a subsystem-block diagram is referred twice, it appears only once in the output. The type of the output(name or handle) is same as the type of the input

### Examples

```
>> Simulink.SubsystemReference.
getAllReferencedSubsystemBlockDiagrams('mdl2')
```

```
ans =
```

```
2×1 cell array
```

```
 {'ssref1'}
 {'ssref2'}
```

### Version History

Introduced in R2022a

Simulink.SubsystemReference

## getNearestParentSubsystemReferenceBlock

Returns the nearest parent subsystem reference for a block

### Syntax

```
Simulink.SubsystemReference.getNearestParentSubsystemReferenceBlock(path)
```

### Description

`Simulink.SubsystemReference.getNearestParentSubsystemReferenceBlock(path)` returns the nearest parent subsystem reference for a block.

### Input Arguments

**path** — Path of the block for which the nearest parent must be returned

string

The path of the block for which the nearest parent must be returned. You can also specify the handle of the block.

### Output Arguments

**path** — Path of the nearest parent

The path of the nearest parent subsystem reference for the given block is returned. If the given block is not inside any subsystem reference block, the output will be empty

### Examples

```
Simulink.SubsystemReference.getNearestParentSubsystemReferenceBlock(gcb)
```

```
ans =
```

```
 'mdl1/Subsystem/Subsystem Reference'
```

### Version History

Introduced in R2022a

`Simulink.SubsystemReference`

# getSystemOwningTheLock

Returns the system that has acquired the lock for editing

## Syntax

```
Simulink.SubsystemReference.getSystemOwningTheLock(path)
```

## Description

`Simulink.SubsystemReference.getSystemOwningTheLock(path)` For a given system, it returns the system that has acquired the lock for editing.

## Input Arguments

**path** — **Path of the subsystem reference**  
(default) |

The path of the subsystem reference specified as a string. You can also specify the handle of the subsystem reference.

## Output Arguments

**path** — **Path of the system owning the lock**

The path of the system owning the lock for the given subsystem reference is returned. Output will be empty if no instance is editing.

## Examples

```
Simulink.SubsystemReference.getSystemOwningTheLock('mdl2/Subsystem Reference')
```

```
ans =
```

```
 'mdl1/Subsystem1'
```

## Version History

Introduced in R2022a

# Simulink.SubsystemReference.getUnitTestNames

**Package:** Simulink.SubsystemReference

Return names of unit tests of subsystem file

## Syntax

```
unitTests = Simulink.SubsystemReference.getUnitTestNames(name)
```

## Description

`unitTests = Simulink.SubsystemReference.getUnitTestNames(name)` returns the names of the test harnesses that are selected as unit tests of the subsystem file name.

## Examples

### Get Unit Test Names

```
unitTests = Simulink.SubsystemReference.getUnitTestNames('slexReusableSS')
```

```
unitTests =
```

```
 1×2 cell array
```

```
 {'ssref1_double'} {'ssref1_int32'}
```

## Input Arguments

### name — Name of subsystem file

string | character vector

Name of the subsystem file, specified as a string or character vector. You can also specify the handle of the subsystem file.

Example: 'slexReusableSS'

Data Types: char | string

## Output Arguments

### unitTests — Names of unit tests

cell array

Names of unit tests of the subsystem file, specified as a cell array.

Data Types: cell

## Version History

**Introduced in R2023a**

## isSystemLocked

Checks if the system is locked due to an edit or update to the subsystem reference

### Syntax

```
Simulink.SubsystemReference.isSystemLocked(path)
```

### Description

`Simulink.SubsystemReference.isSystemLocked(path)` returns `true`, if the system is locked because of an edit or update to the subsystem reference. It returns `false`, otherwise.

### Input Arguments

**path** — Path of the system

string

The path of the subsystem reference is specified as string. You can also specify the handle of the system.

### Examples

```
Simulink.SubsystemReference.isSystemLocked('mdl2/Subsystem Reference')
```

```
ans =
```

```
 logical
```

```
 1
```

### Version History

**Introduced in R2022a**

# Simulink.SubsystemReference.removeSignatures

**Package:** Simulink.SubsystemReference

Remove previously generated unit test signatures of subsystem file

## Syntax

```
Simulink.SubsystemReference.removeSignatures(name)
Simulink.SubsystemReference.removeSignatures(name,testHarness)
Simulink.SubsystemReference.removeSignatures(name,
{testHarness1,...,testHarnessN})
```

## Description

`Simulink.SubsystemReference.removeSignatures(name)` removes all of the previously generated unit test signatures from the subsystem file name.

`Simulink.SubsystemReference.removeSignatures(name,testHarness)` removes the signature of the unit test `testHarness` from the subsystem file name.

`Simulink.SubsystemReference.removeSignatures(name, {testHarness1,...,testHarnessN})` removes the signatures of the unit tests `testHarness1,...,testHarnessN` from the subsystem file name.

## Examples

### Remove All Unit Test Signatures

Remove the signatures of all the unit tests from the subsystem file.

```
Simulink.SubsystemReference.removeSignatures('slexReusableSS')
```

### Remove Specific Unit Test Signatures

Remove the signatures of the specified unit tests from the subsystem file.

```
Simulink.SubsystemReference.removeSignatures('slexReusableSS',{'ssref1_double','ssref1_int32'})
```

## Input Arguments

### **name** — Name of subsystem file

string | character vector

Name of the subsystem file, specified as a string or character vector. You can also specify the handle of the subsystem file.

Example: 'slexReusableSS'

Data Types: char | string

**testHarness — Name of unit test**

string | character vector

Name of the unit test, specified as a string or character vector.

Example: 'ssref1\_double'

Data Types: char | string

**{testHarness1, ..., testHarnessN} — Names of unit tests**

cell array

Names of the unit tests, specified as a cell array.

Example: {'ssref1\_double', 'ssref1\_int32'}

Data Types: cell

## Version History

# Simulink.SubsystemReference.showSignatureDiffDialogForSS

**Package:** Simulink.SubsystemReference

Open dialog to show difference in signatures of two subsystem blocks

## Syntax

```
Simulink.SubsystemReference.showSignatureDiffDialogForSS(subBlock1,subBlock2,
CodeGenOrSimulation)
```

## Description

`Simulink.SubsystemReference.showSignatureDiffDialogForSS(subBlock1,subBlock2,CodeGenOrSimulation)` opens a dialog to show the difference in the signatures of the subsystem blocks `subBlock1` and `subBlock2`. `CodeGenOrSimulation` specifies whether the signatures are generated to simulate or build a model.

## Examples

### Show Signature Difference Dialog

Consider two subsystem blocks `Speed Control-1` and `Speed Control-2` with signatures generated in the context of code generation. Use the command to open a dialog to see the difference in their signatures.

```
Simulink.SubsystemReference.showSignatureDiffDialogForSS('Speed Control-1','Speed Control-2',1)
```

## Input Arguments

### **subBlock1** — Subsystem block

string | character vector

Subsystem block in a model, specified as a string or character vector.

Example: `Speed Control-1`

Data Types: `char` | `string`

### **subBlock2** — Subsystem block

string | character vector

Subsystem block in a model, specified as a string or character vector.

Example: `Speed Control-2`

Data Types: `char` | `string`

### **CodeGenOrSimulation** — Option to specify use of signatures

boolean

Option to specify the use of signatures of the subsystem blocks in a model, specified as 0 or 1.

- 0 — Use signatures to simulate a model.
- 1 — Use signatures to generate code for a model.

Example: 1

Data Types: `logical`

## **Version History**

# Simulink.SubsystemReference.showSignatureDiffDialogForUnitTests

**Package:** Simulink.SubsystemReference

Open dialog to show difference in signatures of subsystem reference instance with unit test signatures

## Syntax

```
Simulink.SubsystemReference.showSignatureDiffDialogForUnitTests(
ssrefInstance)
```

## Description

`Simulink.SubsystemReference.showSignatureDiffDialogForUnitTests(ssrefInstance)` opens a dialog to show the difference in signatures of the subsystem reference instance `ssrefInstance` with the captured unit test signatures of the subsystem reference block in the test harnesses.

## Examples

### Show Signature Difference Dialog

Consider a subsystem file `slexReusableSS` with two unit tests `ssref1_double` and `ssref1_int32`. The signature of an instance of `slexReusableSS`, `slexModelUsingReusableSS/sr3` does not match any of the unit test signatures. Use the command to open a dialog to see the difference in signatures.

```
Simulink.SubsystemReference.showSignatureDiffDialogForUnitTests('slexModelUsingReusableSS/sr3')
```

## Input Arguments

**ssrefInstance** — Instance of subsystem file in model

string | character vector

Instance of the subsystem file in a model, specified as a string or character vector.

Example: `slexModelUsingReusableSS/sr3`

Data Types: `char` | `string`

## Version History

Introduced in R2023a

# Simulink.suppressDiagnostic

Suppress a diagnostic from a specific block

## Syntax

```
Simulink.suppressDiagnostic(source, message_id)
Simulink.suppressDiagnostic(diagnostic)
```

## Description

`Simulink.suppressDiagnostic(source, message_id)` suppresses all instances of diagnostics represented by `message_id` thrown by the blocks specified by `source`.

`Simulink.suppressDiagnostic(diagnostic)` suppresses the diagnostics associated with MSLDiagnostic object `diagnostic`.

## Examples

### Suppress a Warning Thrown By a Block

To suppress a warning thrown by a block, use `getDiagnosticObjects.m`, `suppressor_script.m`, and the `Suppressor_CLI_Demo.slx` model. The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model. Open the model. To access `Simulink.SimulationMetadata` class, set the `ReturnWorkspaceOutputs` parameter value to 'on'. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

Use the `Simulink.suppressDiagnostic` function to suppress the parameter precision loss warning thrown by the Constant block, `one`.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', ...
 'SimulinkFixedPoint:util:fxpParameterPrecisionLoss');
```

## Input Arguments

### **source** — Block or model object throwing the diagnostic

block path | block handle

The source of the diagnostic, specified as a block path, block handle, cell array of block paths, or cell array of block handles.

To get the block path, use the `gcb` function.

To get the block handle, use the `getSimulinkBlockHandle` function.

Data Types: char | cell

**message\_id – message identifier of diagnostic**

message identifier | cell array of message identifiers

Message identifier of the diagnostic, specified as a character vector or a cell array of character vectors. You can find the message identifier of diagnostics thrown during simulation by accessing the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object associated with a simulation. You can also use the `lastwarn` function.

Data Types: char | cell

**diagnostic – Diagnostic object**

`MSLDiagnostic` object

Diagnostic specified as an `MSLDiagnostic` object. Access the `MSLDiagnostic` object through the `ExecutionInfo` property of the `Simulink.SimulationMetadata` object.

Data Types: struct

**See Also**

`Simulink.getSuppressedDiagnostics` | `Simulink.restoreDiagnostic` | `restore` | `Simulink.SuppressedDiagnostic`

**Topics**

“Suppress Diagnostic Messages Programmatically”

# addChoice

**Package:** Simulink

Add choices to variant parameter object

## Syntax

```
P = addChoice(P,Choices{Condition,Value})
```

## Description

`P = addChoice(P,Choices{Condition,Value})` adds a new variant choice to the variant parameter object `P`. A variant choice consists of a variant condition and a value specified as `Condition` and `Value`, respectively. You can add multiple choices to `p` by specifying condition-value pairs in a cell array. No two values of a variant variable can be associated with the same variant condition.

---

**Note** Adding a value to an existing variant condition results in an error.

---

## Examples

### Add Variant Choice

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable;
```

Add a variant choice to the object.

```
P = addChoice(P, {'V==1', 3.5});
```

### Add Multiple Variant Choices

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable;
```

Add multiple variant choices to the object.

```
P = addChoice(P, {'V==1', 3.5, 'V==2', 8.3});
```

## Input Arguments

**P** — Variant parameter object

`Simulink.VariantVariable` object

Variant parameter object created using `Simulink.VariantVariable`, specified as a `Simulink.VariantVariable` object. The choices that you specify using `addChoice` are added to this object.

**Condition, Value — Variant condition and associated value**

cell array

Variant condition and associated value, specified as a cell array. A variant condition is a control expression that determines the active value of the variant parameter object. During simulation, when a variant condition evaluates to `true`, the value associated with the condition becomes active. When a variant condition evaluates to `false`, the value associated the condition becomes inactive. You can add multiple values of the object by specifying condition-value pairs in a cell array.

You can specify the variant condition as boolean MATLAB expressions that contain one or more operands and operators. See “Types of Variant Control Variables (Operands) in Variant Parameters” and “Types of Operators in Variant Parameters”.

You can specify values of numeric, enumerated, or `Simulink.Parameter` type. See, “Numeric Variant Control Values for Rapid Prototyping of Variant Parameters”, “Improve Code Readability of Variant Parameters Using Enumerated Types”, and “Reuse Variant Parameter Values from Handwritten Code Using `Simulink.Parameter` Variables”.

Example: `{'V==2',5}`

Data Types: `struct`

## Version History

**Introduced in R2021a**

### Topics

“Change Active Values and Activation Time of Variant Parameters”

# getChoice

**Package:** Simulink

Return choices of variant parameter object

## Syntax

```
choices = getChoice(P)
choices = getChoice(P,Condition)
```

## Description

`choices = getChoice(P)` returns all the choices of variant parameter `p` in a cell array.

`choices = getChoice(P,Condition)` returns the value associated with the variant condition `Condition`. You can specify multiple conditions of variant parameter `p` in a cell array.

## Examples

### Get All Variant Choices

Create a `Simulink.VariantVariable` object.

```
p = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9})
```

Get all variant choices of the object.

```
choices = getChoice(p)
```

### Get Specific Variant Choices

Create a `Simulink.VariantVariable` object.

```
p = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9})
```

Get the value associated with variant condition `V==1`.

```
choice = getChoice(p, 'V==2')
```

## Input Arguments

### **P** — Variant parameter object

`Simulink.VariantVariable` object

Variant parameter object created using `Simulink.VariantVariable`, specified as a `Simulink.VariantVariable` object.

**Condition – Variant control expression**

string

Variant control expression corresponding to the value to be returned, specified as a string. You can get multiple choices of the object by specifying conditions in a cell array.

Example: 'V==2'

Data Types: char

**Version History**

**Introduced in R2021a**

**Topics**

“Change Active Values and Activation Time of Variant Parameters”

# removeChoice

**Package:** Simulink

Remove choices from variant parameter object

## Syntax

```
P = removeChoice(P,Condition)
```

## Description

`P = removeChoice(P,Condition)` removes the condition-value pair from variant variable `P` corresponding to condition `Condition`. You can remove multiple choices from `P` by specifying conditions in a cell array. Specifying variant conditions that do not exist results in an error.

## Examples

### Remove Variant Choice

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9, 'V==3',20})
```

Remove the variant choice associated with condition `V==2`.

```
P = removeChoice(P, 'V==2');
```

### Remove Multiple Variant Choices

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9, 'V==3',20})
```

Remove variant choices associated with conditions `V==2` and `V==3`.

```
P = removeChoice(P, {'V==2','V==3'});
```

## Input Arguments

### **P** — Variant parameter object

`Simulink.VariantVariable` object

Variant parameter object created using `Simulink.VariantVariable`, specified as an `Simulink.VariantVariable` object. The choices that you specify using `removeChoice` are removed from this object.

### **Condition** — Variant control expression

string

Variant control expression corresponding to the value to be removed, specified as a string. You can remove multiple choices from the object by specifying conditions in a cell array.

Example: 'V==2'

Data Types: char

## **Version History**

**Introduced in R2021a**

### **See Also**

`addChoice` | `setChoice` | `getChoice` | `Simulink.VariantVariable`

### **Topics**

“Change Active Values and Activation Time of Variant Parameters”

# setChoice

**Package:** Simulink

Modify existing choices of variant parameter object

## Syntax

```
P = setChoice(P,Choices{Condition,Value})
```

## Description

`P = setChoice(P,Choices{Condition,Value})` replaces the value associated with the variant condition `Condition` by the new value `Value`. You can modify multiple values of variant variable `P` by specifying condition-value pairs in a cell array. If the choice corresponding to the specified condition already exists, the associated value is overridden. Otherwise, a new choice is added.

## Examples

### Modify Variant Choice

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9})
```

Modify a variant choice associated with the variant condition `V==1`.

```
P = setChoice(P, {'V==1', 3.5});
```

### Modify Multiple Variant Choices

Create a `Simulink.VariantVariable` object.

```
P = Simulink.VariantVariable('Choices',{ 'V==1',8, 'V==2',9, 'V==3',12})
```

Modify variant choices associated with variant conditions `V==1` and `V==3`.

```
P = setChoice(P, {'V==1', 3.5, 'V==3',20});
```

## Input Arguments

### **P** — Variant parameter object

`Simulink.VariantVariable` object

Variant parameter object created using `Simulink.VariantVariable`, specified as a `Simulink.VariantVariable` object. This object is updated with the new values that you specify using `setChoice`.

**Condition, Value — Variant condition and associated value**

cell array

Variant condition and its associated value, specified as a cell array. Simulink replaces the existing value of the specified variant condition with the new value. You can modify multiple values of the object by specifying condition-value pairs in a cell array.

You can specify the variant condition as boolean MATLAB expressions that contain one or more operands and operators. See “Types of Variant Control Variables (Operands) in Variant Parameters” and “Types of Operators in Variant Parameters”.

Example: { 'V==2' , 5 }

Data Types: struct

# slblocksearchdb.trainfrommodel

Train suggestion engine to improve quick insert results based on one model

## Syntax

```
slblocksearchdb.trainfrommodel(model)
```

## Description

`slblocksearchdb.trainfrommodel(model)` improves quick insert search results based on a single model.

## Examples

### Use a Single Model for Training

Train the suggestion engine to use a model to improve results. Assume 'MyModels' is in the current folder. This code uses a relative path.

```
slblocksearchdb.trainfrommodel('MyModels/model.slx')
```

## Input Arguments

**model** — Model for training the suggestion engine

model path

Model to train the suggestion engine, specified as a character vector or string scalar of the full model path or relative path. Include the `.slx` or `.mdl` extension

Example: 'H:/MyModels/model.slx' 'mymodel.slx'

## Version History

Introduced in R2018a

## See Also

## slblocksearchdb.trainfrommodelsindir

Train suggestion engine to improve quick insert results based on models in a folder

### Syntax

```
slblocksearchdb.trainfrommodelsindir(folder)
slblocksearchdb.trainfrommodelsindir(folder,'exclude',exclusions)
```

### Description

`slblocksearchdb.trainfrommodelsindir(folder)` improves search results based on the models in `folder`, recursively.

`slblocksearchdb.trainfrommodelsindir(folder,'exclude',exclusions)` excludes the specified models from updating the suggestion engine.

### Examples

#### Train Suggestion Engine and Exclude Folders and Models

Create the cell array `exPath` for a folder you want to exclude and a model you want to exclude. To train the suggestion engine, use the cell array in the `slblocksearchdb.trainfrommodelsindir` command.

```
exPath = {'MyModels/testmodels' 'MyModels/myvdp.slx'}
slblocksearchdb.trainfrommodelsindir('MyModels','exclude',exPath)
```

The command uses the models in the folder 'MyModels' with the exclusions you specified.

### Input Arguments

#### **folder** — Folder whose models to use for training

folder path

Folder whose models to use for training the suggestion engine, specified as an absolute or relative path character vector or string scalar.

Example: 'H:/MyModels/trainingmodels' 'MyModels'

#### **exclusions** — Models to exclude from training models

cell array of character vectors | string array

Models to exclude from training the suggestion engine, specified as a cell array of character vectors or a string array. Specify folders or models to exclude as a full or relative path. Model names must include the file extension `.slx` or `.mdl`.

```
Example: {'H:/MyModels/trainingmodels' 'MyModels/trainingmodels2' 'MyModels/
myvdp.slx'}
```

## **Version History**

**Introduced in R2018a**

### **See Also**

slblocksearchdb.untrainmodelsindir | slblocksearchdb.trainfrommodel

### **Topics**

“Improve Quick Block Insert Results”

## **slblocksearchdb.untrainall**

Remove the effects of all added models from the suggestion engine

### **Syntax**

```
slblocksearchdb.untrainall
```

### **Description**

`slblocksearchdb.untrainall` removes the models added to the suggestion engine to improve quick insert results. Use this function when you want to return the database to the default state.

### **Examples**

#### **Add Models and Remove All**

Add some models to the suggestion engine.

```
slblocksearchdb.trainfrommodelsindir('MyModels')
slblocksearchdb.trainfrommodel('C:/users/TrainingModels/mymodel.slx')
```

Remove all added models from the suggestion engine.

```
slblocksearchdb.untrainall
```

### **Version History**

**Introduced in R2018a**

### **See Also**

```
slblocksearchdb.untrainmodelsindir | slblocksearchdb.untrainmodel |
slblocksearchdb.trainfrommodelsindir | slblocksearchdb.trainfrommodel
```

### **Topics**

“Improve Quick Block Insert Results”

# slblocksearchdb.untrainmodel

Remove the effect of a model from the suggestion engine

## Syntax

```
slblocksearchdb.untrainmodel('model')
```

## Description

`slblocksearchdb.untrainmodel('model')` removes the effects of a single model from the suggestion engine.

## Examples

### Remove a Model from the Suggestion Engine

Train the suggestion engine to use a model to improve results.

```
slblocksearchdb.trainfrommodel('MyModels/model.slx')
```

Remove the model from the suggestion engine.

```
slblocksearchdb.untrainmodel('MyModels/model.slx')
```

## Input Arguments

### **model** — Model to remove from the suggestion engine

model path

Model whose effects to remove from the suggestion engine, specified as the full or relative path character vector or string scalar. Include the `.slx` or `.mdl` extension.

Example: `'H:/MyModels/model.slx'`

## Version History

Introduced in R2018a

## See Also

## slblocksearchdb.untrainmodelsindir

Remove the effects of models from the suggestion engine

### Syntax

```
slblocksearchdb.untrainmodelsindir(folder)
slblocksearchdb.untrainmodelsindir(folder,'exclude',exclusions)
```

### Description

`slblocksearchdb.untrainmodelsindir(folder)` removes models in `folder` from the suggestion engine, recursively.

`slblocksearchdb.untrainmodelsindir(folder,'exclude',exclusions)` excludes the specified models from updating the suggestion engine.

### Examples

#### Remove the Effects of Models from Suggestion Engine

Create the cell array `exPath` for a folder and a model whose effects you do not want to remove from the suggestion engine. Then use the cell array in the `slblocksearchdb.untrainmodelsindir` command.

```
exPath = {'MyModels/subfolder' 'MyModels/myvdp.slx'}
slblocksearchdb.untrainmodelsindir('MyModels','exclude',exPath)
```

The command removes the models in the folder 'MyModels' with the exclusions you specified.

### Input Arguments

#### **folder** — Folder whose models to remove from the suggestion engine

folder path

Folder whose models to remove from the suggestion engine, specified as an absolute or relative path character vector or string scalar.

Example: 'H:/MyModels/trainingmodels' 'MyModels'

#### **exclusions** — Folders and models to exclude from removing

cell array of character vectors | string array

Folders or models to exclude from removing from the suggestion engine, specified as a cell array of character vectors or a string array. Specify the folders or models to exclude as a full or relative path. For models, include the `.slx` or `.mdl` extension.

Example: {'H:/MyModels/trainingmodels' 'MyModels/trainingmodels2' 'MyModels/myvdp.slx'}

## **Version History**

**Introduced in R2018a**

## slbuild

Build standalone executable file or model reference target for model

### Syntax

```
slbuild(model)
slbuild(model,buildSpec)
slbuild(model,Name,Value)
blockHandle = slbuild(subsystem)
blockHandle = slbuild(subsystem,'Mode','ExportFunctionCalls')
blockHandle = slbuild(subsystem,Name,Value)
```

### Description

`slbuild(model)` builds a standalone Simulink Coder binary executable file from the specified model, using the current configuration parameter settings. If the model is not loaded, `slbuild` loads the model before starting the build process.

`slbuild(model,buildSpec)` builds a standalone Simulink Coder binary executable file from the model according to the specified code generation action.

`slbuild(model,Name,Value)` builds a standalone Simulink Coder binary executable file from the model as specified by one or more name-value arguments.

`blockHandle = slbuild(subsystem)` generates subsystem code and builds a Simulink Coder binary executable file by using the current configuration parameter settings of your model. If the selected system target file creates an S-Function block, the function returns a non-empty block handle to an autogenerated S-Function wrapper. Before you run the command, you must open or load the parent model.

`blockHandle = slbuild(subsystem,'Mode','ExportFunctionCalls')` generates code from the subsystem that includes function calls that you can export to external application code. This command requires Embedded Coder. If the **Create block** configuration parameter is set to SIL, the function returns the handle to a Model block in SIL mode. You can then use the Model block for numerical equivalence testing.

`blockHandle = slbuild(subsystem,Name,Value)` generates subsystem code and builds a Simulink Coder binary executable file as specified by one or more name-value arguments.

### Examples

#### Generate Code and Build Executable File for Model

Generate C code for model `rtwdemo_rtwintr`.

```
slbuild('rtwdemo_rtwintr')
% Same operation as ...
% slbuild('rtwdemo_rtwintr','StandaloneCoderTarget')
```

For the generic real-time (GRT) target, the coder generates these code files and places them in folders `rtwdemo_rtwintrg_grt_rtw` and `slprj/grt/_sharedutils`.

| Model Files                             | Shared Files                        | Interface Files        | Other Files |
|-----------------------------------------|-------------------------------------|------------------------|-------------|
| <code>rtwdemo_rtwintrg.c</code>         | <code>rtwtypes.h</code>             | <code>rtmodel.h</code> | none        |
| <code>rtwdemo_rtwintrg.h</code>         | <code>multiword_types.h</code>      |                        |             |
| <code>rtwdemo_rtwintrg_private.h</code> | <code>builtin_typeid_types.h</code> |                        |             |
| <code>rtwdemo_rtwintrg_types.h</code>   |                                     |                        |             |

If the following model configuration parameters settings apply, the coder generates additional results.

| Parameter Setting                                                                 | Results                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Code Generation &gt; Generate code only</b> pane is cleared                    | Executable file <code>rtwdemo_rtwintrg.exe</code>                                                                                                                                              |
| <b>Code Generation &gt; Report &gt; Create code generation report</b> is selected | Report appears, providing information and links to generated code files, subsystem and code interface reports, entry-point functions, inports, outports, interface parameters, and data stores |

## Build Multiple Top Models

This example shows how to use `slbuild` to generate executable code for two models, `sldemo_mdhref_depgraph` and `rtwdemo_counter`. `sldemo_mdhref_depgraph` is a top model that references models. The example also shows how to build the referenced models in parallel.

Create a local folder.

```
if exist(fullfile('.', 'myTempFolder'), 'dir')
 rmdir('myTempFolder', 's')
end
mkdir myTempFolder
cd myTempFolder
```

Copy `sldemo_mdhref_depgraph`, which references models, to the local folder.

```
src_dir = fullfile(matlabroot, ...
 'toolbox', ...
 'simulink', ...
 'simdemos', ...
 'simfeatures', ...
 'modelreference');
copyfile(fullfile(src_dir, ...
 'sldemo_mdhref_depgraph.slx'), ...
 '.');
```

Enable parallel building of models referenced by `sldemo_mdhref_depgraph`.

```
load_system('sldemo_mdhref_depgraph')
set_param('sldemo_mdhref_depgraph', ...
'EnableParallelModelReferenceBuilds', 'on');
```

Initialize MATLAB workers for parallel building of referenced models.

```
set_param('sldemo_mdhref_depgraph', ...
'ParallelModelReferenceMATLABWorkerInit', ...
'Copy Base Workspace');
```

Build the models.

```
slbuild({'sldemo_mdhref_depgraph', 'rtwdemo_counter'})
```

In myTempFolder, the build process creates standalone executable files, sldemo\_mdhref\_depgraph.exe and rtwdemo\_counter.exe.

For each model, in the Command Window, the build process displays a build summary.

```
Build Summary|
Code generation targets built:
Model Action Rebuild Reason
=====
sldemo_mdhref_F2C Code generated and compiled sldemo_mdhref_F2C.c does not exist.
sldemo_mdhref_thermostat Code generated and compiled sldemo_mdhref_thermostat.c does not exist.
sldemo_mdhref_heat2cost Code generated and compiled sldemo_mdhref_heat2cost.c does not exist.
sldemo_mdhref_house Code generated and compiled sldemo_mdhref_house.c does not exist.
sldemo_mdhref_heater Code generated and compiled sldemo_mdhref_heater.c does not exist.
sldemo_mdhref_outdoor_temp Code generated and compiled sldemo_mdhref_outdoor_temp.c does not exist.

Top model targets built:
Model Action Rebuild Reason
=====
sldemo_mdhref_depgraph Code generated and compiled Code generation information file does not exist.

7 of 7 models built (0 models already up to date)
Build duration: 0h 3m 56.859s
Starting build procedure for: rtwdemo_counter
Successful completion of build procedure for: rtwdemo_counter

Build Summary
Top model targets built:
Model Action Rebuild Reason
=====
rtwdemo_counter Code generated and compiled Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 12.556s
```

### Force Top Model Build

Generate code and build an executable file for the model TopModelCode, which refers to model ReferenceModelCode, regardless of model checksums and parameter settings.

```
openExample('simulinkcoder/FilePackagingModelsCodeAndDataExample',...
'supportingFile','TopModelCode');
```

```
slbuild('TopModelCode','StandaloneCoderTarget',...
 'ForceTopModelBuild',true)
```

## Generate Code and Build Executable File for Subsystem

Generate C code for subsystem Amplifier in model rtwdemo\_rtwintr.

```
rtwdemo_rtwintr
slbuild('rtwdemo_rtwintr/Amplifier')
```

The code generator produces code files in the Amplifier\_grt\_rtw and slprj/grt/\_sharedutils folders.

In your current working folder, the build process creates an executable file (Amplifier.exe).

## Build Subsystem for Exporting Code to External Application

To export function calls to external application code, build an executable file from a function-call subsystem.

```
rtwdemo_exporting_functions
set_param('rtwdemo_exporting_functions','GenCodeOnly','off');
slbuild('rtwdemo_exporting_functions/rtwdemo_subsystem','Mode','ExportFunctionCalls')
```

The executable file rtwdemo\_subsystem.exe appears in your working folder.

## Create Model Block for SIL Testing

From a function-call subsystem, create a Model block that you can use to test the code generated from a model.

Open subsystem rtwdemo\_subsystem in model rtwdemo\_exporting\_functions.

Set the **Code Generation > Verification > Advanced parameters > Create block** configuration parameter to SIL.

Create the Model block.

```
mysilblockhandle = slbuild('rtwdemo_exporting_functions/rtwdemo_subsystem',...
 'Mode','ExportFunctionCalls')
```

The code generator produces the Model block in a temporary model. The Model block is configured as follows:

- **Model name** is set to the name of a new model that contains the content of the original subsystem.
- **Simulation mode** is set to Software-in-the-loop (SIL).

You can add the block to an environment or test harness model that supplies test vectors or stimulus input. You can then run simulations that perform SIL tests and verify that the Model block produces the same result as the original subsystem.

## Input Arguments

### **model** — Specifies model for the build process

handle | character vector | cell array of handles or character vectors

If you specify the model name as a handle or character vector, the build process creates a standalone executable file or model reference target.

If you specify multiple models through a cell array of handles or character vectors, the build process applies `buildSpec` to each model in the cell array.

Example: `gcs`

### **subsystem** — Subsystem name

handle | character vector | cell array of handles or character vectors

Name of subsystem from which you want to generate code or build an executable file, specified as a handle or character vector representing the subsystem name or the full block path.

You can specify multiple subsystems through a cell array of handles or character vectors

Example: `'rtwdemo_exporting_functions/rtwdemo_subsystem'`

### **buildSpec** — Specifies the code generation action for the build process

'StandaloneCoderTarget' (default) | 'ModelReferenceSimTarget' |  
'ModelReferenceCoderTarget' | 'CleanTopModel'

`buildSpec` directs the code generator to perform the selected build action for the model and the build process:

- Honors the setting of the **Rebuild** parameter on the **Model Referencing** pane of the Configuration Parameters dialog box.
- Requires a Simulink Coder license only if you build a model reference Simulink Coder target, not if you build a model reference simulation target only.

The `buildSpec` argument must be one of the following.

| <b>buildSpec Value</b>      | <b>Build Action</b>                                                                                                                                                                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'StandaloneCoderTarget'     | Builds a standalone Simulink Coder binary executable file for the specified model, using the current model configuration settings. It also builds model reference coder targets for the referenced models.<br><br>If the specified model is not loaded, <code>slbuild</code> loads it before initiating the build process. |
| 'ModelReferenceSimTarget'   | Builds a model reference simulation target (does not require a Simulink Coder license).                                                                                                                                                                                                                                    |
| 'ModelReferenceCoderTarget' | Builds a model reference Simulink Coder target.                                                                                                                                                                                                                                                                            |

| <b>buildSpec Value</b> | <b>Build Action</b>                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------|
| 'CleanTopModel'        | Cleans the model build area enough to trigger regeneration of the top model code at the next build. |

Example: 'ModelReferenceSimTarget'

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'UpdateThisModelReferenceTarget', 'Force'

### **UpdateThisModelReferenceTarget — Conditional rebuild option for model reference build**

'Force' | 'IfOutOfDateOrStructuralChange' | 'IfOutOfDate'

Conditional rebuild option for the model reference build, specified as the comma-separated pair consisting of 'UpdateThisModelReferenceTarget' and 'Force', 'IfOutOfDateOrStructuralChange', or 'IfOutOfDate'.

This option applies only to the specified model, not to any models referenced by the specified model.

| <b>'UpdateThisModelReferenceTarget' Value</b> | <b>Equivalent Rebuild Option</b>          | <b>Rebuild Action</b>                                                                            |
|-----------------------------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------|
| 'Force'                                       | Always                                    | Unconditionally rebuilds the model.                                                              |
| 'IfOutOfDateOrStructuralChange'               | If changes detected                       | Rebuilds the model if the build process detects any changes.                                     |
| 'IfOutOfDate'                                 | If changes in known dependencies detected | Rebuilds the model if the build process detects any changes in known dependencies of this model. |

For more information on the different rebuild options, see **Rebuild**.

Example: 'UpdateThisModelReferenceTarget', 'Force'

### **Dependencies**

To use this option, set `buildSpec` to 'ModelReferenceSimTarget' or 'ModelReferenceCoderTarget'.

Data Types: char | string

### **ForceTopModelBuild — Force top model of model hierarchy to build**

false (default) | true

Option to force the top model of the model hierarchy to build, specified as the comma-separated pair consisting of 'ForceTopModelBuild' and true or false.

Setting the value to true directs the code generator to generate code and build an executable file for the top model of the model hierarchy, regardless of model checksums and parameter settings.

Example: 'ForceTopModelBuild', true

**Dependencies**

To use this option, set `buildSpec` to `'StandaloneCoderTarget'`.

Data Types: `logical`

**GenerateCodeOnly — Generate code only**

`false` | `true`

If you do not specify a value, the **Generate code only** (`GenCodeOnly`) option on the **Code Generation** pane controls build process behavior.

If you specify a value, the argument overrides the **Generate code only** (`GenCodeOnly`) option on the **Code Generation** pane:

- `true` -- Generate code only.
- `false` -- Generate code and build executable file.

**Mode — Export function calls (for subsystem builds only)**

`'ExportFunctionCalls'` | `'Normal'`

- `'ExportFunctionCalls'` -- If you have Embedded Coder, generates code from subsystem that includes function calls that you can export to external application code.
- `'Normal'` -- Does not export function calls.

**ExportFunctionFileName — Function name**

character vector

Name the exported function for the specified subsystem.

Example:

```
slbuild(subsystem, 'Mode', 'ExportFunctionCalls', 'ExportFunctionFileName',
fcname)
```

**OpenBuildStatusAutomatically — Display build information**

`false` (default) | `true`

Option to display the build information, specified as the comma-separated pair consisting of `'OpenBuildStatusAutomatically'` and `true` or `false`.

To display build information in the Build Status window, specify `true`. The default is `false`. For more information about using the status window, see “Monitor Parallel Building of Referenced Models” (Simulink Coder).

The Build Status window supports parallel builds of referenced model hierarchies. Do not use the Build Status window for serial builds.

**Dependencies**

To use this option, set `buildSpec` to `'StandaloneCoderTarget'`.

Data Types: `logical`

**ObfuscateCode — Generate obfuscated C code**

`false` (default) | `true`

Specify whether to generate obfuscated C code:

- `true` -- Generate obfuscated C code that you can share with third parties with reduced likelihood of compromising intellectual property.
- `false` -- Generated C code is not obfuscated.

### **IncludeModelReferenceSimulationTargets — Build model reference simulation targets**

`false` (default) | `true`

Option to build model reference simulation targets, specified as the comma-separated pair consisting of 'IncludeModelReferenceSimulationTargets' and `true` or `false`.

#### **Dependencies**

To use this option, set `buildSpec` to 'StandaloneCoderTarget'.

Data Types: `logical`

## **Output Arguments**

### **blockHandle — Block handle**

`handle`

Block handle to an autogenerated S-Function wrapper block or Model block.

## **Version History**

**Introduced before R2006a**

### **R2020b: slbuild does not generate model reference simulation targets by default**

*Behavior changed in R2020b*

Starting in R2020b, the `slbuild` function does not generate model reference simulation targets by default. Excluding the model reference simulation targets allows for faster code generation for model hierarchies.

You can generate both the simulation and code generation targets with the default `buildSpec` value ('StandaloneCoderTarget') by setting `IncludeModelReferenceSimulationTargets` to `true`.

When you specify 'ModelReferenceCoderTarget' for the `buildSpec` argument, `slbuild` no longer builds a model reference simulation target. It builds only a model reference Simulink Coder target.

### **R2020b: 'ModelReferenceCoderTargetOnly' is not recommended**

*Not recommended starting in R2020b*

Starting in R2020b, the `buildSpec` argument values 'ModelReferenceCoderTarget' and 'ModelReferenceCoderTargetOnly' have the same behavior. 'ModelReferenceCoderTargetOnly' is not recommended. Use 'ModelReferenceCoderTarget' instead.

There are no plans to remove 'ModelReferenceCoderTargetOnly'.

### **R2019a: 'StandaloneRTWTarget', 'ModelReferenceRTWTarget', and 'ModelReferenceRTWTargetOnly' are not recommended**

*Not recommended starting in R2019a*

In R2019a, these `buildSpec` argument values received new names for clarity:

- 'StandaloneRTWTarget' — Use 'StandaloneCoderTarget' instead.
- 'ModelReferenceRTWTarget' — Use 'ModelReferenceCoderTarget' instead.
- 'ModelReferenceRTWTargetOnly' — Use 'ModelReferenceCoderTargetOnly' instead.

There are no plans to remove the legacy `buildSpec` argument values.

## Extended Capabilities

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To build referenced models in parallel, in the top model, select the configuration parameter check box **Enable parallel model reference builds**. For more information, see “Reduce Build Time for Referenced Models by Using Parallel Builds” (Simulink Coder).

In Parallel Computing Toolbox commands, for example, a `parfor` or `spm` loop, do not invoke `rtwbuild`, `rtwrebuild`, or `slbuild` commands that build models that are configured for parallel builds.

# slCharacterEncoding

Specify encoding to use in code generated from Simulink models

## Syntax

```
slCharacterEncoding(encoding)
encoding = slCharacterEncoding()
```

## Description

`slCharacterEncoding(encoding)` specifies the character set used in the code generated from Simulink models. The character set encoding affects the comments in the generated code.

`encoding = slCharacterEncoding()` returns the current Simulink character set encoding.

## Examples

### Specify Encoding for ASCII Characters

Suppose that you generate code for an embedded target and the compiler you use requires that the source code contain only ASCII characters.

Use this command:

```
slCharacterEncoding('US-ASCII')
```

### Specify Encoding for Non-ASCII Characters

Suppose that you have a model that contains non-ASCII characters (multilingual characters, special symbols) and you want these annotations to be easily readable in your generated code.

If your compiler supports UTF-8, on Windows, use this command:

```
slCharacterEncoding('UTF-8')
```

UTF-8 is the default encoding on Linux® and Mac.

### Specify Encoding for Non-English Locale

Suppose that your model contains Japanese text but your machine is configured for an English-language locale. You want to generate code with 'Shift\_JIS' encoded text so that your team members who use 'Shift\_JIS' as their locale-specific encoding can see the Japanese text in the generated code.

Use this command:

```
slCharacterEncoding('Shift_JIS')
```

## Input Arguments

**encoding** – Character encoding to use for the generated code  
'US-ASCII' | 'UTF-8' | other supported encodings

Set the character encoding to a supported encoding value.

## Version History

Introduced before R2006a

# slConvertCustomMenus

Convert custom toolbar menu into toolstrip tab

## Syntax

```
slConvertCustomMenus
slConvertCustomMenus(Name=Value)
```

## Description

`slConvertCustomMenus` converts a custom Simulink toolbar menu into a toolstrip tab that is stored in a toolstrip component called `custom` in the current folder. The new tab has the title **Custom** and contains a single section with the same name as the top level of the toolbar menu. The section is populated with the converted toolbar menu items:

- Action schemas and toggle schemas are converted into push buttons.
- Container schemas are converted into drop-down buttons.

The toolbar menu is not automatically deleted during the conversion. To remove it, delete or comment out the corresponding `addCustomMenuFcn` call in the `sl_customization.m` file, save the file, and rebuild the toolstrip by entering `sl_refresh_customizations` in the MATLAB Command Window.

If a toolstrip component called `custom` already exists in the current folder, a prompt will appear in the Command Window asking you for permission to overwrite the component.

When the conversion is complete, the new tab can be edited like any other custom toolstrip tab. You can adjust the layout of the tab, its labels, and its functionality. See “Create Custom Simulink Toolstrip Tabs” for details.

`slConvertCustomMenus(Name=Value)` converts a custom Simulink toolbar menu into a toolstrip tab that is stored in a toolstrip component whose name and resource location can be specified by name-value arguments.

Permission to overwrite an existing toolstrip component of the same name and at the same location as the one that the conversion creates can be specified via name-value argument as well. If you do not specify this argument and such a component exists, a prompt will appear in the Command Window asking you for permission to overwrite the component.

## Examples

### Convert Toolbar Menu into Toolstrip Tab

Start with the custom Simulink toolbar menu defined by this `sl_customization.m` file.

```
function sl_customization(cm)
 cm.addCustomMenuFcn('Simulink:ToolsMenu', @toolsMenu);
end

%% Tool Menu customization
```

```
function schemas = toolsMenu()
 schemas = {
 @toolsMenu1, ...
 @toolsMenu2, ...
 @toolsMenu3
 };
end

function schema = toolsMenu1(cbinfo)
 schema = sl_action_schema;
 schema.tag = 'toolsMenu1';
 schema.label = 'Tools Menu 1';
 schema.callback = @toolsMenu1CB;
end

function schema = toolsMenu2(cbinfo)
 schema = sl_action_schema;
 schema.tag = 'toolsMenu2';
 schema.label = 'Tools Menu 2';
 schema.callback = @toolsMenu2CB;
end

function schema = toolsMenu3(cbinfo)
 schema = sl_container_schema;
 schema.tag = 'toolsMenu3';
 schema.label = 'Tools Menu 3';
 schema.childrenFcns = {
 @toolsMenu31, ...
 @toolsMenu32
 };
end

function schema = toolsMenu31(cbinfo)
 schema = sl_action_schema;
 schema.tag = 'toolsMenu31';
 schema.label = 'Tools Menu 31';
 schema.callback = @toolsMenu31CB;
end

function schema = toolsMenu32(cbinfo)
 schema = sl_action_schema;
 schema.tag = 'toolsMenu32';
 schema.label = 'Tools Menu 32';
 schema.callback = @toolsMenu32CB;
end

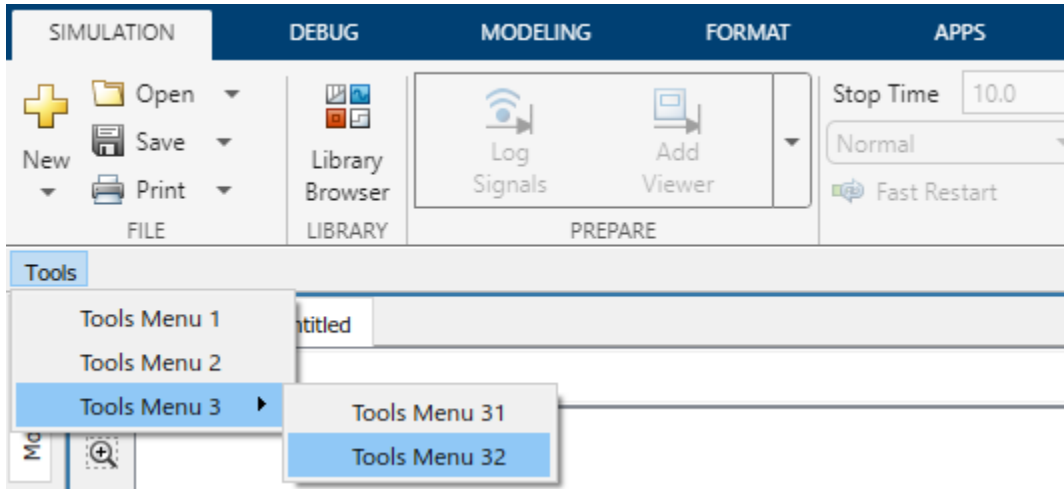

function toolsMenu1CB(cbinfo)
 disp('Executing toolsMenu1');
end

function toolsMenu2CB(cbinfo)
 disp('Executing toolsMenu2');
end

function toolsMenu31CB(cbinfo)
 disp('Executing toolsMenu31');
end
```

```
function toolsMenu32CB(cbinfo)
 disp('Executing toolsMenu32');
end
```

To see the toolbar menu, open Simulink.

If this menu is converted in its current state, the conversion of its callback functions will fail because they are saved in the `sl_customization.m` file. To enable the conversion of the callback functions for Tools Menu 2 and Tools Menu 3, save them in separate function files: `toolsMenu2CB.m`, `toolsMenu31CB.m`, and `toolsMenu32CB.m`.

For comparison, leave the callback function for Tools Menu 1 in the `sl_customization.m` file.

Convert the toolbar menu into a toolstrip tab. In the Command Window, enter this:

```
slConvertCustomMenus;
```

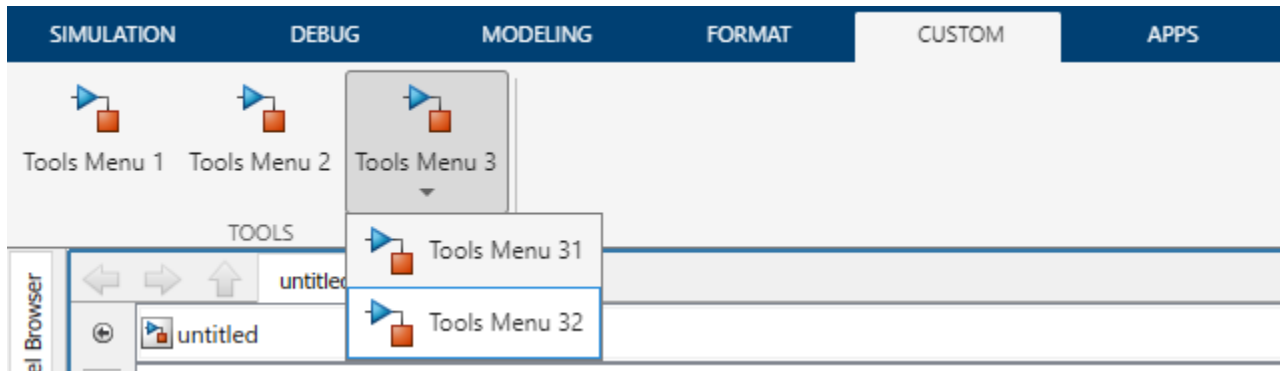

Delete the custom toolbar menu by commenting out the `addCustomMenuFcn` call in the `sl_customization.m` file, and then saving the file.

```
function sl_customization(cm)
 %cm.addCustomMenuFcn('Simulink:ToolsMenu', @toolsMenu);
end
```

To see the results of the menu conversion, open a blank model in Simulink.

Rebuild the toolstrip by entering the `sl_refresh_customizations` command in the Command Window.

Open and view the **Custom** tab.

The tab has a single section titled **Tools** because that is the title of the top level of the toolbar menu from which the tab was created.

The action schemas `Tools Menu 1` and `Tools Menu 2` from the toolbar menu are converted into push buttons of the same names in the tab.

The container schema `Tools Menu 3` in the toolbar menu has a pop-up list, and is converted into a drop-down button.

Click on the `Tools Menu 1` push button. The diagnostic viewer shows an error message, stating that the callback of the `Tools Menu 1` action schema failed to convert. This is because the callback function of that schema is saved in the `sl_customization.m` file.

Click on the `Tools Menu 2`, `Tools Menu 31`, and `Tools Menu 32` buttons. The callbacks execute without error because the callback functions for these buttons are saved in separate function files.

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `slConvertCustomMenus(CompName="Name", CompFolder="Folder")`

#### **CompName** — Name of toolstrip component

"custom" (default) | string | character vector

Name of toolstrip component, specified as a string or character vector.

Data Types: char | string

#### **CompFolder** — File path of toolstrip component

pwd (default) | string | character vector

File path of toolstrip component, specified as a string or character vector.

Data Types: char | string

## Replace — Permission to overwrite

true or 1 | false or 0

Permission to overwrite an existing toolbar component of the same name and at the same location as the one that the conversion creates, specified as a numeric or logical 1 (**true**) or 0 (**false**).

Data Types: `logical`

## Limitations

- When converting a custom toolbar menu into a toolbar tab, any functionality that custom tabs do not support is ignored. However, you can edit the generated tab. For more information, see “Create Custom Simulink Toolbar Tabs”.
- If a toolbar component with the name specified by `CompName` already exists in the `CompFolder` location at the time of conversion, a prompt will appear in the Command Window asking you for permission to overwrite the component. If a component of another name already exists in the `CompFolder` location, the menu cannot be converted.
- The conversion of a schema callback fails if its function handle points to a function local to the `sl_customization.m` file. Move all callback functions into separate function files.

## Tips

To delete custom tab elements that are the result of a conversion, you can do one of the following:

- Call `slDestroyToolbarComponent`.
- Delete the resources folder located at `CompFolder` and call `slReloadToolbarConfig`.
- Delete the JSON files of the tab in the resources folder located at `CompFolder` and call `slReloadToolbarConfig`.

## Version History

Introduced in R2022a

## See Also

## Topics

“Add Items to Model Editor Menus”

“Create Custom Simulink Toolbar Tabs”

# slCreateToolstripComponent

Create custom Simulink Toolstrip component

## Syntax

```
slCreateToolstripComponent(component)
slCreateToolstripComponent(component,Name=Value)
```

## Description

`slCreateToolstripComponent(component)` creates a `resources` folder for a custom Simulink Toolstrip component in the current folder and adds the current folder to the MATLAB path.

`slCreateToolstripComponent(component,Name=Value)` sets properties using name-value arguments. For example, `slCreateToolstripComponent("custom",Location="B:\path\customtab")` creates the `resources` folder for a component named `custom` in the `B:\path\customtab` directory and adds `B:\path\customtab` to the MATLAB path.

## Examples

### Create Simulink Toolstrip Component

A Simulink Toolstrip component contains the definition for one or more custom tabs. Before you create a custom tab, you must create the component that will contain it.

To work with the Simulink Toolstrip, start Simulink. For example, in the MATLAB Command Window, enter:

```
start_simulink
```

Create a custom Simulink Toolstrip component by using the `slCreateToolstripComponent` function. For example, name the component `custom`.

```
slCreateToolstripComponent("custom");
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

### Create Temporary Simulink Toolstrip Component

By default, Simulink Toolstrip components persist across sessions. You can create a temporary Simulink Toolstrip component that persists only during the current session.

Create a temporary custom Simulink Toolstrip component by using the `slCreateToolstripComponent` function. For example, name the component `temp`.

```
slCreateToolstripComponent("temp",Persist=false);
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

When you open a new MATLAB session, the `temp` component is not loaded.

## Input Arguments

### **component** — Component name

character vector | string scalar

Component name, specified as a character vector or string scalar.

The component name appears in the `sl_toolstrip_plugins.json` file as the value for the `Name` property. Do not edit this file.

Example: `slCreateToolstripComponent("custom")`

Data Types: `char` | `string`

### **Name-Value Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `slCreateToolstripComponent("custom",Location="B:\path\customtab",Persist=false)`

### **Location** — Storage location for component files

current folder (default) | character vector | string scalar

Storage location for component files, specified as a character vector or string scalar. The function adds the storage location to the MATLAB path.

By default, the function generates the component files in a `resources` folder in the current folder.

Example: `slCreateToolstripComponent("custom",Location="B:\path\customtab")`

Data Types: `char` | `string`

### **Persist** — Option to load component for new MATLAB sessions

true or 1 (default) | false or 0

Option to load component for new MATLAB sessions, specified as a numeric or logical 1 (`true`) or 0 (`false`).

Example: `slCreateToolstripComponent("custom",Persist=false)`

Data Types: double | logical

## **Version History**

“Create Custom Simulink Toolstrip Tabs”  
“Add Prepopulated Custom Tab to Simulink Toolstrip”

# slCreateToolstripTab

Create custom tab for Simulink Toolstrip

## Syntax

```
slCreateToolstripTab(tab,component)
slCreateToolstripTab(tab,component,Name=Value)
```

## Description

`slCreateToolstripTab(tab,component)` creates a blank custom tab in the specified Simulink Toolstrip component, opens the JSON file that defines the custom tab, and reloads the toolstrip configuration.

`slCreateToolstripTab(tab,component,Name=Value)` sets properties using name-value arguments. For example, `slCreateToolstripTab('toolsTab','custom',Title="Tools")` creates a **Tools** tab.

## Examples

### Create Untitled Custom Tab in Simulink Toolstrip

A Simulink Toolstrip component contains the definition for one or more custom tabs. Before you create a custom tab, you must create the component to contain it.

To work with the Simulink Toolstrip, start Simulink. For example, in the MATLAB Command Window, enter:

```
start_simulink
```

Create a custom Simulink Toolstrip component by using the `slCreateToolstripComponent` function. For example, name the component `custom`.

```
slCreateToolstripComponent("custom");
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

Create an untitled custom tab with the `slCreateToolstripTab` function.

For example, create the tab `customTab` in the `custom` component.

```
slCreateToolstripTab("customTab","custom");
```

The function creates a JSON file in the `json` folder that contains information about the tab. For example:

```
{
 "version": "1.0",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": ""
 }
]
}
```

Open a model. For example, open the vdp model.

vdp

The Simulink Toolstrip displays a blank tab without a title.

### Create Titled Custom Tab in Simulink Toolstrip

A Simulink Toolstrip component contains the definition for one or more custom tabs. Before you create a custom tab, you must create the component to contain it.

To work with the Simulink Toolstrip, start Simulink. For example, in the MATLAB Command Window, enter:

```
start_simulink
```

Create a custom Simulink Toolstrip component by using the `slCreateToolstripComponent` function. For example, name the component `custom`.

```
slCreateToolstripComponent("custom");
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

Create a custom tab with the `slCreateToolstripTab` function.

For example, create the tab `customTab` in the `custom` component, and title the tab `CUSTOM TAB`.

```
slCreateToolstripTab("customTab","custom",Title="CUSTOM TAB");
```

The function creates a JSON file named `customTab.json` in the `json` folder that defines the tab.

Open a model. For example, open the vdp model.

vdp

The Simulink Toolstrip displays a blank tab titled CUSTOM TAB.

## Input Arguments

### **tab** — Tab ID

character vector | string scalar

Tab ID, specified as a character vector or string scalar.

The tab ID appears in the JSON file that defines the tab as the value for the `id` property in the JSON object where `"type": "Tab"`.

Data Types: `char` | `string`

### **component** — Component name

character vector | string scalar

Component name, specified as a character vector or string scalar.

The component name appears in the `sl_toolstrip_plugins.json` file as the value for the `Name` property. Do not edit this file.

Data Types: `char` | `string`

## Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `slCreateToolstripTab('customTab','custom',Title='Custom Tab')`

### **Title** — Tab title

`""` (default) | character vector | string scalar

Tab title, specified as a character vector or string scalar.

Tab titles use all uppercase letters even when you specify a title with lowercase letters.

The tab title appears in the JSON file that defines the tab as the value for the `title` property of the JSON object where `"type": "Tab"`.

Data Types: `char` | `string`

**FileName — Name of file that defines tab**

<tabname>.json (default) | character vector | string scalar

Name of file that defines the tab, specified as a character vector or string scalar.

Data Types: char | string

## Version History

**Introduced in R2021b**

### Topics

“Create Custom Simulink Toolstrip Tabs”

“Add Prepopulated Custom Tab to Simulink Toolstrip”

# sldebug

Start simulation debugging session for Simulink model

## Syntax

```
sldebug mdl
```

## Description

`sldebug mdl` starts a programmatic simulation debugging session for the model specified by `mdl`. The simulation starts and pauses just before the initialization phase.

When you start a programmatic simulation debugging session, the MATLAB command prompt becomes the `sldebug` command prompt. Instead of `>>`, you see `(sldebug @0): >>`. To control the debugging session, enter commands in the MATLAB Command Window, at the `sldebug` command prompt, using the Simulink debugging programmatic interface.

During a programmatic simulation debugging session, you can use the debugging functions to:

- Set model, signal, and block breakpoints
- Run the simulation one block method at a time
- Run the simulation one time step at a time
- Continue the simulation to the next breakpoint
- Examine simulation data

To end a programmatic simulation debugging session, use the `stop` function.

## Examples

### Start and Stop Debug Simulation

Start and then stop a simulation debugging session for the model `vdp`.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp.slx")
```

Use the `sldebug` function to start the simulation debugging session for the model.

```
sldebug("vdp")
```

```
%-----%
[TM = 0] simulate(vdp)
```

The MATLAB command prompt changes from `>>` to `(sldebug @0): >>` to indicate that a debug simulation is in progress and that the Simulink debugging programmatic interface is available.

Use the `step` command to step the simulation to the start of the next major time step.

```
step top
```

```
%-----%
[TM = 0] vdp.Outputs.Major
```

You can continue using the `step` command to progress the simulation and observe the results in the Scope block.

Use the `stop` function to stop the debug simulation.

```
stop
```

```
%-----%
% Simulation stopped
```

## Input Arguments

### **mdl** — Name of model to debug

string | character vector

Name of model to debug, specified as a string or a character vector.

Example: `sdebug("vdp")` starts a simulation debugging session for the model `vdp`.

Data Types: `char` | `string`

## Tips

As an alternative to programmatic debugging, you can debug and analyze models in the Simulink Editor using similar functionality available in the Simulink Toolstrip. Using the **Debug** tab, you can:

- Add breakpoints that pause simulation within a time step
- Step from one major time step to the next
- Step from one block output method to the next
- Step into and out of atomic subsystems, model references, and Stateflow charts
- Add port value labels to display block output values for major time steps
- View the execution order
- Annotate the block diagram with sample time information

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

When you start a simulation debugging session interactively, the simulation pauses just before executing the first block output method.

“Simulink Debugging Programmatic Interface”

# slDestroyToolstripComponent

Destroy Simulink Toolstrip component

## Syntax

```
slDestroyToolstripComponent(component)
slDestroyToolstripComponent(component,RemoveFromPath)
```

## Description

`slDestroyToolstripComponent(component)` destroys the specified Simulink Toolstrip component, removes the component directory from the MATLAB path, and deletes the resource subdirectory that the component directory contains.

`slDestroyToolstripComponent(component,RemoveFromPath)` destroys the specified Simulink Toolstrip component and deletes the resource subdirectory that the component directory contains. When `RemoveFromPath` is set to `true`, the command also removes the component directory from the MATLAB path. When `RemoveFromPath` is set to `false`, the command does not remove the component directory from the MATLAB path.

## Examples

### Delete Custom Simulink Toolstrip Component

Suppose you have a Simulink Toolstrip component that you no longer need named `custom`.

Delete the component named `custom`. In the MATLAB Command Window, enter:

```
slDestroyToolstripComponent("custom")
```

## Input Arguments

### **component** — Component name

character vector | string scalar

Component name, specified as a character vector or string scalar.

The component name appears in the `sl_toolstrip_plugins.json` file as the value for the "Name" property. Do not edit this file.

Example: `slDestroyToolstripComponent("custom")`

Data Types: `char` | `string`

### **RemoveFromPath** — Option to remove component resource directory from path

`true` or `1` (default) | `false` or `0`

Option to remove component resource directory from path, specified as a numeric or logical 1 (`true`) or 0 (`false`).

Example: `slDestroyToolstripComponent("custom",RemoveFromPath=false)`

Data Types: `logical`

## **Version History**

**Introduced in R2021b**

## sldiagnostics

Display diagnostic information about Simulink system

### Syntax

```
sldiagnostics('sys')
[txtRpt, sRpt] = sldiagnostics('sys')
[txtRpt, sRpt] = sldiagnostics('sys', options)
[txtRpt, sRpt] = sldiagnostics('sys', 'CompileStats')
[txtRpt, sRpt] = sldiagnostics('sys', 'RTWBuildStats')
```

### Description

`sldiagnostics('sys')` displays the following diagnostic information associated with the model or subsystem specified by `sys`:

- Number of each type of block
- Number of each type of Stateflow object
- Number of states, outputs, inputs, and sample times of the root model.
- Names of libraries referenced and instances of the referenced blocks
- Time and additional memory used for each compilation phase of the root model

If the model specified by `sys` is not loaded, then `sldiagnostics` loads the model before performing the analysis.

The command `sldiagnostics('sys', options)` displays only the diagnostic information associated with the specific operations listed as `options` character vectors. The table below summarizes the options available and their corresponding valid input and output.

With `sldiagnostics`, you can input the name of a model or the path to a subsystem. For some analysis options, `sldiagnostics` can analyze only a root model. If you provide an incompatible input for one of these analyses, then `sldiagnostics` issues a warning. Finally, if you input a Simulink Library, then `sldiagnostics` cannot perform options that require a model compilation (**Update Diagram**). Instead, `sldiagnostics` issues a warning.

During the analysis, `sldiagnostics` will follow library links but will not follow or analyze Model References. See `find_mdhrefs` for more information on finding all Model blocks and referenced models in a specified model.

| Option      | Valid Inputs                      | Output                                                                                                                                                   |
|-------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| CountBlocks | root model, library, or subsystem | Lists all unique blocks in the system and the number of occurrences of each. This includes blocks that are nested in masked subsystems or hidden blocks. |
| CountSF     | root model, library, or subsystem | Lists all unique Stateflow objects in the system and the number of occurrences of each.                                                                  |

| Option        | Valid Inputs                      | Output                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sizes         | root model                        | Lists the number of states, outputs, inputs, and sample times, as well as a flag indicating direct feedthrough, used in the root model.                                                                                                                                                                                                                     |
| Libs          | root model, library, or subsystem | Lists all unique libraries referenced in the root model, as well as the names and numbers of the library blocks.                                                                                                                                                                                                                                            |
| CompileStats  | root model                        | Lists the time and additional memory used for each compilation phase of the root model. This information helps users troubleshoot model compilation speed and memory issues.                                                                                                                                                                                |
| RTWBuildStats | root model                        | Lists the same information as the <code>CompileStats</code> diagnostic. When issued with the second output argument <code>sRpt</code> , it captures the same statistics included in <code>CompileStats</code> and also the Simulink Coder build statistics.<br><br>You must explicitly specify this option, because it is not part of the default analysis. |
| All           | not applicable                    | Performs all diagnostics.                                                                                                                                                                                                                                                                                                                                   |

**Note** Running the `CompileStats` diagnostic before simulating a model for the first time will show greater memory usage. However, subsequent runs of the `CompileStats` diagnostic on the model will require less memory usage.

`[txtRpt, sRpt] = sldiagnostics('sys')` returns the diagnostic information as a textual report `txtRpt` and a structure array `sRpt`, which contains the following fields that correspond to the diagnostic options:

- `blocks`
- `stateflow`
- `sizes`
- `links`
- `compilestats`

`[txtRpt, sRpt] = sldiagnostics('sys', options)` returns only the specified options. If your chosen options specify just one type of analysis, then `sRpt` contains the results of only that analysis.

`[txtRpt, sRpt] = sldiagnostics('sys', 'CompileStats')` returns information on time and memory usage in `txtRpt` and `sRpt`.

`[txtRpt, sRpt] = sldiagnostics('sys', 'RTWBuildStats')` includes Simulink Coder build statistics in addition to the information reported for `CompileStats` in the `sRpt` output.

- `txtRpt` contains the formatted textual output of time spent in each of the phases in Simulink and Simulink Coder (if you specified `RTWBuildStats`), for example:

```

Compile Statistics For: rtdemo_counter
 Cstat1: 0.00 seconds Model compilation pre-start
 Cstat2: 0.00 seconds Stateflow compile pre-start notification
 Cstat3: 0.10 seconds Post pre-comp-start engine event
 Cstat4: 10.10 seconds Stateflow compile start notification
 Cstat5: 0.00 seconds Model compilation startup completed

```

- `sRpt` is a MATLAB structure containing time and memory usage for each of the phases, for example:

```

sRpt =
Model: 'myModel1'
Statistics: [1x134 struct]

```

The size of the `sRpt.Statistics` array indicates the number of compile and build phases executed during the operation. Examine the Statistics fields:

```

sRpt.Statistics(1) =
Description: 'Phase1'
CPUTime: 7.2490
WallClockTime 4.0092
ProcessMemUsage: 26.2148
ProcessMemUsagePeak: 28.6680
ProcessVMSize: 15.9531

```

`CPUTime` and `WallClockTime` show the elapsed time for the phase in seconds. `ProcessMemUsage`, `ProcessMemUsagePeak` and `ProcessVMSize` show the memory consumption during execution of the phase in MB.

Examine these key metrics to understand the performance:

- `WallClockTime`—The real-time elapsed in each phase in seconds. Sum the `WallClockTime` in each phase to get the total time taken to perform the operation:

```
ElapsedTime = sum([statRpt.Statistics(:).WallClockTime]);
```

- `ProcessMemUsage`—The amount of memory consumed in each phase. Sum the `ProcessMemUsage` across all the phases to get the memory consumption during the entire operation:

```
TotalMemory = sum([statRpt.Statistics(:).ProcessMemUsage]);
```

- `ProcessMemUsagePeak`—The maximum amount of allocated memory in each phase. Get the maximum of this metric across all the phases to find the peak memory allocation during the operation:

```
PeakMemory = max([statRpt.Statistics(:).ProcessMemUsagePeak]);
```

---

**Note** Memory statistics are available only on the Microsoft Windows platform.

---

## Examples

The following command counts and lists each type of block used in the `sldemo_bounce` model that comes with Simulink software.

```

openExample('simulink_general/sldemo_bounceExample')
sldiagnostics('sldemo_bounce', 'CountBlocks')

```

The following command counts and lists both the unique blocks and Stateflow objects used in the `sf_boiler` model that comes with Stateflow software; the textual report returned is captured as `myReport`.

```
openExample('stateflow/BangBangControlUsingTemporalLogicExample')
myReport = sldiagnostics('sf_boiler', 'CountBlocks', 'CountSF')
```

The following commands open the `f14` model that comes with Simulink software, and counts the number of blocks used in the `Controller` subsystem.

```
openExample('simulink_aerospace/AircraftLongitudinalFlightControlExample')
sldiagnostics('f14/Controller', 'CountBlocks')
```

The following command runs the `Sizes` and `CompileStats` diagnostics on the `f14` model, capturing the results as both a textual report and structure array.

```
[txtRpt, sRpt] = sldiagnostics('f14', 'Sizes', 'CompileStats')
```

## Version History

Introduced in R2006a

## sldiagviewer.createStage

Create a stage to display diagnostic messages

### Syntax

```
myStage = sldiagviewer.createStage(StageName)
myStage = sldiagviewer.createStage(__, 'modelName', Value)
```

### Description

`myStage = sldiagviewer.createStage(StageName)` creates a stage with the given stage name in the model specified. In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. When you create a stage object, Simulink initializes the stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer.

`myStage = sldiagviewer.createStage(__, 'modelName', Value)` is a required name-value pair that specifies the model in which the diagnostics is run.

### Examples

#### Create Stage and Display Diagnostic Messages

Use the `createStage` function to create a stage to display diagnostic messages in the Diagnostic Viewer.

```
% Create a Stage to display all the messages
```

```
myStage = sldiagviewer.createStage('Analysis', 'modelName', 'vdp');
```

```
myStage =
 Stage with no properties.
```

### Input Arguments

#### StageName — Name of stage

character vector

Name of the stage, specified as a character vector.

Example: 'Analysis'

Data Types: `string`

#### Value — Name of model

character vector

Name of model, specified as a comma-separated pair consisting of 'ModelName' and a character vector or string.

Example: 'vdp'

## Output Arguments

**myStage** — Handle to created stage

stage object

Handle to the created stage, returned as a stage object.

## Version History

Introduced in R2014a

## sldiagviewer.diary

Log simulation warnings and errors and build information to file

### Syntax

```
sldiagviewer.diary
sldiagviewer.diary(filename)
sldiagviewer.diary(toggle)
sldiagviewer.diary(filename, 'UTF-8')
```

### Description

`sldiagviewer.diary` intercepts build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current folder.

`sldiagviewer.diary(filename)` toggles the logging state of the text file specified by `filename`.

`sldiagviewer.diary(toggle)` turns logging to the log file on or off. The setting applies to the last file name you specified for logging or to `diary.txt` if you did not specify a file name.

`sldiagviewer.diary(filename, 'UTF-8')` specifies the character encoding for the log file `filename`.

### Examples

#### Log Build Information and Simulation Warnings and Errors

Start logging build information and simulation warnings and errors to `diary.txt`.

```
sldiagviewer.diary
open_system('vdp')
slbuild('vdp')
```

Open `diary.txt` to view logs.

```
Starting build procedure for model: vdp
Build procedure for model: 'vdp' aborted due to an error.
...
```

#### Log to Specific File

Set up logging to a file.

```
sldiagviewer.diary('C:\MyLogs\log1.txt')
```

## Toggle File Logging State

Switch the logging state of a file.

```
sdiagviewer.diary('C:\MyLogs\log1.txt') % Start logging
open_system('vdp')
slbuild('vdp')

sdiagviewer.diary('off') % Switch off logging

openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
open_system('sldemo_fuelSYS')
slbuild('sldemo_fuelSYS')

sdiagviewer.diary('on') % Resume logging
```

## Specify Log File Name and Character Encoding

Set the file name to log to and the character encoding to use.

```
sdiagviewer.diary('C:\MyLogs\log1.txt','UTF-8')
```

## Input Arguments

### toggle — Logging state

'off' | 'on'

Logging state, specified as 'on' or 'off'.

Example: `sdiagviewer.diary('on')`

### filename — Name of file to log data to

character vector

Name of file to log data to, specified as a character vector.

Example: `sdiagviewer.diary('C:\Simulations\mySimulationDiary.txt')`

## sldiagviewer.reportError

Report error messages in Diagnostic Viewer

### Syntax

```
output = sldiagviewer.reportError(Message)
myStage = sldiagviewer.reportError(__, 'Component', Value)
```

### Description

`output = sldiagviewer.reportError(Message)` reports the message as an error.

`myStage = sldiagviewer.reportError(__, 'Component', Value)` specifies the name of the component. For example, Stateflow or Model Advisor.

### Examples

#### Report an Error Message

Create a stage and use the `reportError` function to report an error message in the Diagnostic Viewer for the specified model.

```
vdp

% Create a stage
my_stage = sldiagviewer.createStage('StageName', 'ModelName', 'vdp');
%% write some code inside try, which will throw an error
try
 i = p;
catch error
end
sldiagviewer.reportError(error);

output =
 logical
 1
```

The diagnostic window opens up for the model vdp. It shows the StageName and the error message

## Input Arguments

### Message — Message to be displayed

MSLException object | MException object | string

This message is displayed as an error in the Diagnostic Viewer.

Example: 'This is a custom error message.'

### Value — Component name

character vector | string

The name of the component specified as the comma-separated pair consisting of 'Component' and a character vector or string.

Example: Stateflow

## Output Arguments

### output — shows the success or failure of the operation

logical

Shows whether the message was displayed successfully.

## Version History

Introduced in R2014a

## sldiagviewer.reportInfo

Report information messages in Diagnostic Viewer

### Syntax

```
output = sldiagviewer.reportInfo(Message)
myStage = sldiagviewer.reportInfo(__, 'Component' Value)
```

### Description

`output = sldiagviewer.reportInfo(Message)` reports the message as information.

`myStage = sldiagviewer.reportInfo(__, 'Component' Value)` specifies the name of the component.

### Examples

#### Report an Information Message

Create a stage and use the `reportInfo` function to report a message as information in the Diagnostic Viewer for the specified model.

```
% Create a Stage to display all the messages
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');

% Report a custom info message to Diagnostic Viewer
sldiagviewer.reportInfo('Information message.', 'Component', 'Stateflow');

output =
 logical
 1
```

### Input Arguments

#### Message — Message to be displayed

MSLException object | MException object | string

This message is displayed in the Diagnostic Viewer as an information.

Example: 'This is a custom information message.'

#### Value — Component name

character vector | string

The name of the component specified as the comma-separated pair consisting of 'Component' and a character vector or string.

Example: Stateflow

## Output Arguments

**output** — shows the success or failure of the operation  
logical

Shows whether the message was displayed successfully.

## Version History

Introduced in R2014a

## sldiagviewer.reportWarning

Report warning messages in Diagnostic Viewer

### Syntax

```
output = sldiagviewer.reportWarning(Message)
myStage = sldiagviewer.reportWarning(__, 'Component', Value)
```

### Description

`output = sldiagviewer.reportWarning(Message)` reports a message as warning in the diagnostic Viewer.

`myStage = sldiagviewer.reportWarning(__, 'Component', Value)` specifies the name of the component. For example, Model Advisor or Stateflow.

### Examples

#### Report a Warning in Diagnostic Viewer

Create a stage and use the `reportWarning` function to report a warning message in the Diagnostic Viewer for the specified model.

```
vdp

% Create a stage
my_stage = sldiagviewer.createStage('StageName', 'ModelName', 'vdp');
%% write some code inside try, which will throw an error
try
 i = p;
catch error
end
sldiagviewer.reportWarning(error);
```

```
output =
 logical
 1
```

The diagnostic window opens up for the model `vdp`. It shows the `StageName` and the warning message in yellow.

## Input Arguments

### Message — Message to display

MSLException object | MException object | string

This message is displayed as a warning in the Diagnostic Viewer.

Example: 'This is a custom warning message.'

### Value — Component name

character vector | string

The name of the component specified as the comma-separated pair consisting of 'Component' and a character vector or string.

Example: Stateflow

## Output Arguments

### output — shows the success or failure of the operation

logical

Shows whether the message was displayed successfully.

# sldiagviewer.reportSimulationMetadataDiagnostic S

Display errors and warnings in `Simulink.SimulationOutput` object using Diagnostic Viewer

## Syntax

```
sldiagviewer.reportSimulationMetadataDiagnostics(simOut)
```

## Description

`sldiagviewer.reportSimulationMetadataDiagnostics(simOut)` displays errors and warnings saved in the `Simulink.SimulationOutput` object `simOut` using the Diagnostic Viewer.

## Examples

### Display Errors in Diagnostic Viewer

You can use the `sldiagviewer.reportSimulationMetadataDiagnostics` function to display error and warning messages captured in a `Simulink.SimulationOutput` object using the Diagnostic Viewer.

Open the model `ex_sldemo_bounce`.

```
model = "ex_sldemo_bounce";
open_system(model)
```

Introduce an error into the model by specifying the **Value** parameter for the block `Initial Velocity` as the undefined variable `z`.

```
set_param("ex_sldemo_bounce/Initial Velocity", "Value", "z");
```

Create a `Simulink.SimulationInput` object to configure the simulation.

```
simIn = Simulink.SimulationInput(model);
```

Simulate the model. When you specify the `StopOnError` option as `off`, errors and warnings that occur during simulation are captured in the `SimulationOutput` object and are not reported in the Command Window or script and do not interrupt the process of the script.

```
simOut = sim(simIn, "StopOnError", "off", "ShowProgress", "off");
```

```
Warning: One or more simulations completed with errors. For more information, inspect the SimulationOutput object.
[1]
```

Use the `sldiagviewer.reportSimulationMetadataDiagnostics` function to display the warning and error messages from the simulation in the Diagnostic Viewer.

```
sldiagviewer.reportSimulationMetadataDiagnostics(simOut)
```

## Input Arguments

**simOut** — Simulation output that contains errors and warnings

Simulink.SimulationOutputobject

Simulation output that contains errors and warnings, specified as a Simulink.SimulationOutput object.

## Version History

Introduced in R2020b

### See Also

## sldiscmdl

Discretize model that contains continuous blocks

### Syntax

```
sldiscmdl('model_name',sample_time)
sldiscmdl('model_name',sample_time,method)
sldiscmdl('model_name',sample_time,options)
sldiscmdl('model_name',sample_time,method,freq)
sldiscmdl('model_name',sample_time,method,options)
sldiscmdl('model_name',sample_time,method,freq,options)
[old_blks,new_blks] = sldiscmdl('model_name',sample_time,method,freq,options)
```

### Description

`sldiscmdl('model_name',sample_time)` discretizes the model named '*model\_name*' using the specified *sample\_time*. The model does not need to be open, and the units for *sample\_time* are simulation seconds.

`sldiscmdl('model_name',sample_time,method)` discretizes the model using *sample\_time* and the transform method specified by *method*.

`sldiscmdl('model_name',sample_time,options)` discretizes the model using *sample\_time* and criteria specified by the *options* cell array. This array consists of four elements: {*target*, *replace\_with*, *put\_into*, *prompt*}.

`sldiscmdl('model_name',sample_time,method,freq)` discretizes the model using *sample\_time*, *method*, and the critical frequency specified by *freq*. The units for *freq* are Hz. When you specify *freq*, *method* must be 'prewarp'.

`sldiscmdl('model_name',sample_time,method,options)` discretizes the model using *sample\_time*, *method*, and *options*.

`sldiscmdl('model_name',sample_time,method,freq,options)` discretizes the model using *sample\_time*, *method*, *freq*, and *options*. When you specify *freq*, *method* must be 'prewarp'.

`[old_blks,new_blks] = sldiscmdl('model_name',sample_time,method,freq,options)` discretizes the model using *sample\_time*, *method*, *freq*, and *options*. When you specify *freq*, *method* must be 'prewarp'. The function also returns two cell arrays that contain full path names of the original, continuous blocks and the new, discretized blocks.

### Input Arguments

#### model\_name

Name of the model to discretize.

#### sample\_time

Sample-time specification for the model:

|                    |                                                  |
|--------------------|--------------------------------------------------|
| Scalar value       | Sample time with zero offset, such as 1          |
| Two-element vector | Sample time with nonzero offset, such as [1 0.1] |

### method

Method of converting blocks from continuous to discrete mode:

|                 |                                                |
|-----------------|------------------------------------------------|
| 'zoh' (default) | Zero-order hold on the inputs                  |
| 'foh'           | First-order hold on the inputs                 |
| 'tustin'        | Bilinear (Tustin) approximation                |
| 'prewarp'       | Tustin approximation with frequency prewarping |
| 'matched'       | Matched pole-zero method                       |

For single-input, single-output (SISO) systems only

### freq

Critical frequency in Hz. This input applies only when the *method* input is 'prewarp'.

### options

Cell array {*target*, *replace\_with*, *put\_into*, *prompt*}, where each element can take the following values:

|                     |                       |                                                                                              |
|---------------------|-----------------------|----------------------------------------------------------------------------------------------|
| <i>target</i>       | 'all' (default)       | Discretize all continuous blocks                                                             |
|                     | 'selected'            | Discretize only selected blocks in the model                                                 |
|                     | 'full_blk_path'       | Discretize specified block                                                                   |
| <i>replace_with</i> | 'parammask' (default) | Create discrete blocks whose parameters derive from the corresponding continuous blocks      |
|                     | 'hardcoded'           | Create discrete blocks with hard-coded parameters placed directly into each block dialog box |
| <i>put_into</i>     | 'copy' (default)      | Create discretization in a copy of the original model                                        |
|                     | 'variant'             | Create discretization candidate in a variant subsystem                                       |
|                     | 'current'             | Apply discretization to the current model                                                    |
|                     | 'untitled'            | Create discretization in a new untitled window                                               |
| <i>prompt</i>       | 'on' (default)        | Show discretization information at the command prompt                                        |
|                     | 'off'                 | Do not show discretization information at the command prompt                                 |

## Examples

Discretize all continuous blocks in the `slexAircraftExample` model using a 1-second sample time:

```
openExample('slexAircraftExample');
sldiscmdl('slexAircraftExample',1);
```

Discretize the `Aircraft Dynamics Model` subsystem in the `slexAircraftExample` model using a 1-second sample time, a 0.1-second offset, and a first-order hold transform method:

```
sldiscmdl('slexAircraftExample',[1 0.1],'foh',...
{'slexAircraftExample/Aircraft Dynamics Model',...
'parammask','copy','on'});
```

Discretize the `Aircraft Dynamics Model` subsystem in the `slexAircraftExample` model and retrieve the full path name of the second discretized block:

```
[old_blks,new_blks] = sldiscmdl('slexAircraftExample',[1 0.1],...
'foh',{'slexAircraftExample/Aircraft Dynamics Model','parammask',...
'copy','on'});
% Get full path name of the second discretized block
new_blks{2}
```

Discretize all continuous blocks in the `slexAircraftExample` model using a 1-second sample time:

```
openExample('slexAircraftExample');
[old_blk,new_blk] = sldiscmdl('f14',1,'zoh',...
{'f14/Aircraft Dynamics Model',...
'parammask','variant','on'})
```

--discretizing 'f14/Aircraft Dynamics Model' and putting results into a variant subsystem

```
old_blk =
 1x1 cell array
 {'f14/Aircraft Dynamics Model'}
new_blk =
 1x1 cell array
 {'f14/Aircraft↵Dynamics↵Model'}
```

## Version History

Introduced before R2006a

# slEditToolstripAction

Open file that defines custom Simulink Toolstrip action

## Syntax

```
slEditToolstripAction(action)
```

## Description

`slEditToolstripAction(action)` opens the file that defines the specified custom toolstrip action.

## Examples

### Edit Custom Toolstrip Action

Suppose you have many JSON files that define actions for a custom tab in a toolstrip component named `custom`.

To open the file that defines a custom action, such as `myAction`, use the `slEditToolstripAction` function.

```
slEditToolstripAction("custom:myAction")
```

## Input Arguments

### action — Fully qualified action name

character vector | string scalar

Fully qualified action name, specified as a character vector or string scalar. The fully qualified name is the name of the toolstrip component followed by a colon and the full path to the action within the toolstrip component.

When an action is defined at the top level of a toolstrip component, the fully qualified action name consists of these parts:

- 1 Name of the toolstrip component followed by a colon
- 2 Action ID

When an action is defined in the JSON object for a control, the action does not use an action ID. The fully qualified action name consists of these parts:

- 1 Name of the toolstrip component followed by a colon
- 2 Tab ID followed by a forward slash
- 3 Section ID or index followed by a forward slash
- 4 Column ID or index followed by a forward slash

**5** Control ID or index

Example: `slEditToolstripAction("custom:myAction")` opens the file that defines `myAction` for the custom toolstrip component.

Example: `slEditToolstripAction("custom:customTab/2/1/3")` opens the file that defines the action for the third control in the first column of the second section on the tab named `customTab` in the custom toolstrip component.

Data Types: `char` | `string`

## **Version History**

**Introduced in R2021b**

### **See Also**

### **Topics**

“Create Custom Simulink Toolstrip Tabs”

“Add Prepopulated Custom Tab to Simulink Toolstrip”

# slEditToolstripCommand

Open file that defines custom Simulink Toolstrip command

## Syntax

```
slEditToolstripCommand(action)
```

## Description

`slEditToolstripCommand(action)` opens the file that defines the custom Simulink Toolstrip command.

For scripts, the file that defines the action also defines the command. When you set `commandType` to `Script`, the `command` property directly specifies the script. When you set the `command` property to the name of a script on the MATLAB path, the function opens the JSON file, not the referenced MATLAB script.

## Examples

### Edit Custom Toolstrip Command

Suppose you have many files that define commands for a custom tab in a toolstrip component named `custom`.

To open the file that defines a command for an action, such as `myAction`, use the `slEditToolstripCommand` function.

```
slEditToolstripCommand("custom:myAction");
```

## Input Arguments

### **action** — Fully qualified action name

character vector | string scalar

Fully qualified action name, specified as a character vector or string scalar. The fully qualified name is the name of the toolstrip component followed by a colon and the full path to the action within the toolstrip component.

When an action is defined at the top level of a toolstrip component, the fully qualified action name consists of these parts:

- 1 Name of the toolstrip component followed by a colon
- 2 Action ID

When an action is defined in the JSON object for a control, the action does not use an action ID. The fully qualified action name consists of these parts:

- 1 Name of the toolstrip component followed by a colon

- 2** Tab ID followed by a forward slash
- 3** Section ID or index followed by a forward slash
- 4** Column ID or index followed by a forward slash
- 5** Control ID or index

Example: `slEditToolstripCommand("custom:myAction")` opens the file that defines `myAction` for the custom toolstrip component.

Example: `slEditToolstripCommand("custom:customTab/2/1/3")` opens the file that defines the command for the third control in the first column of the second section on the tab named `customTab` in the custom toolstrip component.

Data Types: `char` | `string`

## **Version History**

# slEditToolstripIcon

Open file that defines custom Simulink Toolstrip icon

## Syntax

```
slEditToolstripIcon(icon)
```

## Description

slEditToolstripIcon(icon) opens the file that defines the specified custom toolstrip icon.

## Examples

### Edit Custom Toolstrip Icon

Suppose you have many JSON files that define icons for a custom tab in a toolstrip component named `custom`.

To open the file that defines a custom icon, such as `myIcon`, use the `slEditToolstripIcon` function.

```
slEditToolstripIcon("custom:myIcon");
```

## Input Arguments

### icon — Fully qualified icon name

character vector | string scalar

Fully qualified icon name, specified as a character vector or string scalar. The fully qualified name is the name of the toolstrip component followed by a colon and the full path to the icon within the toolstrip component.

When an icon is defined at the top level of a toolstrip component, the fully qualified icon name consists of these parts:

- 1 Name of the toolstrip component followed by a colon
- 2 Icon ID

When an icon is defined in the JSON object for a top-level action, the fully qualified icon name consists of these parts:

- 1 Name of the toolstrip component followed by a colon
- 2 Action ID

When an icon is defined in the JSON object for a nested action, the fully qualified icon name consists of these parts:

- 1 Name of the toolstrip component followed by a colon

- 2** Tab ID followed by a forward slash
- 3** Section ID or index followed by a forward slash
- 4** Column ID or index followed by a forward slash
- 5** Control ID or index

Example: `slEditToolstripIcon("custom:myIcon")` opens the file that defines `myIcon` for the `custom` toolstrip component.

Example: `slEditToolstripIcon("custom:customTab/2/1/3")` opens the file that defines the icon for the third control in the first column of the second section on the tab named `customTab` in the `custom` toolstrip component.

Data Types: `char` | `string`

## Version History

“Add Prepopulated Custom Tab to Simulink Toolstrip”

# sLEditToolstripWidget

Open file that defines custom Simulink Toolstrip tab, section, column, or control

## Syntax

```
sLEditToolstripWidget(widget)
```

## Description

`sLEditToolstripWidget(widget)` opens the file that defines the specified custom toolstrip widget, which can be a custom tab, section, column, or control.

## Examples

### Edit Custom Toolstrip Widget

Suppose you have multiple JSON files that define custom tabs in a toolstrip component named `custom`.

To open the file that defines a custom tab named `customTab`, use the `sLEditToolstripWidget` function.

```
sLEditToolstripWidget("custom:customTab")
```

## Input Arguments

### **widget** — Fully qualified widget name

character vector | string scalar

Fully qualified widget name, specified as a character vector or string scalar. The fully qualified name is the name of the toolstrip component followed by a colon and the full path to the widget within the toolstrip component. When the widget has a parent JSON object, the fully qualified name includes the ID or index of each JSON object above the widget.

Example: `sLEditToolstripWidget("custom:customTab")` opens the file that defines the tab named `customTab` in the `custom` toolstrip component.

Example: `sLEditToolstripWidget("custom:customTab/2")` opens the file that defines the second section on the tab named `customTab` in the `custom` toolstrip component.

Example: `sLEditToolstripWidget("custom:customTab/2/1")` opens the file that defines the first column of the second section on the tab named `customTab` in the `custom` toolstrip component.

Example: `sLEditToolstripWidget("custom:customTab/2/1/3")` opens the file that defines the third control in the first column of the second section on the tab named `customTab` in the `custom` toolstrip component.

Data Types: char | string

# slExportFavoriteCommands

Export favorite commands from Simulink quick access toolbar

## Syntax

```
slExportFavoriteCommands(file)
```

## Description

`slExportFavoriteCommands(file)` exports the contents of the Simulink **Favorite Commands** gallery to the specified file.

## Examples

### Export Simulink Favorite Commands

Suppose you create a set of favorite commands in the Simulink **Favorite Commands** gallery that you want to share with team members. You can export the contents of your Simulink **Favorite Commands** gallery to a file.

For example, export the gallery contents to a file named `slFavorites.mat` in the `B:\path\` directory.

In the MATLAB Command Window, enter:

```
slExportFavoriteCommands('B:\path\slFavorites.mat');
```

## Input Arguments

### file — File name or path

character vector | string scalar

File name or path, specified as a character vector or string scalar.

Example: `slExportFavoriteCommands('B:\path\slFavorites.mat')`

Data Types: `char` | `string`

## Version History

Introduced in R2021b

## See Also

`slImportFavoriteCommands` | `slResetFavoriteCommands`

## Topics

## slexpr

Generate expression to use in value of parameter object

### Syntax

```
expressionOut = slexpr(expressionIn)
```

### Description

`expressionOut = slexpr(expressionIn)` converts the MATLAB-syntax expression `expressionIn` to an object, `expressionOut`, that you can use to set the `Value` property of a parameter object (such as `Simulink.Parameter`). When you use multiple parameter objects to set block parameter values, you can use the expression to model mathematical relationships between the objects. For more information, see “Set Variable Value by Using a Mathematical Expression”.

### Examples

#### Model Relationship Between Mass, Length, and Moment of Inertia of Metronome

In the base workspace, create three `Simulink.Parameter` objects that represent the mass, length, and moment of inertia of a pointlike metronome.

```
m = Simulink.Parameter;
r = Simulink.Parameter;
J = Simulink.Parameter;
```

Set the mass to 0.1 kg and the length to 1.0 m.

```
m.Value = 0.1;
r.Value = 1.0;
```

Set the value of the moment of inertia to the mass times the square of the length.

```
J.Value = slexpr('m*r^2');
```

Simulink preserves the expression,  $m*r^2$ . If you change the value of the mass or the length, Simulink recalculates the value of the moment of inertia.

### Input Arguments

#### **expressionIn** — Target expression

string | character vector

Target expression, specified as a string or character vector.

Example: "myParam + myOtherParam"

Data Types: char | string

## Output Arguments

### **expressionOut — Simulink representation of expression**

`Simulink.data.Expression` object

Simulink representation of the target expression, returned as a `Simulink.data.Expression` object. A `Simulink.data.Expression` object has no use outside the `Value` property of a parameter object.

## Version History

**Introduced in R2018a**

### **See Also**

`Simulink.Parameter`

### **Topics**

“Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder)

## slImportFavoriteCommands

Import favorite commands to Simulink quick access toolbar

### Syntax

```
backup = slImportFavoriteCommands(file)
backup = slImportFavoriteCommands(file,'overwrite')
```

### Description

`backup = slImportFavoriteCommands(file)` imports favorite commands and categories from the specified `file` to the Simulink **Favorite Commands** gallery. The specified `file` must be generated by exporting the contents of a Simulink **Favorite Commands** gallery using `slExportFavoriteCommands`.

`backup = slImportFavoriteCommands(file,'overwrite')` overwrites the contents of the Simulink **Favorite Commands** gallery with the contents of the specified `file`. The specified `file` must be generated by exporting the contents of a Simulink **Favorite Commands** gallery using `slExportFavoriteCommands`.

### Examples

#### Import Simulink Favorite Commands

Suppose a team member shares a file that contains favorite commands you want to use in Simulink, and you want to merge the file contents with the contents of your Simulink **Favorite Commands** gallery.

In the MATLAB Command Window, enter this command:

```
slImportFavoriteCommands('B:\path\slFavorites.mat');
```

#### Overwrite Simulink Favorite Commands

Suppose a team member shares a file that contains favorite commands you want to use in Simulink, and you want to overwrite the contents of your Simulink **Favorite Commands** gallery with the file contents.

In the MATLAB Command Window, enter this command:

```
slImportFavoriteCommands('B:\path\slFavorites.mat','overwrite');
```

### Input Arguments

**file** — File name or path  
character vector | string scalar

File name or path, specified as a character vector or string scalar.

Example: `slImportFavoriteCommands('B:\path\slFavorites.mat')`

Data Types: `char` | `string`

## Output Arguments

### **backup** — Backup of previous state

character vector

Path to backup of previous state, returned as a character vector.

To restore the previous state, you can pass the returned value as the input to the function and overwrite the current state.

## Version History

**Introduced in R2021b**

## See Also

`slExportFavoriteCommands` | `slResetFavoriteCommands`

## slIsFileChangedOnDisk

Determine whether model has changed since it was loaded

### Syntax

```
tf = slIsFileChangedOnDisk(sys)
```

### Description

`tf = slIsFileChangedOnDisk(sys)` returns whether the file that contains block diagram `sys` has changed on disk since the block diagram was loaded.

### Examples

#### Return Error When File Has Changed

To ensure that code is not generated for a model whose file has changed on disk since it was loaded, include the following in the 'entry' section of the `STF_make_rtw_hook.m` file.

```
if (slIsFileChangedOnDisk(sys))
 error('File has changed on disk since it was loaded. Aborting code generation.');
```

For more information, see “Customize Build Process with STF\_make\_rtw\_hook File” (Simulink Coder).

### Input Arguments

#### **sys** — System name

character vector | string scalar

System name, specified as a character vector or string scalar.

Data Types: `char` | `string`

### Output Arguments

#### **tf** — True or false result

1 | 0

True or false result, returned as a 1 or 0 of data type `logical`.

- 1 (`true`) — File that contains block diagram `sys` has changed on disk since the block diagram was loaded.
- 0 (`false`) — File that contains block diagram `sys` has not changed on disk since the block diagram was loaded.

## Version History

Introduced in R2007b

## **See Also**

### **Topics**

“Customize Build Process with STF\_make\_rtw\_hook File” (Simulink Coder)

“Model File Change Notification”

## sLibraryBrowser

Open, load, and close Simulink Library Browser, create and get handle of Library Browser object

### Syntax

```
sLibraryBrowser
libraryhandle = sLibraryBrowser
sLibraryBrowser('open')
sLibraryBrowser('noshow')
sLibraryBrowser('close')
```

### Description

`sLibraryBrowser` opens the Simulink Library Browser in standalone mode. For more information on standalone mode, see Library Browser in Standalone Mode.

---

#### Note

- If you want to load the Simulink block library, use `load_system simulink` instead.
  - If you want to start Simulink without opening any windows, use the faster `start_simulink` instead.
- 

`libraryhandle = sLibraryBrowser` creates the Library Browser object `LibraryBrowser.LBStandalone` and returns the object handle. When you have the object handle, you can use the object properties and functions to display, hide, size, position, and refresh the Library Browser in standalone mode. For more information, see Library Browser in Standalone Mode, `LibraryBrowser.LBStandalone`, `show`, `hide`, `getPosition`, `setPosition`, and `refresh`.

When you use `sLibraryBrowser` to get the object handle:

- If the Library Browser is open in standalone mode, the Library Browser window moves in front of all other Simulink windows.
- If the Library Browser is not open in standalone mode, the Library Browser opens in standalone mode.

---

**Note** You can also use `LibraryBrowser.LibraryBrowser2` to create and get the handle of the Library Browser object. `LibraryBrowser.LibraryBrowser2` does not open a Library Browser in standalone mode or move the Library Browser in front of other Simulink windows.

---

`sLibraryBrowser('open')` opens the Library Browser in standalone mode.

`sLibraryBrowser('noshow')` loads the Library Browser in memory without making it visible. Use this to make future calls to `sLibraryBrowser('open')` faster.

`sLibraryBrowser('close')` closes the Library Browser in standalone mode.

## Examples

### Open and Close Library Browser in Standalone Mode

```
sLibraryBrowser
sLibraryBrowser('close')
```

### Load Library Browser and Get Handle

```
libraryhandle = sLibraryBrowser('noshow')
```

## Limitations

The `sLibraryBrowser` function does not act on a docked Library Browser. To use the `sLibraryBrowser` function, open the Library Browser in standalone mode by clicking the Launch standalone library browser button .

## Version History

### Introduced in R2016a

### R2016b: LibraryBrowser.LBStandalone object replaces LibraryBrowser.LibraryBrowser2 object

*Behavior changed in R2016b*

In previous releases, these two commands returned a `LibraryBrowser.LibraryBrowser2` object:

```
lb = sLibraryBrowser
lb = LibraryBrowser.LibraryBrowser2
```

Starting in R2016b, each command returns a `LibraryBrowser.LBStandalone` object. The functions to access Library Browser operations such as `show` and `refresh` support `LibraryBrowser.LBStandalone` objects.

## See Also

### Functions

`LibraryBrowser.LibraryBrowser2` | `simulink` | `start_simulink`

### Tools

**Library Browser**

### Objects

`LibraryBrowser.LBStandalone`

“Add Blocks to Models Using Library Browser”

## slLoadedToolstripComponents

Find loaded custom Simulink Toolstrip components

### Syntax

```
components = slLoadedToolstripComponents
```

### Description

`components = slLoadedToolstripComponents` returns the name, path, and persistence of loaded custom Simulink Toolstrip components.

### Examples

#### Remove Custom Tab by Finding Loaded Custom Simulink Toolstrip Components

Suppose you have a custom tab that you want to remove from the Simulink Toolstrip.

Find the loaded custom Simulink Toolstrip components. In the MATLAB Command Window, enter:

```
components = slLoadedToolstripComponents
```

```
components =
```

```
 1×2 struct array with fields:
```

```
 name
 path
 persisted
```

The function finds two loaded components.

Get information about the first component.

```
components(1)
```

```
ans =
```

```
 struct with fields:
```

```
 name: 'tools'
 path: 'B:\path\components\tools'
 persisted: 0
```

The function returns the name (`tools`), path (`B:\path\components\tools`), and persistence (`0`) of the component. This component does not persist across MATLAB sessions.

Get information about the second component.

```
components(2)
```

```
ans =

 struct with fields:
 name: 'custom'
 path: 'B:\path\customtab'
 persisted: 1
```

The function returns the name (`custom`), path (`B:\path\customtab`), and persistence (`1`) of the component. This component persists across MATLAB sessions.

Inspect the JSON files in the `B:\path\customtab\resources\json` folder of the second component to determine whether the second component defines the custom tab you want to remove. Also check whether the component defines custom tabs that you want to keep.

Remove the custom tab by performing one of these actions:

- Remove the parent folder of the `resources` folder from the MATLAB path.
- Stop the custom Simulink Toolstrip component from persisting across MATLAB sessions by using the `slPersistToolstripComponent` function.
- Rename the `resources` folder to prevent it from being found.
- Edit the JSON file that defines the custom tab.
- Destroy the custom Simulink Toolstrip component using the `slDestroyToolstripComponent` function.

Then, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

## Output Arguments

**components** — Name, path, and persistence of loaded components

structure array

Name, path, and persistence of loaded components, returned as a structure array.

## Version History

Introduced in R2021b

## See Also

## slmdliscui

Open Model Discretizer GUI

### Syntax

```
slmdliscui
slmdliscui('model')
```

### Description

`slmdliscui` opens the Model Discretizer. A model does not need to be open.

`slmdliscui('model')` opens the Model Discretizer for the model or library called '*name*'.

To use the Model Discretizer, you must have a Control System Toolbox license, version 5.2 or later.

### Examples

Open the Model Discretizer for the `slexAircraftExample` model:

```
openExample('slexAircraftExample');
slmdliscui('slexAircraftExample')
```

Open the Model Discretizer for the `discretizing` library:

```
slmdliscui('discretizing')
```

## Version History

**Introduced before R2006a**

### See Also

# slPersistToolstripComponent

Specify whether custom Simulink Toolstrip component persists across MATLAB sessions

## Syntax

```
slPersistToolstripComponent(component,persistence)
```

## Description

`slPersistToolstripComponent(component,persistence)` specifies whether to add the path for the specified custom Simulink Toolstrip component to the list of paths to restore for each MATLAB session.

## Examples

### Remember Custom Simulink Toolstrip Component Across Sessions

Suppose you create a custom tab that you want to remain in the Simulink Toolstrip the next time you open Simulink.

Specify that the component persists in future MATLAB sessions. For example, specify that a component named `custom` persists across sessions. In the MATLAB Command Window, enter:

```
slPersistToolstripComponent("custom",true);
```

## Input Arguments

### **component** — Name of component to persist across sessions

character vector | string scalar

Name of component to persist across sessions, specified as a character vector or string scalar.

Data Types: `char` | `string`

### **persistence** — Option for component to persist across sessions

`true` | `false`

Option for component to persist across sessions, specified as `true` or `false`.

Data Types: `logical`

## Version History

Introduced in R2021b

## See Also

# slprofreport

(Not recommended) Regenerate profiler report from data, ProfileData, saved from previous run

## Syntax

```
slprofreport(model_nameProfileData)
```

## Description

When you run a model with the profiler enabled, the simulation generates the data and saves it in the variable, `model_nameProfileData`. `slprofreport(model_nameProfileData)` generates a profiler report based on the data in `model_nameProfileData`, saved from the model run.

## Input Arguments

### ProfileData

Variable containing profiler data from a model run. The variable name consists of the model name and ProfileData, for example, `vdpProfileData`.

**Default:** None

## Examples

### Regenerate Simulink Profiler Results

Regenerate the Profiler report for model `vdp`

In the MATLAB Command Window, start the `vdp` model.

In the Simulink editor window, run `vdp` model with Simulink Profiler enabled.

Simulink stores the data to the variable `vdpProfileData`.

To review the report, in the MATLAB Command Window

```
slprofreport(vdpProfileData)
```

The Simulink Profiler Report window is displayed.

## Version History

**Introduced in R2012a**

**R2020a: slprofreport is not recommended**

*Not recommended starting in R2020a*

Starting in R2020a, the `slprofreport` function is no longer recommended to load saved **Simulink Profiler** reports. The reports are saved to a MAT file and can be directly loaded into the current workspace.

For profiling reports saved before R2019b, you can use the `slprofreport` function to load the report.

# slproject.create

(Not recommended) Create blank project

---

**Note** `slproject.create` is not recommended. Use `matlab.project.createProject` instead. For more information, see “Compatibility Considerations”.

---

## Syntax

```
proj = slproject.create
proj = slproject.create(path)
proj = slproject.create(name)
```

## Description

`proj = slproject.create` creates and opens a project using the blank project template from the Simulink start page, and returns a project object. Use the project object to manipulate the currently open project at the command line. The new project is created in the default project folder. To change the default folder for new projects, on the MATLAB Home tab, click **Preferences**. In the Preferences dialog box, on the MATLAB Project pane, set the **Default folder**.

`proj = slproject.create(path)` creates the project at the location specified by `path`.

`proj = slproject.create(name)` creates the project in the default folder, with the name specified by `name`.

## Examples

### Create a Blank Project in the Default Folder

```
slproject.create
```

You can control the default folder for new projects using the project preferences.

### Create a Blank Project in a Specified Folder

```
proj = slproject.create('C:\work\myprojectname');
```

### Create a Named Blank Project in the Default Folder

```
proj = slproject.create('myprojectname');
```

## Input Arguments

**path** — Path for the new project location

character vector

Path for the new project location, specified as a character vector. If you do not specify the path, `slproject.create` creates the project in the default location. You can change the default location in the project preferences.

Example: `C:\work\projectname`

Data Types: `char`

### **name — Name for the new project**

character vector

Name for the new project, specified as a character vector.

Example: `myproject`

Data Types: `char`

## **Output Arguments**

### **proj — Project**

project object

Project, returned as a project object. Use the project object to manipulate the currently open project at the command line.

Properties of `proj` output argument.

| <b>Project Property</b> | <b>Description</b>                                                                                                                             |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Name                    | Project name                                                                                                                                   |
| Information             | Information about the project such as the description, source control integration, repository location, and whether it is a top-level project. |
| Dependencies            | Dependencies between project files in a MATLAB digraph object.                                                                                 |
| Shortcuts               | Shortcut files in the project.                                                                                                                 |
| ProjectPath             | Folders that the project puts on the MATLAB path.                                                                                              |
| ProjectReferences       | Folders that contain referenced projects. Contains read-only project objects for referenced projects.                                          |
| Categories              | Categories of project labels.                                                                                                                  |
| Files                   | Paths and names of project files.                                                                                                              |
| RootFolder              | Full path to project root folder.                                                                                                              |

## **Version History**

**Introduced in R2017a**

**R2019a: Simulink project API is not recommended**

*Not recommended starting in R2019a*

Starting in R2019a, instead of `simulinkproject` and related functions, use the `currentProject` or `openProject` functions in MATLAB. The Simulink project API will continue to be supported, but, after R2019a, new features will be available only if you use the new MATLAB project API. There are no plans to remove the Simulink project API at this time.

You can continue to use `simulinkproject` and related functions listed in `methods(simulinkproject)`. New functions added after R2019a, such as `runChecks` and `listImpactedFiles`, do not work with `simulinkproject`. Use `currentProject` instead.

The new MATLAB project API is part of the R2019a functionality enabling you to use projects in MATLAB, with or without Simulink. You can now share projects with users who do not have Simulink.

## slproject.getCurrentProject

(To be removed) Manipulate current project at command line

---

**Note** `slproject.getCurrentProject` will be removed in a future release. Use `currentProject` instead.

---

### Syntax

```
proj = slproject.getCurrentProject
```

### Description

`proj = slproject.getCurrentProject` gets the current project open in the Project Tool and returns a project object `proj` that you can use to manipulate the project programmatically. If no project is open, then you see an error.

---

**Note** `slproject.getCurrentProject` is replaced by `slproject.getCurrentProjects`.

---

### Examples

#### Get Airframe Example Project

Open the Airframe project and use `slproject.getCurrentProject` to get a project object to manipulate the project at the command line.

```
sldemo_slproject_airframe
proj = slproject.getCurrentProject
```

```
proj =
```

```
 ProjectManager with properties:
```

```
 Name: 'Simulink Project Airframe Example'
 Categories: [1x1 slproject.Category]
 Shortcuts: [1x8 slproject.Shortcut]
 ProjectPath: [1x7 slproject.PathFolder]
 ProjectReferences: [1x0 slproject.ProjectReference]
 Files: [1x30 slproject.ProjectFile]
 RootFolder: 'C:\Work\Simulink\Projects\slexamples\airframe'
```

### Output Arguments

#### **proj** – Project

project object

Project, returned as a project object. Use the project object to manipulate the currently open project at the command line.

## **Version History**

**Introduced in R2013a**

### **See Also**

#### **Functions**

[currentProject](#) | [simulinkproject](#) | [slproject.getCurrentProjects](#) | [slproject.loadProject](#)

## slproject.getCurrentProjects

(Not recommended) List all top-level projects

---

**Note** `slproject.getCurrentProjects` is not recommended. Use `matlab.project.rootProject` instead. For more information, see “Compatibility Considerations”.

---

### Syntax

```
projects = slproject.getCurrentProjects
```

### Description

`projects = slproject.getCurrentProjects` returns a list of all open top-level projects. Currently only one or zero top-level projects can be loaded. Returns an object array of 1 or 0 `ProjectManager` objects `projects` that you can use to manipulate the project programmatically. Use `slproject.getCurrentProjects` for project automation scripts.

If you execute `slproject.getCurrentProjects` inside a project shortcut, it returns only the project that the shortcut belongs to. If the shortcut belongs to a referenced project, it returns the referenced project.

### Examples

#### Get Airframe Example Project

Open the Airframe project and use `slproject.getCurrentProjects` to get a project object to manipulate the project at the command line.

```
sldemo_slproject_airframe
proj = slproject.getCurrentProjects
```

```
proj =
```

```
ProjectManager with properties:
```

```
 Name: 'Simulink Project Airframe Example'
 Categories: [1x1 slproject.Category]
 Shortcuts: [1x8 slproject.Shortcut]
 ProjectPath: [1x7 slproject.PathFolder]
 ProjectReferences: [1x0 slproject.ProjectReference]
 Files: [1x30 slproject.ProjectFile]
 RootFolder: 'C:\Work\Simulink\Projects\airframe'
```

#### Find Project Commands

Open the airframe project and create a project object.

```

sldemo_slproject_airframe
proj = slproject.getCurrentProject

proj =

 ProjectManager with properties:

 Name: 'Simulink Project Airframe Example'
 Categories: [1x1 slproject.Category]
 Shortcuts: [1x8 slproject.Shortcut]
 ProjectPath: [1x7 slproject.PathFolder]
 ProjectReferences: [1x0 slproject.ProjectReference]
 Files: [1x30 slproject.ProjectFile]
 RootFolder: 'C:\Work\Simulink\Projects\airframe'

```

Find out what you can do with your project.

```
methods(proj)
```

close isLoaded
createCategory listModifiedFiles
export refreshSourceControl

```

```

reload
removeCategory
removeFile

```

### Examine Project Properties

After you get a project object, you can examine project properties.

Open the airframe project and create a project object.

```

sldemo_slproject_airframe
proj = slproject.getCurrentProjects;

```

Examine the project files.

```
files = proj.Files
```

```
files =
```

```
1x30 ProjectFile array with properties:
```

```

 Path
 Labels
 Revision
 SourceControlStatus

```

Examine the labels of the eighth file.

```
proj.Files(8).Labels
```

```
ans =

 Label with properties:
 File: 'C:\Work\airframe\data\system_model.sldd'
 Data: []
 DataType: 'none'
 Name: 'Design'
 CategoryName: 'Classification'
```

Get a particular file.

```
myfile = findFile(proj, 'models/AnalogControl.slx')
```

```
myfile =
```

```
 ProjectFile with properties:
 Path: 'C:\Temp\airframe\models\AnalogControl.slx'
 Labels: [1x1 slproject.Label]
 Revision: '2'
 SourceControlStatus: Unmodified
```

Find out what you can do with the file.

```
methods(myfile)
```

```
Methods for class slproject.ProjectFile:
```

```
addLabel
removeLabel
findLabel
```

## Output Arguments

### projects – Projects

object array of 1 or 0 ProjectManager objects

Projects, returned as an object array of 1 or 0 ProjectManager objects. Use the project object to manipulate the currently open project at the command line.

Properties of ProjectManager objects in output argument.

| Project Property  | Description                                      |
|-------------------|--------------------------------------------------|
| Name              | Project name                                     |
| Categories        | Categories of project labels                     |
| Shortcuts         | Shortcut files in project                        |
| ProjectPath       | Folders that the project puts on the MATLAB path |
| ProjectReferences | Folders that contain referenced projects         |
| Files             | Paths and names of project files                 |
| RootFolder        | Full path to project root folder                 |

## Tips

Alternatively, you can use `simulinkproject` to get a project object, but `simulinkproject` also opens and gives focus to the Project Tool. Use `simulinkproject` to open projects and explore projects interactively. Use `slproject.getCurrentProjects` for project automation scripts.

## Version History

### Introduced in R2016a

#### **R2019a: Simulink project API is not recommended**

*Not recommended starting in R2019a*

Starting in R2019a, instead of `simulinkproject` and related functions, use the `currentProject` or `openProject` functions in MATLAB. The Simulink project API will continue to be supported, but, after R2019a, new features will be available only if you use the new MATLAB project API. There are no plans to remove the Simulink project API at this time.

You can continue to use `simulinkproject` and related functions listed in `methods(simulinkproject)`. New functions added after R2019a, such as `runChecks` and `listImpactedFiles`, do not work with `simulinkproject`. Use `currentProject` instead.

The new MATLAB project API is part of the R2019a functionality enabling you to use projects in MATLAB, with or without Simulink. You can now share projects with users who do not have Simulink.

### Functions

`matlab.project.rootProject` | `simulinkproject` | `slproject.loadProject` | `slproject.getCurrentProject`

## slproject.loadProject

(Not recommended) Load project

---

**Note** `simulinkproject` is not recommended. Use `currentProject` or `openProject` instead. For more information, see “Compatibility Considerations”.

---

### Syntax

```
slproject.loadProject(projectPath);
proj = slproject.loadProject(projectPath)
```

### Description

`slproject.loadProject(projectPath)`; loads the project specified by the `.prj` file or folder `projectPath` in the Project Tool, and closes any currently open project.

`proj = slproject.loadProject(projectPath)` loads the project and returns a project object `proj` for manipulating the project. Use `slproject.loadProject` for project automation scripts.

### Examples

#### Load Project

Load a project from a folder called 'C:/projects/project1/'. Replace this path with the location of your project.

```
proj = slproject.loadProject('C:/projects/project1/')
```

#### Get Airframe Example Project

Open the Airframe project and use `slproject.getCurrentProjects` to get a project object to manipulate the project at the command line.

```
sldemo_slproject_airframe
proj = slproject.getCurrentProjects
```

```
proj =
```

```
 ProjectManager with properties:
```

```
 Name: 'Simulink Project Airframe Example'
 Categories: [1x1 slproject.Category]
 Shortcuts: [1x8 slproject.Shortcut]
 ProjectPath: [1x7 slproject.PathFolder]
 ProjectReferences: [1x0 slproject.ProjectReference]
```

```
Files: [1x30 slproject.ProjectFile]
RootFolder: 'C:\Work\Simulink\Projects\airframe'
```

### Find Project Commands

Get the Airframe project.

```
sldemo_slproject_airframe
proj = slproject.getCurrentProjects;
```

Find project commands.

```
methods(proj)
```

Methods for class slproject.ProjectManager:

```
addFile findCategory
addFolderIncludingChildFiles findFile
close isLoading
createCategory listModifiedFiles
export refreshSourceControl
```

```
reload
removeCategory
removeFile
```

### Examine Project Properties

After you get a project object, you can examine project properties.

Get the airframe project.

```
sldemo_slproject_airframe
proj = slproject.getCurrentProjects;
```

Examine the project files.

```
files = proj.Files
```

```
files =
```

```
1x30 ProjectFile array with properties:
```

```
Path
Labels
Revision
SourceControlStatus
```

Examine the labels of the 13th file.

```
proj.Files(13).Labels
```

```
ans =
```

Label with properties:

```
File: 'C:\Temp\airframe\models\AnalogControl.slx'
 Data: []
 DataType: 'none'
 Name: 'Design'
 CategoryName: 'Classification'
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.slx')
```

```
myfile =
```

ProjectFile with properties:

```
Path: 'C:\Temp\airframe\models\AnalogControl.slx'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified
```

Find out what you can do with the file.

```
methods(myfile)
```

Methods for class slproject.ProjectFile:

```
addLabel
removeLabel
findLabel
```

## Input Arguments

### **projectPath** — Full path to project file or folder

character vector

Full path to project .prj file or the path to the project root folder, specified as a character vector.

Example: 'C:/projects/project1/myProject.prj'

Example: 'C:/projects/project1/'

## Output Arguments

### **proj** — Project

project object

Project, returned as a project object. Use the project object to manipulate and explore the project at the command line.

Properties of proj output argument.

| Project Property | Description                  |
|------------------|------------------------------|
| Name             | Project name                 |
| Categories       | Categories of project labels |

| Project Property  | Description                                      |
|-------------------|--------------------------------------------------|
| Shortcuts         | Shortcut files in project                        |
| ProjectPath       | Folders that the project puts on the MATLAB path |
| ProjectReferences | Folders that contain referenced projects         |
| Files             | Paths and names of project files                 |
| RootFolder        | Full path to project root folder                 |

## Version History

### Introduced in R2013a

### R2019a: Simulink project API is not recommended

*Not recommended starting in R2019a*

Starting in R2019a, instead of `simulinkproject` and related functions, use the `currentProject` or `openProject` functions in MATLAB. The Simulink project API will continue to be supported, but, after R2019a, new features will be available only if you use the new MATLAB project API. There are no plans to remove the Simulink project API at this time.

You can continue to use `simulinkproject` and related functions listed in `methods(simulinkproject)`. New functions added after R2019a, such as `runChecks` and `listImpactedFiles`, do not work with `simulinkproject`. Use `currentProject` instead.

The new MATLAB project API is part of the R2019a functionality enabling you to use projects in MATLAB, with or without Simulink. You can now share projects with users who do not have Simulink.

### Functions

`simulinkproject` | `slproject.getCurrentProjects`

### Topics

“What Are Projects?”

## sl\_refresh\_customizations

Refresh customizations in the current MATLAB session

### Syntax

```
sl_refresh_customizations
```

### Description

`sl_refresh_customizations`:

- Runs all `sl_customization.m` files on the MATLAB path and in the current folder
- Rebuilds the Simulink Toolstrip
- Rebuilds all Simulink Editor menus
- Rebuilds the Simulink Library Browser menus and toolbars
- Clears the Library Browser cache and refreshes the Library Browser
- Reloads the Viewers and Generators Manager data

### Examples

#### Refresh Library Browser and Toolstrip Tab

Use the `sl_refresh_customizations` command to show the changes that an `sl_customization.m` file makes to the order of the libraries in the Simulink Library Browser and the changes that a modified JSON file makes to the Simulink Toolstrip. Start by changing the order of the libraries in the Library Browser. By default, the libraries are listed in ascending order of priority, and libraries that have the same priority are in alphabetical order. The Simulink library has a sort priority of `-1`. All other libraries have a sort priority of `0`. The Simulink library is the first library listed in the browser because it has the highest priority.

Open a blank model in Simulink.

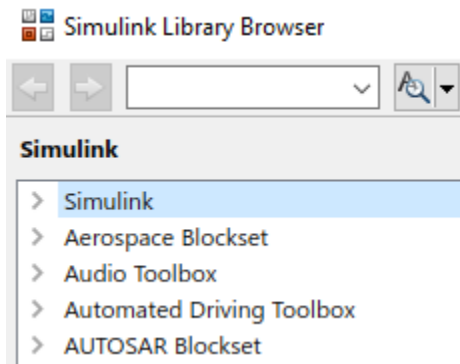

Open the Simulink Library Browser. The first library listed in the browser is the Simulink library.

Create an `sl_customization.m` file that gives the Simulink Extras library a priority of `-2`. This priority is higher than that of the Simulink library.

```
function sl_customization(cm)
 cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras', -2});
end
```

Save the `sl_customization.m` file to the MATLAB path.

Check the Simulink Library Browser. The order of the libraries is unchanged.

Now, modify the toolstrip. Create an empty custom toolstrip tab by entering this in the MATLAB Command Window.

```
slCreateToolstripComponent("custom");
slCreateToolstripTab("customTab","custom",Title="CUSTOM TAB");
```

In the `customTab.json` file that is generated, change the title of the tab from `CUSTOM TAB` to `NEW NAME`.

```
{
 "version": "1.0",
 "entries":
 [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "NEW TAB"
 }
]
}
```

Save the `customTab.json` file.

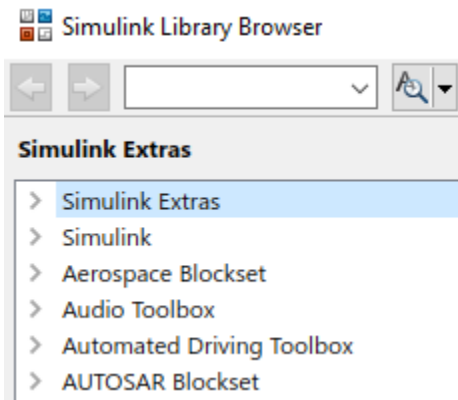

Check the title of the custom tab. Even though the title in the `customTab.json` file is now `NEW NAME`, the title displayed in the toolstrip is still `CUSTOM TAB`.

To see your changes implemented on the Library Browser and toolstrip, rebuild both with this single command.

```
sl_refresh_customizations
```

Check the Library Browser. The order of the libraries has changed: the `Simulink Extras` library is above the `Simulink` library.

Check the toolstrip. The name of the custom tab has changed from CUSTOM TAB to NEW TAB.

### Tips

If you only need to refresh the Library browser displayed in the current MATLAB session, you can also do so using the `refresh` command.

If you only need to refresh the toolstrip displayed in the current MATLAB session, you can also do so using the `slReloadToolstripConfig` command.

## Version History

Introduced in R2022a

# slReloadToolstripConfig

Reload Simulink Toolstrip configuration

## Syntax

```
slReloadToolstripConfig
```

## Description

`slReloadToolstripConfig` reloads the Simulink Toolstrip configuration. Use this function after you make changes to the JSON files that define custom tabs.

## Examples

### Reload Simulink Toolstrip

After you modify a JSON file that defines a custom tab, use the `slReloadToolstripConfig` function to reload the toolstrip configuration with your changes.

In the MATLAB Command Window, enter:

```
slReloadToolstripConfig;
```

The function searches the MATLAB path for `resources` folders that contain a valid `sl_toolstrip_plugins.json` file.

To temporarily modify the toolstrip configuration, perform one of these actions before you call this function:

- Add folders that contain `resources` folders to the MATLAB path.
- Remove folders that contain `resources` folders from the MATLAB path.

If the custom tab does not appear:

- Debug and correct errors in the JSON code.
- Add the folder that contains the corresponding `resources` folder to the MATLAB path.

# slResetFavoriteCommands

Reset Simulink Favorite Commands gallery

## Syntax

```
backup = slResetFavoriteCommands
```

## Description

`backup = slResetFavoriteCommands` resets the Simulink **Favorite Commands** gallery and saves a backup of the previous state of the gallery.

## Examples

### Reset Simulink Favorite Commands Gallery

Suppose you want to delete all the commands and custom categories in the Simulink **Favorite Commands** gallery.

In the MATLAB Command Window, enter:

```
slResetFavoriteCommands;
```

## Output Arguments

### **backup** — Backup of previous state

character vector

Backup of previous state, returned as a character vector.

To restore the previous state, you can pass the returned value as the input to the `slImportFavoriteCommands` function and overwrite the current state.

## Version History

Introduced in R2021b

## See Also

`slImportFavoriteCommands` | `slExportFavoriteCommands`

## Topics

“Access Frequently Used Features and Commands in Simulink”

## slsim.allowedModelChanges

Determine changes you can make to model based on simulation status

### Syntax

```
changeLevel = slsim.allowedModelChanges mdl
```

### Description

`changeLevel = slsim.allowedModelChanges(mdl)` returns a string, `changeLevel`, that indicates the types of changes you can make to the model `mdl` based on the simulation status of the model.

Use this function to control the execution of code that modifies a model and runs during simulation, including model, block, and simulation callback functions. You can also use this function to check which changes are allowed in iterative simulation workflows that use fast restart.

### Examples

#### Check Which Changes Are Allowed for Model

Open and simulate the model `sldemo_autotrans`.

```
mdl = "sldemo_autotrans";
open_system(mdl)
out = sim(mdl, "ReturnWorkspaceOutputs", "on");
```

Use the `slsim.allowedModelChanges` function to check which kinds of changes you can make to the model. Use the `get_param` function to check the simulation status.

```
changeLevel = slsim.allowedModelChanges(mdl)

changeLevel =
'any'

simStatus = get_param(mdl, "SimulationStatus")

simStatus =
'stopped'
```

Because the model does not have fast restart enabled, the model does not stay compiled between simulations, and you can make any change to the model between simulations, including structural changes.

Suppose you want to run a set of simulations for each input scenario in the file the Signal Editor block loads. Enable fast restart so that you only need to compile the model once in that set of simulations.

```
set_param(mdl, "FastRestart", "on")
```

Simulate the model again.

```
out = sim mdl;
```

Check which changes are allowed and the simulation status. Because the model has fast restart enabled, the model remains compiled after the simulation finishes, and you cannot make structural changes to the model. You can change only run-to-run and runtime tunable parameters.

```
changeLevel = slsim.allowedModelChanges mdl)

changeLevel =
'runtorun'

simStatus = get_param mdl, "SimulationStatus")

simStatus =
'compiled'
```

Disable fast restart for the model.

```
set_param mdl, "FastRestart", "off")
```

Check which changes are allowed and the simulation status.

```
changeLevel = slsim.allowedModelChanges mdl)

changeLevel =
'any'

simStatus = get_param mdl, "SimulationStatus")

simStatus =
'stopped'
```

## Input Arguments

### **mdl** — Name of model to be modified

string | character vector

Name of model to be modified, specified as a string or a character vector.

Example: "vdp"

Data Types: char | string

## Output Arguments

### **changeLevel** — Changes allowed for simulation status of model

"any" | "runtorun" | "runtime" | "none"

Changes allowed for simulation status of model, returned as one of these options:

- "any" — All types of changes are allowed, including structural changes and tuning run-to-run and runtime tunable parameters.
- "runtorun" — Only changes to run-to-run and runtime tunable parameters are allowed. Structural changes to the model are not allowed.
- "runtime" — Only changes to runtime tunable parameters are allowed. Structural changes and changes to run-to-run tunable parameters are not allowed.

- "none" — No changes to the model are allowed.

# slToolstripDeveloperMode

Enable developer mode for Simulink Toolstrip

## Syntax

```
tf = slToolstripDeveloperMode(status)
```

## Description

`tf = slToolstripDeveloperMode(status)` enables a developer mode that lets you get action and icon names for controls, such as push buttons, in the Simulink Toolstrip. You can use the action name to add a control that performs the same action to a custom tab. For an example, see “Specify Built-In Simulink Actions”. You can use the icon name to add a control that has the same icon to a custom tab. For an example, see “Define Custom Actions”.

To activate developer mode, set `status` to `'on'`. Then, click anywhere on the Simulink Toolstrip.

If you click away from the Simulink Toolstrip, developer mode is temporarily deactivated. To reactivate developer mode, click anywhere on the Simulink Toolstrip.

When developer mode is active, to display the action and icon names in the MATLAB Command Window, pause on the control in the Simulink Toolstrip and press **Ctrl**. On a Mac, press **command** (⌘) instead of **Ctrl**.

## Examples

### Enable Simulink Toolstrip Developer Mode

In the MATLAB Command Window, enable developer mode for the Simulink Toolstrip.

```
slToolstripDeveloperMode('on')
```

```
ans =
 logical
 0
```

The function enables developer mode for the Simulink Toolstrip. The returned value indicates that developer mode was not enabled before you entered this command.

To activate developer mode, click anywhere on the Simulink Toolstrip.

On the Simulink Toolstrip, pause your pointer on a control. For example, pause on the **Library Browser** button.

Press **Ctrl**. The output in the MATLAB Command Window shows the shows the action and icon names for the button.

Action: `showLibraryBrowserELBAction`  
Icon: `libraryBrowser`  
-----

## Input Arguments

### **status** — Desired status of developer mode

on/off logical value

Desired status of developer mode, specified as specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

By default, developer mode for the Simulink Toolstrip is disabled. Enable developer mode when you want to get the action and icon names of items in the Simulink Toolstrip.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

## Output Arguments

### **tf** — Previous status of developer mode

1 | 0

Previous status of developer mode, returned as a 1 or 0 of data type `logical`.

## Version History

Introduced in R2021b

# slxcinfo

Query contents of Simulink cache files

## Syntax

```
info = slxcinfo(filename)
```

## Description

`info = slxcinfo(filename)` creates a MATLAB table that lists the contents of the specified Simulink cache file. The table information includes the corresponding Simulink model name, MATLAB release, platform, and target type.

## Examples

### Query Contents of Simulink Cache File

Suppose you have a Simulink cache file named `model.slxc`. To return a table that lists the artifacts in the Simulink cache file, you would enter:

```
info = slxcinfo('model.slxc')
```

```
info =
```

```
7x4 table
```

| Model   | Release  | Platform | Target                             |
|---------|----------|----------|------------------------------------|
| "model" | "R2020a" | "all"    | "Variable usage information"       |
| "model" | "R2020a" | "win64"  | "Rapid accelerator target"         |
| "model" | "R2020a" | "win64"  | "Accelerator target"               |
| "model" | "R2020b" | "all"    | "Variable usage information"       |
| "model" | "R2020b" | "win64"  | "Rapid accelerator target"         |
| "model" | "R2020b" | "win64"  | "Accelerator target"               |
| "model" | "R2020b" | "win64"  | "grt   Top model   Model specific" |

## Input Arguments

### filename — Name or path of Simulink cache file

character vector | string scalar

Name or path of the Simulink cache file, including the `.slxc` extension, specified as a character vector or string scalar.

Example: `slxcinfo('model.slxc')`

Data Types: `char` | `string`

## Output Arguments

### info — Simulink cache file contents

MATLAB table

Simulink cache file contents, returned as a MATLAB table.

## **Alternative Functionality**

In the Current Folder browser, double-click the Simulink cache file to open the Simulink cache report.

## **Version History**

**Introduced in R2020b**

# slxcunpack

Unpack simulation and code generation targets from Simulink cache file

## Syntax

```
info = slxcunpack(filename)
info = slxcunpack(filename,Name,Value)
```

## Description

`info = slxcunpack(filename)` unpacks the simulation and code generation artifacts from the specified Simulink cache file for the current platform and MATLAB release. Code generation artifacts must apply to the current system target file and folder configuration.

When using this function, consider these limitations:

- Do not use this function during model callbacks, model updates, simulation, or code generation. This function loads the model associated with the Simulink cache file.
- Do not use this function as part of asynchronous functions, such as `parfor` and `parfeval`.
- The contents of the Simulink cache file might be out of date. Simulation and code generation can update the artifacts on disk and in the Simulink cache file.

`info = slxcunpack(filename,Name,Value)` specifies additional options using one or more name-value pair arguments.

## Examples

### Unpack Artifacts from Simulink Cache File

Suppose you have this setup:

- R2020b MATLAB release
- 64-bit Windows operating system
- `grt.tlc` system target file — For more information, see **System target file**.
- `Model specific` code generation folder structure — For more information, see **Code generation folder structure**.

And you have two Simulink cache files:

- `topmodel.slxc` is a Simulink cache file for the top model in a model hierarchy.
- `refmodel.slxc` is a Simulink cache file for the only referenced model in the model hierarchy.

To unpack the simulation and code generation artifacts that correspond to your setup from the Simulink cache file, you would enter:

```
info = slxcunpack('topmodel.slxc')
```

```
info =
```

5×4 table

| Model      | Release  | Platform | Target                                   |
|------------|----------|----------|------------------------------------------|
| "topmodel" | "R2020b" | "win64"  | "Rapid accelerator target"               |
| "topmodel" | "R2020b" | "win64"  | "Accelerator target"                     |
| "topmodel" | "R2020b" | "win64"  | "grt   Top model   Model specific"       |
| "refmodel" | "R2020b" | "win64"  | "Model reference simulation target"      |
| "refmodel" | "R2020b" | "win64"  | "grt   Model reference   Model specific" |

The returned table lists the artifacts that the function unpacks into the **Simulation cache folder** and **Code generation folder**.

### Unpack Only Simulation Artifacts from Simulink Cache File

Suppose you have this setup:

- R2020b MATLAB release
- 64-bit Windows operating system

And you have two Simulink cache files:

- `topmodel.slxc` is a Simulink cache file for the top model in a model hierarchy.
- `refmodel.slxc` is a Simulink cache file for the only referenced model in the model hierarchy.

To unpack the simulation artifacts that correspond to your setup from the Simulink cache file and display status messages, you would enter:

```
info = slxcunpack('topmodel.slxc','Target','Simulation','Verbose',true)
```

```
Rapid accelerator target for 'topmodel': Unpacked.
Accelerator target for 'topmodel': Unpacked.
Model reference simulation target for 'refmodel': Unpacked.
```

```
info =
```

3×4 table

| Model      | Release  | Platform | Target                              |
|------------|----------|----------|-------------------------------------|
| "topmodel" | "R2020b" | "win64"  | "Rapid accelerator target"          |
| "topmodel" | "R2020b" | "win64"  | "Accelerator target"                |
| "refmodel" | "R2020b" | "win64"  | "Model reference simulation target" |

The returned table lists the artifacts that the function unpacks into the **Simulation cache folder**.

## Input Arguments

### filename — Name of Simulink cache file

character vector | string scalar

Name of the Simulink cache file, including the `.slxc` extension, specified as a character vector or string scalar.

---

**Note** The Simulink cache file must be in the **Simulation cache folder**, which, by default, is the current working folder (`pwd`).

---

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `slxcunpack('model.slxc','Target','Simulation')`

### Target — Type of target to unpack

`'All'` (default) | `'Simulation'` | `'CodeGeneration'`

Type of target to unpack, specified as the comma-separated pair consisting of `'Target'` and `'All'`, `'Simulation'`, or `'CodeGeneration'`. If `'All'`, the function unpacks both simulation and code generation targets.

The unpacked simulation targets can be accelerator targets, rapid accelerator targets, and model reference simulation targets.

Data Types: `char` | `string`

### UnpackReferencedModels — Option to unpack referenced model targets

`true` (default) | `false`

Option to unpack referenced model targets, specified as the comma-separated pair consisting of `'UnpackReferencedModels'` and `true` or `false`. If `true`, the function also unpacks the Simulink cache files that correspond to referenced models.

Data Types: `logical`

### Verbose — Option to display status messages

`false` (default) | `true`

Option to display status messages, specified as the comma-separated pair consisting of `'Verbose'` and `true` or `false`.

Data Types: `logical`

## Output Arguments

### info — Unpacked Simulink cache file contents

MATLAB table

Unpacked Simulink cache file contents, returned as a MATLAB table.

## Version History

Introduced in R2020b

# solverprofiler.profileModel

Examine model for performance analysis using the Solver Profiler programmatic interface

## Syntax

```
res = solverprofiler.profileModel(model)
res = solverprofiler.profileModel(model, Name, Value)
```

## Description

`res = solverprofiler.profileModel(model)` runs the Solver Profiler on the specified model and stores the results in `res`.

`res = solverprofiler.profileModel(model, Name, Value)` specifies the Solver Profiler parameters using one or more `Name, Value` arguments.

## Examples

### Examine a Model with Default Settings

Examine the model `f14` using the default settings.

```
model = 'f14';
res = solverprofiler.profileModel(model);
```

Inspect the summary of the results.

```
res.summary

struct with fields:

 solver: 'ode45'
 tStart: 0
 tStop: 60
 absTol: 1.0000e-06
 relTol: 1.0000e-04
 hMax: 0.1000
 hAverage: 0.0444
 steps: 1352
 profileTime: 0.9974
 zcNumber: 0
 resetNumber: 600
 jacobianNumber: 0
 exceptionNumber: 195
```

Open the results in the Solver Profiler to visualize them. This step is equivalent to enabling `OpenSP` when calling the function.

```
solverprofiler.exploreResult(res)
```

## Configure Solver Profiler and Examine a Model

Examine the model `ssc_actuator_custom_pneumatic` with a fully specified configuration.

```
model = 'ssc_actuator_custom_pneumatic';
res = solverprofiler.profileModel(model, ...
 'SaveStates' , 'On' , ...
 'SaveZCSignals' , 'On' , ...
 'SaveSimscapeStates' , 'On' , ...
 'SaveJacobian' , 'On' , ...
 'StartTime' , 5 , ...
 'StopTime' , 50 , ...
 'BufferSize' , 10000 , ...
 'TimeOut' , 5 , ...
 'OpenSP' , 'On' , ...
 'DataFullFile' , fullfile(pwd, 'ssc_profiling_result.mat'));
```

## Input Arguments

### **model** — Name of model to profile

string | character vector

Name of model to profile, specified as a string or a character vector.

Example: `h = solverprofiler.profileModel('vdp')`

### **Name-Value Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'StartTime',0,'StopTime',10,'SaveStates','On'`

### **SaveStates** — Save model states to file

off (default) | on

By default, the profiler does not save the states of the model. Enabling this parameter configures the profiler to save the states to a MAT-file.

Example: `'SaveStates','On'`

### **SaveSimscapeStates** — Save Simscape states to file

off (default) | on

Enable this parameter to save Simscape states to a MAT-file.

Example: `'SaveSimscapeStates','On'`

### **SaveJacobian** — Save model Jacobian

off (default) | on

Option to log the solver Jacobian matrices to memory. This option is useful for simulations that use implicit solvers. For a comparison of solvers, see “Compare Solvers”.

Example: `'SaveJacobian','On'`

**SaveZCSignals — Save zero-crossing signal to MAT file**

off (default) | on

Option to save the zero-crossing signal to a MAT file, specified as either 'off' or 'on'.

Example: 'SaveZCSignals', 'On'

**StartTime — Profiler start time**

model start time (default) | scalar

Time, in seconds, of the simulation that the profiler starts analyzing the model. This is not the same as the start time of the simulation.

Example: 'StartTime', 5

**StopTime — Profiler stop time**

model stop time (default) | scalar

Time, in seconds, of the simulation to which the profiler should profile the model. By default, the analysis continues until the end of the simulation. Changing this parameter does not change the stop time of the model which you specify in the Model Configuration Parameters.

A value less than the configured stop time of the model stops the profiling and simulation at **StopTime**.

Example: 'StopTime', 30

**BufferSize — Memory impact of logging**

50000 (default) | positive scalar

Maximum number of events that are logged. If the number of logged events reaches this value and memory is available, increase **BufferSize**. If memory is limited, consider lowering the value.

Example: 'BufferSize', 60000

**TimeOut — Maximum time to wait for solver to resume**

positive scalar

Time, in seconds, to wait before the profiler stops running. This option is useful in situations where the simulation is unable to proceed. The profiler waits for the specified time and quits if no progress has been made.

Example: 'TimeOut', 10

**OpenSP — Open the Solver Profiler dialog box**

off (default) | on

Option to open the Solver Profiler dialog box after profiling has completed.

Example: 'OpenSP', 'On'

**DataFullFile — Path and name of saved results**

character vector of full file path

By default, the profiling results are saved in a MAT-file named `model_@_dd_Month_yyyy_hh_mm_ss.mat` in the current working folder. You can specify a different file name by which to save the results in the current working folder. To save the file in a different location, specify the full path of the file, including the file name.

Example: 'DataFullFile', 'C:\Users\myusername\Documents\profiled\vdpr\_results.mat'

## Output Arguments

### res — High-level summary of profiling results

structure

Profiling results, returned as a structure with the fields:

### file — Full path and name of saved results

character vector

Path and name of the MAT-file where the results of the profiling operation are stored as MAT file. By default, they are stored in the current working folder with a file name having the pattern: `model_@_dd_Month_yyyy_hh_mm_ss.mat`. To store them in a different location or by a different name, specify `DataFullFile` when calling `solverprofiler.profileModel`.

### summary — Summary of profiling results

structure

A high-level summary of the results of the profiling operation, returned as a structure. The summary provides an overview of the performance of the simulation and health of the model.

The summary structure contains these fields.

| Field               | Purpose                          | Values                                          | Description                                                                                                                                                                                                                    |
|---------------------|----------------------------------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>solver</code> | Solver used by simulation        | any of the solvers supported by Solver Profiler | Solver used by the simulation as configured in the Configuration Parameters for the model. For a list of all the solvers, see <code>Solver</code> . The Solver Profiler does not support models without any continuous states. |
| <code>tStart</code> | Start time of simulation         | scalar                                          | Start time, in seconds, for the simulation of the model during the profiling operation.                                                                                                                                        |
| <code>tStop</code>  | Stop time of simulation          | scalar                                          | Stop time, in seconds, of the simulation during the profiling operation. If <code>StopTime</code> is set to be earlier than the configured <code>StopTime</code> of the model, the simulation stops at <code>StopTime</code> . |
| <code>absTol</code> | Absolute tolerance of the solver | positive scalar                                 | Absolute tolerance of the solver as specified in the configuration settings for the model. For more information, see <code>Absolute tolerance</code>                                                                           |
| <code>relTol</code> | Relative tolerance of the solver | positive scalar                                 | Relative tolerance of the solver as specified in the configuration settings of the model. For more information, see <code>Relative tolerance</code>                                                                            |
| <code>hMax</code>   | Maximum step size                | positive scalar                                 | Largest time step that the solver can take. See <code>Max step size</code> .                                                                                                                                                   |

| Field           | Purpose                        | Values             | Description                                                                                                                                                                                                                                                    |
|-----------------|--------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hAverage        | Average step size              | positive scalar    | Average size of the time step taken by the solver.                                                                                                                                                                                                             |
| steps           | Total steps taken              | positive scalar    | Total number of time steps taken by the solver.                                                                                                                                                                                                                |
| profile Time    | Time to profile                | positive scalar    | Time, in seconds, taken by the Solver Profiler to examine the model.                                                                                                                                                                                           |
| zcNumber        | Total number of zero crossings | nonnegative scalar | Number of times zero crossings occur during the simulation of the model. The detection of these zero crossings incurs computational cost and can slow down the simulation. For information on zero-crossing detection, see “Zero-Crossing Detection”.          |
| resetNumber     | Number of solver resets        | nonnegative scalar | Number of times the solver has to reset its parameters.                                                                                                                                                                                                        |
| jacobiannNumber | Number of Jacobian updates     | nonnegative scalar | Number of times the solver Jacobian matrix is updated during a simulation. For more information, see “Explicit Versus Implicit Continuous Solvers”.                                                                                                            |
| exceptionNumber | Number of solver exceptions    | nonnegative scalar | Total number of solver exceptions encountered during a simulation. These exceptions are events where the solver is unable to solve the model states to the specified accuracy. As a result, the solver runs adjusted trials which increase computational cost. |

Data Types: struct

## Version History

Introduced in R2017b

“Choose a Solver”

## start\_simulink

Start Simulink without opening any windows

### Syntax

```
start_simulink
```

### Description

`start_simulink` starts Simulink without opening any models, the Start Page, or the Simulink Library Browser. Use this in startup scripts to start Simulink without any other window taking the focus away from the MATLAB Desktop. For example, use `start_simulink` in the MATLAB `startup.m` file, when starting MATLAB with the `-r` command line option, or in project startup scripts. Opening a model for the first time in a MATLAB session is much quicker after running `start_simulink`.

If you want to open the Simulink Start Page to create or open models, use the `simulink` function instead.

If you want to open the Library Browser, use `sLibraryBrowser`.

### Examples

#### Start Simulink When Starting MATLAB

Use the `-r` command line option to start Simulink when starting MATLAB, without opening any windows.

On Windows, in the operating system prompt, enter:

```
"matlabroot\bin\win64\matlab.exe" -r start_simulink
```

Alternatively, create a desktop shortcut. Right-click the desktop and select **New > Shortcut**.

On Linux and Mac, enter:

```
matlab -r start_simulink
```

# stringtype

Create string data type

## Syntax

```
string = stringtype(maximum_length)
stringtype(maximum_length)
```

## Description

`string = stringtype(maximum_length)` creates a Simulink string data type with a maximum length. Alternatively, you can also create string data types using the String Constant, String Concatenate, and Compose String blocks.

`stringtype(maximum_length)` creates a Simulink string data type with a maximum length that you can type directly on the MATLAB command line or in the **Output data type** parameter of the String Constant, String Concatenate, or Compose String block.

---

**Tip** Specifying `stringtype(0)` creates a string data type with no maximum length. This syntax is the same as specifying `string` for Simulink block data types.

---

## Examples

### Create a String Data Type of Maximum Length 10

Create a string data type of maximum length 10.

```
h=stringtype(10)
```

h =

StringType with properties:

```
MaximumLength: 10
Description: ''
DataScope: 'Auto'
HeaderFile: ''
```

## Input Arguments

### maximum\_length — Maximum length

scalar

Maximum length of string data type, specified as a scalar, from 1 to 32766. This value can be an integer, MATLAB variable, or MATLAB expression.

Data Types: double

## Output Arguments

**string** — String data type object

scalar

String object, specified as a scalar.

## Version History

**Introduced in R2018a**

## trim

Find trim point of dynamic system

### Syntax

```
[x,u,y,dx] = trim('sys')
[x,u,y,dx] = trim('sys',x0,u0,y0)
[x,u,y,dx] = trim('sys',x0,u0,y0,ix,iu,iy)
[x,u,y,dx] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx)
[x,u,y,dx,options] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx,options)
[x,u,y,dx,options] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx,options,t)
```

### Description

---

**Note** `trim` provides only basic trimming functionality. For full trimming functionality, use Simulink Control Design software. For more information, see “Compute Steady-State Operating Points” (Simulink Control Design).

---

A trim point, also known as an equilibrium point, is a point in the parameter space of a dynamic system at which the system is in a steady state. For example, a trim point of an aircraft is a setting of its controls that causes the aircraft to fly straight and level. Mathematically, a trim point is a point where the system's state derivatives equal zero. `trim` starts from an initial point and searches, using a sequential quadratic programming algorithm, until it finds the nearest trim point. You must supply the initial point implicitly or explicitly. If `trim` cannot find a trim point, it returns the point encountered in its search where the state derivatives are closest to zero in a min-max sense; that is, it returns the point that minimizes the maximum deviation from zero of the derivatives. `trim` can find trim points that meet specific input, output, or state conditions, and it can find points where a system is changing in a specified manner, that is, points where the system's state derivatives equal specific nonzero values.

`[x,u,y,dx] = trim('sys')` finds the equilibrium point of the model 'sys', nearest to the system's initial state, `x0`. Specifically, `trim` finds the equilibrium point that minimizes the maximum absolute value of `[x-x0,u,y]`. If `trim` cannot find an equilibrium point near the system's initial state, it returns the point at which the system is nearest to equilibrium. Specifically, it returns the point that minimizes `abs(dx)` where `dx` represents the derivative of the system. You can obtain `x0` using this command.

```
[sizes,x0,xstr] = sys([],[],[],0)
```

`[x,u,y,dx] = trim('sys',x0,u0,y0)` finds the trim point nearest to `x0`, `u0`, `y0`, that is, the point that minimizes the maximum value of

```
abs([x-x0; u-u0; y-y0])
```

`[x,u,y,dx] = trim('sys',x0,u0,y0,ix,iu,iy)` finds the trim point closest to `x0`, `u0`, `y0` that satisfies a specified set of state, input, and/or output conditions. The integer vectors `ix`, `iu`, and `iy` select the values in `x0`, `u0`, and `y0` that must be satisfied. If `trim` cannot find an equilibrium point that satisfies the specified set of conditions exactly, it returns the nearest point that satisfies the conditions, namely,

```
abs([x(ix)-x0(ix); u(iu)-u0(iu); y(iy)-y0(iy)])
```

`[x,u,y,dx] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx)` finds specific nonequilibrium points, that is, points at which the system's state derivatives have some specified nonzero value. Here, `dx0` specifies the state derivative values at the search's starting point and `idx` selects the values in `dx0` that the search must satisfy exactly.

`[x,u,y,dx,options] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx,options)` specifies an array of optimization parameters that `trim` passes to the optimization function that it uses to find trim points. The optimization function, in turn, uses this array to control the optimization process and to return information about the process. `trim` returns the `options` array at the end of the search process. By exposing the underlying optimization process in this way, `trim` allows you to monitor and fine-tune the search for trim points.

The following table describes how each element affects the search for a trim point. Array elements 1, 2, 3, 4, and 10 are particularly useful for finding trim points.

| No. | Default                   | Description                                                                                                    |
|-----|---------------------------|----------------------------------------------------------------------------------------------------------------|
| 1   | 0                         | Specifies display options. 0 specifies no display; 1 specifies tabular output; -1 suppresses warning messages. |
| 2   | $10^{-4}$                 | Precision the computed trim point must attain to terminate the search.                                         |
| 3   | $10^{-4}$                 | Precision the trim search goal function must attain to terminate the search.                                   |
| 4   | $10^{-6}$                 | Precision the state derivatives must attain to terminate the search.                                           |
| 5   | N/A                       | Not used.                                                                                                      |
| 6   | N/A                       | Not used.                                                                                                      |
| 7   | N/A                       | Used internally.                                                                                               |
| 8   | N/A                       | Returns the value of the trim search goal function ( $\lambda$ in goal attainment).                            |
| 9   | N/A                       | Not used.                                                                                                      |
| 10  | N/A                       | Returns the number of iterations used to find a trim point.                                                    |

| 12  | 0                         | Not used.                                                                                                      |
| 13  | 0                         | Number of equality constraints.                                                                                |
| 14  | 100*(Number of variables) | Maximum number of function evaluations to use to find a trim point.                                            |
| 15  | N/A                       | Not used.                                                                                                      |
| 16  | $10^{-8}$                 | Used internally.                                                                                               |
| 17  | 0.1                       | Used internally.                                                                                               |
| 18  | N/A                       | Returns the step length.                                                                                       |

`[x,u,y,dx,options] = trim('sys',x0,u0,y0,ix,iu,iy,dx0,idx,options,t)` sets the time to `t` if the system is dependent on time.

---

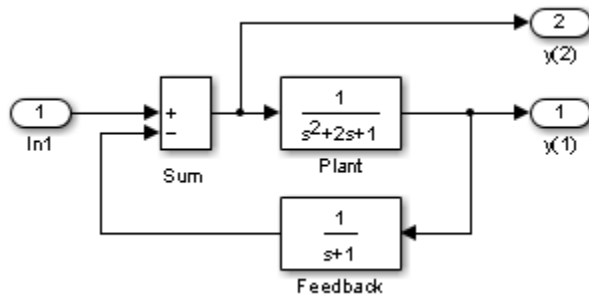

**Note** If you fix any of the state, input or output values, `trim` uses the unspecified free variables to derive the solution that satisfies these constraints.

---

## Examples

### Finding Steady-State Points

The Simulink `trim` function uses a model to determine steady-state points of a dynamic system that satisfy input, output, and state conditions that you specify. Consider, for example, this model, called `ex_lmod`.

You can use the `trim` function to find the values of the input and the states that set both outputs to 1. First, make initial guesses for the state variables ( $x$ ) and input values ( $u$ ), then set the desired value for the output ( $y$ ).

```
x = [0; 0; 0];
u = 0;
y = [1; 1];
```

Use index variables to indicate which variables are fixed and which can vary.

```
ix = []; % Don't fix any of the states
iu = []; % Don't fix the input
iy = [1;2]; % Fix both output 1 and output 2
```

Invoking `trim` returns the solution. Your results might differ because of roundoff error.

```
[x,u,y,dx] = trim('lmod',x,u,y,ix,iu,iy)
```

```
x =
 0.0000
 1.0000
 1.0000
u =
 2
y =
 1.0000
 1.0000
dx =
 1.0e-015 *
 -0.2220
 -0.0227
 0.3331
```

Note that there might be no solution to equilibrium point problems. If that is the case, `trim` returns a solution that minimizes the maximum deviation from the desired result after first trying to set the derivatives to zero. For a description of the `trim` syntax, see `trim`.

### Finding Equilibrium Points

Consider a linear state-space system modeled using a State-Space block

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx + Du\end{aligned}$$

The  $A$ ,  $B$ ,  $C$ , and  $D$  matrices to enter at the command line or in the block parameters dialog are:.

```
A = [-0.09 -0.01; 1 0];
B = [0 -7; 0 -2];
C = [0 2; 1 -5];
D = [-3 0; 1 0];
```

#### Example 1

To find an equilibrium point in this model called `sys`, use:

```
[x,u,y,dx,options] = trim('sys')
x =
 0
 0
u =
 0
 0
y =
 0
 0
dx =
 0
 0
```

The number of iterations taken is:

```
options(10)
ans =
 7
```

#### Example 2

To find an equilibrium point near  $x = [1;1]$ ,  $u = [1;1]$ , enter

```
x0 = [1;1];
u0 = [1;1];
[x,u,y,dx,options] = trim('sys', x0, u0);
x =
 1.0e-13 *
 -0.5160
 -0.5169
u =
 0.3333
 0.0000
y =
 -1.0000
```

```

 0.3333
dx =
 1.0e-12 *
 0.1979
 0.0035

```

The number of iterations taken is

```

options(10)
ans =
 25

```

### Example 3

To find an equilibrium point with the outputs fixed to 1, use:

```

y = [1;1];
iy = [1;2];
[x,u,y,dx] = trim('sys', [], [], y, [], [], iy)
x =
 0.0009
 -0.3075
u =
 -0.5383
 0.0004
y =
 1.0000
 1.0000
dx =
 1.0e-15 *
 -0.0170
 0.1483

```

### Example 4

To find an equilibrium point with the outputs fixed to 1 and the derivatives set to 0 and 1, use

```

y = [1;1];
iy = [1;2];
dx = [0;1];
idx = [1;2];
[x,u,y,dx,options] = trim('sys', [], [], y, [], [], iy, dx, idx)
x =
 0.9752
 -0.0827
u =
 -0.3884
 -0.0124
y =
 1.0000
 1.0000
dx =
 0.0000
 1.0000

```

The number of iterations taken is

```
options(10)
ans =
 13
```

## Limitations

The trim point found by `trim` starting from any given initial point is only a local value. Other, more suitable trim points may exist. Thus, if you want to find the most suitable trim point for a particular application, it is important to try a number of initial guesses for  $x$ ,  $u$ , and  $y$ .

## Algorithms

`trim` uses a sequential quadratic programming algorithm to find trim points. See “Sequential Quadratic Programming (SQP)” (Optimization Toolbox) for a description of this algorithm.

## Version History

Introduced before R2006a

# tunablevars2parameterobjects

Create Simulink parameter objects from tunable parameters

## Syntax

```
tunablevars2parameterobjects ('modelName')
tunablevars2parameterobjects ('modelName', class)
```

## Description

`tunablevars2parameterobjects ('modelName')` creates `Simulink.Parameter` objects in the base workspace for the variables listed in the specified model's Tunable Parameters dialog, then deletes the source information from the dialog. To preserve the information, save the resulting Simulink parameter objects into a MAT-file.

If a tunable variable is already defined as a numeric variable in the base workspace, the variable will be replaced by a parameter object and the original variable will be copied to the object's Value property.

If a tunable variable is already defined as a Simulink parameter object, the object will not be modified but the information for the variable will still be deleted from the Tunable Parameters dialog.

If a tunable variable is defined as any other class of variable, the variable will not be modified and the information for the variable will not be deleted from the Tunable Parameters dialog.

`tunablevars2parameterobjects ('modelName', class)` creates objects of the specified class rather than `Simulink.Parameter` objects.

## Input Arguments

### **modelName**

Model name or handle

### **class**

Parameter class to use for creating objects

**Default:** `Simulink.Parameter`

## Version History

**Introduced in R2007b**

# Upgrade Advisor

Improve and upgrade models to the current release

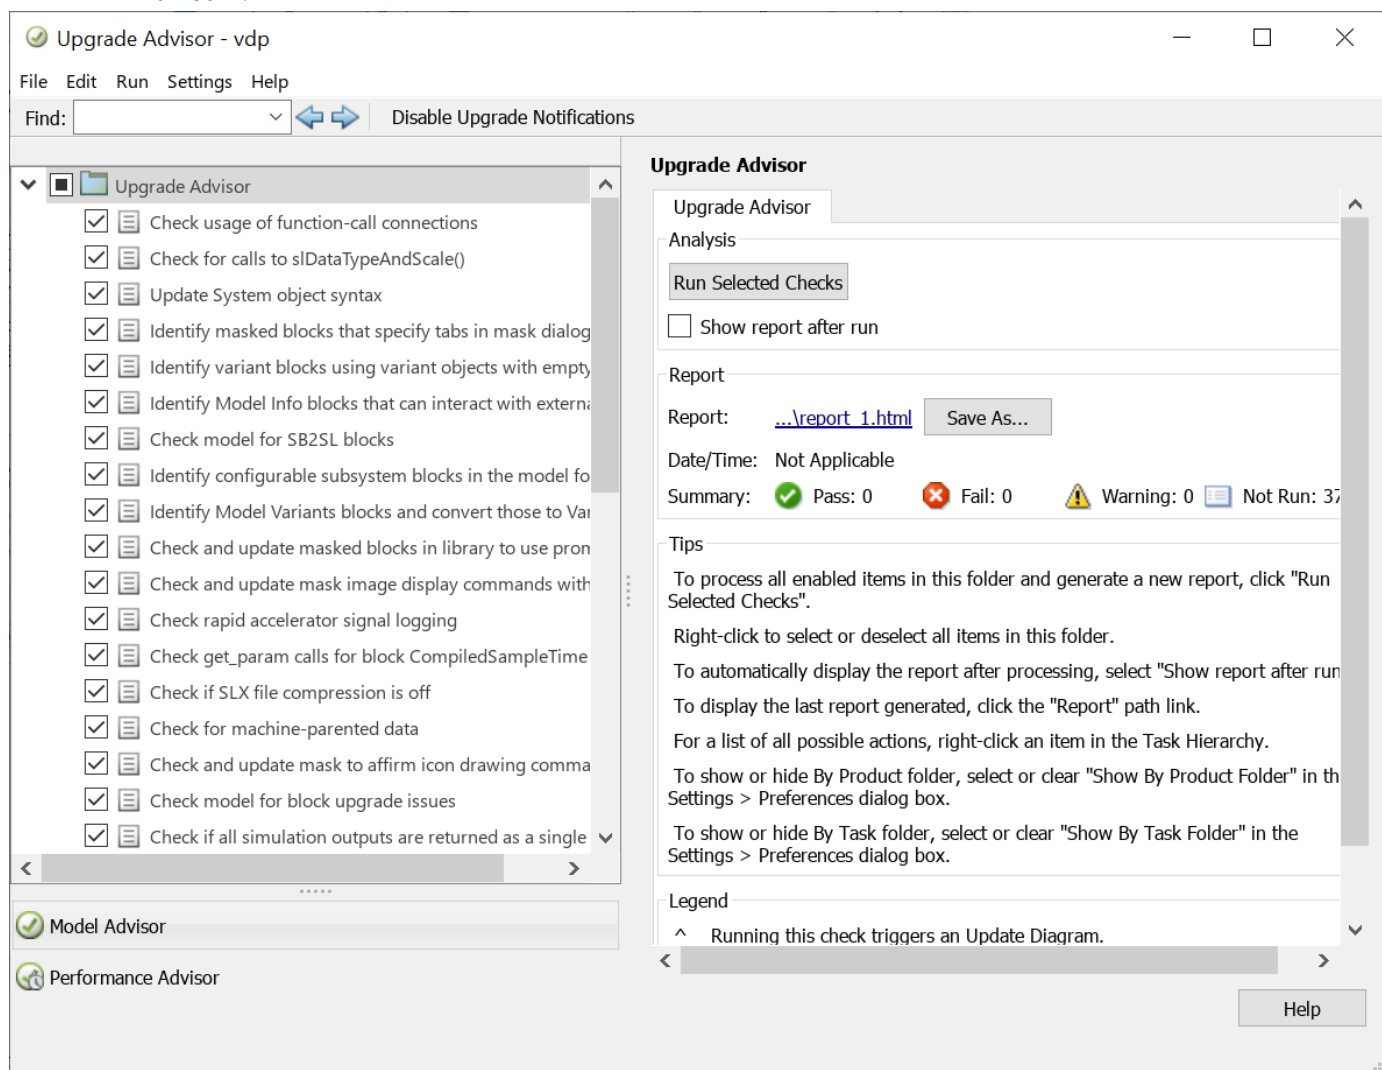

## Description

Use the **Upgrade Advisor** to improve and upgrade your models to the current release.

The Upgrade Advisor helps you:

- Identify models that no longer work because of behavior changes or improvements in Simulink.
- Identify models that you can enhance by using newly released features and settings in Simulink.
- Transition to new technologies and upgrade a model hierarchy by performing automatic upgrades or providing instructions for manual fixes.

For more information about using Upgrade Advisor with your models, see “Consult the Upgrade Advisor”.

## Open the Upgrade Advisor

- Simulink Editor: On the **Modeling** tab, select **Model Advisor > Upgrade Advisor**.
- MATLAB Command Window:
 

```
upgradeadvisor("modelname")
```
- Model Advisor: In the Model Advisor, click **Upgrade Advisor**.

## Examples

### Programmatically Open Upgrade Advisor

- 1 Open the Upgrade Advisor for the vdp example model.
 

```
openExample("vdp.slx");
upgradeadvisor("vdp")
```
- 2 Open the Upgrade Advisor for the currently selected model.
 

```
upgradeadvisor(bdroot)
```

### Programmatically Analyze and Upgrade Model

This example shows how to analyze and upgrade your model, and then apply automatic fixes when they are available.

1. Load your model and create an `upgrader` object.

```
load_system("sldemo_mdref_depgraph.slx");
upgrader = upgradeadvisor("sldemo_mdref_depgraph.slx")

upgrader =
 Upgrader with properties:

 ChecksToSkip: {}
 SkipLibraries: 0
 SkipBlocksets: 1
 OneLevelOnly: 0
 ShowReport: 1
 VerboseLogging: 0
 RootModel: 'sldemo_mdref_depgraph'
 ReportFile: ''
```

Run "upgrade" on this Upgrader object to analyze and automatically upgrade your models.

2. Analyze the model for recommended upgrades, following library links and model references.

```
analyze(upgrader);

Build duration: 0h 0m 0.98152s

```

3. Specify an output to find the location of the report.

```
reportLocation = upgrader.ReportFile;
```

4. Configure options before you analyze or upgrade your model.

- To skip a check, in the Upgrade Advisor, right-click the check, select **Send Check ID to Workspace**, and set the ChecksToSkip property.

```
upgrader.ChecksToSkip = {"mathworks.design.CSStoVSSConvert"};
```

- To analyze or upgrade the current model without analyzing library links, model references, or test harnesses that are saved as external models, enable the OneLevelOnly property.

```
upgrader.OneLevelOnly = true;
```

- To analyze or upgrade the current model and model references but not library links, enable the SkipLibraries property.

```
upgrader.SkipLibraries = true;
```

- To analyze and upgrade the current models and files in blocksets or toolboxes, set the disable the SkipBlocksets property. By default, the Upgrade Advisor does not upgrade files in blocksets or toolboxes. The Upgrade Advisor detects blocksets from the output of the ver function and the existence of the Contents file.

```
upgrader.SkipBlocksets = false;
```

- To turn off showing the report after you analyze or upgrade your model, disable the ShowReport property.

```
upgrader.ShowReport = false;
```

5. Upgrade the model and apply automatic fixes when they are available.

```
upgrade(upgrader);
```

```

The Upgrade Advisor displays the list of found issues and automatic fixes.

The Upgrade Advisor saves fixes to the model files.

- “Consult the Upgrade Advisor”
- “Run Model Advisor Checks”
- “Upgrade Simulink Models Using a Project” on page 13-500

## Programmatic Use

`upgradeadvisor("modelname")` opens the Upgrade Advisor for the model specified by `modelname`. This command loads the model if necessary, but does not open it in the Simulink Editor. Use the Upgrade Advisor to upgrade and improve models with features in the current release.

`upgrader = upgradeadvisor("modelname")` returns an object that you can use to analyze and upgrade a hierarchy of models programmatically. If you specify an output, then the Upgrade Advisor does not open. You can use the `analyze` and `upgrade` object functions with the `upgrader` object that the `upgradeadvisor` function returns.

- To programmatically analyze a model for recommended upgrades, create an `upgrader` object and use the `analyze` object function.
- To programmatically analyze and upgrade a model, create an `upgrader` object and use the `upgrade` object function.
- For information about how to configure options before you analyze or upgrade your model, see “Programmatically Analyze and Upgrade Model” on page 2-1244.

## Tips

For an example that shows how to upgrade your entire project, see “Upgrade Simulink Models Using a Project” on page 13-500.

# view\_mdhrefs

Analyze and visualize model referencing dependencies without library dependencies

## Syntax

```
view_mdhrefs(sys)
```

## Description

`view_mdhrefs` opens the Dependency Analyzer with library dependencies omitted. To open a specific configuration of the Dependency Analyzer, use `depview` with programmatic options. The Dependency Analyzer provides the same options regardless of how you open it.

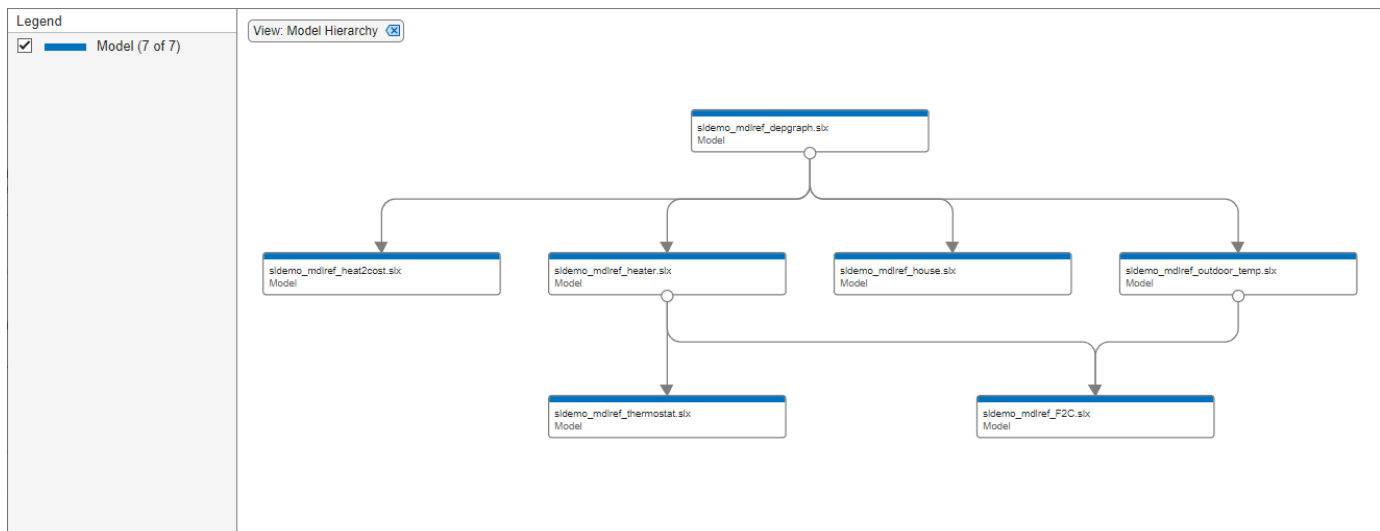

`view_mdhrefs(sys)` opens the Dependency Analyzer. It displays a graph of model referencing dependencies for the specified model. The nodes in the graph represent Simulink models. The directed lines indicate model dependencies.

## Examples

### Open Dependency Analyzer without Library Dependencies

Open the Dependency Analyzer for the `sldemo_mdhref_depgraph` model.

```
view_mdhrefs('sldemo_mdhref_depgraph');
```

## Input Arguments

**sys** — Model name or path  
character vector

The full name or path of a model, specified as a character vector.

Data Types: char

## **Version History**

**Introduced before R2006a**

# addCrossPortConstraint

Create cross-port constraint among ports of the same masked block

## Syntax

```
maskObj.addCrossPortConstraint(
crossPortConsObj),maskObj.addCrossPortConstraint(Name=Value)
```

## Description

`maskObj.addCrossPortConstraint(crossPortConsObj),maskObj.addCrossPortConstraint(Name=Value)` creates cross-port constraint with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### **crossPortConsObj** — Cross-port constraint object

`Simulink.Mask.CrossPorConstraint` object (default)

Cross-port constraint object, specified as a `Simulink.Mask.CrossPortConstraint` object.

Data Types: `char` | `string` | `cell`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

```
maskObj.addCrossPortConstraint(Name='CheckDimensions',Rule='SameDimension'...
,ParameterConditions={'Name','checkCrossPortDimension','Values',{'on'}},...
Associations={'Input_1','Input_2'},DiagnosticLevel='error',...
DiagnosticMessage="The inputs to the masked block must be of same
dimensions")
```

### **Name** — Name of constraint

character vector (default)

Name of cross-port constraint, specified as a character vector.

Data Types: `char` | `string`

### **Rule** — Rule for constraint

`Same Dimension` (default) | `Same Datatype`

Rule for the cross-port constraint, specified as a character vector.

Data Types: `char` | `string`

**ParameterConditions — Parameter conditions for cross-port constraint**

Simulink.Mask.ParameterCondition object (default)

Mask parameter conditions, specified as an object of Simulink.Mask.ParameterCondition.

Data Types: char | string

**Associations — Associate port identifiers to the cross-port constraints**

cell array (default)

Associate port identifiers with cross-port constraints, specified as a cell array. Separate identifiers with commas.

Data Types: cell

**DiagnosticLevel — Type of diagnostic message**

error (default) | warning

Type of diagnostic message displayed when validation condition fails, specified as error or warning.

Data Types: char | string

**DiagnosticMessage — Diagnostic message**

error (default) | warning

Diagnostic message to display when validation fails, specified as character vector.

Data Types: char | string

## Examples

**Add Cross Port Constraint**

This example shows how to create cross port constraint programmatically using cross port constraint object and name=value pair arguments.

**Create Cross Port Constraint Using Name=Value Pair**

```

new_system('crossportconstraint');
add_block('built-in/subsystem','crossportconstraint/subsystem');
save_system;
open_system('crossportconstraint');
% Create mask
maskObj= Simulink.Mask.create(gcb);
% Add a mask parameter to create parameter condition
maskObj.addParameter(Name='checkCrossPortDimension',Type='edit');
% Create port identifiers to associate it to the cross port constraint
maskObj.addPortIdentifier(Name='Input_1',Type='Input',IdentifierType='index',Identifier='1');
maskObj.addPortIdentifier(Name='Input_2',IdentifierType='name',Identifier='Input_2');
maskObj.addPortIdentifier(Name='Output_1',Type='Output',IdentifierType='index',Identifier='1');
% Create cross port constraint
maskObj.addCrossPortConstraint(Name='CheckDimensions',Rule='SameDimension'...
 ,ParameterConditions={'Name','checkCrossPortDimension','Values',{'on'}},...
 Associations={'Input_1','Input_2'},DiagnosticLevel='error',...
 DiagnosticMessage="The inputs to the masked block must be of same dimensions")

ans =
 CrossPortConstraint with properties:

```

```

 Name: 'CheckDimensions'
 Rule: 'SameDimension'
ParameterConditions: [1x1 Simulink.Mask.ParameterCondition]
 Associations: {2x1 cell}
 DiagnosticLevel: 'error'
 DiagnosticMessage: 'The inputs to the masked block must be of same dimensions'

```

## Create Cross Parameter Constraint Using Object of Simulink.Mask.CrossPortConstraint

```

% Create an instance of Simulink.Mask.CrossPortConstraint
crossPortConst = Simulink.Mask.CrossPortConstraint;
% Set the properties of the object using dot notation
crossPortConst.Name = 'CheckDatatype';
crossPortConst.Rule = 'SameDatatype';
crossPortConst.Associations = {'Input_1','Input_2','Output_1'};
crossPortConst.DiagnosticLevel = 'error';
crossPortConst.DiagnosticMessage = 'The Input_1 and Output_1 should have same Datatype';
maskObj.addCrossPortConstraint(crossPortConst)

```

```

ans =
 CrossPortConstraint with properties:

 Name: 'CheckDatatype'
 Rule: 'SameDatatype'
ParameterConditions: [0x0 Simulink.Mask.ParameterCondition]
 Associations: {3x1 cell}
 DiagnosticLevel: 'error'
 DiagnosticMessage: 'The Input_1 and Output_1 should have same Datatype'

```

```
save_system;
```

## Version History

## getCrossPortConstraint

Display attributes of cross-port constraint

### Syntax

```
amaskobj.getCrossPortConstraint(name)
```

### Description

`amaskobj.getCrossPortConstraint(name)` displays the attributes of a cross-port constraint.

### Input Arguments

#### **name** — Name of cross-port constraint

character vector (default)

Name of cross-port constraint, specified as a character vector. If the cross-port constraint does not exist, the software returns an error.

Data Types: `char` | `string`

### Examples

#### **View Cross-Port Constraint**

View the attributes of a cross-port constraints of a mask object.

```
%Get mask object and view cross port constraints
```

```
amaskobj.getCrossPortConstraint('CheckDatatype')
```

```
ans =
```

```
 CrossPortConstraint with properties:
```

```
 Name: 'CheckDatatype'
 Rule: 'SameDataType'
ParameterConditions: [0×0 Simulink.Mask.ParameterCondition]
 Associations: {3×1 cell}
 DiagnosticLevel: 'error'
DiagnosticMessage: 'The Input_1 and Output_1 should have same DataType'
```

## Version History

## removeCrossPortConstraint

Remove cross-port constraint

### Syntax

```
maskobj.removeCrossPortConstraint(Name)
```

### Description

`maskobj.removeCrossPortConstraint(Name)` removes cross-port constraint from the mask object.

### Input Arguments

#### Name — Name of cross-port constraint

character vector (default)

Name of cross-port constraints removed from the mask object, specified as a character vector. If the port constraint does not exist, the software returns an error.

Data Types: `char` | `string`

### Examples

#### Remove Cross Port Constraint

```
amaskobj = Simulink.Mask.get('myModel/Subsystem');
amaskobj.removeCrossPortConstraint('CheckDatatype');
```

Constraints 'CheckDatatype' is not available in the block 'myModel/Subsystem'.

### Version History

Introduced in R2023a

# removeAllCrossPortConstraints

Remove all cross-port constraints from mask object

## Syntax

```
maskobj.removeAllCrossPortConstraints()
```

## Description

`maskobj.removeAllCrossPortConstraints()` removes all cross-port constraints from the mask object.

## Examples

### Remove All Cross Port Constraints

```
amaskobj = Simulink.Mask.get('myModel/Subsystem');
amaskobj.removeAllCrossPortConstraints();
amaskobj.getCrossPortConstraint('CheckDimensions');
```

Constraints 'CheckDimensions' is not available in the block 'myModel/Subsystem'.

# Simulink.Mask.Constraints.convertMatToXML

**Package:** Simulink

Convert shared constraints from MAT to XML file format

## Syntax

```
Simulink.Mask.Constraints.convertMatToXML(matFileName,xmlFileName)
```

## Description

`Simulink.Mask.Constraints.convertMatToXML(matFileName,xmlFileName)` convert a MAT file containing constraints into an XML file.

## Examples

### Convert Mat to XML File Format

Specify the name of the MAT file, `exampleSharedConstraints` and the XML file, `sharedConstraintsfile` as the argument to the method.

```
Simulink.Mask.Constraints.convertMatToXML('exampleSharedConstraints'...
, 'sharedConstraintsfile')
```

## Input Arguments

### **matFileName** — Name of MAT file

character vector (default) | string

Name of the MAT file that contains the shared constraints, specified as a character vector or string.

Data Types: char | string

### **xmlFileName** — Name of XML file

character vector (default) | string

Name of the XML file, specified as a character vector or string.

Data Types: char | string

## Version History

Introduced in R2023a

## See Also

## addConstraint

**Package:** Simulink

Add constraint to XML file

### Syntax

```
fileobj.addConstraint(constraint)
```

### Description

`fileobj.addConstraint(constraint)` adds a constraint in XML file format. Constraint is a `Simulink.Mask.Constraints` object that you must first create by using `saveConstraints`.

### Examples

#### Add Constraint to XML File

Create a `Simulink.Mask.Constraint` object to create a parameter constraint.

```
constraintObj = Simulink.Mask.Constraints;
```

Assign a name to the constraint.

```
constraintObj.Name = 'numericconst';
```

Add parameter constraint rules to the constraint.

```
constraintObj.AddParameterConstraintRule('DataTypes',{'numeric'},'Fraction',{'integer'});
```

Create a `Simulink.Mask.SharedConstraintFile` object to add constraint to an XML file.

```
% fileobj is an object of Simulink.Mask.SharedConstraintFile
fileobj = Simulink.Mask.SharedConstraintFile;
fileobj.FileName = "sharedconstraint";
fileobj.addConstraint(constraint)
```

```
ans =
```

```
Constraints with properties:
```

```
 Name: 'numericconst'
ConstraintRules: [1x1 Simulink.Mask.ParameterConstraintRules]
```

### Input Arguments

#### **constraint** — Parameter constraint

`Simulink.Mask.Constraints` object (default)

Parameter constraint, specified as a `Simulink.Mask.Constraints` object. Save the constraint using `saveConstraints`.

Data Types: cell

## **Version History**

**Introduced in R2023a**

### **See Also**

`Simulink.Mask.SharedConstraintFile` | `Simulink.Mask.Constraints` | `removeConstraint` | `saveConstraints`

### **Topics**

“Share Parameter Constraints Across Multiple Block Masks”

## saveConstraints

Saves the constraint in the XML file

### Syntax

```
fileobj.saveConstraints()
```

### Description

`fileobj.saveConstraints()` saves a constraint in an XML file in the current directory. Use an instance of `Simulink.Mask.SharedConstraintFile`, `fileobj` to save the constraint in the XML file.

### Examples

#### Save Shared Constraint in XML File

Save a shared constraint as an XML file by using a `Simulink.Mask.SharedConstraintFile` object.

```
fileobj.saveConstraints()
```

### Version History

Introduced in R2023a

### See Also

`Simulink.Mask.SharedConstraintFile` | `addConstraint` | `removeConstraint` | `Simulink.Mask.Constraints`

### Topics

“Share Parameter Constraints Across Multiple Block Masks”

# removeConstraint

**Package:** Simulink

Remove specified constraint from XML file

## Syntax

```
fileobj.removeConstraint(constraintName)
```

## Description

Use an instance of `Simulink.Mask.SharedConstraintFile`, `fileobj` to remove the specified constraint from the XML file. `fileobj.removeConstraint(constraintName)` removes the specified constraint from the XML file.

## Examples

### Remove Specified Constraint from XML File

Create an object, `fileobj` of `Simulink.Mask.SharedConstraintFile` to remove the constraint from the XML file.

```
fileobj.removeConstraint('numericconst')
```

## Input Arguments

### **constraintName** — Name of constraint

character vector (default) | string

Name of the constraint present in the XML file, specified as a character vector.

Data Types: char | string

## Version History

Introduced in R2023a

## See Also

`Simulink.Mask.SharedConstraintFile` | `addConstraint` | `Simulink.Mask.Constraints` | `saveConstraints`

# Mask Icon Drawing Commands

---

|            |                                                                 |
|------------|-----------------------------------------------------------------|
| color      | Change drawing color of subsequent mask icon drawing commands   |
| disp       | Display text on masked subsystem icon                           |
| dpoly      | Display transfer function on masked subsystem icon              |
| droots     | Display transfer function on masked subsystem icon              |
| fprintf    | Displays variable text centered on masked subsystem icon        |
| image      | Display RGB image on masked subsystem icon                      |
| patch      | Draw color patch of specified shape on masked subsystem icon    |
| plot       | Draw graph connecting series of points on masked subsystem icon |
| port_label | Draw port label on masked subsystem icon                        |
| text       | Display text at specific location on masked subsystem icon      |
| block_icon | Promote a block icon image to the masked Subsystem              |

## color

Change drawing color of subsequent mask icon drawing commands

### Syntax

```
color(colorstr)
```

### Description

`color(colorstr)` sets the drawing color of all subsequent mask drawing commands to the color specified by the string `colorstr`.

### Examples

#### Set the Drawing Color of all Subsequent Mask Drawing Commands

Set the colors cyan and magenta in the mask icon of the Subsystem.

```
color('cyan');
droots([-1], [-2 -3], 4)
color('magenta')
port_label('input',1,'in')
port_label('output',1,'out')
```

### Input Arguments

**colorstr** — Color for the mask drawing commands is specified as string

blue | green | red | cyan | magenta | yellow | black

Entering any other string or specifying the color using RGB values results in a warning at the MATLAB command prompt. Simulink ignores the color change. The specified drawing color does not influence the color used by the `patch` or `image` drawing commands.

Data Types: `string`

## Version History

Introduced in R2006b

### See Also

`droots` | `port_label`

## disp

Display text on masked subsystem icon

### Syntax

```
disp(text)
disp(text, 'texmode', 'on')
```

### Description

`disp(text)` displays *text* centered on the block icon. *text* is any MATLAB expression that evaluates to a string.

`disp(text, 'texmode', 'on')` allows you to use TeX formatting commands in *text*. The TeX formatting commands in turn allow you to include symbols and Greek letters in icon text. See "Interpreter" for information on the TeX formatting commands supported by Simulink software.

### Examples

The following command

```
disp('\itEquation: \alpha^2 + \beta^2 \rightarrow \gamma^2, \chi, \phi_3 = cool', 'texmode', 'on')
```

draws the equation that appears on this masked block icon.

Equation

## Version History

Introduced in R2007a

### See Also

`fprintf` | `port_label` | `text`

## dpoly

Display transfer function on masked subsystem icon

### Syntax

```
dpoly(num, den)
```

```
dpoly(num, den, 'character')
```

### Description

`dpoly(num, den)` displays the transfer function whose numerator is *num* and denominator is *den*.

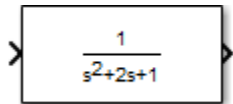

`dpoly(num, den, 'character')` specifies the name of the transfer function independent variable. The default is *s*.

When Simulink draws the block icon, the initialization commands execute and the resulting equation appears on the block icon, as in the following examples:

- To display a continuous transfer function in descending powers of *s*, enter

```
dpoly(num, den)
```

For example, for `num = [0 0 1]`; and `den = [1 2 1]` the icon looks like:

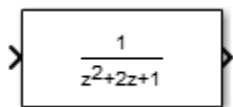

$$\frac{1}{s^2 + 2s + 1}$$

- To display a discrete transfer function in descending powers of *z*, enter

```
dpoly(num, den, 'z')
```

For example, for `num = [0 0 1]`; and `den = [1 2 1]`; the icon looks like:

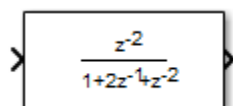

$$\frac{1}{z^2 + 2z + 1}$$

- To display a discrete transfer function in ascending powers of  $1/z$ , enter

```
dpoly(num, den, 'z-')
```

For example, for *num* and *den* as defined previously, the icon looks like:

$$\frac{z^{-2}}{1 + 2z^{-1} + z^{-2}}$$

If the parameters are not defined or have no values when you create the icon, Simulink software displays three question marks (? ? ?) in the icon. When you define parameter values in the Mask

Settings dialog box, Simulink software evaluates the transfer function and displays the resulting equation in the icon.

**See Also**

`disp` | `port_label` | `text` | `droots`

## droots

Display transfer function on masked subsystem icon

### Syntax

```
droots(zero, pole, gain)
droots(zero, pole, gain, 'z')
droots(zero, pole, gain, 'z-')
```

### Description

`droots(zero, pole, gain)` displays the transfer function whose *zero* is *zero*, *pole* is *pole*, and *gain* is *gain*.

`droots(zero, pole, gain, 'z')` and `droots(zero, pole, gain, 'z-')` expresses the transfer function in terms of *z* or  $1/z$ .

When Simulink draws the block icon, the initialization commands execute and the resulting equation appears on the block icon, as in the following examples:

- To display a zero-pole gain transfer function, enter

```
droots(z, p, k)
```

For example, the preceding command creates this icon for these values:

```
z = []; p = [-1 -1]; k = 1;
```

If the parameters are not defined or have no values when you create the icon, Simulink software displays three question marks (? ? ?) in the icon. When you define parameter values in the Mask Settings dialog box, Simulink software evaluates the transfer function and displays the resulting equation in the icon.

## Version History

Introduced in R2007a

### See Also

`disp` | `port_label` | `text` | `dpoly`

# fprintf

Displays variable text centered on masked subsystem icon

## Syntax

```
fprintf(text)
fprintf(formatspec,var)
```

## Description

`fprintf(text)` command displays formatted text centered on the icon .

`fprintf(formatspec,var)` formats `var` as specified in `formatSpec`.

## Examples

### Display Text on the Block Icon

Display the text Hello on the icon.

```
fprintf('Hello');
```

### Display Formatted Text on the Block Icon

Convert the character a to an integer 97 and display it on the block icon.

```
myvar = 'a'
fprintf('hello = %d',myvar);
```

## Input Arguments

### text — Text that appears on the block

(default) | string

Text that appears on the block is specified as string

Data Types: `char` | `string`

### formatspec — Formatting character for the variable

(default) | string

Conversion character for the variable is specified.

## Formatting Operator

A formatting operator starts with a percent sign, %, and ends with a conversion character. It is mandatory to specify the conversion character. Optionally, you can specify identifier, flags, field width, precision, and subtype operators between % and the conversion character. Spaces are invalid between operators and are shown here only for readability.

### Conversion Character

This table shows conversion characters to format numeric and character data as text.

| Value Type            | Conversion | Details                                                                                                                             |
|-----------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Integer, signed       | %d or %i   | Base 10                                                                                                                             |
| Integer, unsigned     | %u         | Base 10                                                                                                                             |
|                       | %o         | Base 8 (octal)                                                                                                                      |
|                       | %x         | Base 16 (hexadecimal), lowercase letters a-f                                                                                        |
|                       | %X         | Same as %x, uppercase letters A-F                                                                                                   |
| Floating-point number | %f         | Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)                            |
|                       | %e         | Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)      |
|                       | %E         | Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.) |
|                       | %g         | The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)        |
|                       | %G         | The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)        |
| Characters or strings | %c         | Single character                                                                                                                    |
|                       | %s         | Character vector or string array. The type of the output text is the same as the type of formatSpec.                                |

Data Types: char | string

**var** — Variable containing the value is specified

(default) | string

The variable is formatted as per the formatting character specified in formatSpec.

**Note** While this `fprintf` function is identical in name to its corresponding MATLAB function, it provides only the functionality described on this page.

## image

Display RGB image on masked subsystem icon

### Syntax

```
image(a)
image(a, position)
image(a, position, rotation)
```

### Description

`image(a)` displays the image *a*, where *a* is an *m*-by-*n*-by-3 array of RGB values. If necessary, use the MATLAB commands `imread` and `ind2rgb` to read and convert bitmap files (such as GIF) to the necessary matrix format.

`image(a, position)` creates the image at the specified position as follows.

| Position                    | Description                                                                                                                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[x, y, w, h]</code>   | Position ( <i>x</i> , <i>y</i> ) and size ( <i>w</i> , <i>h</i> ) of the image where the position is relative to the lower-left corner of the mask. The image scales to fit the specified size. |
| <code>'center'</code>       | Center of the mask                                                                                                                                                                              |
| <code>'top-left'</code>     | Top left corner of the mask, unscaled                                                                                                                                                           |
| <code>'bottom-left'</code>  | Bottom left corner of the mask, unscaled                                                                                                                                                        |
| <code>'top-right'</code>    | Top right corner of the mask, unscaled                                                                                                                                                          |
| <code>'bottom-right'</code> | Bottom right corner of the mask, unscaled                                                                                                                                                       |

`image(a, position, rotation)` allows you to specify whether the image rotates (`'on'`) or remains stationary (`'off'`) as the icon rotates. The default is `'off'`.

---

**Note** Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` (full version) cannot be used as block mask images.

---

### Examples

You can use different commands depending on your requirement to add an image. These commands can be added in the **Icon & Ports** pane of the Mask Editor dialog box.

| Syntax                                                                              | Description                                                                               |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <code>image('icon.jpg')</code>                                                      | Reads the icon image from a JPEG file named <code>icon.jpg</code> in the MATLAB path.     |
| <code>[data, map]=image('label.gif');</code><br><code>pic=ind2rgb(data,map);</code> | Reads and converts a GIF file, <code>label.gif</code> , to the appropriate matrix format. |
| <code>image(pic)</code>                                                             | Reads the converted label image.                                                          |

## **Version History**

Introduced before R2006a

### **See Also**

patch | plot

## patch

Draw color patch of specified shape on masked subsystem icon

### Syntax

```
patch(x, y)
patch(x, y, [r g b])
```

### Description

`patch(x, y)` creates a solid patch having the shape specified by the coordinate vectors `x` and `y`. The patch's color is the current foreground color.

`patch(x, y, [r g b])` creates a solid patch of the color specified by the vector `[r g b]`, where `r` is the red component, `g` the green, and `b` the blue. For example,

```
patch([0 .5 1], [0 1 0], [1 0 0])
```

creates a red triangle on the mask's icon.

### Examples

The command

```
patch([0 .5 1], [0 1 0], [1 0 0])
```

creates a red triangle on the mask's icon.

## Version History

Introduced before R2006a

### See Also

`image` | `plot`

# plot

Draw graph connecting series of points on masked subsystem icon

## Syntax

```
plot(Y)
plot(X1,Y1,X2,Y2,...)
```

## Description

`plot(Y)` plots, for a vector  $Y$ , each element against its index. If  $Y$  is a matrix, it plots each column of the matrix as though it were a vector.

`plot(X1,Y1,X2,Y2,...)` plots the vectors  $Y1$  against  $X1$ ,  $Y2$  against  $X2$ , and so on. Vector pairs must be the same length and the list must consist of an even number of vectors.

Plot commands can include `NaN` and `inf` values. When Simulink software encounters `NaNs` or `infs`, it stops drawing, and then begins redrawing at the next numbers that are not `NaN` or `inf`. The appearance of the plot on the icon depends on the units defined by the **Icon units** option in the Mask Editor.

Simulink software displays three question marks (? ? ?) in the block icon and issues warnings in these situations:

- When you have not defined values for the parameters used in the drawing commands (for example, when you first create the mask, but have not yet entered values in the Mask Settings dialog box)
- When you enter a masked block parameter or drawing command incorrectly

The `plot` command in masking supports a subset of the syntax of the MATLAB `plot` command. The `plot` command in masking supports all numeric data types and accepts only numbers as input.

## Examples

The command

```
plot([0 1 5], [0 0 4])
```

generates the plot that appears on the icon for the Ramp block, in the Sources library.

## Version History

Introduced before R2006a

**See Also**  
image

## port\_label

Draw port label on masked subsystem icon

### Syntax

```
port_label('port_type', port_number, 'label')
port_label('port_type', port_number, 'label', 'texmode', 'on')
```

### Description

`port_label('port_type', port_number, 'label')` draws a label on a port. Valid values for `port_type` include the following.

| Value   | Description                                                                          |
|---------|--------------------------------------------------------------------------------------|
| input   | Simulink input port                                                                  |
| output  | Simulink output port                                                                 |
| lconn   | Physical Modeling connection port on the left side of a masked subsystem             |
| rconn   | Physical Modeling connection port on the right side of a masked subsystem            |
| reset   | Label for the reset port in a masked Resettable Subsystem.                           |
| Enable  | Label for the enable port in a masked Triggered or Enabled and Triggered subsystem.  |
| trigger | Label for the trigger port in a masked Triggered or Enabled and Triggered subsystem. |
| action  | Label for the action port in a masked Switch Case Action Subsystem.                  |

The input argument `port_number` is an integer, and `label` is text specifying the port's label.

---

**Note** Physical Modeling port labels are assigned based on the nominal port location. If the masked subsystem has been rotated or flipped, for example, a port labeled using 'lconn' as the `port_type` may not appear on the left side of the block.

---

`port_label('port_type', port_number, 'label', 'texmode', 'on')` lets you use TeX formatting commands in `label`. The TeX formatting commands allow you to include symbols and Greek letters in the port label. See “Interpreter” for information on the TeX formatting commands that the Simulink software supports.

---

**Note** Simulink does not support LaTeX formatting commands.

---

### Examples

The command

```
port_label('input', 1, 'a')
```

defines **a** as the label of input port 1.

The command

```
port_label('reset', 'R')
```

defines **R** as the label of reset port.

The command

```
port_label('Enable', 'En')
```

defines **En** as the label of Enable port.

The command

```
port_label('trigger', 'Tr')
```

defines **Tr** as the label of trigger port.

The command

```
port_label('action', 'Switch():')
```

defines **Switch():** as the label of action port.

The command

```
port_label('trigger', '\surd m', 'interpreter', 'tex')
```

defines the label of trigger port with TeX interpretation.

The commands

```
disp('Card\nSwapper');
port_label('input', 1, '\spadesuit', 'texmode', 'on');
port_label('output', 1, '\heartsuit', 'texmode', 'on');
```

draw playing card symbols as the labels of the ports on a masked subsystem.

## **Version History**

**Introduced before R2006a**

## **See Also**

disp | fprintf | text

## text

Display text at specific location on masked subsystem icon

### Syntax

```
text(x, y, 'text')
text(x, y, 'text', 'horizontalAlignment', 'halign',
 'verticalAlignment', 'valign')
text(x, y, 'text', 'texmode', 'on')
```

### Description

The `text` command places a character vector at a location specified by the point  $(x, y)$  whose units are defined by the **Icon units** option in the Mask Editor.

`text(x, y, text, 'texmode', 'on')` allows you to use TeX formatting commands in `text`. The TeX formatting commands in turn allow you to include symbols and Greek letters in icon text. See “Interpreter” for information on the TeX formatting commands supported by Simulink software.

You can optionally specify the horizontal and/or vertical alignment of the text relative to the point  $(x, y)$  in the `text` command.

The `text` command offers the following horizontal alignment options.

| Option   | Aligns                                           |
|----------|--------------------------------------------------|
| 'left'   | The left end of the text at the specified point  |
| 'right'  | The right end of the text at the specified point |
| 'center' | The center of the text at the specified point    |

The `text` command offers the following vertical alignment options.

| Option   | Aligns                                               |
|----------|------------------------------------------------------|
| 'base'   | The baseline of the text at the specified point      |
| 'bottom' | The bottom line of the text at the specified point   |
| 'middle' | The midline of the text at the specified point       |
| 'cap'    | The capitals line of the text at the specified point |
| 'top'    | The top of the text at the specified point           |

---

**Note** While this `text` function is identical in name to its corresponding MATLAB function, it provides only the functionality described on this page.

---

### Examples

## Text Alignment

Center the mask icon text foobar.

```
text(0.5, 0.5, 'foobar', 'horizontalAlignment', 'center')
```

## Equation in Mask Icon

Draw a left-aligned equation as the mask icon.

In the Icons & Ports dialog of the Mask Editor, set **Icon units** to Normalized.

In the **Icon drawing commands** text box, enter the following command.

```
text(.05,.5,'\itEquation:} \Sigma \alpha^2 +
\beta^2 \rightarrow \infty, \Pi, \phi_3 = {\bfcool}',
'hor','left','texmode','on')
```

Equation

## Version History

Introduced before R2006a

## **block\_icon**

Promote a block icon image to the masked Subsystem

### **Syntax**

```
block_icon(BlockName)
```

### **Description**

`block_icon(BlockName)` displays the underneath block icon image on the masked Subsystem icon. For more information, see “Draw Mask Icon Using Drawing Commands” .

### **Input Arguments**

#### **BlockName — Name of the underneath block**

`string`

The name of the underneath block whose icon image you want to display on the Subsystem block that encapsulates the specified block. For more information, see “Draw Mask Icon Using Drawing Commands”

Data Types: `string`

### **Version History**

**Introduced in R2006b**

### **See Also**

`simulink.mask` | “Draw Mask Icon Using Drawing Commands”

# Simulink Debugger Commands

---

## ashow

Identify and highlight algebraic loops in simulation debugging session

### Syntax

```
ashow
ashow blk
ashow aloop
ashow clear
```

### Description

`ashow` displays in the MATLAB Command Window a list of algebraic loops in the model for the current simulation debugging session.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

`ashow blk` displays in the MATLAB Command Window information about the algebraic loop that contains the block `blk`. When the block `blk` is part of an algebraic loop, this command also highlights the algebraic loop that contains the block `blk` in the block diagram.

`ashow aloop` displays in the MATLAB Command Window information about the algebraic loop `aloop` and highlights the algebraic loop in the block diagram.

`ashow clear` removes algebraic loop highlighting from the block diagram.

### Examples

#### Examine Algebraic Loops in Simulation Debugging Session

Use the `ashow` function to examine algebraic loops in the model `sldemo_hydcyl`.

Open the model `sldemo_hydcyl`.

```
openExample("simulink_general/sldemo_hydcylExample",...
 supportingFile="sldemo_hydcyl.slx")
```

Start a simulation debugging session for the model using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`((sldebug @0): >> )`).

```
sldebug sldemo_hydcyl
```

```
(sldebug @0): >>
```

Use the `step` function to step to the first method in the first major time step for the simulation.

```
step top
```

```
%-----%
[TM = 0] sldemo_hydcyl.Outputs.Major
```

Use the `ashow` function to show a list of algebraic loops in the model.

```
ashow
```

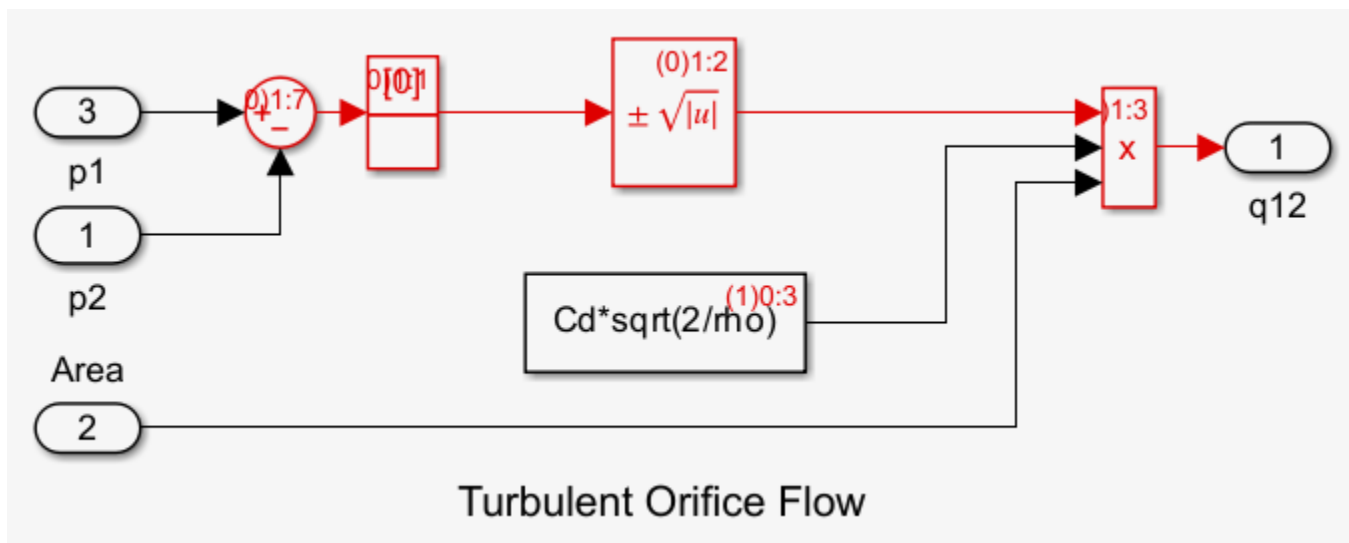

```
Found 1 Algebraic loop(s):
System number#Algebraic loop id, number of blocks in loop
- (0)0#1, 9 block(s) in loop
```

Use the algebraic loop identifier in the information returned by the `ashow` function to get more information about the algebraic loop. The `ashow` function lists the paths to the nine blocks in the loop and identifies which blocks correspond to algebraic variables in the loop.

```
ashow (0)0#1
```

```
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/IC
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/Sqrt
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/Product
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/laminar flow pressure drop
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Sum7
- sldemo_hydcyl/Pump/IC
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/Sum1 (algebraic variable)
- sldemo_hydcyl/Pump/Sum1
- sldemo_hydcyl/Pump/leakage (algebraic variable)
```

The `ashow` function also highlights the specified loop in the block diagram. In this model, the loop includes blocks in two different levels of the model hierarchy so only the blocks in the Control Valve Flow masked subsystem are visible.

When you have finished analyzing and debugging the model, use the `stop` function to end the simulation debugging session.

stop

### Input Arguments

#### **blk** — Block in model

(t)s:b | gcb

Block in model, specified as one of these options:

- gcb — Current block
- (t)s:b — Block ID, where **t** is the index of the task that contains the block, **s** is the index of the system that contains the block, and **b** is the block index

.

#### **alloop** — Algebraic loop

algebraic loop ID

Algebraic loop, specified as an algebraic loop ID. Algebraic loop IDs have the form (t)s#n, where **t** is the index of the task that contains the algebraic loop, **s** is the index of the system that contains the algebraic loop, and **n** is the index of the algebraic loop in the system.

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the **stop** command, are available for use in the MATLAB Command Window.

## Version History

Introduced before R2006a

### See Also

sldebug | atrace

### Topics

“Simulink Debugging Programmatic Interface”

## atrace

Configure simulation debugging session to display information each time algebraic loop is solved

### Syntax

```
atrace lvl
```

### Description

`atrace lvl` configures the simulation debugging session to display information each time an algebraic loop is solved in the simulation. Specify the level of information to display using the `lvl` input argument.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the `'debug'` name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Input Arguments

#### `lvl` — Level of information to display

0 | 1 | 2 | 3 | 4

Level of information to display, specified as one of these options:

- 0 — No information
- 1 or 2 — Loop variable solution, number of iterations required to solve loop, estimated solution error
- 3 — All information for 1 and 2 plus the Jacobian matrix used to solve the loop
- 4 — All information for 3 plus intermediate solutions for the loop variable

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

“Simulink Debugging Programmatic Interface”

# bafter

Insert breakpoint after specified method in simulation debugging session

## Syntax

```
bafter
bafter m:mid
bafter blk
bafter blk mth tid:t
bafter mdlName blk mth tid:t
bafter sys
bafter sys mth tid:t
bafter mdl
bafter mdl mth tid:t
```

## Description

bafter inserts a breakpoint after the current method.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

`bafter m:mid` inserts a breakpoint after the method with the method ID `mid`.

`bafter blk` inserts a breakpoint after each method for the block `blk`.

`bafter blk mth tid:t` inserts a breakpoint after the method `mth` of block `blk` in the task with task ID `t`.

`bafter mdlName blk mth tid:t` inserts a breakpoint after the method `mth` of block `blk` that is executed in the task with task ID `t` in the referenced model with the name `mdlName`.

`bafter sys` inserts a breakpoint after each method in the system `sys`.

`bafter sys mth tid:t` inserts a breakpoint after the method `mth` in the system `sys` with task id `t`.

`bafter mdl` inserts a breakpoint after each method of the model `mdl`.

`bafter mdl mth tid:t` inserts a breakpoint after the method `mth` in the task with task ID `t` of model `mdl`.

## Input Arguments

### **mid** — Method after which to insert breakpoint

method ID

Method after which to insert breakpoint, specified as a method ID.

### **blk** — Block

(t)s:b | gcb

Block, specified as one of these options:

- (t)s:b — Block with index b in system with index s and task with task ID t
- gcb — Current block

### **mth** — Method name

string | character vector

Method name, specified as a string or a character vector. For example, this command sets a breakpoint before the `Outputs` method of the currently selected block.

`break` gcb `Outputs`

### **t** — Task ID

task ID

Task ID, specified as a task ID.

### **mdlName** — Name of referenced model

string | character vector

Name of referenced model, specified as a string or a character vector.

### **sys** — System

s:sysIdx | gcs

System, specified as one of these options:

- s:sysIdx — System specification, where sysIdx is the system index
- gcs — Current system

### **mdl** — Model name

string | character vector

Model name, specified as a string or a character vector.

## Tips

To determine the current location within the simulation, use the `where` function.

## Version History

Introduced before R2006a

## break

Insert breakpoint before specified method in simulation debugging session

### Syntax

```
break
break m:mid
break blk
break blk mth tid:t
break mdlName blk mth tid:t
break sys
break sys mth tid:t
break mdl
break mdl mth tid:t
```

### Description

`break` inserts a breakpoint before the current method.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

`break m:mid` inserts a breakpoint before the method with the method ID `mid`.

`break blk` inserts a breakpoint before each method for the block `blk`.

`break blk mth tid:t` inserts a breakpoint before the method `mth` of block `blk` in the task with task ID `t`.

`break mdlName blk mth tid:t` inserts a breakpoint before the method `mth` of block `blk` that is executed in the task with task ID `t` in the referenced model with the name `mdlName`.

`break sys` inserts a breakpoint before each method in the system `sys`.

`break sys mth tid:t` inserts a breakpoint before the method `mth` in the system `sys` with task id `t`.

`break mdl` inserts a breakpoint before each method of the model `mdl`.

`break mdl mth tid:t` inserts a breakpoint before the method `mth` in the task with task ID `t` of model `mdl`.

### Input Arguments

#### **mid** — Method ID

method ID

Method ID, specified as a method ID.

**blk — Block**

(t)s:b | gcb

Block, specified as one of these options:

- (t)s:b — Block with index b in system with index s and task with task ID t
- gcb — Current block

**mth — Method name**

string | character vector

Method name, specified as a string or a character vector. For example, this command sets a breakpoint before the `Outputs` method of the currently selected block.

`break` gcb `Outputs`

**t — Task ID**

task ID

Task ID, specified as a task ID.

**mdlName — Name of referenced model**

string | character vector

Name of referenced model, specified as a string or a character vector.

**sys — System**

s:sysIdx | gcs

System, specified as one of these options:

- s:sysIdx — System specification, where sysIdx is the system index
- gcs — Current system

**mdl — Model name**

string | character vector

Model name, specified as a string or a character vector.

**Tips**

To determine the current location within the simulation, use the `where` function.

**Version History**

Introduced before R2006a

# bshow

Highlight block in model with specified block ID during simulation debugging session

## Syntax

```
bshow blk
bshow mdl blk
```

## Description

`bshow blk` selects and highlights in the block diagram the block in the top model that corresponds to the block ID `blk`.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sdebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

`bshow mdl blk` selects and highlights in the block diagram the block in the referenced model `mdl` that corresponds to the block ID `blkID`.

## Input Arguments

### **blk** — Block to show

debugging session block ID

Block to show, specified as a debugging session block ID. The debugging session block ID has the form `(t)s:b`, where `t` is the index of the task that contains the block, `s` is the index of the system that contains the block, and `b` is the index of the block within the system that contains it.

For a list of block IDs in a model, use the `slist` function.

### **mdl** — Name of referenced model that contains block

string | character vector

Name of referenced model that contains block, specified as a string or a character vector.

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## **Version History**

**Introduced before R2006a**

### **See Also**

sldebug | slist

### **Topics**

“Simulink Debugging Programmatic Interface”

## clear

Clear breakpoint in simulation debugging session

### Syntax

```
clear
clear m:mid
clear brID
clear blk
```

### Description

clear clears the breakpoint from the current method.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

clear m:mid clears the breakpoint from the method with the method ID mid.

clear brID clears the breakpoint from the breakpoint with the breakpoint ID brID.

clear blk clears all breakpoints from the block blk.

### Input Arguments

#### **mid** — Method from which to remove breakpoint

method ID

Method from which to remove breakpoint, specified as a method ID.

#### **brID** — Breakpoint ID for breakpoint to remove

breakpoint ID

Breakpoint ID for breakpoint to remove, specified as a breakpoint ID.

#### **blk** — Block from which to remove all breakpoints

(t)s:b | gcb

Block from which to remove all breakpoints, specified using one of these options:

- (t)s:b — Block ID, where t is the index of the task in which the block executes, s is the index of the system that contains the block, and b is the index of the block within the system
- gcb — Current block

### Version History

Introduced before R2006a

# continue

Continue simulation debugging session

## Syntax

continue

## Description

continue continues the simulation debugging session. The simulation continues until a breakpoint pauses the simulation, you pause the simulation, or the simulation completes the final time step.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

To run the simulation to the end, ignoring breakpoints, use the `run` function.

## Version History

Introduced before R2006a

## See Also

`sldebug` | `run` | `stop` | `quit`

## Topics

“Simulink Debugging Programmatic Interface”

## disp

Display information about specified block when simulation debugging session pauses

### Syntax

```
disp blk
disp mdl blk
disp
```

### Description

`disp blk` registers a display point for the block specified by `blk`. The software displays information about all registered display points each time the simulation pauses.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

`disp mdl blk` registers a display point for the block specified by `blk` in the referenced model specified by `mdl`.

`disp` displays a list of registered display points for the current simulation debugging session.

### Input Arguments

#### **blk** — Block to register as a display point

(t)s:b | gcb

Block to register as a display point, specified as one of these options:

- (t)s:b — Block with index `b` in system with index `s` and task with index `t`
- gcb — Current block

When you specify the name of the referenced model that contains the block, you must specify the block to register as a display point in the form (t)s:b.

#### **mdl** — Name of referenced model that contains block to register as display point

string | character vector

Name of referenced model that contains block to register as display point, specified as a string or a character vector.

When you specify this argument, you must specify the block to register as a display point in the form (t)s:b.

### Tips

- To clear a registered display point, use the `undisp` function.

- The software displays the level of information configured for the simulation debugging session. To specify the level of information to display, use the `probe` function.

## **Version History**

**Introduced before R2006a**

### **See Also**

“Simulink Debugging Programmatic Interface”

## ebreak

Set or clear breakpoint to pause when solver error occurs in simulation debugging session

### Syntax

ebreak

### Description

ebreak sets or clears a breakpoint that pauses simulation when a recoverable solver error occurs during a simulation debugging session.

- If the breakpoint was not set, the command sets the breakpoint.
- If the breakpoint had been set, the command clears the breakpoint.

When you do not set this breakpoint, the solver recovers from the error and continues simulation. When an unrecoverable error occurs with or without this breakpoint set, the error stops the simulation.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

## Version History

Introduced before R2006a

# elist

Display execution order in simulation debugging session

## Syntax

```
elist m:mid
elist sys mthName tid:t
elist blk mthName tid:t
elist mdlName blk mthName tid:t
```

## Description

`elist m:mid` displays the list of methods invoked by the method with the method ID `mid` in the order in which they execute.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

`elist sys mthName tid:t` displays the list of methods invoked by the method `mthName` of the specified system `sys` that executes as part of the task with the task ID `t`.

`elist blk mthName tid:t` displays the list of methods invoked by the method `mthName` of block `blk` that executes as part of the task with task ID `t`.

`elist mdlName blk mthName tid:t` displays the list of methods invoked by the method `mthName` of block `blk` in referenced model `mdlName` that executes as part of the task with task ID `t`.

## Input Arguments

### **mid** — Method ID

positive integer

Method, specified as a positive integer.

### **sys** — System

`s:sysIdx` | `gcs`

System, specified as one of these options:

- `s:sysIdx` — System with the system index `sysIdx`
- `gcs` — Current system

**mthName — Method name**

string | character vector

Method name, specified as a string or a character vector.

**t — Task ID**

positive integer

Task ID, specified as a positive integer.

**blk — Block**

(t)s:b | gcb

Block, specified using one of these options:

- (t)s:b — Block ID, where t is the task ID for the task in which the block executes, s is the system index for the system that contains the block, and b is the index of the block within the system
- gcb — Current block

**mdlName — Name of referenced model**

string | character vector

Name of referenced model, specified as a string or a character vector.

## Tips

- To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.
- You can view the execution order for the output methods of blocks in a model using the Execution Order viewer. Using the Execution Order viewer, you can also annotate the block diagram with the execution order for the model. For more information, see “Control and Display Execution Order”.

# emode

Switch between accelerator and normal mode during simulation debugging session

## Syntax

emode

## Description

emode switches the simulation mode between accelerator mode and normal mode during a simulation debugging session.

The Simulink debugging programmatic interface supports only normal mode and accelerator mode simulations. Rapid accelerator mode is not supported.

To switch between accelerator mode and normal mode, you must start the simulation debugging session with the model in accelerator mode. Before starting the simulation debugging session, in the Simulink Toolstrip, on the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the drop-down list.

Starting a simulation debugging session in accelerator mode can speed up a simulation debugging session. For example, if you know you need to investigate the simulation after a certain simulation time, you can start the simulation debugging session in accelerator mode, specify a time breakpoint, and continue. The simulation runs faster in accelerator mode than it would in normal mode to reach the time breakpoint. Then, for access to complete debugging capabilities, you can change to normal mode.

You must switch to normal mode execution to step the simulation block by block and to use these functions:

- trace
- break
- zcbreak
- nanbreak

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sdebug` function or using the `sim` function with the 'debug' name-value argument.

---

## Examples

### Use Accelerator Mode in Simulation Debugging Session

For complex models and long simulations, accelerator mode can decrease the time required to debug a simulation. This example shows how to switch between simulation modes for a simulation of the model `vdp`.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp")
```

To use accelerator mode during a simulation debugging session, you must start the simulation debugging session with the model configured to simulate in accelerator mode. In the Simulink Toolstrip, on the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the simulation drop-down list.

Start a simulation debugging session for the model `vdp` using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
```

```
(sldebug @0): >>
```

Use the `tbreak` function to set a breakpoint for a simulation time of 5 seconds.

```
tbreak 5
```

```
Time break point : enabled (t>=5.0)
```

Use the `continue` function to progress the simulation debugging session to the time breakpoint. This portion of the simulation runs in accelerator mode.

```
continue
```

```
Interrupting model execution at time break point (tbreak 5)
%-----%
[Tm = 5.0073507114851168] vdp.Outputs.Minor
```

Only a subset of the debugging capabilities are available while the model runs in accelerator mode. To use the full Simulink debugging programmatic interface to debug the model at this point of interest, use the `emode` function to switch to normal mode.

```
emode
```

```
Execution Mode : Normal
Normal execution mode. All break points are enabled.
```

Use the `step` function to progress the simulation. This portion of the simulation debugging session runs using normal mode.

```
step top
```

```
%-----%
[TM = 5.051795155929562] vdp.Outputs.Major
```

After investigating this point of interest, you can:

- Continue the simulation debugging session in normal mode
- Set a breakpoint for another point of interest, use the `emode` function to switch back to accelerator mode, and use the `continue` function to progress the simulation to the point of interest

- Use the `stop` function to end the simulation debugging session

## etrace

Configure simulation debugging session to display information when entering and exiting methods

### Syntax

```
etrace lvl
```

### Description

`etrace lvl` configures method tracing for certain methods according to the value you specify for `lvl`. You can configure a simulation debugging session to trace:

- No methods
- Model methods
- Model and system methods
- Model, block, and system methods

The simulation debugging session displays information each time the simulation enters or exits a traced method. The information displayed includes the current simulation time, whether the simulation entered or exited the method, the method name, the method ID, and the name of the model, system, or block to which the method belongs.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the `'debug'` name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Input Arguments

**lvl — Methods to trace**

0 | 1 | 2 | 3

Methods to trace, specified as one of these options:

- 0 — No methods
- 1 — Model methods

- 2 — Model and system methods
- 3 — Model, system, and block methods

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

# help

Display help for Simulink debugging programmatic interface during simulation debugging session

## Syntax

```
help
```

## Description

`help` displays complete help information available for the Simulink debugging programmatic interface.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. # nanbreak

Set or clear breakpoint to pause when Inf or NaN value occurs in simulation debugging session

## Syntax

nanbreak

## Description

nanbreak sets or clears a breakpoint that pauses simulation when a NaN or Inf value occurs in the model during a simulation debugging session.

- If the breakpoint was not set, the command sets the breakpoint.
- If the breakpoint had been set, the command clears the breakpoint.

The Inf or NaN value breakpoint can help locate and investigate computational issues in your model.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## probe

Display input, output, and state data for specified block in simulation debugging session

### Syntax

```
probe blk
probe mdl blk
probe level lvl
```

### Description

`probe blk` displays in the MATLAB Command Window information about the block specified by `blk`.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

`probe mdl blk` displays information about the block specified by `blk` in the model specified by `mdl`.

`probe level lvl` sets the level of detail for the information displayed when you call the `probe`, `trace`, or `disp` functions in a simulation debugging session. By default, the software displays all information about the specified block, including input, output, state, and zero-crossing information.

### Examples

#### Display Information for Currently Selected Block

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp.slx");
```

Start a simulation debugging session using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
(sldebug @0): >>
```

Use the `probe` function to view information about the current block.

```
probe gcb
```

```
probe: Data of Outport block 'vdp/Out2':
U1 = [0]
```

Use the `step` function to step to the start of the first major time step.

```
step top
```

```
%-----%
[TM = 0] vdp.Outputs.Major
```

In the block diagram, select the block `Mu`. Then use the `probe` function to view information about the currently selected block.

```
probe gcb
```

```
probe: Data of SubSystem block (virtual) 'vdp/Mu':
U1 = [0]
Y1 = [0]
```

When you have finished probing blocks, use the `stop` function to end the simulation debugging session.

```
stop
```

## Input Arguments

### **blk** — Block to probe

(t)s:b | gcb

Block to probe, specified as one of these options:

- (t)s:b — Display information about block in task with task ID `t` and system index `s` with block index `b`.
- gcb — Display information for current block.

When you specify the name of the referenced model that contains the block, you must specify the block to register as a display point in the form (t)s:b.

### **mdl** — Name of referenced model that contains block to probe

string | character vector

Name of referenced model that contains block to probe, specified as a string or a character vector.

When you specify this argument, you must specify the block to register as a display point in the form (t)s:b.

### **lvl** — Level of detail for information displayed

all (default) | io

Level of detail for information displayed, specified as one of these options:

- all — Displays input and output values as well as information about states and zero crossings.
- io — Displays only input and output values.

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## quit

End simulation debugging session

### Syntax

```
quit
```

### Description

quit ends a simulation debugging session.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

### Examples

#### Start and End Simulation Debugging Session

Use the `sldebug` function to start a simulation debugging session for the model `vdp`. Then, use the `quit` function to end the simulation debugging session.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp.slx");
```

Start a simulation debugging session using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
```

```
(sldebug @0): >>
```

Use the `quit` function to end the simulation debugging session.

```
quit
```

“Simulink Debugging Programmatic Interface”

# rbreak

Configure simulation debugging session to pause before solver reset

## Syntax

```
rbreak
```

## Description

rbreak sets or clears the solver reset breakpoint that causes the simulation debugging session to pause before each solver reset.

- If the breakpoint was not set, the command sets the breakpoint.
- If the breakpoint had been set, the command clears the breakpoint.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

### run

Run simulation debugging session from current point to end of simulation, ignoring breakpoints

### Syntax

run

### Description

run continues the simulation debugging session from the current point until the end of the simulation, ignoring breakpoints and display points. At the end of the simulation, the software exits the `sldebug` command prompt and returns to the MATLAB command prompt. To continue debugging the model, you must start a new simulation debugging session.

To continue the simulation debugging session from the current point until the simulation pauses on a breakpoint, use the `continue` function.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

# slist

Display sorted list of blocks in model during simulation debugging session

## Syntax

```
slist
```

## Description

`slist` displays in the MATLAB Command Window the sorted list of blocks in the root system and each nonvirtual subsystem or referenced model in the root system. For the root system, each nonvirtual subsystem, and each referenced model, the returned information includes:

- A title line that indicates the name of the system, the number of nonvirtual blocks in the system, and the number of blocks in the system that have ports with direct feedthrough
- An entry for each block in the system in the order in which the blocks appear in the sorted list

Each block entry includes:

- The block ID in the form of  $(t)s:b$ , where  $t$  is the task index,  $s$  is the system index, and  $b$  is the block index.
- The number and indices of input ports on the block.
- The number and indices of output ports on the block.

The `slist` function displays only nonvirtual blocks in the model. Virtual blocks do not appear in the sorted list.

When a block is part of an algebraic loop, the sorted list information also includes the algebraic loop identifier for the block. The algebraic loop identifier has the form `algID=s#n`, where  $s$  is the index of the subsystem that contains the algebraic loop and  $n$  is the index of the algebraic loop within the system. During a simulation debugging session, you can use the `ashow` function to highlight the blocks in an algebraic loop.

The software uses the sorted list to create block method execution lists for the root system, each nonvirtual subsystem, and each referenced model. Typically, the block methods are invoked in the same order that they appear in the sorted list. In some cases, the execution order does differ from the order in the sorted list. For example, in models that group blocks that execute at the same rate into separate tasks, the block execution order can differ from the order of blocks in the sorted list.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `slddebug` function
- Programmatically, using the `sim` function with the `'debug'` name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Examples

### Display Sorted List for Model

Use the `slist` function to display the sorted list for the model `vdp` in a simulation debugging session.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp")
```

Start a simulation debugging session for the model `vdp` using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
```

```
(sldebug @0): >>
```

Use the `slist` function to view the sorted list for the model.

```
slist
```

```
---- Sorted list for 'vdp' [13 nonvirtual block(s), directFeed=0]
 Total number of tasks = 2
- Sorted list of task index [0], 12 nonvirtual block(s)

```

When you have finished debugging, use the `stop` function to end the simulation debugging session.

`stop`

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## states

Display state values during simulation debugging session

### Syntax

```
states
```

### Description

`states` displays in the MATLAB Command Window the current state values for the model running in the current simulation debugging session. The information displayed for each state includes the state index, state value, and block name.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Examples

#### Display State Values During Simulation Debugging Session

Use the `states` function to display the current values for states in the model `vdp` in a simulation debugging session.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp")
```

Start a simulation debugging session for the model `vdp` using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
```

```
(sldebug @0): >>
```

Use the `states` function to view a list of states in the model and their current values.

```
states
```

```
Continuous States for 'vdp':
Idx Value (system:block:element Name 'BlockName')
 0. 0 (0:0:0 CSTATE 'vdp/x1')
 1. 0 (0:2:0 CSTATE 'vdp/x2')
```

When you have finished debugging, use the `stop` function to end the simulation debugging session.

`stop`

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## status

Display options used in current simulation debugging session

### Syntax

status

### Description

status displays in the MATLAB Command Window a list of all debugging options and the values in effect for the current simulation debugging session. Debugging options include:

- Model-wide breakpoints, such as the zero crossing breakpoint and the Inf or NaN value breakpoint
- Active display and trace points
- Level of information to display for the probe function, display points, and trace points

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## step

Advance simulation by specified increment

### Syntax

```
step
step amt
```

### Description

`step` advances the simulation to the next method in the current time step.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sdebug` function or using the `sim` function with the 'debug' name-value argument.

---

`step amt` advances the simulation by the amount specified by `amt`. For example, to advance the simulation to the first method in the next time step, specify `amt` as `top`.

```
step top
```

### Input Arguments

#### **amt** — Amount to advance simulation

`in` (default) | `over` | `out` | `top` | `blockmth`

Amount to advance simulation, specified as one of these options:

- `in` — Advance simulation to the next method in the current time step and pause before the first method within the next method. If the next method does not contain any methods, the simulation debugging session pauses at the end of the next method.
- `over` — Advance simulation over the next method in the current time step.
- `out` — Advance simulation to the end of the current simulation point in the execution hierarchy.
- `top` — Advance simulation to the first method in the next time step.
- `blk_mth` — Advance simulation to next block method.

Example: `step top` advances the simulation debugging session to the first method in the next time step.

Data Types: `char` | `string`

### Tips

After executing a block method in a programmatic simulation debugging session, the software displays this information in the MATLAB Command Window:

- Current simulation time `Tm`

- Block ID
- Next method to execute
- Block input values  $U_1, \dots, U_n$
- Block output values  $Y_1, \dots, Y_n$
- Block continuous state vector CSTATE
- Block discrete state vector DSTATE

The image shows typical Command Window output after calling the step function.

```

Current time Next method
 ↓ ↓

[tm = 2.009509145207664e-05] 0:2 Integrator.Derivatives 'vdp/x2'
(sldebug @49):
Data of 0:2 Integrator block 'vdp/x2':
U1 = [-1.9998794294512876]
Y1 = [-4.0190182904153282e-05]
CSTATE = [-4.0190182904153282e-05]

[tm = 3.014263717811496e-05] vdp.Outputs.Minor

```

# stimes

Display information about sample times in model during simulation debugging session

## Syntax

```
stimes
```

## Description

`stimes` displays in the MATLAB Command Window information about the sample times in the model that is running in the current simulation debugging session. The sample time information includes the period, offset, and task ID for each sample time.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the `'debug'` name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Examples

### Display Information About Sample Times in Model

Use the `stimes` function to display information about the sample times in the model `vdp` during a simulation debugging session.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample",...
 supportingFile="vdp")
```

Start a simulation debugging session for the model `vdp` using the `sldebug` function. The MATLAB Command Prompt (`>>`) becomes the Simulink debugger prompt (`(sldebug @0): >>`).

```
sldebug vdp
```

```
(sldebug @0): >>
```

Use the `stimes` function to display information about the sample times in the model. The model `vdp` contains three sample times.

```
stimes
```

```
--- Sample times for 'vdp' [Number of sample times = 3]
 1. tid=0 (continuous)
```

2. tid=1 (continuous but fixed-in-minor-step)
3. tid=2 (value = inf in ModelWideParameterChangeEvent)

When you have finished debugging, use the `stop` function to end the simulation debugging session.

`stop`

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

### Version History

Introduced before R2006a

“Simulink Debugging Programmatic Interface”

## stop

Stop simulation debugging session

### Syntax

stop

### Description

stop stops a simulation debugging session.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

To stop a simulation using a logical signal in your model, use the Stop Simulation block.

To stop a simulation that was started using the **Run** button or by using the `set_param` function to specify a simulation command, click the **Stop** button or use the `set_param` function to specify the stop simulation command.

```
set_param mdl, "SimulationCommand", "stop"
```

---

## Examples

### Start and Stop Debug Simulation

Start and then stop a simulation debugging session for the model `vdp`.

Open the model `vdp`.

```
openExample("simulink_general/VanDerPolOscillatorExample", ...
 supportingFile="vdp.slx")
```

Use the `sldebug` function to start the simulation debugging session for the model.

```
sldebug("vdp")
```

```
%-----%
[TM = 0] simulate(vdp)
```

The MATLAB command prompt changes from `>>` to `(sldebug @0): >>` to indicate that a debug simulation is in progress and that the Simulink debugging programmatic interface is available.

Use the `step` command to step the simulation to the start of the next major time step.

```
step top
```

```
%-----%
[TM = 0] vdp.Outputs.Major
```

You can continue using the `step` command to progress the simulation and observe the results in the Scope block.

Use the `stop` function to stop the debug simulation.

```
stop
```

```
%-----%
% Simulation stopped
```

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

# strace

Display solver information in simulation debugging session

## Syntax

```
strace lvl
```

## Description

`strace lvl` configures a simulation debugging session to display information about the solver as you step through a simulation. Specify the level of information to display using the `lvl` input argument.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

Displaying solver information in a simulation debugging session can help you determine whether choosing a different solver could improve simulation performance.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `slddebug` function
- Programmatically, using the `sim` function with the `'debug'` name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Input Arguments

### **lvl** — Level of solver information to display

scalar between 0 and 4, inclusive

Level of solver information to display, specified as a scalar between 0 and 4, inclusive. A higher value indicates a higher level of information. To stop displaying solver information in a simulation debugging session, specify the argument as 0.

## Tips

- When you configure a simulation debugging session to display solver information, the software displays several types of timing information related to the solver computations. For information about the notation, use this command.

```
help time
```

- To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

# systems

List nonvirtual subsystems in model or model hierarchy during simulation debugging session

## Syntax

```
systems
```

## Description

`systems` displays in the MATLAB Command Window a list of nonvirtual subsystems in the model or model hierarchy being simulated in the active simulation debugging session. When the active simulation debugging session is for a model hierarchy, the list of nonvirtual subsystems is grouped by model.

The `systems` function displays only nonvirtual subsystems and not virtual subsystems.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

## tbreak

Set or clear breakpoint that pauses simulation debugging session at specified time

### Syntax

```
tbreak t
```

### Description

`tbreak t` sets or clears a breakpoint that pauses simulation after the simulation reaches the specified time `t`. The simulation debugging session pauses on the `Outputs.Major` method for the model in the first time step after time `t`.

- If a breakpoint was not already set for time `t`, the command sets the breakpoint.
- If a breakpoint had been set for time `t`, the command clears the breakpoint.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sdebug` function or using the `sim` function with the 'debug' name-value argument.

---

### Input Arguments

#### **t** — Time to pause simulation debugging session

scalar

Time to pause simulation debugging session, specified as a scalar. The software pauses simulation on the `Outputs.Major` method for the model in the time step that follows the specified time.

### Version History

Introduced before R2006a

## trace

Display information about specified block each time block executes in simulation debugging session

### Syntax

```
trace blk
```

### Description

`trace blk` registers the block specified by `blk` as a trace point in the simulation debugging session. The software displays information about the block that corresponds to a trace point each time that block executes in the simulation debugging session.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Input Arguments

**blk** — Block to register as trace point

(t)s:b | gcb

Block to register as trace point, specified as one of these options:

- (t)s:b — Block with index `b` in system with index `s` and task with index `t`
- `gcb` — Current block

### Tips

- To clear a registered trace point, use the `untrace` function.
- The software displays the level of information configured for the simulation debugging session. To specify the level of information to display, use the `probe` function.
- To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

# undisp

Remove display point in simulation debugging session

## Syntax

```
undisp blk
```

## Description

`undisp blk` removes the display point for the block `blk` from the list of display points for the current simulation debugging session. The software displays information for each registered display point each time the simulation pauses.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sdebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Input Arguments

**blk** — Block that corresponds to display point to remove

(t)s:b | gcb

Block that corresponds to display point to remove, specified as one of these options:

- (t)s:b — Block ID, where `t` is the index of the task in which the block executes, `s` is the system that contains the block, and `b` is the index of the block within the system
- gcb — Current block

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

# untrace

Remove trace point in simulation debugging session

## Syntax

```
untrace blk
```

## Description

`untrace blk` removes the trace point for the block `blk` from the list of trace points for the current simulation debugging session. The software displays information about the block that corresponds to a trace point each time the block executes in the simulation debugging session.

- When you start the simulation debugging session programmatically, the information is displayed in the MATLAB Command Window.
- When you start the simulation debugging session using the Simulink Editor, the information is displayed in the Diagnostic Viewer.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sdebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

## Input Arguments

**blk** — Block that corresponds to trace point to remove

(t)s:b | gcb

Block that corresponds to trace point to remove, specified using one of these options:

- (t)s:b — Block ID where `t` is the index of the task in which the block executes, `s` is the index of the system that contains the block, and `b` is the index of the block within the system
- gcb — Current block

## Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. ## where

Display current location within simulation loop during simulation debugging session

### Syntax

where

### Description

where displays the current location within the simulation loop for the debugging session, including information about the call stack.

The display consists of a hierarchical list of simulation nodes, where the last node in the list indicates the next node the simulation will enter or the node the simulation is about to leave. Each entry in the list includes:

- The method ID
- A symbol that indicates the method status:
  - >> — Active method
  - >| — Next method simulation enters
  - <| — Method simulation is about to leave
- The name of the method invoked.
- The block ID for the block on which the method is invoked, if the method is invoked on a block.
- The name of the block or system on which the method is invoked.

```
0:0 Integrator.Outputs.Major 'vdp/x1'
```

```
0 >> simulate(vdp)
25 >> simulationPhase
28 >> vdp.Outputs.Major
29 >| 0:0 Integrator.Outputs.Major 'vdp/x1' [tid=0]
```

Method ID    Method Status    Block ID    Method Name    Block Name

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sdebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

# xbreak

Set or clear breakpoint to pause when state limits step size in simulation debugging session

## Syntax

```
xbreak
```

## Description

xbreak sets or clears a breakpoint that pauses simulation when the value of a state in the model limits the step size in a simulation debugging session that uses a variable-step solver.

- If the breakpoint was not set, the command sets the breakpoint.
- If the breakpoint had been set, the command clears the breakpoint.

The step-size limiting state breakpoint can help debug and analyze models that require more steps than expected in a variable-step simulation.

---

**Note** This function is supported only for simulation debugging sessions started programmatically using the `sldebug` function or using the `sim` function with the 'debug' name-value argument.

---

## zcbreak

Configure simulation debugging session to pause when nonsampled zero-crossing events occur

### Syntax

```
zcbreak
```

### Description

zcbreak sets or clears a breakpoint that pauses simulation when a nonsampled zero-crossing event occurs.

- If the breakpoint was not set, the command sets the breakpoint.
- If the breakpoint had been set, the command clears the breakpoint.

You can use this function in a simulation debugging session started:

- Interactively, using the Simulink Toolstrip
- Programmatically, using the `sldebug` function
- Programmatically, using the `sim` function with the 'debug' name-value argument

---

**Note** This function is available only for simulation debugging sessions started programmatically and for interactive simulation debugging sessions while paused within a time step.

---

### Tips

To start a simulation debugging session interactively, add one or more breakpoints to your model and in the **Breakpoints List**, check that **Pause within time step** is selected. When the simulation pauses on a breakpoint, some of the programmatic debugging commands, such as the `stop` command, are available for use in the MATLAB Command Window.

| Simulink.BlockPreCompInputPortData      | Provide precompilation information about block input port                                                            |
| Simulink.BlockPreCompOutputPortData     | Provide precompilation information about block output port                                                           |
| Simulink.dialog.Image                   | Create an image dialog control                                                                                       |
| Simulink.dialog.Panel                   | Create an instance of a panel dialog control                                                                         |
| Simulink.dialog.parameter.CustomTable   | Create custom tables programmatically                                                                                |
| Simulink.dialog.TabContainer            | Create an instance of a tab container dialog control                                                                 |
| Simulink.dialog.Text                    | Create a text dialog control                                                                                         |
| Simulink.GlobalDataTransfer             | Configure concurrent execution data transfers                                                                        |
| Simulink.MSFcnRunTimeBlock              | Get run-time information about Level-2 MATLAB S-function block                                                       |
| Simulink.RunTimeBlock                   | Allow Level-2 MATLAB S-function and other MATLAB programs to get information about block while simulation is running |
| Simulink.SampleTime                     | Object containing sample time information                                                                            |
| Simulink.SimulationData.BlockPath       | Fully specified Simulink block path                                                                                  |
| Simulink.SimulationData.DataStoreMemory | Container for data store logging information                                                                         |
| Simulink.SimulationData.State           | State logging element                                                                                                |
| Simulink.SimulationMetadata             | Access metadata of simulation runs                                                                                   |

## coder.BuildConfig class

**Package:** coder

Build context during code generation

### Description

The code generator creates an object of this class to facilitate access to the build context. The build context encapsulates the settings used by the code generator including:

- Target language
- Code generation target
- Target hardware
- Build toolchain

Use `coder.BuildConfig` methods in the methods that you write for the `coder.ExternalDependency` class.

### Class Attributes

Abstract true

For information on class attributes, see “Class Attributes”.

## Creation

The code generator creates objects of this class.

## Methods

### Public Methods

|                                        |                                                                            |
|----------------------------------------|----------------------------------------------------------------------------|
| <code>getHardwareImplementation</code> | Get handle of copy of hardware implementation object                       |
| <code>getStdLibInfo</code>             | Get standard library information                                           |
| <code>getTargetLang</code>             | Get target code generation language                                        |
| <code>getToolchainInfo</code>          | Returns handle of copy of toolchain information object                     |
| <code>isCodeGenTarget</code>           | Determine if build context represents specified target                     |
| <code>isMatlabHostTarget</code>        | Determine if hardware implementation object target is MATLAB host computer |

## Examples

### Use `coder.BuildConfig` methods to access the build context in `coder.ExternalDependency` methods

This example shows how to use `coder.BuildConfig` methods to access the build context in `coder.ExternalDependency` methods. In this example, you use:

- `coder.BuildConfig.isMatlabHostTarget` to verify that the code generation target is the MATLAB host. If the host is not MATLAB report an error.
- `coder.BuildConfig.getStdLibInfo` to get the link-time and run-time library file extensions. Use this information to update the build information.

Write a class definition file for an external library that contains the function `adder`.

```

=====
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
=====

classdef AdderAPI < coder.ExternalDependency
 %#codegen

 methods (Static)

 function bName = getDescriptiveName(~)
 bName = 'AdderAPI';
 end

 function tf = isSupportedContext(buildContext)
 if buildContext.isMatlabHostTarget()
 tf = true;
 else
 error('adder library not available for this target');
 end
 end

 function updateBuildInfo(buildInfo, buildContext)
 % Get file extensions for the current platform
 [~, linkLibExt, execLibExt, ~] = buildContext.getStdLibInfo();

 % Add file paths
 hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
 buildInfo.addIncludePaths(hdrFilePath);

 % Link files
 linkFiles = strcat('adder', linkLibExt);
 linkPath = hdrFilePath;
 linkPriority = '';
 linkPrecompiled = true;
 linkLinkOnly = true;
 group = '';
 buildInfo.addLinkObjects(linkFiles, linkPath, ...
 linkPriority, linkPrecompiled, linkLinkOnly, group);

 % Non-build files for packaging
 nbFiles = 'adder';
 nbFiles = strcat(nbFiles, execLibExt);
 buildInfo.addNonBuildFiles(nbFiles, '', '');
 end

 %API for library function 'adder'
 function c = adder(a, b)
 if coder.target('MATLAB')

```

```
 % running in MATLAB, use built-in addition
 c = a + b;
 else
 % Add the required include statements to the generated function code
 coder.cinclude('adder.h');
 coder.cinclude('adder_initialize.h');
 coder.cinclude('adder_terminate.h');
 c = 0;

 % Because MATLAB Coder generated adder, use the
 % housekeeping functions before and after calling
 % adder with coder.ceval.

 coder.ceval('adder_initialize');
 c = coder.ceval('adder', a, b);
 coder.ceval('adder_terminate');
 end
end
end
end
```

# coder.ExternalDependency class

**Package:** coder

Interface to external code

## Description

`coder.ExternalDependency` is an abstract class for developing an interface between external code and MATLAB code intended for code generation. You can define classes that derive from `coder.ExternalDependency` to encapsulate the interface to external libraries, object files, and C/C++ source code. This encapsulation allows you to separate the details of the interface from your MATLAB code.

To define a class derived from `coder.ExternalDependency`, create a subclass. For example:

```
classdef myClass < coder.ExternalDependency
```

You must define all of the methods listed in “Methods” on page 5-5. These methods are static and are not compiled. The code generator invokes these methods in MATLAB after code generation is complete to configure the build for the generated code. The `RTW.BuildInfo` and `coder.BuildConfig` objects that describe the build information and build context are automatically created during the build process. The `updateBuildInfo` method provides access to these objects. For more information on build information customization, see “Build Process Customization” (MATLAB Coder).

You also define methods that call the external code. These methods are compiled. For each external function that you want to call, write a method to define the programming interface to the function. In the method, use `coder.ceval` to call the external function.

## Class Attributes

Abstract true

For information on class attributes, see “Class Attributes”.

## Methods

### Public Methods

|                                                          |                                                         |
|----------------------------------------------------------|---------------------------------------------------------|
| <code>coder.ExternalDependency.getDescriptiveName</code> | Return descriptive name for external dependency         |
| <code>coder.ExternalDependency.isSupportedContext</code> | Determine if build context supports external dependency |
| <code>coder.ExternalDependency.updateBuildInfo</code>    | Update build information                                |

## Examples

### Encapsulate the Interface to an External C Dynamic Library

This example shows how to encapsulate the interface to an external C dynamic linked library using `coder.ExternalDependency`.

Write a function `adder` that returns the sum of its inputs.

```
function c = adder(a,b)
%#codegen
c = a + b;
end
```

Generate a library that contains `adder`.

```
codegen('adder', '-args', {-2,5}, '-config:dll', '-report')
```

Write the class definition file `AdderAPI.m` to encapsulate the library interface.

```
%=====
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
%=====

classdef AdderAPI < coder.ExternalDependency
 %#codegen

 methods (Static)

 function bName = getDescriptiveName(~)
 bName = 'AdderAPI';
 end

 function tf = isSupportedContext(buildContext)
 if buildContext.isMatlabHostTarget()
 tf = true;
 else
 error('adder library not available for this target');
 end
 end

 function updateBuildInfo(buildInfo, buildContext)
 % Get file extensions for the current platform
 [~, linkLibExt, execLibExt, ~] = buildContext.getStdLibInfo();

 % Add file paths
 hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
 buildInfo.addIncludePaths(hdrFilePath);

 % Link files
 linkFiles = strcat('adder', linkLibExt);
 linkPath = hdrFilePath;
 linkPriority = '';
 linkPrecompiled = true;
 linkLinkOnly = true;
 group = '';
 buildInfo.addLinkObjects(linkFiles, linkPath, ...
 linkPriority, linkPrecompiled, linkLinkOnly, group);

 % Non-build files for packaging
 nbFiles = 'adder';
 nbFiles = strcat(nbFiles, execLibExt);
 buildInfo.addNonBuildFiles(nbFiles, '', '');
 end
 end
end
```

```

end

%API for library function 'adder'
function c = adder(a, b)
 if coder.target('MATLAB')
 % running in MATLAB, use built-in addition
 c = a + b;
 else
 % Add the required include statements to the generated function code
 coder.cinclude('adder.h');
 coder.cinclude('adder_initialize.h');
 coder.cinclude('adder_terminate.h');
 c = 0;

 % Because MATLAB Coder generated adder, use the
 % housekeeping functions before and after calling
 % adder with coder.ceval.

 coder.ceval('adder_initialize');
 c = coder.ceval('adder', a, b);
 coder.ceval('adder_terminate');
 end
end
end
end
end

```

Write a function `adder_main` that calls the external library function `adder`.

```

function y = adder_main(x1, x2)
 %#codegen
 y = AdderAPI.adder(x1, x2);
end

```

Generate a MEX function for `adder_main`. The MEX Function exercises the `coder.ExternalDependency` methods.

```
codegen('adder_main', '-args', {7,9}, '-report')
```

Copy the library to the current folder using the file extension for your platform. For Windows, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dll'));
```

For Linux, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.so'));
```

Run the MEX function and verify the result.

```
adder_main_mex(2,3)
```

# eventData

Provide information about block method execution events

## Description

Simulink software creates an instance of this class when a block method execution event occurs during simulation and passes it to any listeners registered for the event (see `add_exec_event_listener`). The instance specifies the type of event that occurred and the block whose method execution triggered the event. See “Access Block Data During Simulation” for more information.

# io.reader class

**Package:** io

Base class used to define custom variable or file reader for Simulation Data Inspector

## Description

Use the `io.reader` base class to specify how to import custom variable and file formats into the **Simulation Data Inspector**. Write a class definition file that uses the `io.reader` methods to specify how to extract information like time and data values from the variable or file. Use this syntax as the first line in the class definition file to inherit from the `io.reader` class, where `MyReader` is the name of your subclass:

```
classdef MyReader < io.reader
```

For an example that shows how to write and use a custom file reader, see “Import Data Using a Custom File Reader”.

For an example that shows how to write and use a custom workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

The `io.reader` class is a `handle` class.

## Class Attributes

|                  |      |
|------------------|------|
| Abstract         | true |
| HandleCompatible | true |

For information on class attributes, see “Class Attributes”.

## Properties

### FileName — Name of imported file

'' (default) | character array

Name of imported file when using the subclass to import a file, specified as a character array.

Example: 'MyCustomFile'

### Attributes:

|           |        |
|-----------|--------|
| GetAccess | public |
| SetAccess | public |

### VariableName — Name of imported variable

'' (default) | character array

Name of imported variable or signal, specified as a character array.

Example: 'MyVar'

**Attributes:**

|           |        |
|-----------|--------|
| GetAccess | public |
| SetAccess | public |

**VariableValue — Imported variable**

variable

Imported variable. The VariableValue property has the same data type as the variable in the workspace or file. Use the VariableValue property to access the variable data inside method definitions.

Example: MyVar

**Attributes:**

|           |        |
|-----------|--------|
| GetAccess | public |
| SetAccess | public |

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | string | struct | enumerated | bus | table | cell | categorical | datetime | duration | calendarDuration | fi

# getChildren

**Class:** `io.reader`

**Package:** `io`

Return custom reader object for each node and signal in data imported using a custom reader

## Syntax

```
childObj = getChildren(obj)
```

## Description

`childObj = getChildren(obj)` returns an array of custom reader objects that correspond to hierarchical nodes and signals in data imported into the Simulation Data Inspector using a custom file or workspace reader. Use the `getChildren` method to preserve the hierarchy for imported data. When you import multiple signals from a file, you can use the `getChildren` method to import the data as a flat list of signals contained under a top-level node that corresponds to the file.

## Input Arguments

**obj — Custom data reader**

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

## Output Arguments

**childObj — Hierarchical nodes and signals**

cell array of `io.reader` subclass objects

Hierarchical nodes and signals in imported data, returned as a cell array of `io.reader` subclass objects.

## Examples

### Structure Data Imported from File

This example uses the `getChildren` method to import multiple signals from a file as a flat list of signals contained in a top-level node that represents the file. Specify code for the `getChildren` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods. For an example that shows the complete class definition and import workflow, see “Import Data Using a Custom File Reader”.

In this example, the `getChildren` method reads the data from the file using the `readtable` function. The custom reader in this example always uses the data in the first column as time, so the

first variable name is cleared and not used. The `getChildren` method creates a custom reader object for the top-level node that corresponds to the file and for each signal in the file and assigns values to the `FileName` and `VariableName` properties.

```
classdef ExcelFirstColumnTimeReader < io.reader
 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if isempty(obj.VariableName)
 t = readtable(obj.FileName);
 vars = t.Properties.VariableNames;
 vars(1) = [];
 childObj = cell(size(vars));
 for idx = 1:numel(vars)
 childObj{idx} = ExcelFirstColumnTimeReader;
 childObj{idx}.FileName = obj.FileName;
 childObj{idx}.VariableName = vars{idx};
 end
 end
 end
 end

 % ...
end
end
```

### Structure Data Imported from Workspace

This example uses the `getChildren` method to import an array of structures stored in a variable in the base workspace. Specify code for the `getChildren` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods, and workspace data readers need to define the `supportsVariable` method. For an example that shows the complete class definition and import workflow for a workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

In this example, the `getChildren` method creates a custom reader object for each structure in the input variable when the variable is an array of structures. The workspace reader in this example defines a `ChannelIndex` property that the `getChildren` method uses to identify each object it creates.

```
classdef SimpleStructReader < io.reader

 properties
 ChannelIndex
 end

 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
```

```
numChannels = numel(obj.VariableValue);
childObj = cell(numChannels,1);
for idx = 1:numChannels
 childObj{idx} = SimpleStructReader;
 childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
 childObj{idx}.VariableValue = obj.VariableValue;
 childObj{idx}.ChannelIndex = idx;
end
end
end
% ...
end
end
```

## getDataValues

**Class:** `io.reader`

**Package:** `io`

Return data values for data imported using a custom reader

### Syntax

```
dataVals = getDataValues(obj)
```

### Description

`dataVals = getDataValues(obj)` returns data values to use for data imported into the Simulation Data Inspector using a custom file or workspace variable reader. Specify code for the `getDataValues` method to extract signal values from a proprietary file or variable format.

### Input Arguments

**obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

### Output Arguments

**dataVals** — Signal values

numeric array | enum array | logical array | string array

Signal values, returned as an array of numeric, enumeration, logical, or string values. For scalar signals and wide signals, the first dimension of the array aligns with time and must match the length of the time vector returned by `getTimeValues`. For multidimensional signals, the last dimension aligns with time and must match the length of the time vector returned by `getTimeValues`.

### Attributes

Abstract true

To learn about attributes of methods, see Method Attributes.

### Examples

#### Get Signal Values for Data Imported from File

Write the function definition for the `getDataValues` method to return signal values to use for data imported from a file. The custom reader in this example imports the data from the file with a

hierarchical structure, treating the file as the top node. Specify the code for the `getDataValues` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods. For an example that shows the complete class definition and import workflow, see “Import Data Using a Custom File Reader”.

In this example, the `getChildren` method reads the data from the file using the `readtable` function and returns an array of custom reader objects for the top-level node that corresponds to the file and for each signal in the file. Then, the `getDataValues` method reads the data using the `readtable` function and selects the signal data to return for each signal in the file using the `VariableName` property of each custom reader object.

```
classdef ExcelFirstColumnTimeReader < io.reader
 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if isempty(obj.VariableName)
 t = readtable(obj.FileName);
 vars = t.Properties.VariableNames;
 vars(1) = [];
 childObj = cell(size(vars));
 for idx = 1:numel(vars)
 childObj{idx} = ExcelFirstColumnTimeReader;
 childObj{idx}.FileName = obj.FileName;
 childObj{idx}.VariableName = vars{idx};
 end
 end
 end

 function dataVals = getDataValues(obj)
 dataVals = [];
 if ~isempty(obj.VariableName)
 t = readtable(obj.FileName);
 dataVals = t.(obj.VariableName);
 end
 end

 % ...
 end
end
```

### Get Signal Values from Workspace Variable

Write the function definition for the `getDataValues` method to return signal values from a workspace variable. Specify the code executed by the `getDataValues` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods, and workspace data readers need to define the `supportsVariable` method. For an example that shows the complete class definition and import workflow for a workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

The custom reader in this example imports a structure or an array of structures from the workspace. The structures must contain fields for the signal data (*d*), the time data (*t*), and the signal name (*n*). When the variable to import is a scalar structure, the `getDataValues` method returns the data from the *d* field of the structure.

When the variable is an array of structures, the custom reader uses both the `getDataValues` and `getChildren` methods to import the data. The `getChildren` method creates a custom reader object for each structure in the array and sets the `ChannelIndex` property to identify the index of the signal data within the array. Then, the `getDataValues` method uses the `ChannelIndex` property value to select the appropriate structure from the `VariableValue` property value, which is the array of structures.

```
classdef SimpleStructReader < io.reader

 properties
 ChannelIndex
 end

 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
 numChannels = numel(obj.VariableValue);
 childObj = cell(numChannels,1);
 for idx = 1:numChannels
 childObj{idx} = SimpleStructReader;
 childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
 childObj{idx}.VariableValue = obj.VariableValue;
 childObj{idx}.ChannelIndex = idx;
 end
 end
 end

 function dataVals = getDataValues(obj)
 if isscalar(obj.VariableValue)
 dataVals = obj.VariableValue.d;
 elseif ~isempty(obj.ChannelIndex)
 varVal = obj.VariableValue(obj.ChannelIndex);
 dataVals = varVal.d;
 else
 dataVals = [];
 end
 end

 % ...
 end
end
```

## getName

**Class:** `io.reader`

**Package:** `io`

Get names for data imported using a custom reader

### Syntax

```
retName = getName(obj)
```

### Description

`retName = getName(obj)` returns the name to use in the **Simulation Data Inspector** for a signal or hierarchical node in data imported from the workspace or a file.

### Input Arguments

**obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

### Output Arguments

**retName** — Signal name

character array

Signal name used by the **Simulation Data Inspector**, returned as a character array.

### Attributes

Abstract true

To learn about attributes of methods, see Method Attributes.

### Examples

#### Get Names for Data Imported from File

Write the function definition for the `getName` method to return names for signals imported from a file. The custom reader in this example imports the data from the file with a hierarchical structure, treating the file as the top node. Specify code for the `getName` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods. For an example that shows the complete class definition and import workflow, see “Import Data Using a Custom File Reader”.

In this example, the `getName` and `getChildren` methods work together to assign the appropriate name to each imported signal. The `getChildren` method reads the data from the file using the `readtable` function. The method then constructs a cell array that contains a custom reader object for each signal read from the file.

The `getName` method uses the `FileName` property of the custom reader object to return the file name as the name for the top-level node. The `getName` method uses the `VariableName` property to return the signal name extracted from the file to use as the signal name for each imported signal.

```
classdef ExcelFirstColumnTimeReader < io.reader
 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if isempty(obj.VariableName)
 t = readtable(obj.FileName);
 vars = t.Properties.VariableNames;
 vars(1) = [];
 childObj = cell(size(vars));
 for idx = 1:numel(vars)
 childObj{idx} = ExcelFirstColumnTimeReader;
 childObj{idx}.FileName = obj.FileName;
 childObj{idx}.VariableName = vars{idx};
 end
 end
 end

 function retName = getName(obj)
 if isempty(obj.VariableName)
 fullName = obj.FileName;
 splitName = split(fullName,["\" "/""]);
 retName = splitName{end};
 else
 retName = obj.VariableName;
 end
 end

 % ...
 end
end
```

### Get Names for Data Imported from Workspace

Write the function definition for the `getName` method to return signal names for data imported from the workspace. Specify code for the `getName` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods, and workspace data readers need to define the `supportsVariable` method. For an example that shows the complete class definition and import workflow for a workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

The custom reader in this example imports a structure or an array of structures from the workspace. The structures must contain fields for the signal data (`d`), the time data (`t`), and the signal name (`n`).

When the variable to import is a scalar structure, the `getName` method returns the value in the `n` field of the imported structure.

When the variable is an array of structures, the custom reader uses both the `getName` and `getChildren` methods to return signal names. The `getChildren` method creates a custom reader object for each structure in the array and sets the `ChannelIndex` property to identify the index of the signal data within the array. Then, the `getName` method uses the `ChannelIndex` property value to select the appropriate structure from the `VariableValue` property value, which is the array of structures.

```
classdef SimpleStructReader < io.reader

 properties
 ChannelIndex
 end

 methods
 % ...

 function childObj = getChildren(obj)
 childObj = {};
 if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
 numChannels = numel(obj.VariableValue);
 childObj = cell(numChannels,1);
 for idx = 1:numChannels
 childObj{idx} = SimpleStructReader;
 childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
 childObj{idx}.VariableValue = obj.VariableValue;
 childObj{idx}.ChannelIndex = idx;
 end
 end
 end

 function retName = getName(obj)
 if isscalar(obj.VariableValue)
 retName = char(obj.VariableValue.n);
 elseif ~isempty(obj.ChannelIndex)
 varVal = obj.VariableValue(obj.ChannelIndex);
 retName = char(varVal.n);
 else
 retName = 'Signal Array';
 end
 end

 % ...
 end
end
```

## io.reader.getRegisteredFileReaders

**Class:** io.reader

**Package:** io

Return all custom file readers registered for the Simulation Data Inspector

### Syntax

```
readers = io.reader.getRegisteredFileReaders
```

### Description

`readers = io.reader.getRegisteredFileReaders` returns an array of strings that indicate all custom file readers registered for the Simulation Data Inspector.

### Output Arguments

**readers** — Custom file readers registered for the Simulation Data Inspector

array of strings

Custom file readers registered for the Simulation Data Inspector, returned as an array of strings.

### Attributes

Static true

To learn about attributes of methods, see Method Attributes.

### Examples

#### Register Custom File Reader for the Simulation Data Inspector

This example shows how to register a custom file reader with the Simulation Data Inspector, verify registration was successful, and unregister a file reader.

#### Register the Custom File Reader

This example registers the file reader `ExcelFirstColumnTime`. For an example that shows how to author the custom file reader, see “Import Data Using a Custom File Reader”. As the name suggests, the custom file reader for this example supports Microsoft Excel™ files. Register the reader for the `.xlsx` and `.xls` extensions.

```
registerFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"]);
```

#### Verify Custom Reader Registration

To verify registration of a custom reader, you can use the `io.reader.getRegisteredFileReaders` method or the `io.reader.getSupportedReadersForFile` method.

The `io.reader.getRegisteredFileReaders` returns a string array that contains the names of all registered custom file readers.

```
io.reader.getRegisteredFileReaders
```

```
ans =
"ExcelFirstColumnTimeReader"
```

You can also use the `io.reader.getSupportedReadersForFile` method to see all reader options for a specific file. The `built-in` option in the returned string array indicates that the Simulation Data Inspector has a built-in Excel file reader.

```
io.reader.getSupportedReadersForFile('CustomFile.xlsx')
```

```
ans = 1x2 string
"ExcelFirstColumnTimeReader" "built-in"
```

### Unregister a Custom File Reader

To unregister a custom file reader, use the `unregisterFileReader` method. All custom readers are unregistered when you close a MATLAB™ session.

```
unregisterFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"])
```

## Version History

Introduced in R2020b

## io.reader.getSupportedReadersForFile

**Class:** io.reader

**Package:** io

Return all readers available to import file

### Syntax

```
readers = io.reader.getSupportedReadersForFile(filename)
```

### Description

`readers = io.reader.getSupportedReadersForFile(filename)` returns all readers in the Simulation Data Inspector that support importing the file specified by `filename`.

### Input Arguments

**filename** — Name of or path to file to import

character array | string

Name of or path to file to import, specified as a character array or string.

Example: 'MyDataFile.csv'

Data Types: char | string

### Output Arguments

**readers** — File readers available to import file

array of strings

File readers available to import file, returned as an array of strings. When the Simulation Data Inspector has a built-in reader for the file, the array contains "built-in".

### Attributes

Static true

To learn about attributes of methods, see Method Attributes.

### Examples

#### Register Custom File Reader for the Simulation Data Inspector

## getTimeValues

**Class:** `io.reader`

**Package:** `io`

Return time values for data imported using a custom reader

### Syntax

```
timeVals = getTimeValues(obj)
```

### Description

`timeVals = getTimeValues(obj)` returns time values to use for data imported into the **Simulation Data Inspector** using a custom file or workspace variable reader. Specify code for the `getTimeValues` method to extract the data from a proprietary file or variable format.

### Input Arguments

**obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

### Output Arguments

**timeVals** — Time values for imported data

column vector

Time values for imported data, returned as a column vector.

### Attributes

Abstract true

To learn about attributes of methods, see [Method Attributes](#).

### Examples

#### Get Time Values for Data Imported from File

Write the function definition for the `getTimeValues` method to return time values to use for data imported from a file. The custom reader in this example always uses the data in the first column of the file as time. Specify the code for the `getTimeValues` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods. For an example that shows the complete class definition and import workflow, see “Import Data Using a Custom File Reader”.

In this example, the `getTimeValues` method reads the data from the file using the `readtable` function and returns the data from the first column to use as the time values for imported signals.

```
classdef ExcelFirstColumnTimeReader < io.reader
 methods
 % ...

 function timeVals = getTimeValues(obj)
 timeVals = [];
 if ~isempty(obj.VariableName)
 t = readtable(obj.FileName);
 timeName = t.Properties.VariableNames{1};
 timeVals = t.(timeName);
 end
 end
 end

 % ...
end
end
```

### Get Time Values for Data Imported from Workspace

Write the function definition for the `getTimeValues` method to return time values for data imported from the workspace. Specify the code executed by the `getTimeValues` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods, and workspace data readers need to define the `supportsVariable` method. For an example that shows the complete class definition and import workflow for a workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

The custom reader in this example imports a structure or an array of structures from the workspace. The structures must contain fields for the signal data (`d`), the time data (`t`), and the signal name (`n`). When the variable to import is a scalar structure, the `getTimeValues` method returns the value in the `t` field of the imported structure.

When the variable is an array of structures, the custom reader uses both the `getTimeValues` and `getChildren` methods to return time data. The `getChildren` method creates a custom reader object for each structure in the array and sets the `ChannelIndex` property to identify the index of the signal data within the array. Then, the `getTimeData` method uses the `ChannelIndex` property value to select the appropriate structure from the `VariableValue` property value, which is the array of structures.

```
classdef ExcelFirstColumnTimeReader < io.reader

 properties
 ChannelIndex
 end
end
```

```
methods
% ...

function childObj = getChildren(obj)
 childObj = {};
 if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
 numChannels = numel(obj.VariableValue);
 childObj = cell(numChannels,1);
 for idx = 1:numChannels
 childObj{idx} = SimpleStructReader;
 childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
 childObj{idx}.VariableValue = obj.VariableValue;
 childObj{idx}.ChannelIndex = idx;
 end
 end
end

function timeVals = getTimeValues(obj)
 if isscalar(obj.VariableValue)
 timeVals = obj.VariableValue.t;
 elseif ~isempty(obj.ChannelIndex)
 varVal = obj.VariableValue(obj.ChannelIndex);
 timeVals = varVal.t;
 else
 timeVals = [];
 end
end

% ...
end
end
```

# registerFileReader

**Class:** `io.reader`

**Package:** `io`

Register custom file reader for use in the Simulation Data Inspector

## Syntax

```
registerFileReader(obj,ext)
```

## Description

`registerFileReader(obj,ext)` registers the custom file reader `obj` with the Simulation Data Inspector to use for files with extensions specified by `ext`. To use a custom file reader in the Simulation Data Inspector, you must register the reader at the start of each MATLAB session.

---

**Tip** To verify registration, use the `io.reader.getRegisteredFileReaders` method or the `io.reader.getSupportedReadersForFile` method.

---

## Input Arguments

### **obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

### **ext** — File extensions supported by custom reader

character vector | string | cell array of character vectors | cell array of strings

File extensions supported by custom reader, specified as a character vector, string, cell array of character vectors, or cell array of strings.

Example: `[".xlsx" ".xls"]`

Data Types: `char` | `string` | `cell`

## Examples

### **Register Custom File Reader for the Simulation Data Inspector**

This example shows how to register a custom file reader with the Simulation Data Inspector, verify registration was successful, and unregister a file reader.

#### **Register the Custom File Reader**

This example registers the file reader `ExcelFirstColumnTime`. For an example that shows how to author the custom file reader, see “Import Data Using a Custom File Reader”. As the name suggests,

the custom file reader for this example supports Microsoft Excel™ files. Register the reader for the .xlsx and .xls extensions.

```
registerFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"]);
```

### Verify Custom Reader Registration

To verify registration of a custom reader, you can use the `io.reader.getRegisteredFileReaders` method or the `io.reader.getSupportedReadersForFile` method.

The `io.reader.getRegisteredFileReaders` returns a string array that contains the names of all registered custom file readers.

```
io.reader.getRegisteredFileReaders
```

```
ans =
"ExcelFirstColumnTimeReader"
```

You can also use the `io.reader.getSupportedReadersForFile` method to see all reader options for a specific file. The `built-in` option in the returned string array indicates that the Simulation Data Inspector has a built-in Excel file reader.

```
io.reader.getSupportedReadersForFile('CustomFile.xlsx')

ans = 1x2 string
 "ExcelFirstColumnTimeReader" "built-in"
```

### Unregister a Custom File Reader

To unregister a custom file reader, use the `unregisterFileReader` method. All custom readers are unregistered when you close a MATLAB™ session.

```
unregisterFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"]);
```

## Version History

Introduced in R2020b

# supportsFile

**Class:** `io.reader`

**Package:** `io`

Return logical indication of whether custom reader supports file

## Syntax

```
supported = supportsFile(obj, filename)
```

## Description

`supported = supportsFile(obj, filename)` returns the logical value `supported` that indicates whether the custom reader specified by `obj` supports the file specified by `filename`. The Simulation Data Inspector always checks whether a file is supported based on the file extension alone. Use the `supportsFile` method to specify code for additional support validation.

## Input Arguments

### **obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

### **filename** — Name of file to import

character vector | string

Name of file to import, specified as a character vector or string.

Example: `'MyDataFile.xlsx'`

Data Types: `char` | `string`

## Output Arguments

### **supported** — Whether custom reader supports file

logical

Whether custom reader supports file, returned as a logical value.

## Examples

### **Determine Whether Custom File Reader Supports File**

Write the function definition for the `supportsFile` method to determine whether the custom reader supports the data in the file. This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods. For

an example that shows the complete class definition and import workflow, see “Import Data Using a Custom File Reader”.

In this example, the `supportsFile` method reads the data in the file using the `readtable` function and checks that the file contains data in more than one column.

```
classdef ExcelFirstColumnTimeReader < io.reader
 methods
 % ...

 function childObj = getChildren(obj)
 try
 t = readtable(filename);
 supported = height(t) > 0 && numel(t.Properties.VariableNames) > 1;
 catch
 supported = false;
 end
 end
 end
 % ...
end
end
```

## Version History

Introduced in R2020b

# supportsVariable

**Class:** `io.reader`

**Package:** `io`

Return logical indication of whether custom reader supports variable

## Syntax

```
supported = supportsVariable(obj,var)
```

## Description

`supported = supportsVariable(obj,var)` returns the logical value `supported` that indicates whether the custom workspace reader specified by `obj` supports the variable specified by `var`. When you write a custom workspace reader, you must implement the `supportsVariable` method in the class definition.

## Input Arguments

**obj — Custom data reader**

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomReader`

**var — Workspace variable to import**

variable

Workspace variable to import, specified as a variable in the base workspace.

Example: `myVar`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `duration` | `calendarDuration` | `fi`

Complex Number Support: Yes

## Output Arguments

**supported — Whether custom reader supports variable**

logical

Whether the custom reader supports variable, returned as a logical value.

## Examples

### Determine Whether Custom Reader Supports Variable

Write the function definition for the `supportsVariable` method to return true only when the reader can import the input variable. Specify the code for the `supportsVariable` method in the class definition file.

This example does not show a complete class definition. All custom readers must define behavior for the `getName`, `getTimeValues`, and `getDataValues` methods, and workspace data readers need to define the `supportsVariable` method. For an example that shows the complete class definition and import workflow for a workspace data reader, see “Import Workspace Variables Using a Custom Data Reader”.

The custom reader in this example imports a structure or an array of structures from the workspace. The structures must contain fields for the signal data (`d`), the time data (`t`), and the signal name (`n`). The `supportsVariable` method returns true when:

- 1 The input variable is a structure or array of structures that contains the appropriate fields.
- 2 The `n` field of each structure contains a character array or string to represent the signal name.
- 3 The `t` field of each structure is a column vector of double data.
- 4 The `d` field of each structure contains numeric data and is the same size as the `t` field, meaning there is a sample value for each time step.

```
classdef ExcelFirstColumnTimeReader < io.reader

 methods
 % ...

 function supported = supportsVariable(~, val)
 % Support structure with fields t (time), d (data), and n (name)
 supported = ...
 isstruct(val) && ...
 isfield(val,'t') && ...
 isfield(val,'d') && ...
 isfield(val,'n');
 if supported
 for idx = 1:numel(val)
 varName = val(idx).n;
 time = val(idx).t;
 varData = val(idx).d;

 % Name must be string or character array
 if ~ischar(varName) && ~isstring(varName)
 supported = false;

 % Time must be double column vector
 elseif ~isa(time,'double') || ~iscolumn(time)
 supported = false;

 % Data size must match time size
 else
 timeSz = size(time);
 dataSz = size(varData);

 if ~isnumeric(varData) || ~isequal(dataSz, timeSz)
 supported = false;
 end
 end
 end
 end
 end
 end
end
```

```
 end
 end
end
end

% ...
end
end
```

## unregisterFileReader

**Class:** `io.reader`

**Package:** `io`

Unregister custom file reader for the Simulation Data Inspector

### Syntax

```
unregisterFileReader(obj,ext)
```

### Description

`unregisterFileReader(obj,ext)` unregisters the custom file reader specified by `obj` for the extensions specified by `ext`. All custom file and workspace variable readers are unregistered when you close MATLAB.

---

**Tip** To verify the unregister operation, use the `io.reader.getRegisteredFileReaders` method or the `io.reader.getSupportedReadersForFile` method.

---

### Input Arguments

**obj — Custom data reader**

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomFileReader`

**ext — File extensions supported by custom reader**

character vector | string | cell array of character vectors | cell array of strings

File extensions supported by custom reader, specified as a character vector, string, cell array of character vectors, or cell array of strings.

Example: `[".xlsx" ".xls"]`

Data Types: `char` | `string` | `cell`

### Examples

**Register Custom File Reader for the Simulation Data Inspector**

This example shows how to register a custom file reader with the Simulation Data Inspector, verify registration was successful, and unregister a file reader.

**Register the Custom File Reader**

This example registers the file reader `ExcelFirstColumnTime`. For an example that shows how to author the custom file reader, see “Import Data Using a Custom File Reader”. As the name suggests,

the custom file reader for this example supports Microsoft Excel™ files. Register the reader for the .xlsx and .xls extensions.

```
registerFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"]);
```

### Verify Custom Reader Registration

To verify registration of a custom reader, you can use the `io.reader.getRegisteredFileReaders` method or the `io.reader.getSupportedReadersForFile` method.

The `io.reader.getRegisteredFileReaders` returns a string array that contains the names of all registered custom file readers.

```
io.reader.getRegisteredFileReaders
```

```
ans =
"ExcelFirstColumnTimeReader"
```

You can also use the `io.reader.getSupportedReadersForFile` method to see all reader options for a specific file. The `built-in` option in the returned string array indicates that the Simulation Data Inspector has a built-in Excel file reader.

```
io.reader.getSupportedReadersForFile('CustomFile.xlsx')

ans = 1x2 string
 "ExcelFirstColumnTimeReader" "built-in"
```

### Unregister a Custom File Reader

To unregister a custom file reader, use the `unregisterFileReader` method. All custom readers are unregistered when you close a MATLAB™ session.

```
unregisterFileReader(ExcelFirstColumnTimeReader, [".xlsx" ".xls"]);
```

## Version History

Introduced in R2020b

## unregisterWorkspaceReader

**Class:** `io.reader`

**Package:** `io`

Unregister custom workspace reader for the Simulation Data Inspector

### Syntax

```
unregisterWorkspaceReader(obj)
```

### Description

`unregisterWorkspaceReader(obj)` unregisters the custom workspace reader specified by `obj` from the Simulation Data Inspector. All custom file and workspace variable readers are unregistered when you close MATLAB.

### Input Arguments

**obj** — Custom data reader

`io.reader` subclass object

Custom data reader, specified as an object of a class that inherits from the `io.reader` base class.

Example: `MyCustomReader`

### Examples

#### Register Custom Workspace Reader for the Simulation Data Inspector

This example shows how to register a custom workspace data reader with the Simulation Data Inspector, verify registration was successful, and unregister the workspace reader.

This example registers a custom workspace data reader called `SimpleStructReader`. For an example that shows how to author the custom workspace reader, see “Import Workspace Variables Using a Custom Data Reader”.

```
registerWorkspaceReader(SimpleStructReader);
```

To verify registration of a custom workspace reader, use the `io.reader.getRegisteredWorkspaceReaders` method, which returns a string array that contains the names of all registered custom workspace readers.

```
io.reader.getRegisteredWorkspaceReaders
```

```
ans =
"SimpleStructReader"
```

To unregister a custom workspace reader, use the `unregisterWorkspaceReader` method. All readers are unregistered when you close the MATLAB™ session.

```
unregisterWorkspaceReader(SimpleStructReader);
```

## matlab.io.datastore.sd datastore class

**Package:** matlab.io.datastore

Datastore for Simulation Data Inspector signals

### Description

A `matlab.io.datastore.sd datastore` object provides access to signals logged to the Simulation Data Inspector that are too large to fit into memory. An `sd datastore` object references the data for a single signal. The `read` method loads the signal data referenced by an `sd datastore` object in a chunk-wise manner such that each chunk always fits into memory. You can use an `sd datastore` object to create a tall timetable for your signal data. For more information about working with tall arrays, see “Tall Arrays”.

---

**Note** `matlab.io.datastore.sd datastore` does not support parallel computations. If you have a Parallel Computing Toolbox license, use `mapreducer(0)` to set the execution environment to the local MATLAB client before creating a tall timetable from the `matlab.io.datastore.sd datastore`.

---

### Construction

`ds = dsrObj.getAsDatastore(arg)` creates the `sd datastore`, `ds`, for the signal in the `Simulink.sdi.DatasetRef` object selected by the search criterion `arg`. You can specify `arg` as an integer representing the index of the desired signal within the `Simulink.sdi.DatasetRef` object, or as a character vector containing the name of the signal.

`ds = matlab.io.datastore.sd datastore(signalID)` creates the `sd datastore`, `ds`, for the signal corresponding to the specified `signalID`.

### Input Arguments

#### **arg** — Element selection criterion

character vector | integer

Search criterion used to retrieve the element from the `Simulink.sdi.DatasetRef` object. For name-based searches, specify `arg` as a character vector. For index-based searches, `arg` is an integer, representing the index of the desired element.

Example: 'MySignal'

Example: 3

#### **signalID** — Numeric signal identifier

integer

Numeric signal identifier generated for the signal by the Simulation Data Inspector. You can get the signal ID for a signal using methods of the `Simulink.sdi.Run` object containing the signal or as a return from the `Simulink.sdi.createRun` function.

## Properties

### Name — Signal name

character vector

Name of the signal specified as a character vector.

Example: 'My Signal'

### Signal — Simulink.sdi.Signal object

Simulink.sdi.Signal object

Simulink.sdi.Signal object associated with the sdidatastore. The Signal property provides access to the signal data and metadata.

## Methods

|         |                                           |
|---------|-------------------------------------------|
| hasdata | Determine if data is available to read    |
| preview | Return preview of data in sdidatastore    |
| read    | Read a chunk of data from an sdidatastore |
| readall | Read all data from an sdidatastore        |
| reset   | Reset the read position                   |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects.

## Examples

### Create a Tall Timetable for a Simulation Data Inspector Signal

This example shows how to create a tall timetable for a signal in the Simulation Data Inspector repository. You can create the tall timetable using a Simulink.sdi.Signal object or by first creating a matlab.io.datastore.sdidatastore for the signal. You can use a matlab.io.datastore.sdidatastore to incrementally read and process signal data for signals that do not fit into memory. A tall timetable handles the data chunking and processing in the background. In general, you can work with tall timetables very similarly to how you work with in-memory data.

### Create Data and Access Signal ID

Whether you create your tall timetable using a Simulink.sdi.Signal object or a matlab.io.datastore.sdidatastore, start by creating data and accessing the signal ID for a signal of interest. The sldemo\_fuelsys model is configured to log signals which stream to the Simulation Data Inspector repository when you simulate the model.

```
open_system('sldemo_fuelsys')
sim('sldemo_fuelsys')
```

Then, use the Simulation Data Inspector programmatic interface to access the signal ID for a signal of interest. For example, access the ego signal.

```
runCount = Simulink.sdi.getRunCount;
latestRunID = Simulink.sdi.getRunIDByIndex(runCount);
latestRun = Simulink.sdi.getRun(latestRunID);

egoSigID = latestRun.getSignalIDByIndex(7);
```

### Create a Tall Timetable Using a `matlab.io.datastore.sd datastore`

In general, tall timetables are backed by datastores. Create a `matlab.io.datastore.sd datastore` object to reference the signal data in the Simulation Data Inspector repository.

```
egoDs = matlab.io.datastore.sd datastore(egoSigID);
```

Check the name of the datastore to verify you have the signal you expect.

```
egoDs.Name
```

```
ans =
'fuel'
```

Create a tall timetable from the `matlab.io.datastore.sd datastore` to use for processing the signal data. When you have a Parallel Computing Toolbox™ license, you need to explicitly set the execution environment to the local MATLAB® session using `mapreducer` before creating the tall timetable. The `matlab.io.datastore.sd datastore` object does not support parallel computations.

```
mapreducer(0);
```

```
egoTt = tall(egoDs)
```

```
egoTt =
```

```
Mx1 tall timetable
```

| Time           | Data   |
|----------------|--------|
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| ⋮              | ⋮      |
| ⋮              | ⋮      |

### Create a Tall Timetable Using a `Simulink.sdi.Signal` Object

The `Simulink.sdi.Signal` class has a method to create a tall timetable directly, allowing you to skip the step of creating a datastore by creating it behind the scenes. Use the signal ID to access the `Simulink.sdi.Signal` object for the ego signal. Then, use the `getTable` method to create the tall timetable.

```
egoSig = Simulink.sdi.getSignal(egoSigID);
```

```
egoTt = egoSig.getAsTall
```

```
egoTt =
```

```
Mx1 tall timetable
```

| Time           | Data   |
|----------------|--------|
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| :              | :      |
| :              | :      |

### Use the Tall Timetable to Process Your Signal Data

When you use the tall timetable `egoTt`, its underlying datastore reads chunks of data and passes them to the tall timetable to process. Neither the datastore nor the tall timetable retain any of the data in memory after processing. Also, the tall timetable defers processing for many operations. For example, calculate the mean value of the signal.

```
egoMean = mean(egoTt.Data)
```

```
egoMean =
```

```
tall double
```

```
?
```

You can use the `gather` function to evaluate a variable and write its value to the workspace, or you can use the `write` function to write the results to disc. When you use `gather`, be sure the results fit into memory.

```
egoMean = gather(egoMean)
```

```
Evaluating tall expression using the Local MATLAB Session:
```

```
- Pass 1 of 1: Completed in 5.7 sec
```

```
Evaluation completed in 6.1 sec
```

```
egoMean = 1.3292
```

When you perform multiple operations on a tall timetable, evaluation of the results for each step is deferred until you explicitly request the results with `write` or `gather`. During evaluation, MATLAB optimizes the number of passes it makes through the tall timetable, which can significantly speed up processing time for analyzing very large signals. For more information about working with tall arrays, see “Tall Arrays for Out-of-Memory Data”.

### Process Signal Data Using a `matlab.io.datastore.sdidatastore`

A `matlab.io.datastore.sdidatastore` references signal data in the Simulation Data Inspector repository. When the signal is too large to fit into memory, you can use the

`matlab.io.datastore.sd datastore` to incrementally process the data manually or to create a tall timetable for the signal that handles the incremental processing for you. This example shows how to process data using a `matlab.io.datastore.sd datastore`.

### Create a `matlab.io.datastore.sd datastore` for a Signal

Simulate the `sl demo_fuelsys` model, which is configured to log several signals, to create data in the Simulation Data Inspector repository.

```
sim('sl demo_fuelsys')
```

Use the Simulation Data Inspector programmatic interface to get the signal ID for the signal.

```
runCount = Simulink.sdi.getRunCount;
latestRunID = Simulink.sdi.getRunIDByIndex(runCount);
latestRun = Simulink.sdi.getRun(latestRunID);
speedSigID = latestRun.getSignalIDByIndex(4);
```

Use the signal ID to create a `matlab.io.datastore.sd datastore` for the speed signal.

```
speedSDIDs = matlab.io.datastore.sd datastore(speedSigID);
```

### Verify the Contents of the Datastore

Check the `Name` property of the `matlab.io.datastore.sd datastore` to verify that it matches your expectations.

```
speedSDIDs.Name
```

```
ans =
'map'
```

You can also use the `preview` method to check that the first ten samples in the signal look correct.

```
speedSDIDs.preview
```

```
ans=10x1 timetable
 Time Data

0 sec 0.589
0.00056199 sec 0.58772
0.0033719 sec 0.58148
0.01 sec 0.56765
0.02 sec 0.54897
0.03 sec 0.53264
0.04 sec 0.51837
0.05 sec 0.50594
0.055328 sec 0.5
0.055328 sec 0.5
```

### Process Signal Data with the `matlab.io.datastore.sd datastore`

When your signal is too large to fit into memory, you can use the `readData` method to read chunks of data from the Simulation Data Inspector repository to incrementally process your data. Use the

hasdata method as the condition for a while loop to incrementally process the whole signal. For example, find the maximum signal value.

```
latestMax = [];

while speedSDIds.hasdata
 speedChunk = speedSDIds.read;
 speedChunkData = speedChunk.Data;
 latestMax = max([speedChunkData; latestMax]);
end

latestMax

latestMax = 0.8897
```

On each read operation, the read method updates the read position for the start of the next read operation. After reading some or all of the `matlab.io.datastore.sd datastore`, you can reset the read position to start again from the beginning of the signal.

```
speedSDIds.reset
```

### Process Signal Data in Memory

When the signal referenced by your `matlab.io.datastore.sd datastore` fits into memory, you can use the `readall` method to read all the signal data into memory for processing, rather than reading and processing the data incrementally with the `read` method. The `readall` method returns a `timetable` with all the signal data.

```
speedTimetable = speedSDIds.readall;

speedMax = max(speedTimetable.Data)

speedMax = 0.8897
```

## Version History

## hasdata

**Class:** `matlab.io.datastore.sd datastore`

**Package:** `matlab.io.datastore`

Determine if data is available to read

### Syntax

```
tf = sdi_ds.hasdata
```

### Description

`tf = sdi_ds.hasdata` returns logical 1 if the `matlab.io.datastore.sd datastore`, `sdi_ds`, has data available to read. When `sdi_ds` does not have data available to read, `hasdata` returns 0.

### Output Arguments

**tf** — Data availability indication

logical

Logical indication of whether the `matlab.io.datastore.sd datastore` has data available to read. When data is available, `tf` is 1. When data is not available, `tf` is 0.

### Examples

#### Process Signal Data Using a `matlab.io.datastore.sd datastore`

A `matlab.io.datastore.sd datastore` references signal data in the Simulation Data Inspector repository. When the signal is too large to fit into memory, you can use the `matlab.io.datastore.sd datastore` to incrementally process the data manually or to create a tall timetable for the signal that handles the incremental processing for you. This example shows how to process data using a `matlab.io.datastore.sd datastore`.

#### Create a `matlab.io.datastore.sd datastore` for a Signal

Simulate the `sldemo_fuelsys` model, which is configured to log several signals, to create data in the Simulation Data Inspector repository.

```
sim('sldemo_fuelsys')
```

Use the Simulation Data Inspector programmatic interface to get the signal ID for the signal.

```
runCount = Simulink.sdi.getRunCount;
```

```
latestRunID = Simulink.sdi.getRunIDByIndex(runCount);
```

```
latestRun = Simulink.sdi.getRun(latestRunID);
```

```
speedSigID = latestRun.getSignalIDByIndex(4);
```

Use the signal ID to create a `matlab.io.datastore.sd datastore` for the speed signal.

```
speedSDIds = matlab.io.datastore.sd datastore(speedSigID);
```

### Verify the Contents of the Datastore

Check the Name property of the `matlab.io.datastore.sd datastore` to verify that it matches your expectations.

```
speedSDIds.Name
```

## preview

**Class:** `matlab.io.datastore.sd datastore`

**Package:** `matlab.io.datastore`

Return preview of data in `sd datastore`

### Syntax

```
dataPreview = sdi_ds.preview
```

### Description

`dataPreview = sdi_ds.preview` returns the first 10 samples of signal data in the `matlab.io.datastore.sd datastore`, `sdi_ds`. The `preview` method does not change the read position. Use the `preview` method to verify that the data in your `matlab.io.datastore.sd datastore` appears as you expect.

### Output Arguments

**dataPreview** — Preview of the data

`timetable`

First 10 samples of the signal referenced by the `matlab.io.datastore.sd datastore` in a `timetable`.

### Examples

#### Process Signal Data Using a `matlab.io.datastore.sd datastore`

A `matlab.io.datastore.sd datastore` references signal data in the Simulation Data Inspector repository. When the signal is too large to fit into memory, you can use the `matlab.io.datastore.sd datastore` to incrementally process the data manually or to create a tall `timetable` for the signal that handles the incremental processing for you. This example shows how to process data using a `matlab.io.datastore.sd datastore`.

#### Create a `matlab.io.datastore.sd datastore` for a Signal

Simulate the `sldemo_fuelsys` model, which is configured to log several signals, to create data in the Simulation Data Inspector repository.

```
sim('sldemo_fuelsys')
```

Use the Simulation Data Inspector programmatic interface to get the signal ID for the signal.

```
runCount = Simulink.sdi.getRunCount;
```

```
latestRunID = Simulink.sdi.getRunIDByIndex(runCount);
```

```
latestRun = Simulink.sdi.getRun(latestRunID);
```

```
speedSigID = latestRun.getSignalIDByIndex(4);
```

Use the signal ID to create a `matlab.io.datastore.sd datastore` for the speed signal.

```
speedSDIds = matlab.io.datastore.sd datastore(speedSigID);
```

### Verify the Contents of the Datastore

Check the `Name` property of the `matlab.io.datastore.sd datastore` to verify that it matches your expectations.

```
speedSDIds.Name
```

```
ans =
'map'
```

You can also use the `preview` method to check that the first ten samples in the signal look correct.

```
speedSDIds.preview
```

```
ans=10x1 timetable
 Time Data

0 sec 0.589
0.00056199 sec 0.58772
0.0033719 sec 0.58148
0.01 sec 0.56765
0.02 sec 0.54897
0.03 sec 0.53264
0.04 sec 0.51837

0.055328 sec 0.5
0.055328 sec 0.5
```

### Process Signal Data with the `matlab.io.datastore.sd datastore`

When your signal is too large to fit into memory, you can use the `readData` method to read chunks of data from the Simulation Data Inspector repository to incrementally process your data. Use the `hasdata` method as the condition for a `while` loop to incrementally process the whole signal. For example, find the maximum signal value.

```
latestMax = [];
```

```
while speedSDIds.hasdata
```

```
 speedChunk = speedSDIds.read;
 speedChunkData = speedChunk.Data;
 latestMax = max([speedChunkData; latestMax]);
```

```
end
```

```
latestMax
```

```
latestMax = 0.8897
```

On each read operation, the `read` method updates the read position for the start of the next read operation. After reading some or all of the `matlab.io.datastore.sd datastore`, you can reset the read position to start again from the beginning of the signal.

```
speedSDIds.reset
```

### **Process Signal Data in Memory**

When the signal referenced by your `matlab.io.datastore.sd datastore` fits into memory, you can use the `readall` method to read all the signal data into memory for processing, rather than reading and processing the data incrementally with the `read` method. The `readall` method returns a `timetable` with all the signal data.

```
speedTimetable = speedSDIds.readall;
```

```
speedMax = max(speedTimetable.Data)
```

```
speedMax = 0.8897
```

## **Version History**

**Introduced in R2017b**

## read

**Class:** `matlab.io.datastore.sd datastore`

**Package:** `matlab.io.datastore`

Read a chunk of data from an `sd datastore`

### Syntax

```
data = sdi_ds.read
```

### Description

`data = sdi_ds.read` reads a chunk of samples from the `matlab.io.datastore.sd datastore`, `sdi_ds`, and updates the read position for `sdi_ds` to the point following the endpoint of the returned data. The samples are returned in the `timetable`, `data`. The number of samples read by the `read` method vary, and the returned `timetable` always fits into memory. Use the `read` method to incrementally process signals that are too large to fit into memory.

### Output Arguments

**data** — Chunk of data read from `sd datastore`

`timetable`

Chunk of samples read from the `matlab.io.datastore.simulationdatastore`, returned as a `timetable`.

### Examples

#### Process Signal Data Using a `matlab.io.datastore.sd datastore`

A `matlab.io.datastore.sd datastore` references signal data in the Simulation Data Inspector repository. When the signal is too large to fit into memory, you can use the `matlab.io.datastore.sd datastore` to incrementally process the data manually or to create a tall `timetable` for the signal that handles the incremental processing for you. This example shows how to process data using a `matlab.io.datastore.sd datastore`.

#### Create a `matlab.io.datastore.sd datastore` for a Signal

Simulate the `sldemo_fuelsys` model, which is configured to log several signals, to create data in the Simulation Data Inspector repository.

```
sim('sldemo_fuelsys')
```

Use the Simulation Data Inspector programmatic interface to get the signal ID for the signal.

```
runCount = Simulink.sdi.getRunCount;
```

```
latestRunID = Simulink.sdi.getRunIDByIndex(runCount);
```

```
latestRun = Simulink.sdi.getRun(latestRunID);
```

```
speedSigID = latestRun.getSignalIDByIndex(4);
```

Use the signal ID to create a `matlab.io.datastore.sd datastore` for the speed signal.

```
speedSDIds = matlab.io.datastore.sd datastore(speedSigID);
```

### Verify the Contents of the Datastore

Check the `Name` property of the `matlab.io.datastore.sd datastore` to verify that it matches your expectations.

```
speedSDIds.Name
```

```
ans =
'map'
```

You can also use the `preview` method to check that the first ten samples in the signal look correct.

### Process Signal Data with the `matlab.io.datastore.sd datastore`

When your signal is too large to fit into memory, you can use the `readData` method to read chunks of data from the Simulation Data Inspector repository to incrementally process your data. Use the `hasdata` method as the condition for a while loop to incrementally process the whole signal. For example, find the maximum signal value.

```
latestMax = [];
while speedSDIds.hasdata
 speedChunk = speedSDIds.read;
 speedChunkData = speedChunk.Data;
 latestMax = max([speedChunkData; latestMax]);
end
latestMax
latestMax = 0.8897
```

On each read operation, the `read` method updates the read position for the start of the next read operation. After reading some or all of the `matlab.io.datastore.sd datastore`, you can reset the read position to start again from the beginning of the signal.

```
speedSDIds.reset
```

### **Process Signal Data in Memory**

When the signal referenced by your `matlab.io.datastore.sd datastore` fits into memory, you can use the `readall` method to read all the signal data into memory for processing, rather than reading and processing the data incrementally with the `read` method. The `readall` method returns a `timetable` with all the signal data.

```
speedTimetable = speedSDIds.readall;
```

```
speedMax = max(speedTimetable.Data)
```

```
speedMax = 0.8897
```

### **Alternatives**

You can use your `matlab.io.datastore.sd datastore` to create a tall `timetable` to process signals too large to fit into memory. The tall `timetable` handles loading and processing the chunks of signal data for you. The `matlab.io.datastore.sd datastore` reference page includes an example that shows how to process your data using a tall `timetable`. For more information about working with tall `timetables`, see “Tall Arrays”.

# matlab.io.datastore.SimulationDatastore class

**Package:** matlab.io.datastore

Datastore for inputs and outputs of Simulink models

## Description

A `matlab.io.datastore.SimulationDatastore` object enables a Simulink model to interact with big data. You can load big data as simulation input and log big output data from a simulation. To simulate models with big data, you store the data in a MAT-file and refer to the data through a `SimulationDatastore` object. See “Work with Big Data for Simulations”.

A `SimulationDatastore` object refers to big simulation data (which a MAT-file stores) for one signal. If the MAT-file stores simulation data for a bus signal, a `SimulationDatastore` object refers to the data for one leaf signal element in the bus. You can use the datastore object to inspect and access the data and, through a parent object such as `Simulink.SimulationData.Signal`, simulate a Simulink model with the data.

To analyze the datastore data, you can use the methods and properties of the `SimulationDatastore` object as well as MATLAB tools such as the `tall` function. For more information about the MATLAB tools, see “Getting Started with Datastore”.

## Construction

After you store big simulation data in a `Simulink.SimulationData.Dataset` object in a MAT-file, a signal element in the `Dataset` object points to the big data. To create a `matlab.io.datastore.SimulationDatastore` object that refers to the big data:

- 1 At the command prompt or in a script, create a `Simulink.SimulationData.DatasetRef` object that refers to the `Dataset` object in the MAT-file.
- 2 Use one of these techniques:
  - Use one-based, curly-brace indexing (for example, `{1}`) to return an object that represents the target signal element, such as `Simulink.SimulationData.Signal` or `Simulink.SimulationData.State`. For example, for a `DatasetRef` object named `logout_ref`, to create a `Signal` object that refers to the second signal element, use this code:
 

```
myLoggedSig = logout_ref{2}
```
  - Use the `getAsDatastore` method of the `DatasetRef` object to return an object that represents the target signal element. For more information, see `getAsDatastore`.

The `SimulationDatastore` object resides in the `Values` property of the returned object.

## Properties

**FileName** — Name and path of file that contains big data

character vector

Name and path of the file that contains the big data, returned as a character vector. This property is read-only.

Data Types: `char`

### **NumSamples — Total number of samples (time steps) in the datastore**

`integer`

Total number of samples (time steps) in the datastore, returned as an integer. The `readall` method extracts this many samples from the big data. This property is read-only.

Data Types: `uint64`

### **ReadSize — Amount of data to read at a time**

`100` (default) | `scalar double`

Amount of data to read at a time, in number of samples (time steps), specified as a scalar double. The `read` method extracts this many samples from the big data.

Data Types: `double`

## **Methods**

|                              |                                                               |
|------------------------------|---------------------------------------------------------------|
| <code>hasdata</code>         | Determine if data is available to read                        |
| <code>isPartitionable</code> | Determine whether datastore is partitionable                  |
| <code>isShuffleable</code>   | Determine whether datastore is shuffleable                    |
| <code>preview</code>         | Return subset of data from datastore                          |
| <code>progress</code>        | Return percentage of data that you have read from a datastore |
| <code>read</code>            | Read data in datastore                                        |
| <code>readall</code>         | Read all data in datastore                                    |
| <code>reset</code>           | Reset datastore to initial state                              |

## **Copy Semantics**

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#).

## **Limitations**

- `SimulationDatastore` does not support using a parallel pool with Parallel Computing Toolbox installed. To analyze data using tall arrays or run MapReduce algorithms, set the global execution environment to be the local MATLAB session using `mapreducer`. Enter this code:

```
mapreducer(0)
```

For information about controlling parallel resources, see “Run mapreduce on a Parallel Pool” (Parallel Computing Toolbox).

- You cannot use a MATLAB tall variable as simulation input data.

## **Examples**

## Inspect and Analyze Data in Simulation Datastore

This example shows how to log big data from a simulation and inspect and analyze portions of that data by interacting with a `matlab.io.datastore.SimulationDatastore` object.

### Log Big Data from Model

Open the example model `sldemo_fuelsys`.

```
open_system('sldemo_fuelsys')
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

Select **Configuration Parameters > Data Import/Export > Log Dataset data to file.**

```
set_param('sldemo_fuelsys', 'LoggingToFile', 'on')
```

Simulate the model.

```
sim('sldemo_fuelsys')
```

The MAT-file `out.mat` appears in your current folder. The file contains data for logged signals such as `fuel` (which is at the root level of the model).

At the command prompt, create a `DatasetRef` object that refers to the logging variable by name, `sldemo_fuelsys_output`.

```
DSRef = Simulink.SimulationData.DatasetRef('out.mat', 'sldemo_fuelsys_output');
```

### Preview Big Data

Use curly braces (`{` and `}`) to extract the signal element `fuel`, which is the tenth element in `DSRef`, as a `Simulink.SimulationData.Signal` object that contains a `SimulationDatastore` object.

```
SimDataSig = DSRef{10};
```

To more easily interact with the `SimulationDatastore` object that resides in the `Values` property of the `Signal` object, store a handle in a variable named `DStore`.

```
DStore = SimDataSig.Values;
```

Use the `preview` method to inspect the first five samples of logged data for the `fuel` signal.

```
preview(DStore)
```

```
ans =
```

```
10x1 timetable
```

| Time           | Data   |
|----------------|--------|
| -----          | -----  |
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| 0.055328 sec   | 1.0652 |
| 0.055328 sec   | 1.0652 |

### Inspect Specific Sample

Inspect the 603rd sample of logged `fuel` data.

Set the `ReadSize` property of `DStore` to a number that, considering memory resources, your computer can tolerate. For example, set `ReadSize` to 200.

```
DStore.ReadSize = 200;
```

Read from the datastore three times. Each read operation advances the reading position by 200 samples.

```
read(DStore);
read(DStore);
read(DStore);
```

Now that you are very close to the 603rd sample, set `ReadSize` to a smaller number. For example, set `ReadSize` to 5.

```
DStore.ReadSize = 5;
```

Read from the datastore again.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data   |
|----------|--------|
| 5.79 sec | 1.6097 |
| 5.8 sec  | 1.6136 |
| 5.81 sec | 1.6003 |
| 5.82 sec | 1.5904 |
| 5.83 sec | 1.5832 |

The third sample of read data is the 603rd sample in the datastore.

### Inspect Earlier Sample

Inspect the 403rd sample of logged fuel data. Due to previous read operations, the datastore now reads starting from the 606th sample, so you must reset the datastore. Then, you can read from the first sample up to the 403rd sample.

Use the `reset` method to reset `DStore`.

```
reset(DStore);
```

Set `ReadSize` to 200 again.

```
DStore.ReadSize = 200;
```

Read from the datastore twice to advance the read position to the 401st sample.

```
read(DStore);
read(DStore);
```

Set `ReadSize` to 5 again.

```
DStore.ReadSize = 5;
```

Read from the datastore.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data    |
|----------|---------|
| 3.85 sec | 0.999   |
| 3.86 sec | 0.99219 |
| 3.87 sec | 0.98538 |
| 3.88 sec | 0.97858 |

3.89 sec    0.97179

### Extract Multiple Samples

Extract samples 1001 through 1020 (a total of 20 samples).

Reset the datastore.

```
reset(DStore)
```

Advance to sample 1001.

```
DStore.ReadSize = 200;
```

```
for i = 1:5
 read(DStore);
end
```

Prepare to extract 20 samples from the datastore.

```
DStore.ReadSize = 20;
```

Extract samples 1001 through 1020. Store the extracted data in a variable named `targetSamples`.

```
targetSamples = read(DStore)
```

```
targetSamples =
```

```
20x1 timetable
```

| Time     | Data   |
|----------|--------|
| 9.7 sec  | 1.5828 |
| 9.71 sec | 1.5733 |
| 9.72 sec | 1.5664 |
| 9.73 sec | 1.5614 |
| 9.74 sec | 1.5579 |
| 9.75 sec | 1.5553 |
| 9.76 sec | 1.5703 |
| 9.77 sec | 1.582  |
| 9.78 sec | 1.5913 |
| 9.79 sec | 1.5988 |
| 9.8 sec  | 1.605  |
| 9.81 sec | 1.6101 |
| 9.82 sec | 1.6145 |
| 9.83 sec | 1.6184 |
| 9.84 sec | 1.6049 |
| 9.85 sec | 1.595  |
| 9.86 sec | 1.5877 |
| 9.87 sec | 1.5824 |
| 9.88 sec | 1.5785 |
| 9.89 sec | 1.5757 |

## Find Maximum Value of Data in Datastore

Reset the datastore.

```
reset(DStore)
```

Write a while loop, using the `hasdata` method, to incrementally analyze the data in chunks of 200 samples.

```
DStore.ReadSize = 200;
runningMax = [];
while hasdata(DStore)
 tt = read(DStore);
 rawChunk = tt.Data;
 runningMax = max([rawChunk; runningMax]);
end
```

Now, the variable `runningMax` stores the maximum value in the entire datastore.

```
runningMax

### Topics

“Work with Big Data for Simulations”

## hasdata

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Determine if data is available to read

### Syntax

```
tf = hasdata(dst)
```

### Description

`tf = hasdata(dst)` returns logical 1 (true) if there is data available to read from the datastore (`matlab.io.datastore.SimulationDatastore` object) specified by `dst`. Otherwise, it returns logical 0 (false).

### Input Arguments

**dst** — Input datastore

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

### Examples

#### Inspect and Analyze Data in Simulation Datastore

This example shows how to log big data from a simulation and inspect and analyze portions of that data by interacting with a `matlab.io.datastore.SimulationDatastore` object.

#### Log Big Data from Model

Open the example model `sldemo_fuelsys`.

```
open_system('sldemo_fuelsys')
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

Select **Configuration Parameters > Data Import/Export > Log Dataset data to file.**

```
set_param('sldemo_fuelsys', 'LoggingToFile', 'on')
```

Simulate the model.

```
sim('sldemo_fuelsys')
```

The MAT-file `out.mat` appears in your current folder. The file contains data for logged signals such as `fuel` (which is at the root level of the model).

At the command prompt, create a `DatasetRef` object that refers to the logging variable by name, `sldemo_fuelsys_output`.

```
DSRef = Simulink.SimulationData.DatasetRef('out.mat', 'sldemo_fuelsys_output');
```

#### Preview Big Data

Use curly braces (`{` and `}`) to extract the signal element `fuel`, which is the tenth element in `DSRef`, as a `Simulink.SimulationData.Signal` object that contains a `SimulationDatastore` object.

```
SimDataSig = DSRef{10};
```

To more easily interact with the `SimulationDatastore` object that resides in the `Values` property of the `Signal` object, store a handle in a variable named `DStore`.

```
DStore = SimDataSig.Values;
```

Use the `preview` method to inspect the first five samples of logged data for the `fuel` signal.

```
preview(DStore)
```

```
ans =
```

```
10x1 timetable
```

| Time           | Data   |
|----------------|--------|
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| 0.055328 sec   | 1.0652 |
| 0.055328 sec   | 1.0652 |

### Inspect Specific Sample

Inspect the 603rd sample of logged `fuel` data.

Set the `ReadSize` property of `DStore` to a number that, considering memory resources, your computer can tolerate. For example, set `ReadSize` to 200.

```
DStore.ReadSize = 200;
```

Read from the datastore three times. Each read operation advances the reading position by 200 samples.

```
read(DStore);
read(DStore);
read(DStore);
```

Now that you are very close to the 603rd sample, set `ReadSize` to a smaller number. For example, set `ReadSize` to 5.

```
DStore.ReadSize = 5;
```

Read from the datastore again.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data   |
|----------|--------|
| 5.79 sec | 1.6097 |
| 5.8 sec  | 1.6136 |

```

5.81 sec 1.6003
5.82 sec 1.5904
5.83 sec 1.5832

```

The third sample of read data is the 603rd sample in the datastore.

### Inspect Earlier Sample

Inspect the 403rd sample of logged `fuel` data. Due to previous read operations, the datastore now reads starting from the 606th sample, so you must reset the datastore. Then, you can read from the first sample up to the 403rd sample.

Use the `reset` method to reset `DStore`.

```
reset(DStore);
```

Set `ReadSize` to 200 again.

```
DStore.ReadSize = 200;
```

Read from the datastore twice to advance the read position to the 401st sample.

```
read(DStore);
read(DStore);
```

Set `ReadSize` to 5 again.

```
DStore.ReadSize = 5;
```

Read from the datastore.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data    |
|----------|---------|
| 3.85 sec | 0.999   |
| 3.86 sec | 0.99219 |
| 3.87 sec | 0.98538 |
| 3.88 sec | 0.97858 |
| 3.89 sec | 0.97179 |

### Extract Multiple Samples

Extract samples 1001 through 1020 (a total of 20 samples).

Reset the datastore.

```
reset(DStore)
```

Advance to sample 1001.

```
DStore.ReadSize = 200;
```

```
for i = 1:5
 read(DStore);
end
```

Prepare to extract 20 samples from the datastore.

```
DStore.ReadSize = 20;
```

Extract samples 1001 through 1020. Store the extracted data in a variable named `targetSamples`.

```
targetSamples = read(DStore)
```

```
targetSamples =
```

```
20x1 timetable
```

| Time     | Data   |
|----------|--------|
| 9.7 sec  | 1.5828 |
| 9.71 sec | 1.5733 |
| 9.72 sec | 1.5664 |
| 9.73 sec | 1.5614 |
| 9.74 sec | 1.5579 |
| 9.75 sec | 1.5553 |
| 9.76 sec | 1.5703 |
| 9.77 sec | 1.582  |
| 9.78 sec | 1.5913 |
| 9.79 sec | 1.5988 |
| 9.8 sec  | 1.605  |
| 9.81 sec | 1.6101 |
| 9.82 sec | 1.6145 |
| 9.83 sec | 1.6184 |
| 9.84 sec | 1.6049 |
| 9.85 sec | 1.595  |
| 9.86 sec | 1.5877 |
| 9.87 sec | 1.5824 |
| 9.88 sec | 1.5785 |
| 9.89 sec | 1.5757 |

### Find Maximum Value of Data in Datastore

Reset the datastore.

```
reset(DStore)
```

Write a `while` loop, using the `hasdata` method, to incrementally analyze the data in chunks of 200 samples.

```
DStore.ReadSize = 200;
runningMax = [];
while hasdata(DStore)
 tt = read(DStore);
 rawChunk = tt.Data;
```

```
 runningMax = max([rawChunk; runningMax]);
end
```

Now, the variable `runningMax` stores the maximum value in the entire datastore.

```
runningMax
```

```
runningMax =
```

```
 1.6423
```

#### Topics

“Work with Big Data for Simulations”

## isPartitionable

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Determine whether datastore is partitionable

### Syntax

```
tf = isPartitionable(ds)
```

### Description

`tf = isPartitionable(ds)` returns logical 1 (true) if the datastore `ds` is partitionable. Otherwise, the result is logical 0 (false).

### Input Arguments

#### **ds** — Input datastore

datastore

Input datastore. You can use these datastores as input:

- MATLAB datastores — Datastores created using MATLAB datastore functions. For a complete list of datastores, see “Select Datastore for File Format or Application”.
- Combined and transformed datastores — Datastores created using the `combine` and `transform` functions.
- Custom datastores — Datastores created using the custom datastore framework. Any datastore that subclasses from `matlab.io.Datastore` supports the `isPartitionable` function. See “Develop Custom Datastore” for more information.

### Examples

#### **Test Partitionability of Simulation Datastore**

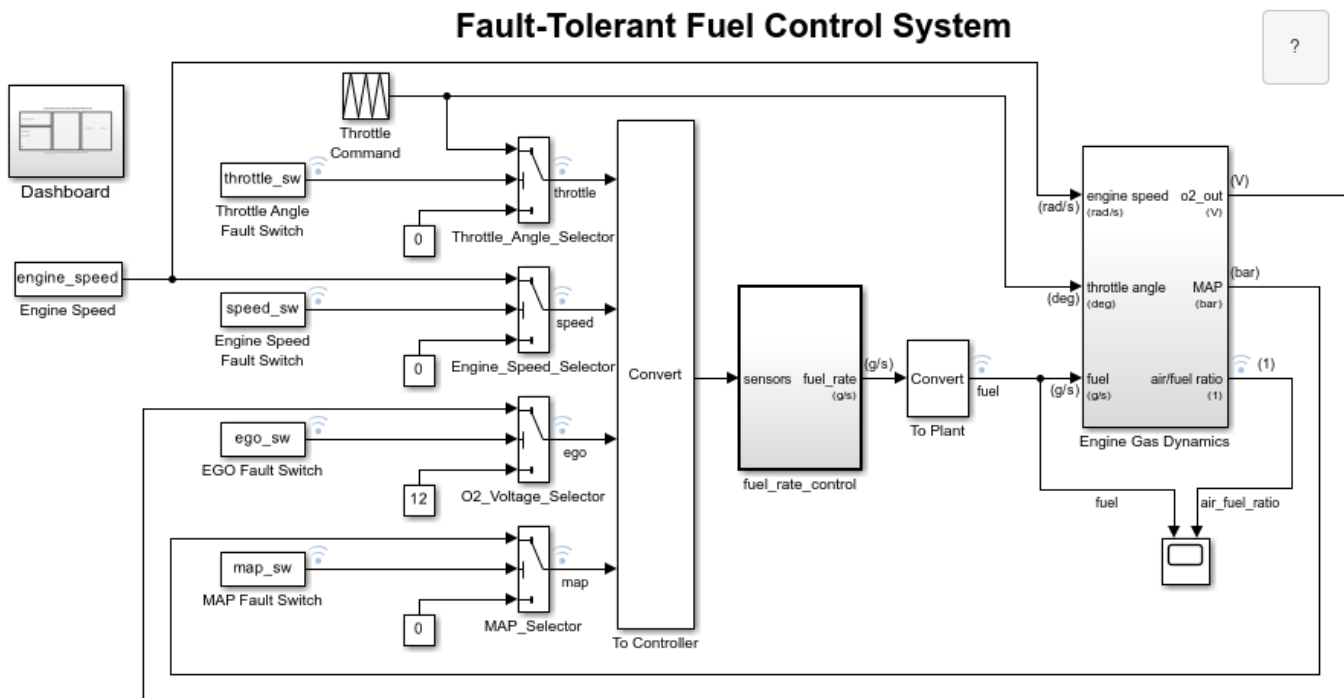

This example shows how to determine the partitionability of a `matlab.io.datastore.SimulationDatastore` object that contains big data from a simulation.

#### **Log Big Data from Model**

Open the example model `sldemo_fuelsys`.

```
open_system('sldemo_fuelsys')
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

Select **Configuration Parameters > Data Import/Export > Log Dataset data to file.**

```
set_param('sldemo_fuelsys', 'LoggingToFile', 'on')
```

Simulate the model.

```
sim('sldemo_fuelsys')
```

The MAT-file `out.mat` appears in your current folder. The file contains data for logged signals such as `fuel` (which is at the root level of the model).

At the command prompt, create a `DatasetRef` object that refers to the logging variable by name, `sldemo_fuelsys_output`.

```
DSRef = Simulink.SimulationData.DatasetRef('out.mat', 'sldemo_fuelsys_output');
```

#### Preview Big Data

Use curly braces (`{` and `}`) to extract the signal element `fuel`, which is the tenth element in `DSRef`, as a `Simulink.SimulationData.Signal` object that contains a `SimulationDatastore` object.

```
SimDataSig = DSRef{10};
```

To more easily interact with the `SimulationDatastore` object that resides in the `Values` property of the `Signal` object, store a handle in a variable named `DStore`.

```
DStore = SimDataSig.Values;
```

Determine if the datastore is partitionable.

```
if isPartitionable(DStore)
 disp('Datastore is partitionable.')
else
 disp('Datatstore is not partitionable.')
end
```

Datatstore is not partitionable.

# isShuffleable

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Determine whether datastore is shuffleable

## Syntax

```
tf = isShuffleable(ds)
```

## Description

`tf = isShuffleable(ds)` returns logical 1 (true) if the datastore `ds` is shuffleable. Otherwise, the result is logical 0 (false).

You can use the `shuffle` function on shuffleable datastores to randomize the ordering of files, while preserving the row associations of files in different datastores.

## Input Arguments

### **ds** — Input datastore

datastore

Input datastore. You can use these datastores as input:

- MATLAB datastores — Datastores created using MATLAB `datastore` functions. For a complete list of datastores, see “Select Datastore for File Format or Application”.
- Combined and transformed datastores — Datastores created using the `combine` and `transform` functions.

## preview

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Return subset of data from datastore

### Syntax

```
data = preview(dst)
```

### Description

`data = preview(dst)` returns a subset of data from datastore (`matlab.io.datastore.SimulationDatastore` object) `dst` without changing its current read position. `preview` returns only the first ten samples (time steps) of data in the datastore. Use this method to quickly inspect and verify that the data appears as you expect.

### Input Arguments

**dst — Input datastore**

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

### Output Arguments

**data — Subset of data**

`timetable` object

Subset of data, returned as a `timetable` object. For information about `timetable`, see “Timetables”.

## Examples

## progress

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Return percentage of data that you have read from a datastore

### Syntax

```
p = progress(dst)
```

### Description

`p = progress(dst)` returns the percentage, as a number between 0 and 1, of the data that you have read from a datastore (`matlab.io.datastore.SimulationDatastore` object). For example, a return value of 0.55 means you have read 55% of the data. Use the `progress` method and the `NumSamples` property to determine the current read position.

You read data from a `SimulationDatastore` object by using the `read` method.

### Input Arguments

**dst** — Input datastore

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

### Output Arguments

**p** — Percentage of data that you have read from the datastore

scalar double

Percentage of data that you have read from the datastore, returned as a scalar double.

Data Types: `double`

“Work with Big Data for Simulations”

# read

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Read data in datastore

## Syntax

```
data = read(dst)
[data,info] = read(dst)
```

## Description

`data = read(dst)` returns data from a datastore (`matlab.io.datastore.SimulationDatastore` object). Subsequent calls to the `read` function continue reading from the endpoint of the previous call. Use the `ReadSize` property of the `SimulationDatastore` object to specify the amount of data, in samples (time steps), to read at a time. Use the `progress` method and the `NumSamples` property to determine the current read position.

`[data,info] = read(dst)` also returns information about the extracted data in `info`.

## Input Arguments

**dst** — Input datastore

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

## Output Arguments

**data** — Output data

`timetable` object

Output data, returned as a `timetable` object. For information about `timetable`, see “Timetables”.

**info** — Information about read data

structure array

Information about read data, returned as a structure. The structure has one field, `FileName`, which is a fully resolved path containing the path string, the name of the file, and the file extension.

## Examples

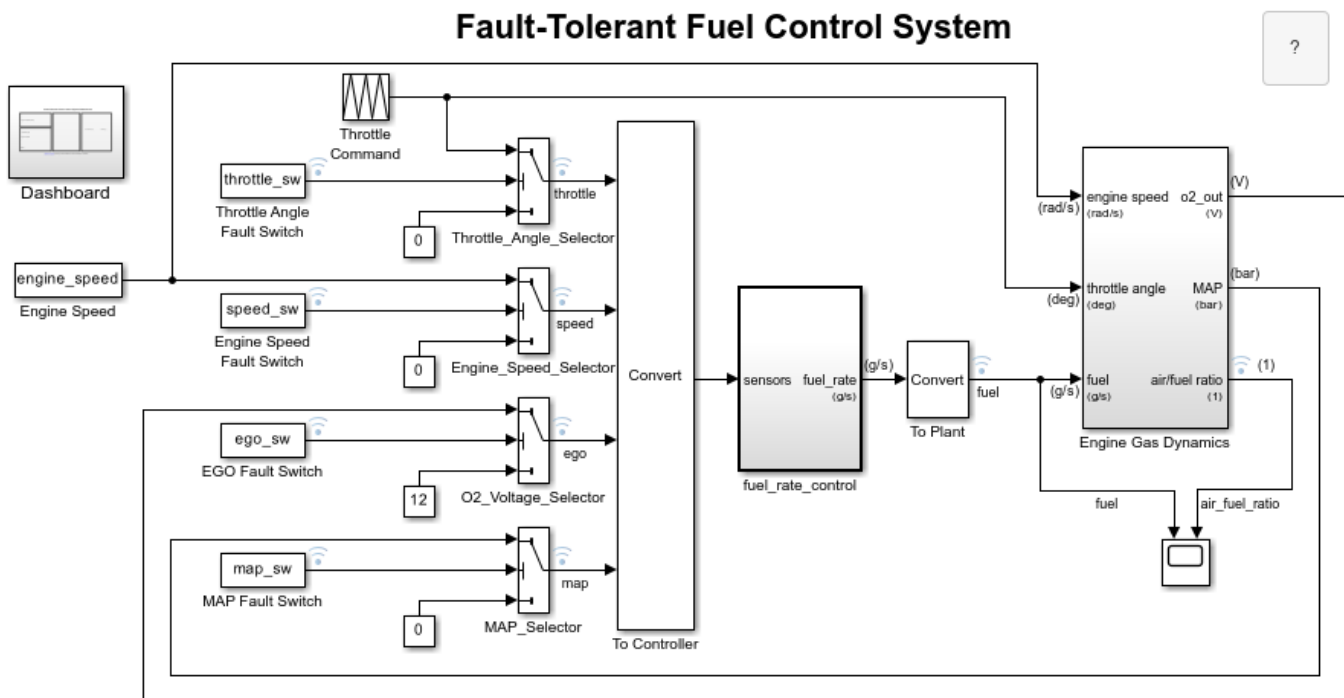

## Inspect and Analyze Data in Simulation Datastore

This example shows how to log big data from a simulation and inspect and analyze portions of that data by interacting with a `matlab.io.datastore.SimulationDatastore` object.

### Log Big Data from Model

Open the example model `sldemo_fuelsys`.

```
open_system('sldemo_fuelsys')
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

Select **Configuration Parameters > Data Import/Export > Log Dataset data to file.**

```
set_param('sldemo_fuelsys','LoggingToFile','on')
```

Simulate the model.

```
sim('sldemo_fuelsys')
```

The MAT-file `out.mat` appears in your current folder. The file contains data for logged signals such as `fuel` (which is at the root level of the model).

At the command prompt, create a `DatasetRef` object that refers to the logging variable by name, `sldemo_fuelsys_output`.

```
DSRef = Simulink.SimulationData.DatasetRef('out.mat','sldemo_fuelsys_output');
```

## Preview Big Data

Use curly braces (`{` and `}`) to extract the signal element `fuel`, which is the tenth element in `DSRef`, as a `Simulink.SimulationData.Signal` object that contains a `SimulationDatastore` object.

```
SimDataSig = DSRef{10};
```

To more easily interact with the `SimulationDatastore` object that resides in the `Values` property of the `Signal` object, store a handle in a variable named `DStore`.

```
DStore = SimDataSig.Values;
```

Use the `preview` method to inspect the first five samples of logged data for the `fuel` signal.

```
preview(DStore)
```

```
ans =
```

```
10x1 timetable
```

| Time           | Data   |
|----------------|--------|
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| 0.055328 sec   | 1.0652 |
| 0.055328 sec   | 1.0652 |

## Inspect Specific Sample

Inspect the 603rd sample of logged `fuel` data.

Set the `ReadSize` property of `DStore` to a number that, considering memory resources, your computer can tolerate. For example, set `ReadSize` to 200.

```
DStore.ReadSize = 200;
```

Read from the datastore three times. Each read operation advances the reading position by 200 samples.

```
read(DStore);
read(DStore);
read(DStore);
```

Now that you are very close to the 603rd sample, set `ReadSize` to a smaller number. For example, set `ReadSize` to 5.

```
DStore.ReadSize = 5;
```

Read from the datastore again.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data   |
|----------|--------|
| 5.79 sec | 1.6097 |
| 5.8 sec  | 1.6136 |
| 5.81 sec | 1.6003 |
| 5.82 sec | 1.5904 |
| 5.83 sec | 1.5832 |

The third sample of read data is the 603rd sample in the datastore.

### Inspect Earlier Sample

Inspect the 403rd sample of logged `fuel` data. Due to previous read operations, the datastore now reads starting from the 606th sample, so you must reset the datastore. Then, you can read from the first sample up to the 403rd sample.

Use the `reset` method to reset `DStore`.

```
reset(DStore);
```

Set `ReadSize` to 200 again.

```
DStore.ReadSize = 200;
```

Read from the datastore twice to advance the read position to the 401st sample.

```
read(DStore);
read(DStore);
```

Set `ReadSize` to 5 again.

```
DStore.ReadSize = 5;
```

Read from the datastore.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data    |
|----------|---------|
| 3.85 sec | 0.999   |
| 3.86 sec | 0.99219 |
| 3.87 sec | 0.98538 |
| 3.88 sec | 0.97858 |

3.89 sec    0.97179

### Extract Multiple Samples

Extract samples 1001 through 1020 (a total of 20 samples).

Reset the datastore.

```
reset(DStore)
```

Advance to sample 1001.

```
DStore.ReadSize = 200;
```

```
for i = 1:5
 read(DStore);
end
```

Prepare to extract 20 samples from the datastore.

```
DStore.ReadSize = 20;
```

Extract samples 1001 through 1020. Store the extracted data in a variable named `targetSamples`.

```
targetSamples = read(DStore)
```

```
targetSamples =
```

```
20x1 timetable
```

| Time     | Data   |
|----------|--------|
| 9.7 sec  | 1.5828 |
| 9.71 sec | 1.5733 |
| 9.72 sec | 1.5664 |
| 9.73 sec | 1.5614 |
| 9.74 sec | 1.5579 |
| 9.75 sec | 1.5553 |
| 9.76 sec | 1.5703 |
| 9.77 sec | 1.582  |
| 9.78 sec | 1.5913 |
| 9.79 sec | 1.5988 |
| 9.8 sec  | 1.605  |
| 9.81 sec | 1.6101 |
| 9.82 sec | 1.6145 |
| 9.83 sec | 1.6184 |
| 9.84 sec | 1.6049 |
| 9.85 sec | 1.595  |
| 9.86 sec | 1.5877 |
| 9.87 sec | 1.5824 |
| 9.88 sec | 1.5785 |
| 9.89 sec | 1.5757 |

### **Find Maximum Value of Data in Datastore**

Reset the datastore.

```
reset(DStore)
```

Write a while loop, using the `hasdata` method, to incrementally analyze the data in chunks of 200 samples.

```
DStore.ReadSize = 200;
runningMax = [];
while hasdata(DStore)
 tt = read(DStore);
 rawChunk = tt.Data;
 runningMax = max([rawChunk; runningMax]);
end
```

Now, the variable `runningMax` stores the maximum value in the entire datastore.

```
runningMax
```

```
runningMax =
```

```
 1.6423
```

## **Version History**

“Work with Big Data for Simulations”

# readall

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Read all data in datastore

## Syntax

```
data = readall(dst)
```

## Description

`data = readall(dst)` returns all the data in the datastore (`matlab.io.datastore.SimulationDatastore` object) specified by `dst`.

If all the data in the datastore does not fit in memory, `readall` returns an error. To determine how many samples (time steps) a datastore holds, inspect the `NumSamples` property of the `SimulationDatastore` object.

## Input Arguments

**dst** — Input datastore

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

## Output Arguments

**data** — All data in the datastore

`timetable` object

All data in the datastore, returned as a `timetable` object. For information about `timetable`, see “Timetables”.

## Version History

Introduced in R2017a

## See Also

### Topics

“Work with Big Data for Simulations”

## reset

**Class:** `matlab.io.datastore.SimulationDatastore`

**Package:** `matlab.io.datastore`

Reset datastore to initial state

### Syntax

```
reset(dst)
```

### Description

`reset(dst)` sets the read position of the datastore (`matlab.io.datastore.SimulationDatastore` object) specified by `dst` to the first sample in the datastore. Use `reset` to reread data from a datastore. You read from a datastore by using the `read` method.

### Input Arguments

**dst** — Input datastore

`matlab.io.datastore.SimulationDatastore` object

Input datastore, specified as a `matlab.io.datastore.SimulationDatastore` object. To create a `SimulationDatastore` object, see `matlab.io.datastore.SimulationDatastore`.

### Examples

#### Inspect and Analyze Data in Simulation Datastore

This example shows how to log big data from a simulation and inspect and analyze portions of that data by interacting with a `matlab.io.datastore.SimulationDatastore` object.

#### Log Big Data from Model

Open the example model `sldemo_fuelsys`.

```
open_system('sldemo_fuelsys')
```

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

Select **Configuration Parameters > Data Import/Export > Log Dataset data to file.**

```
set_param('sldemo_fuelsys', 'LoggingToFile', 'on')
```

Simulate the model.

```
sim('sldemo_fuelsys')
```

The MAT-file `out.mat` appears in your current folder. The file contains data for logged signals such as `fuel` (which is at the root level of the model).

At the command prompt, create a `DatasetRef` object that refers to the logging variable by name, `sldemo_fuelsys_output`.

```
DSRef = Simulink.SimulationData.DatasetRef('out.mat', 'sldemo_fuelsys_output');
```

#### Preview Big Data

Use curly braces (`{` and `}`) to extract the signal element `fuel`, which is the tenth element in `DSRef`, as a `Simulink.SimulationData.Signal` object that contains a `SimulationDatastore` object.

```
SimDataSig = DSRef{10};
```

To more easily interact with the `SimulationDatastore` object that resides in the `Values` property of the `Signal` object, store a handle in a variable named `DStore`.

```
DStore = SimDataSig.Values;
```

Use the `preview` method to inspect the first five samples of logged data for the `fuel` signal.

```
preview(DStore)
```

```
ans =
```

```
10x1 timetable
```

| Time           | Data   |
|----------------|--------|
| 0 sec          | 1.209  |
| 0.00056199 sec | 1.209  |
| 0.0033719 sec  | 1.209  |
| 0.01 sec       | 1.1729 |
| 0.02 sec       | 1.1409 |
| 0.03 sec       | 1.1124 |
| 0.04 sec       | 1.0873 |
| 0.05 sec       | 1.0652 |
| 0.055328 sec   | 1.0652 |
| 0.055328 sec   | 1.0652 |

### Inspect Specific Sample

Inspect the 603rd sample of logged `fuel` data.

Set the `ReadSize` property of `DStore` to a number that, considering memory resources, your computer can tolerate. For example, set `ReadSize` to 200.

```
DStore.ReadSize = 200;
```

Read from the datastore three times. Each read operation advances the reading position by 200 samples.

```
read(DStore);
read(DStore);
read(DStore);
```

Now that you are very close to the 603rd sample, set `ReadSize` to a smaller number. For example, set `ReadSize` to 5.

```
DStore.ReadSize = 5;
```

Read from the datastore again.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data   |
|----------|--------|
| 5.79 sec | 1.6097 |
| 5.8 sec  | 1.6136 |

```

5.81 sec 1.6003
5.82 sec 1.5904
5.83 sec 1.5832

```

The third sample of read data is the 603rd sample in the datastore.

### Inspect Earlier Sample

Inspect the 403rd sample of logged `fuel` data. Due to previous read operations, the datastore now reads starting from the 606th sample, so you must reset the datastore. Then, you can read from the first sample up to the 403rd sample.

Use the `reset` method to reset `DStore`.

```
reset(DStore);
```

Set `ReadSize` to 200 again.

```
DStore.ReadSize = 200;
```

Read from the datastore twice to advance the read position to the 401st sample.

```
read(DStore);
read(DStore);
```

Set `ReadSize` to 5 again.

```
DStore.ReadSize = 5;
```

Read from the datastore.

```
read(DStore)
```

```
ans =
```

```
5x1 timetable
```

| Time     | Data    |
|----------|---------|
| 3.85 sec | 0.999   |
| 3.86 sec | 0.99219 |
| 3.87 sec | 0.98538 |
| 3.88 sec | 0.97858 |
| 3.89 sec | 0.97179 |

### Extract Multiple Samples

Extract samples 1001 through 1020 (a total of 20 samples).

Reset the datastore.

```
reset(DStore)
```

Advance to sample 1001.

```
DStore.ReadSize = 200;
```

```
for i = 1:5
 read(DStore);
end
```

Prepare to extract 20 samples from the datastore.

```
DStore.ReadSize = 20;
```

Extract samples 1001 through 1020. Store the extracted data in a variable named `targetSamples`.

```
targetSamples = read(DStore)
```

```
targetSamples =
```

```
20x1 timetable
```

| Time     | Data   |
|----------|--------|
| 9.7 sec  | 1.5828 |
| 9.71 sec | 1.5733 |
| 9.72 sec | 1.5664 |
| 9.73 sec | 1.5614 |
| 9.74 sec | 1.5579 |
| 9.75 sec | 1.5553 |
| 9.76 sec | 1.5703 |
| 9.77 sec | 1.582  |
| 9.78 sec | 1.5913 |
| 9.79 sec | 1.5988 |
| 9.8 sec  | 1.605  |
| 9.81 sec | 1.6101 |
| 9.82 sec | 1.6145 |
| 9.83 sec | 1.6184 |
| 9.84 sec | 1.6049 |
| 9.85 sec | 1.595  |
| 9.86 sec | 1.5877 |
| 9.87 sec | 1.5824 |
| 9.88 sec | 1.5785 |
| 9.89 sec | 1.5757 |

### Find Maximum Value of Data in Datastore

Reset the datastore.

```
reset(DStore)
```

Write a `while` loop, using the `hasdata` method, to incrementally analyze the data in chunks of 200 samples.

```
DStore.ReadSize = 200;
runningMax = [];
while hasdata(DStore)
 tt = read(DStore);
 rawChunk = tt.Data;
```

```
 runningMax = max([rawChunk; runningMax]);
end
```

Now, the variable `runningMax` stores the maximum value in the entire datastore.

```
runningMax
```

```
runningMax =
```

```
 1.6423
```

# allowModelReferenceDiscreteSampleTimeInheritanceImpl

Model reference sample time inheritance status for discrete sample times

## Syntax

```
flag = allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
```

## Description

`flag = allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)` specifies whether a System object in a referenced model is allowed to inherit the sample time of the parent model. Use this method only for System objects that use discrete sample time and are intended for inclusion in Simulink via the MATLAB System block.

## Run-Time Details

During model compilation, Simulink sets the referenced model sample time inheritance before the System object `setupImpl` method is called.

## Method Authoring Tips

You must set `Access = protected` for this method.

## Input Arguments

### **obj** — System object

System object

System object handle used to access properties, states, and methods specific to the object. If your `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method does not use the object, you can replace this input with `~`.

## Output Arguments

### **flag** — discrete sample time inheritance flag

true | false

Flag indicating whether model reference discrete sample time inheritance is allowed for the MATLAB System block containing the System object, returned as a logical value.

The default value for this argument depends on the number of inputs to the System object. If you want to use the default value, you do not need to include this method in your System object class definition file.

| Number of System object Inputs | Default Value and Override Effects                                                                                                                                                                                                                                                                                |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No inputs                      | <p><b>Default:</b> <code>false</code> — Model reference discrete sample time inheritance is not allowed.</p> <p>If your System object uses discrete sample time in its algorithm, override the default by returning <code>true</code> from <code>allowModelReferenceDiscreteSampleTimeInheritanceImpl</code>.</p> |
| One or more inputs             | <p><b>Default:</b> <code>true</code> — If no other Simulink constraint prevents it, model reference sample time inheritance is allowed.</p>                                                                                                                                                                       |

## Examples

### Set Sample Time Inheritance for System Object

For a System object that has one or more inputs, to disallow model reference discrete sample time inheritance for that object, set the sample time inheritance to `false`. Include this code in your class definition file for the object.

```
methods (Access = protected)
 function flag = allowModelReferenceDiscreteSampleTimeInheritanceImpl(~)
 flag = false;
 end
end
```

# getInputNamesImpl

Names of MATLAB System block input ports

## Syntax

```
names = getInputNamesImpl(obj)
```

## Description

`names = getInputNamesImpl(obj)` specifies the names of the input ports from System object, `obj` implemented in a MATLAB System block. The size of `names` matches the number of inputs returned by the `getNumInputs` method. If you change a property value that changes the number of inputs, the names of those inputs also change.

## Class Information

This method is part of the `matlab.System` class.

## Run-Time Details

`getInputNamesImpl` is called by the MATLAB System block.

## Method Authoring Tips

You must set `Access = protected` for this method.

## Input Arguments

### **obj** — System object

System object

System object handle used to access properties, states, and methods specific to the object. If your `getInputNamesImpl` method does not use the object, you can replace this input with `~`.

## Output Arguments

### **names** — Names of inputs

empty string array (default) | string array

Names of the inputs for the specified object, returned as a string array whose length equals the number of inputs.

## Examples

“Customize MATLAB System Block Appearance”

## Version History

Introduced in R2013b

## getOutputNamesImpl

Names of MATLAB System block output ports

### Syntax

```
names = getOutputNamesImpl(obj)
```

### Description

`names = getOutputNamesImpl(obj)` specifies the names of the output ports from System object, `obj` implemented in a MATLAB System block. The size of `names` matches the number of outputs returned by the `getNumOutputs` method. If you change a property value that affects the number of outputs, the names of those outputs also change.

### Class Information

This method is part of the `matlab.System` class.

### Run-Time Details

`getOutputNamesImpl` is called by the MATLAB System block.

### Method Authoring Tips

You must set `Access = protected` for this method.

### Input Arguments

#### **obj** — System object

System object

System object handle used to access properties, states, and methods specific to the object. If your `getOutputNamesImpl` method does not use the object, you can replace this input with `~`.

### Output Arguments

#### **names** — Names of outputs

empty string array (default) | string array

Names of the outputs for the specified object, returned as a string array whose length equals the number of outputs.

### Examples

“Customize MATLAB System Block Appearance”

## Version History

Introduced in R2013b

## getPropertyGroupsImpl

Property groups for System object display

### Syntax

```
group = getPropertyGroupsImpl
```

### Description

`group = getPropertyGroupsImpl` specifies how to display properties in the block dialog of a MATLAB System block. You can specify:

- Sections — Arrange properties into sections (panel on the MATLAB System block dialog) with `matlab.system.display.Section`.
- Section Groups — Arrange properties and sections into groups (tabs on the MATLAB System block dialog) with `matlab.system.display.SectionGroup`.
- Order of properties — Specify the order of properties within sections/groups
- Order of sections — Specify the order of sections within groups.

If you create a section, but that section is not in a section group, its properties appear above the block dialog tab panels.

### Run-Time Details

In Simulink, `getPropertyGroupsImpl` modifies the MATLAB System block dialog.

If you choose to modify the MATLAB System block dialog from the Mask Editor, the `getPropertyGroupsImpl` method is removed from the System object. All block dialog customizations are then saved in a supporting XML file: `sysObjectName_mask.xml`.

In MATLAB, `getPropertyGroupsImpl` modifies how properties appear when the System object is displayed at the MATLAB command line. `getPropertyGroupsImpl` defines the order and groupings of properties. If your `getPropertyGroupsImpl` defines multiple section groups, only properties from the first section group are displayed at the command line. To display properties in other sections, a link is provided at the end of a System object property display. Group titles are also displayed at the command line.

### Method Authoring Tips

- You must set `Access = protected` for this method.
- If you include a `getPropertyGroupsImpl` method but do not list all properties, the excluded properties do not appear in the dialog box.
- To omit the Main title for the first group of properties, in `matlab.system.display.SectionGroup`, set `TitleSource` to 'Auto'.
- By default if you do not customize this method in your System object, the MATLAB System block dialog displays all public properties in the order specified in the System object class file.
- To customize property names, add comments above each property. For an example, see “System Object to Block Dialog Box Default Mapping”.

## Output Arguments

### **group** — Property sections and groups

array of `SectionGroup` or `Section` objects

Property groups and sections to pass to the MATLAB System block, specified as an array of `matlab.system.display.Section` and `matlab.system.display.SectionGroup` objects.

## Examples

“Customize System Block Dialog Box Using System object”

## Version History

**Introduced in R2013b**

## getSimulateUsingImpl

Specify value for Simulate using parameter

### Syntax

```
simmode = getSimulateUsingImpl
```

### Description

`simmode = getSimulateUsingImpl` specifies the simulation mode of the System object implemented in a MATLAB System block. The simulation mode restricts your System object to simulation using either code generation or interpreted execution. The associated `showSimulateUsingImpl` method controls whether the **Simulate using** option is displayed on the dialog box.

### Run-Time Details

`getSimulateUsingImpl` is called by the MATLAB System block.

### Method Authoring Tips

You must set `Access = protected` and `Static` for this method.

### Output Arguments

#### **simmode** — Simulation mode

"Code generation" | "Interpreted execution"

Simulation mode, returned as the string "Code generation" or "Interpreted execution". If you do not include the `getSimulateUsingImpl` method in your class definition file, the simulation mode is unrestricted. Depending on the value returned by the associated `showSimulateUsingImpl` method, the simulation mode is displayed on the dialog box as either a dropdown list or not at all.

### Examples

#### Specify the Simulation Mode

In the class definition file of your System object, define the simulation mode to display in the MATLAB System block. To prevent **Simulate using** from displaying, see `showSimulateUsingImpl`.

```
methods (Static, Access = protected)
 function simMode = getSimulateUsingImpl
 simMode = "Interpreted execution";
 end
end
```

### Version History

Introduced in R2015a

## **See Also**

showSimulateUsingImpl

## **Topics**

“Control Simulation Type in MATLAB System Block”

## getSimulinkFunctionNamesImpl

Register Simulink function names used in your System object

### Syntax

```
names = getSimulinkFunctionNamesImpl(obj)
```

### Description

`names = getSimulinkFunctionNamesImpl(obj)` specifies the Simulink function names used in the System object `obj`.

If you use a Simulink function in your System object, you can only call a Simulink function from the `stepImpl`, `updateImpl`, or `outputImpl` method.

### Run-Time Details

`getSimulinkFunctionNamesImpl` is invoked by the MATLAB System during model compilation to obtain the list of Simulink functions being called from the System object. Simulink uses this information to resolve the function names to a Simulink function declared in a Simulink Function block. If `getSimulinkFunctionNamesImpl` does not return the name of a function being called in the System object methods, Simulink attempts to resolve the function to a function on the MATLAB path.

### Method Authoring Tips

You must set `Access = protected` for this method.

### Input Arguments

#### **obj** — System object

System object

System object handle used to access properties, states, and methods specific to the object. If your `getSimulinkFunctionNamesImpl` method does not use the object, you can replace this input with `~`.

### Output Arguments

#### **names** — Simulink function names

{ ' ' } (default) | cell array of character vectors | string array

The names of the Simulink function you want to call from your System object.

### Examples

“Call Simulink Functions from a MATLAB System Block”

## Version History

Introduced in R2019a

## getInterfaceImpl

Set System object as message or data

### Syntax

```
interface = getInterfaceImpl(obj)
```

### Description

MATLAB `interface = getInterfaceImpl(obj)` specifies the inputs and outputs of a System block as either data or a message.

### Run-Time Details

`getInterfaceImpl` is part of the `matlab.System` class and is called before the `setupImpl` method.

### Method Authoring Tips

You must set `Access = protected` for this method.

You cannot modify any properties in this method.

### Input Arguments

#### **obj** — System object

System object

System object handle used to access properties, states, and methods specific to the object. If your `getInterfaceImpl` method does not use the object, you can replace this input with `~`.

### Output Arguments

#### **interface** — MATLAB System block interface

scalar of interface objects | vector of interface objects

MATLAB System block interface, returned as a scalar or vector of `matlab.system.interface.*` objects. Use `matlab.system.interface.Input(signalName,signalType)` to define input signal types. Use `matlab.system.interface.Output(signalName,signalType)` to define output signal types.

- `signalName` - Defines the name of the port. Represented by a character array.
- `signalType` - Defines the type of port. The value is either `matlab.system.interface.Data` or `matlab.system.interface.Message`.

### Examples

## Process Message Payload Using MATLAB System Block

This example shows how to send, receive, and process messages using the MATLAB System block. Use System objects to author blocks to model custom behavior to send and receive messages and manipulate the message payload.

### Load and Open the Model

Open the model of the Message Send and Receive system. This model contains a random number generator as a data source. Based on that data, the Message Sender sends a message with a sine wave payload to a queue block. The queue block stores the messages, and the Message Receiver converts the message back to data.

```
open_system('slexMessageArrivalExample');
```

### Use getInterfaceImpl System Object API to Specify Message Ports

`getInterfaceImpl` is used in this example to specify the input and output message ports in the MATLAB System block for both the Message Sender and the Message Receiver. For the Message Sender, `getInterfaceImpl` is used to define the output of the MATLAB System block as a message. This action prompts the System object to create a message output. For the Message Receiver, `getInterfaceImpl` is used to define the input of the System object as a message and the output as data.

```
%Function to send messages
function interface = getInterfaceImpl(~)
 import matlab.system.interface.*;
 interface = Output("Out1", Message);
end

%Function to receive messages and output as data
function interface = getInterfaceImpl(obj)
 import matlab.system.interface.*;
 interface = [Input("In1", Message), ...
 Output("Out1", Data), Output("out2", Data)];
end
```

### Set the Propagators and Sample time

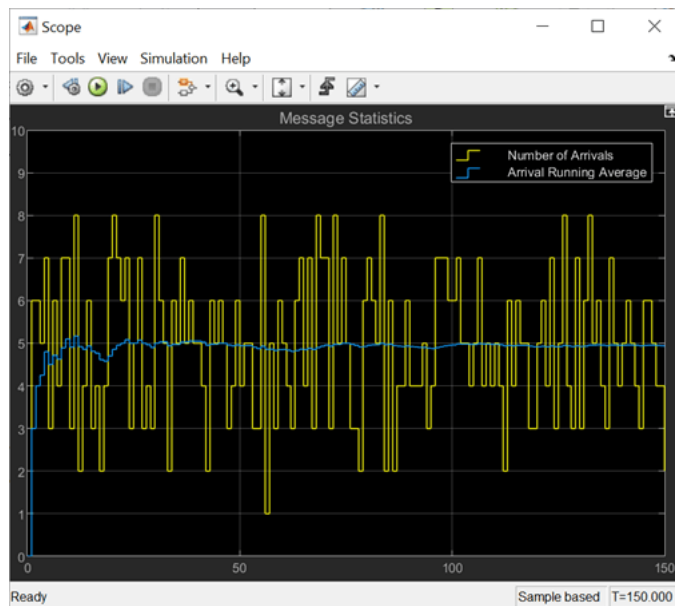

The following four propagators need to be set in the Message Sender: `getOutputSizeImpl`, `getOutputDataTypeImpl`, `isOutputComplexImpl`, `isOutputFixedSizeImpl`.

In this example, the message queue has a maximum capacity of 16 messages. The random number generator has a sample time of 0.1. The receiver has a sample time of 1. The Message Receiver sample time is set in the MATLAB System block using the `getSampleTimeImpl` API.

```
function sts = getSampleTimeImpl(obj)
 sts = createSampleTime(obj, 'Type', 'Discrete', ...
 'SampleTime', obj.SampleTime);
end
```

### Simulate the Model and Review Results

The Scope block displays the results. These results show that as you run more simulations, the random number generator produces a number greater than zero 50% of the time, as expected.

# showFiSettingsImpl

Fixed point data type tab visibility for System objects

## Syntax

```
flag = showFiSettingsImpl
